Chapter 3 Viewing and Navigating 3D Space

General Viewport Concepts .................................................. 66
Home Grid: Views Based on the World Coordinate Axes ............ 68
Understanding Views ............................................................ 72
Setting Viewport Layout ....................................................... 76
Controlling Viewport Rendering ........................................... 79
Controlling Display Performance ......................................... 81
Using Standard View Navigation ......................................... 82
Zooming, Panning, and Rotating Views .................................. 84
ViewCube .............................................................................. 86
   ViewCube Menu .................................................................... 88
   Change the View of the Scene with the ViewCube ............... 89
      Change the Current View .............................................. 89
      Set the View Projection Mode ..................................... 92
      Define the Home View ............................................. 93
SteeringWheels ..................................................................... 93
   Wheel Menu ....................................................................... 97
Navigation Wheels ............................................................... 98
      View Object Wheels .................................................... 99
      Tour Building Wheels ............................................. 100
      Full Navigation Wheels .......................................... 101
Navigation Tools ................................................................. 103
      Center Tool .................................................................. 103
      Forward Tool ............................................................ 104
      Look Tool .................................................................... 105
      Orbit Tool .................................................................... 107
      Pan Tool ....................................................................... 109
      Rewind Tool .............................................................. 109
      Up/Down Tool ............................................................ 111
      Walk Tool .................................................................... 112
      Zoom Tool .................................................................... 113
Using Walkthrough Navigation ............................................ 115
Navigating Camera and Light Views ....................................... 119
Adaptive Degradation ........................................................... 123
Grab Viewport ...................................................................... 125
View-Handling Commands .................................................. 126
      Undo View Change / Redo View Change ...................... 126
      Save Active View ...................................................... 127
      Restore Active View ................................................ 128
      Viewport Background Dialog ................................... 128
      Select Background Image Dialog .............................. 137
      Update Background Image ........................................ 142
      Reset Background Transform .................................... 143
      Show Transform Gizmo .............................................. 143
Select Similar ................................................. 228
Select By ....................................................... 229
  Select By Color ......................................... 229
  Select By Name (Edit Menu) .......................... 229
  Select By Layer ......................................... 230
Selection Region ........................................... 230
  Rectangular Selection Region .......................... 230
  Circular Selection Region .............................. 231
  Fence Selection Region ................................ 232
  Lasso Selection Region ................................ 233
  Paint Selection Region ................................ 234
  Select Region Window .................................. 235
  Region ...................................................... 237
  Select Region Crossing .................................. 237
  Window/Crossing Selection Toggle ....................... 239
Edit Commands ............................................. 239
  Undo/Redo ................................................ 240
  Hold/Fetch .............................................. 242
  Delete .................................................... 243
Groups and Assemblies .................................. 243
  Using Groups ........................................... 243
  Using Assemblies ....................................... 247
  Character Assembly .................................... 254
Group Commands ......................................... 258
  Group ..................................................... 258
  Open ..................................................... 260
  Close ..................................................... 260
  Ungroup .................................................. 261
  Explode ................................................... 261
  Detach .................................................... 262
  Attach ..................................................... 263
Assembly Commands ....................................... 263
  Assemble .................................................. 263
  Open Assembly .......................................... 267
  Close Assembly ......................................... 268
  Disassemble ............................................. 269
  Explode Assembly ...................................... 269
  Detach Assembly ........................................ 270
  Attach Assembly ........................................ 270
Assembly Head Helper Objects ............................ 270
  Assembly Head Helper Object .......................... 271
  Luminaire Helper Object ............................... 271
Character Assembly Commands ............................ 274
  Create Character ....................................... 274
  Destroy Character ...................................... 278
  Lock/Unlock Character .................................. 279
Chapter 5  **Object Properties**  ........................................ 283

Object Properties Dialog Panels ........................................ 283
  General Panel (Object Properties Dialog) ..................... 283
  Advanced Lighting Panel (Object Properties Dialog) .......... 295
  mental ray Panel (Object Properties Dialog) ............... 300
  User Defined Panel (Object Properties Dialog) .......... 303

Rename Objects Tool ..................................................... 306
Custom Attributes ......................................................... 307
Parameter Collector ....................................................... 325
  Parameter Collector Menu Bar .................................. 334
  Notes Dialog (Parameter Collector) ............................ 337
Expression Techniques ................................................... 339
  Trigonometric Functions ....................................... 349
  Vectors ............................................................... 352

Chapter 6  **Creating Geometry** ..................................... 357

Basics of Creating and Modifying Objects ......................... 358
  Using the Create Panel ........................................ 360
  Identifying the Basic Building Blocks ....................... 361
  Creating an Object ............................................... 364
Assigning Colors to Objects ........................................ 367
  Object Color Dialog ............................................. 368
  Color Selector Dialog ........................................... 371
  Color Clipboard Utility ....................................... 378
Adjusting Normals and Smoothing .................................. 380
  Viewing and Changing Normals ............................... 380
  Viewing and Changing Smoothing ............................ 383
Geometric Primitives ................................................... 385
Creating Primitives from the Keyboard ......................... 386
Standard Primitives .................................................... 388
  Box Primitive ...................................................... 389
  Cone Primitive ..................................................... 392
  Sphere Primitive .................................................. 396
  GeoSphere Primitive ........................................... 401
  Cylinder Primitive .............................................. 403
  Tube Primitive .................................................... 406
  Torus Primitive ................................................... 409
  Pyramid Primitive ................................................ 413
  Teapot Primitive .................................................. 416
  Plane Primitive .................................................... 419
Extended Primitives ..................................................... 421
Star Spline .................................................   .599
Text Spline ..............................................   .600
Helix Spline .............................................   .605
Section Spline ..........................................   .607
Extended Splines .......................................   .611
WRectangle Spline ....................................   .611
Channel Spline .........................................   .613
Angle Spline ............................................   .615
Tee Spline ................................................   .617
Wide Flange Spline ..................................   .618
Editable Spline .........................................   .620
Editable Spline (Object) ..............................   .630
Editable Spline (Vertex) ...............................   .634
Editable Spline (Segment) ..............................   .646
Editable Spline (Spline) ...............................   .655
Shape Check Utility .....................................   .665
Compound Objects ........................................   .667
Morph Compound Object ..................................   .667
Scatter Compound Object ...............................   .674
Conform Compound Object ...............................   .688
Connect Compound Object ...............................   .695
BlobMesh Compound Object .............................   .701
ShapeMerge Compound Object .........................   .709
Boolean Compound Object ..............................   .713
Material Attach Options Dialog .......................   .728
Terrain Compound Object ...............................   .730
Loft Compound Object ...................................   .742
Creation Method Rollout ...............................   .745
Surface Parameters Rollout ............................   .746
Path Parameters Rollout ................................   .750
Skin Parameters Rollout ................................   .753
Deformations .............................................   .770
Path Commands ...........................................   .790
Shape Commands .........................................   .790
Mesher Compound Object ...............................   .794
ProBoolean/ProCutter Compound Objects .............   .799
   ProBoolean Compound Object .......................   .801
   ProCutter Compound Object .........................   .823
Quad Meshing and Smoothing .........................   .831
Dynamics Objects ........................................   .841
Damper Dynamics Object ...............................   .842
Spring Dynamics Object ...............................   .849
Systems ...................................................   .856
Bones System .............................................   .857
Using Objects as Bones ................................  .870
Bone Tools ...............................................   .871

Introduction

Autodesk 3ds Max 2010 is a 3D modeling, animation, and rendering solution for design visualization, games, film, and television.
Chapter 1   Introduction
What's New in Autodesk 3ds Max 2010

Autodesk 3ds Max 2010 is more powerful and easier to use, thanks to a wealth of new tools and a redesign to place often-used commands at your fingertips. File functions such as Open and Save are available at the click of a button on the new Caption bar, and the remaining controls are more clearly organized on the Application menu. The Graphite Modeling Tools set combines familiar features with a host of new ones in a dynamic, innovative “ribbon” interface. The third generation of Review technology offers viewport support for ambient occlusion, High Dynamic Range Image (HDRI)-based lighting, soft shadows, and more. For descriptions of these and other new features, consult the remainder of this topic.
NOTE This topic lists all significant new features, but does not include every change in 3ds Max. As you proceed through the documentation, keep an eye out for the icon, which indicates a new feature.

You can also use the index in this help to find topics that contain information about new features. For topics that describe new program features, check the index entry "new feature." For changes in existing features, check the index entry "changed feature."

Following is a list of major new features with brief descriptions and links to the relevant reference topic:

**General Improvements**

- **Viewport Improvements**  With hardware support, you can now preview soft-edged shadows, ambient occlusion, and exposure control in viewports, saving rendering time. For details, see Previewsing Shadows and Other Lighting in Viewports on page 5335 and Lighting and Shadows on page 8392.

  ![Hardware-shaded viewport with shadows and Ambient Occlusion](image)

- The viewport label menus on page 8117 have been reorganized to improve ease of use, and offer quicker access to more display options.

- **Appearance**  The 3ds Max window has been updated for ease of use. See Caption Bar on page 7988 for a description of the most visible menu and toolbar changes.
Also, many graphic buttons have been redesigned for greater clarity. These changes are reflected throughout the help.

**Modeling**

- **Graphite Modeling Tools** on page 2025 combines a wealth of new polygon-modeling features on page 2026, including freeform sculpting and powerful loop-modeling tools, with the tried and true toolset in a dynamic, configurable new “ribbon” interface.

- The new **ProOptimizer modifier** on page 1614 provides a convenient way to improve your models’ polygon count. With the **Batch ProOptimizer utility** on page 2768, you can use the same controls to optimize multiple scenes all at once. Support for optimization of explicit normals has been enhanced in this release.

- **ProBoolean** on page 801 offers two new operations: Attach, which simply combines objects without affecting their geometry, and Insert, which subtracts one shape from another while leaving both operands in place. Also, the new **Quadify Mesh modifier** on page 1641 lets you apply the quadrilateral tessellation feature from ProBoolean to any object, making it easier to obtain nicely rounded edges with MeshSmooth.
Transform Toolbox on page 936 contains functions for easy object rotation, scaling, and positioning as well as for moving object pivots.

xView on page 2873 analyzes mesh models, flags various potential problems and errors, and displays the results in the viewports both graphically and as text. Tests include isolated and overlapping vertices, open edges, various UVW statistics, and more.
Scene and Project Management

The addition of the Containers toolset facilitates collaboration and flexible workflows by giving you the ability to collect multiple objects into a single organizing device when dealing with complex scenes. You can place related objects, such as sections of a city, in a container and treat them as a single element. Opening the container exposes the content, while closing the container externalizes the data. Containers can be temporarily unloaded from the scene, toggling data in and out as needed to manage complexity. Such workflows can save memory, increase viewport performance and decrease load and save times. You can also grant or withhold editing privileges for containers, so that a scene aggregator won’t necessarily be able to alter the contents.

Expanded support for the OBJ file format facilitates importing and exporting 3D model data between Autodesk Mudbox and Autodesk 3ds Max 2010 as well as other 3D applications. You can now see whether an OBJ file contains texture coordinates and smoothing groups. Also new are options for triangulating polygons on import, choosing how normals...
are imported, and for saving presets for normal and polygon import for future use.

- The **AutoCAD 2010** on page 7692 option for exporting DWG files includes support for the new MESH object type as implemented in Autocad 2010 for Subdivision Surfaces workflows. This object type removes size limitations and provides tools within AutoCAD to convert as true ACIS Solid entities.

- The **Scene Explorer** on page 7888 interface has been rearranged and updated for ease of use, and new features have been added. For instance, you can now switch Explorer columns and change Advanced Search terms on the fly. To see all the changes, browse the Scene Explorer topics for the icon.
Scene Explorer interface
Enhanced Autodesk FBX® software data-translation fidelity improves interoperability between 3ds Max and other Autodesk products such as Autodesk MotionBuilder®, Autodesk Toxik® and Autodesk Maya® software.

Materials and Mapping

A new Material Explorer interface on page 5734 makes it easier for you to browse and manage the materials in your scene.
■ **Viewport Canvas** on page 6455 provides tools for painting onto an object's texture directly in the viewport. It turns the active viewport into a
two-dimensional canvas that you can use to paint on and then apply the result to the object’s texture.

Viewport Canvas interface

- **Render Surface Map** on page 6466 provides tools for creating bitmaps automatically based on an object’s UVW mapping. The generated bitmaps display surface properties of the object, including concavity/convexity (dirt map), mesh density, facing direction (dust map), and object thickness. There’s also a Bitmap Select function for selecting sub-objects based on mapping attributes.

- Autodesk 3ds Max 2010 is the first 3D package to integrate the powerful mental mill technology from mental images. With mental mill (installed separately), you can design, test, and maintain hardware-agnostic shaders
and complex shader graphs for hardware and software rendering with real-time visual feedback.

- New tools on the Edit UVWs dialog on page 1856 of the Unwrap UVW modifier significantly ease the tasks of selecting loops and rings of texture sub-objects as well as aligning them, stitching clusters, and more.

- New mental ray shaders are Multi/Sub-Map on page 6414, with which you can vary the surface appearance of multiple objects assigned the same material, and Object Color on page 6418, which lets you incorporate an object’s wireframe color into its material.

![Multi/Sub-Map randomly varies the stains on the seats in a stadium model.](image)

- The DirectX Shader material on page 6175 now supports shaders in MetaSL format, the shader language that is used when you create new shaders using the mental mill® product from mental images®. Also, now mapped components of a DirectX Shader material can use Radiance Image (HDR) files on page 7866 and Photoshop (PSD) files on page 7863 as maps.

**Rendering**

- The Rendered Frame Window on page 6513 (Reveal) interface has been redesigned for Autodesk 3ds Max 2010. When rendering with mental ray, the Render button and Production/Iterative switch now appear on the lower panel with the rest of the mental ray-specific controls; otherwise,
they remain in their former location on the upper panel. Also, the lower panel has been streamlined for greater ease of use. Most important, new global-tuning sliders let you temporarily override the precision of reflections, refractions, and soft shadows for faster or higher-quality rendering. The latter controls are also available on the Render Setup dialog > new Global Tuning Parameters rollout on page 6731.

- The Photon Map and Final Gather Map controls have been enhanced and are now available on their own Reuse rollout on page 6778. New on this rollout are controls for reducing flickering in animations that use final gathering.

- Another new setting for reducing flickering in animations that use final gathering, specific to those with a moving viewpoint, is Project Points from Positions Along Camera Path on page 6764.

- When rendering with mental ray, final gathering on page 6760 now provides a fast progressive-feedback display so you can get an idea of the overall scene lighting more quickly. This feature is automatic whenever Final Gather is enabled.

- Improved bitmap paging allows you to render larger images than previous versions would support. In Autodesk 3ds Max 2010, bitmap paging is always active, and is managed automatically. A new Page File system path allows you to assign the area used for bitmap paging. If you are creating large renderings and have a dedicated, high-performance disk you can use for caching, this option can greatly improve render time. See System Paths on page 8294.

- Changes to how 3ds Max handles gamma correction on page 8330 improve its ease of use. The new topic Gamma Pipeline on page 8341 gives additional information on using this feature, especially with the mental ray renderer.

**Animation**

- PFlowAdvanced, a collection of new Particle Flow tools, makes it easier to organize particles, place them precisely in the scene, customize the system, and more. For details, see What's New in Particle Flow on page 2998.
New features in Particle Flow

PFlowAdvanced also includes the new PFlowElements library with at least 100 samples created by an industry-leading effects artist. You’ll find them on the Sample Files DVD included with Autodesk 3ds Max 2010.

- You can now lock animation tracks on page 3826 and animation layers on page 3467 to prevent inadvertent changes.
- The Link constraint on page 3580 has been enhanced so that assigning a link target creates a key that you can manipulate on the track bar and in Track View.
- ProSound on page 3835 is a real-time, multitrack audio solution for 3ds Max that includes full support for and integration with Track View. Features include up to 100 independent audio tracks and PCM audio in both AVI and WAV files with up to six output channels.

Hair Improvements

A new spline deformation option on page 1090 lets you control hair shape by matching the hair to a spline object.

What's New in Autodesk 3ds Max 2010 | 15
Cloth Improvements

Enhancements to the Cloth and Garment Maker modifiers enable a range of new effects:

■ A new Inherit Velocity toggle makes it easier to create Cloth animations one portion at a time. When this toggle is on, a simulation can begin where the previous one ended. See Cloth Properties on page 1225.

■ A closed volume of cloth can now behave as if it were filled with gas. You can control the pressure within the volume. See Pressure group on page 1233.

■ You can now tear cloth. The interface provides a few different ways to set up cloth tearing. See Tearing Cloth on page 1207.

■ New group-level functions let you shrink and grow vertex selections, select rings and loops of vertices, and select all vertices in an element.

Character-Animation Improvements

The new Knuckles on page 4768 feature allows you to create detailed, more subtle hand animation.
A standard biped hand. This setup doesn’t allow for finely detailed hand animation.

A biped hand with Knuckles turned on. The hand has a small base and individual bones for all its digits, allowing for detailed animation.

3ds Max Documentation Set

The documentation set for 3ds Max® comprises online material only. Most documents are available from the Start menu > Programs > Autodesk >
Help folder, as well as from the Help menu within 3ds Max or the Additional Help dialog.

- **Autodesk 3ds Max 2010 and Autodesk 3ds Max Design 2010 Installation Guide**: Contains complete installation, configuration, and troubleshooting instructions, including system requirements. Also includes information on uninstalling and maintaining 3ds Max, as well as descriptions of the full install documentation set. View the *Installation Guide* in the Installation Wizard.

  **NOTE** The complete installation documentation set is found on your install DVD in the `Docs` folder at the root of the DVD. If you are deploying 3ds Max over a network, refer to the *Autodesk 3ds Max 2010 and Autodesk 3ds Max Design 2010 Network Administrator’s Guide* instead of the *Installation Guide*.

- **Autodesk 3ds Max 2010 Readme (3ds_Max_Readme.rtf)**: Contains the latest information about 3ds Max. You can access this file by clicking View Readme in the Autodesk 3ds Max 2010 Installation Wizard.

- **Autodesk 3ds Max 2010 Help**: This document covers fundamental concepts and strategies for using the product, as well as details about the features of 3ds Max. Access the reference by choosing Help > Autodesk 3ds Max Help.

- **Autodesk 3ds Max 2010 Tutorials**: Contains tutorial information and detailed procedures to walk you through increasingly complex operations. This is the best source for learning 3ds Max. Access the tutorials by choosing Help > Tutorials.

  **NOTE** All the scene files required to do the tutorials are installed by default.

- **MAXScript Help**: Describes the MAXScript scripting language on page 21. Check out the “Learning MAXScript” chapter there if you're new to MAXScript. Access the MAXScript Help by choosing Help > MAXScript Help.

- **Additional mental ray® Help Files**: Documentation from mental images® is available from Help menu > Additional Help. There, you'll find the *mental ray Reference*, comprising the *mental ray Manual, mental ray Shader Reference, and LumeTools Collection*. You’ll also find PDF files documentating various mental ray shader libraries.
NOTE The Autodesk 3ds Max 2010 Help documents most mental ray components available in the 3ds Max user interface. This includes documentation for lights for mental ray and specific shadow types, controls for adding mental ray shaders to lights and cameras, mental ray materials, custom shaders for 3ds Max, and the mental ray renderer controls.

■ Additional Backburner Files: Procedures for using Backburner from inside 3ds Max are documented in this Autodesk 3ds Max Help File. For further information on using and configuring Backburner, refer to the additional Backburner documentation available from Additional Help as well as from the Start menu location described in the introduction of this topic. The two documents related to Autodesk Backburner are called:
  ■ Backburner Installation Guide
  ■ Backburner User’s Guide

NOTE For information on installing Autodesk Backburner, see the Autodesk 3ds Max 2010 and Autodesk 3ds Max Design 2010 Installation Guide.

■ FBX Plug-in Help: Access the FBX Plug-in Help from the Additional Help menu. You can also click the ? (Help) button on the FBX Importer/Exporter dialog. The FBX plug-in changes often, with the result that Autodesk updates it more frequently than it does this program. Be sure to check regularly for updated versions by clicking the Web Updates button on the dialog.

How to Print from the Online Help

If your computer is connected to a printer, you can print single help topics or entire chapters.

To print a topic or chapter, highlight the topic or chapter title and click the Print button at the top of the help display. A dialog opens.
Choose to print only the selected topic, or to print all topics in that chapter. After you make your selection, another dialog appears where you can choose your printer and other options.

The tabs available at the top of the dialog depend on the selected printer. Choose options for the print job, and click OK to begin printing.
How to Contact Us

We are also interested in hearing your views about 3ds Max. We’d like to hear ways you think we can improve our program, features you’re interested in, as well as your views on the documentation set.

Please send us email about the documentation set at:
me.documentation@autodesk.com

About MAXScript

MAXScript is the built-in scripting language for 3ds Max.

With MAXScript, you have the ability to:

■ Script all aspects of 3ds Max use, such as modeling, animation, materials, rendering, and so on.

■ Control 3ds Max interactively through a command-line shell window.

■ Package scripts within custom utility panel rollouts or modeless windows, giving them a standard 3ds Max user interface.

■ Build custom import/export tools using the built-in file I/O.

■ Write procedural controllers that can access the entire state of the scene. Build batch-processing tools, such as batch-rendering scripts.

■ Set up live interfaces to external system using OLE Automation.

The MAXScript language is specifically designed to complement 3ds Max. It is object-oriented, and has several special features and constructs that mirror high-level concepts in the 3ds Max user interface. These include coordinate-system contexts, an animation mode with automatic keyframing, and access to scene objects using hierarchical path names that match the 3ds Max object hierarchy.

The syntax is simple enough for non-programmers to use, with minimal punctuation and formatting rules.

Visual MAXScript

Visual MAXScript is a powerful addition to MAXScript, making the MAXScript feature easier to learn and use. With Visual MAXScript, you can quickly create UI elements and layouts for scripting.
For detailed information about Visual MAXScript, open the MAXScript Help, available from Help menu > MAXScript Help.

See also:
- MAXScript Menu on page 8031

Procedures

To access MAXScript, do one of the following:

1 On the menu bar, choose MAXScript. The MAXScript menu appears.
2 Choose Utilities panel > MAXScript.
   From here, you can either write new scripts, edit or run existing scripts, open the MAXScript Listener, or use the Macro Recorder.
   To access the MAXScript Listener, you can also right-click in the Mini Listener and choose Open Listener Window from the right-click menu.
   For detailed information about the MAXScript utility, open the MAXScript Help, available from Help menu > MAXScript Help.

Getting Started with 3ds Max

You use 3ds Max to quickly create professional-quality 3D models, photorealistic still images, and film-quality animation on your PC.

Before using this reference material, we highly recommend you get to know 3ds Max firsthand by following the included tutorials. You can access the tutorials using the Help menu > Tutorials command.
Project Workflow

Once you’ve installed 3ds Max (see the Installation Guide included with your software package), you open it from the Start menu, or use any other Windows method. The figure below shows the application window with a scene file loaded.

Main program window

NOTE If you open 3ds Max from a Command Prompt window or batch file, you can add command-line switches. See Starting 3ds Max from the Command Line on page 7985.
NOTE 3ds Max is a single-document application, meaning you can work on only one scene at a time. You can run 3ds Max several times and open a different scene in each instance, but doing so requires a lot of RAM. For best performance, open only one instance and work on one scene at a time.

Modeling Objects

You model and animate objects in the viewports, whose layout is configurable. You can start with a variety of 3D geometric primitives. You can also use 2D shapes as the basis for lofted or extruded objects. You can convert objects to a variety of editable surface types, which you can then model further by pulling vertices and using other tools.

Another modeling tool is to apply modifiers to objects. Modifiers can change object geometry. Bend and Twist are examples of modifiers.

Modeling, editing, and animation tools are available in the command panels and toolbar. See Modeling Objects on page 33. Also, you can learn a good deal about modeling from the tutorials available from Help menu > Tutorials.
Material Design

You design materials using the Material Editor, which appears in its own window. You use the Material Editor to create realistic materials by defining hierarchies of surface characteristics. The surface characteristics can represent static materials, or be animated. See Material Editor on page 5641. Tutorials especially helpful for learning about materials include "Overview of Creating a Scene: Still Life" and "Using Materials."

Lights and Cameras

You create lights with various properties to illuminate your scene. The lights can cast shadows, project images, and create volumetric effects for atmospheric lighting. Physically-based lights let you use real-world lighting data in your scenes and Radiosity on page 6615 provides incredibly accurate light simulation in renderings. See Lights on page 5314. You can learn more about lighting by following the Introduction to Lighting tutorial.
The cameras you create have real-world controls for lens length, field of view, and motion control such as truck, dolly, and pan. See Cameras on page 5545.

**Animation**

You can begin animating your scene at any time by turning on the Auto Key button. Turn the button off to return to modeling. You can also perform animated modeling effects by animating the parameters of objects in your scene. You can learn more about animating in the Animating Your Scene topic on page 40 and from most of the tutorials.
When the Auto Key button is on, 3ds Max automatically records the movement, rotation, and scale changes you make, not as changes to a static scene, but as keys on certain frames that represent time. You can also animate many parameters to make lights and cameras change over time, and preview your animation directly in the 3ds Max viewports.

You use Track View on page 3790 to control animation. Track View is a floating window where you edit animation keys, set up animation controllers, or edit motion curves for your animated effects.

**Rendering**

Rendering adds color and shading to your scene. The renderers available with 3ds Max include features such as selective ray tracing, analytical antialiasing, motion blur, volumetric lighting, and environmental effects. See Rendering Your Scene on page 41. The tutorials can help you learn about rendering.
When you use the default scanline renderer, a radiosity solution can provide accurate light simulation in renderings, including the ambient lighting that results from reflected light. When you use the mental ray renderer, a comparable effect is provided by global illumination.

If your workstation is part of a network, network rendering can distribute rendering jobs over multiple workstations. See Network Rendering.

With Video Post, you can also composite the scene with animations stored on disk.

A Typical Project Workflow

These topics explain the basic procedures for creating scenes:

Setting Up Your Scene
Modeling Objects
Using Materials
Placing Lights and Cameras
Animating Your Scene
Setting Up Your Scene

You start with a new unnamed scene when you open 3ds Max. You can also start a new scene at any time by choosing New or Reset from the Application menu on page 7989.

Choosing a Unit Display

You choose a system of unit display on the Units Setup dialog on page 8366. Choose from Metric, Standard US, and Generic methods, or design a custom measuring system. You can switch between different systems of unit display at any time.

NOTE For best results, use consistent units when you are going to:
- Merge scenes and objects on page 7572.
- Use XRef objects on page 7450 or XRef scenes on page 7477.

Setting the System Unit

The System Unit setting, in the Units Setup dialog on page 8366, determines how 3ds Max relates to distance information you input to your scene. The setting also determines the range for round-off error. Consider changing the system unit value only when you model very large or very small scenes.

Setting Grid Spacing

Set spacing for the visible grid in the Grid And Snap Settings dialog > Home Grid panel on page 2833. You can change grid spacing at any time.

See Precision and Drawing Aids on page 2781 for information about the system unit, unit display, and grid spacing.
Setting the Viewport Display

The default four viewports in 3ds Max represent an efficient and popular screen layout. Set options in the Viewport Configuration dialog on page 8374 to change viewport layout and display properties.

See Viewing and Navigating 3D Space on page 65 for more information.

Saving Scenes

Save your scene frequently to protect yourself from mistakes and loss of work. See Backing Up and Archiving Scenes on page 61.

Modeling Objects

You model objects in your scene by creating standard objects, such as 3D geometry and 2D shapes, and then applying modifiers to those objects. 3ds Max includes a wide range of standard objects and modifiers.

Creating Objects

You create objects by clicking an object category and type on the Create panel and then clicking or dragging in a viewport to define the object's creation.
parameters. 3ds Max organizes the Create panel into these basic categories: Geometry, Shapes, Lights, Cameras, Helpers, Space Warps, and Systems. Each category contains multiple subcategories from which you can choose.

You can also create objects from the Create menu by choosing an object category and type and then clicking or dragging in a viewport to define the object's creation parameters. 3ds Max organizes the Create menu into these basic categories: Standard Primitives, Extended Primitives, AEC Objects, Compound, Particles, Patch Grids, NURBS, Dynamics, Shapes, Lights, Cameras, Helpers, Space Warps, and Systems.

See Basics of Creating and Modifying Objects on page 358.

Selecting and Positioning Objects

You select objects by clicking or dragging a region around them. You can also select objects by name or other properties such as color or object category.

After selecting objects, you position them in your scene using the transform tools Move, Rotate, and Scale. Use alignment tools to precisely position objects.

See Selecting Objects on page 171, Moving, Rotating, and Scaling Objects on page 885, and Precision and Drawing Aids on page 2781.

Modifying Objects

You sculpt and edit objects into their final form by applying modifiers from the Modify panel. The modifiers you apply to an object are stored in a stack. You can go back at any time and change the effect of the modifier, or remove it from the object.

See Basics of Creating and Modifying Objects on page 358.

Using Materials

You use the Material Editor to design materials and maps to control the appearance of object surfaces. Maps can also be used to control the appearance of environmental effects such as lighting, fog, and the background.
A variety of materials in the Material Editor’s sample slots

Room on left uses the a neutral, gray material. Room on right uses a realistic materials, including transparent glass and a snowfall.

**Basic Material Properties**

You set basic material properties to control such surface characteristics as default color, shininess, and level of opacity. You can create realistic, single-color materials using just the basic properties.
Using Maps

You extend the realism of materials by applying maps to control surface properties such as texture, bumpiness, opacity, and reflection. Most of the basic properties can be enhanced with a map. Any image file, such as one you might create in a paint program, can be used as a map, or you can choose procedural maps that create patterns based on parameters you set.

3ds Max also includes a raytrace material and map for creating accurate reflections and refraction.

Viewing Materials in the Scene

You can view the effect of materials on objects in a shaded viewport, but the display is just an approximation of the final effect. Render your scene to view materials accurately.

See Designing Materials on page 5620.

Placing Lights and Cameras

You place lights and cameras to complete your scene in much the same way lights and cameras are placed on a movie set prior to filming.
Lights and cameras placed to compose a scene
The resulting scene

**Default Lighting**

Default lighting evenly illuminates the entire scene. Such lighting is useful while modeling, but it is not especially artistic or realistic.

**Placing Lights**

You create and place lights from the Lights category of the Create panel or menu when you are ready to get more specific about the lighting in your scene.

3ds Max includes the following standard light types: omni, spot, and directional lights. You can set a light to any color and even animate the color to simulate dimming or color-shifting lights. All of these lights can cast shadows, project maps, and use volumetric effects.

See *Guidelines for Lighting* on page 5330.
Photometric Lights

Photometric lights on page 5348 provide you with the ability to work more accurately and intuitively using real-world lighting units (lumens and candelas). Photometric lights also support industry-standard photometric file formats (IES on page 5376, CIBSE on page 8532, LTLI on page 8625) so that you can model the characteristics of real-world manufactured luminaires, or even drag ready-to-use luminaires from the Web. Used in conjunction with the 3ds Max radiosity solution on page 6615, photometric lights let you evaluate more accurately (both physically and quantitatively) the lighting performance of your scene.

Photometric lights are available from the Create panel > Lights drop-down list.

Daylight System

The Daylight system on page 5491 combines sunlight on page 8734 and skylight on page 8723 to create a unified system that follows the geographically correct angle and movement of the sun over the earth at a given location. You can choose location, date, time, and compass orientation. You can also animate the date and time. This system is suitable for shadow studies of proposed and existing structures.

Viewing Lighting Effects in the Scene

When you place lights in a scene, the default lighting turns off and the scene is illuminated only by the lights you create. The illumination you see in a viewport is just an approximation of the true lighting. Render your scene to view lighting accurately.

TIP If the Daylight system appears to wash out the scene, try using the Logarithmic exposure control on page 7215.

Placing Cameras

You create and place cameras from the Cameras category of the Create panel. Cameras define viewpoints for rendering, and you can animate cameras to produce cinematic effects such as dollies and truck shots.

You can also create a camera automatically from a Perspective viewport by using the Create Camera from View command on page 150 found on the Views menu. Just adjust your Perspective viewport until you like it, and then choose
Views > Create Camera From View. 3ds Max creates a camera and replaces the Perspective viewport with a Camera viewport showing the same perspective. See Common Camera Parameters on page 5570.

**Animating Your Scene**

You can animate almost anything in your scene. Click the Auto Key button to enable automatic animation creation, drag the time slider, and make changes in your scene to create animated effects.

![Auto Key]

**Controlling Time**

3ds Max starts each new scene with 100 frames for animation. Frames are a way of measuring time, and you move through time by dragging the time slider on page 8068. You can also open the Time Configuration dialog on page 8106 to set the number of frames used by your scene and the speed at which the frames are displayed.

**Animating Transforms and Parameters**

While the Auto Key button is on, 3ds Max creates an animation key on page 8616 whenever you transform an object or change a parameter. To animate a parameter over a range of frames, specify the values at the first and last frames of the range. 3ds Max calculates the values for all of the frames in between. See Animation Concepts and Methods on page 3368.

**Editing Animation**

You edit your animation by opening the Track View window or by changing options on the Motion panel. Track View is like a spreadsheet that displays animation keys along a time line. You edit the animation by changing the keys.

Track View has two modes. You can display the animation as a series of function curves that graphically show how a value changes over time in the Curve Editor mode. Alternatively, you can display your animation as a sequence of keys or ranges on a grid in the Dope Sheet mode. See Track View on page 3790.
Rendering Your Scene

Use the rendering features to define an environment and to produce the final output from your scene.

Rendering "fills in" geometry with color, shadow, lighting effects, and so on.

Defining Environments and Backgrounds

Rarely do you want to render your scene against the default background color. Open the Environment And Effects dialog > Environment panel on page 7163 to define a background for your scene, or to set up effects such as fog.

Setting Rendering Options

To set the size and quality of your final output, you can choose from many options on the Render Setup dialog on page 6506. You have full control over professional grade film and video properties as well as effects such as reflection, antialiasing, shadow properties, and motion blur.
Rendering Images and Animation

You render a single image by setting the renderer to render one frame of your animation. You specify what type of image file to produce and where 3ds Max stores the file.

Rendering an animation is the same as rendering a single image except that you set the renderer to render a sequence of frames. You can choose to render an animation to multiple single frame files or to popular animation formats such as AVI or MOV.

See Render Setup Dialog on page 6506.

The 3ds Max Window

Most of the main window is occupied by the viewports, where you view and work with your scene. The remaining areas of the window hold controls and show status information.

1. Application button
2. Quick Access toolbar
One of the most important aspects of using 3ds Max is its versatility. Many program functions are available from multiple user-interface elements. For example, you can open Track View for animation control from the Main toolbar as well as the Graph Editors menu, but the easiest way to get to a specific object’s track in Track View is to right-click the object, and then choose Track View Selected from the quad menu.

You can customize the user interface in a variety of ways: by adding keyboard shortcuts, moving toolbars and command panels around, creating new toolbars and tool buttons, and even recording scripts into toolbar buttons.

MAXScript lets you create and use custom commands in the built-in scripting language. For more information, access the MAXScript Help from the Help menu.

**Application Button and Quick Access Toolbar**

The Application button and Quick Access toolbar provide file-handling commands. To the right of them on the Caption bar, the InfoCenter controls give you quick access to 3ds Max help and other learning resources. See Caption Bar on page 7988.
Menu Bar

A standard Windows menu bar with typical Edit on page 7999 and Help on page 8032 menus. Special menus include:

- **Tools** on page 8001 contains many important program functions, including precision functions. Many of these options are duplicated on the Main toolbar.
- **Group** on page 8005 contains commands for managing combined objects.
- **Views** on page 8006 contains commands for setting up and controlling the viewports.
- **Create** on page 8008 contains commands for creating objects.
- **Modifiers** on page 8016 contains commands for modifying objects.
- **Animation** on page 8023 contains commands for animating and constraining objects, plus commands such as Bone Tools for setting up animated characters.
- **Graph Editors** on page 8027 provides graphical access to editing objects and animation: Track View lets you open and manage animation tracks in Track View on page 3790 windows, and Schematic View on page 7926 gives you an alternate way to work with the objects in your scene and navigate to them.
- **Rendering** on page 8028 contains commands for rendering, using radiosity on page 6615, and changing the environment.
- **Customize** on page 8029 gives you access to controls that let you customize the user interface.
- **MAXScript** on page 8031 has commands for working with MAXScript, the built-in scripting language.

For more information about the 3ds Max menus, see Menu Bar on page 7998.

Time Controls

The **Auto Key button** on page 3373 turns on animation mode. The other controls navigate through time and play back an animation.
Command Panel

This collection of six panels provides handy access to most of the modeling and animation commands.

You can "tear off" the command panel and place it anywhere you like.

By default, the command panel is docked at the right of your screen. You can access a menu that lets you float on page 8555 or dismiss the command panel by right-clicking just above it. If it is not displayed, or you want to change its location and docking or floating status, right-click in a blank area of any toolbar, and choose from the shortcut menu.

- **Create** on page 8182 holds all object creation tools.
- **Modify** on page 8184 holds modifiers and editing tools.
- **Hierarchy** on page 8213 holds linking and inverse kinematics parameters.
- **Motion** on page 8215 holds animation controllers and trajectories.
- **Display** on page 8217 holds object display controls.
- **Utilities** on page 8223 holds miscellaneous utilities.

Status Bar and Prompt Line

These two lines display prompts and information about your scene and the active command. They also contain system toggles controlling selections, precision, and display properties. See Status Bar Controls on page 8064.
Viewports

You can display from one to four viewports. These can show multiple views of the same geometry, as well as the Track View, Schematic View, and other informational displays. See Viewports on page 8113.

Viewport Navigation Buttons

The button cluster at the lower-right corner of the main window contains controls for zooming, panning, and navigating within the viewports. See Viewport Controls on page 8113.

Special Controls

3ds Max uses some special user interface controls, which are described in this topic.

- Right-click menus on page 46
- Flyouts on page 47
- Rollouts on page 47
- Scrolling panels and toolbars on page 48
- Spinners on page 49
- Numerical Expression Evaluator on page 49
- Entering numbers on page 50
- Controls and color on page 50
- Undoing actions on page 50

Right-Click Menus

3ds Max uses several different types of right-click menus.

For object editing and ActiveShade control on page 6558, you use the quad menu on page 8052. Commands on the quad menu vary depending on the kind of object you are editing and the mode you are in.

Each viewport has three labels that are menus you can access by either clicking or right-clicking. These let you change viewport display settings, choose the
point-of-view to display, how to shade the viewport, and so on. See Viewport Label Menus on page 8117.

Also, the command panel and the Material Editor have right-click menus that let you manage rollouts and navigate the panel quickly. And most other windows, including Schematic View and Track View, have right-click menus that provide fast access to commonly used functions.

**Flyouts**

A flyout on page 8582 is similar to a menu, except that its items are buttons. A flyout button is indicated by a small arrow in the lower-right corner. To display the flyout, click and hold the button for a moment, then choose a button by dragging the cursor to it and then releasing the mouse button.

NOTE You can define customized text annotations for flyouts by editing the maxstart.cui file. See Customize Menu on page 8029.

**Rollouts**

Rollouts are areas in the command panels and dialogs that you can expand (roll out) or collapse (roll in) to manage screen space. In the illustration above, the Keyboard entry rollout is collapsed, as indicated by the + sign, and the Parameters rollout is expanded, as indicated by the − sign.
To open and close a rollout:

- Click the rollout title bar to toggle between expanded and collapsed.

To move a rollout:

- You can move a rollout in the expanded or collapsed state. To move the rollout, drag the rollout title bar to another location on the command panel or dialog. As you drag, a semi-transparent image of the rollout title bar follows the mouse cursor. When the mouse is positioned over or near a qualifying position for the rollout, a blue, horizontal line appears at the position where the rollout will drop when you release the mouse button.

Scrolling Panels and Toolbars

Sometimes a command panel or dialog is not large enough to display all of its rollouts. In this case, a pan ("hand") cursor appears over the inactive parts of the panel. You can scroll command panels and dialogs vertically, and you can scroll a toolbar along its major axis.

To scroll a panel:

1. Place the pointer over an empty area of a panel to display the pan cursor.
2. When the pointer icon changes to a hand, drag the panel up or down. A thin scroll bar also appears on the right side of the scrolling panel. You can use the pointer to drag the scroll bar as well.

To scroll a toolbar:

You can scroll a toolbar only when some tool buttons are not visible. This typically occurs when 3ds Max window is smaller than full screen.

1. First, follow either of the procedures below:
   - Place the pointer over an empty area of a toolbar to display the pan cursor.
   - Place the pointer over any part of a toolbar, then press and hold the middle mouse button.
2. When the pointer icon changes to a hand, drag the toolbar horizontally.
Spinners

A spinner is a mouse-based control for numeric fields. You can click or drag the spinner arrows to change the value in the field.

To change a value using a spinner, do any of the following:

1. Click the spinner's up arrow to increment the value; click the down arrow to decrement the value. Click and hold for continuous change.
2. Drag upward to increase the value, or drag downward to decrease it.
3. Press Ctrl while you drag to increase the rate at which the value changes.
4. Press Alt while you drag to decrease the rate at which the value changes.
5. Right-click a spinner to reset the field to its minimum value.

Numerical Expression Evaluator

While a numeric field is active, you can display a calculator called the Numerical Expression Evaluator. To display the calculator, press Ctrl+N.

The expression you enter is evaluated, and its result is displayed in the Result field. Click Paste to replace the field value with the result of the calculation. Click Cancel to exit the Expression Evaluator.

The expressions you can enter are described in Expression Techniques on page 339. You can't use variables in the Expression Evaluator, but you can enter the constants pi (circular ratio), e (natural logarithm base), and TPS (ticks per second). These constants are case-sensitive: the Expression Evaluator does not recognize PI, E, or tps.
You can also enter a vector expression or an Expression Controller function call, but the result of the expression or function must be a scalar value. Otherwise, the Expression Evaluator won’t evaluate it.

**Entering Numbers**

You can change a numeric value by a relative offset by highlighting the contents of a numeric field (not in the Numerical Expression Evaluator) and typing \texttt{R} or \texttt{r} followed by the offset amount.

For example, a Radius field shows 70 and you highlight it:

- If you enter \texttt{R30}, 30 is added to the radius and the value changes to 100.
- If you enter \texttt{R-30}, 30 is subtracted from the radius and the value changes to 40.

**Controls and Color**

The user interface uses color cues to remind you what state 3ds Max is in.

NOTE You can customize most of these colors by using the Colors panel on page 8272 of the Customize User Interface dialog on page 8249.

- **Red for animation:** The Auto Key button, the time slider background, and the border of the active viewport turn red when you are in Animate mode.

- **Yellow for modal function buttons:** When you turn on a button that puts you in a generic creation or editing mode, the button turns yellow.

- **Yellow for special action modes:** When you turn on a button that alters the normal behavior of other functions, the button is highlighted in yellow. Common examples of this behavior include sub-object selection and locking your current selection set.

You can exit a functional mode by clicking another modal button. Other exit methods supported by some buttons include right-clicking in a viewport, or clicking the modal button a second time.

**Undoing Actions**

You can easily undo changes you make to your scene and your viewports. There are separate Undo buffers for both the scene objects and each viewport.
Use the toolbar **Undo and Redo buttons** on page 240 or the Edit menu > Undo and Redo commands to reverse the effects of most scene operations. You can also use Ctrl+Z for Undo and Ctrl+Y for Redo. Most things you do in 3ds Max can be undone.

Use the Views menu > **Undo and Redo commands** on page 126 to reverse the effects of most viewport operations, such as zooming and panning. You can also use Shift+Z for Undo View Change and Shift+Y for Redo View Change.

You can also undo actions by using the Hold and Fetch commands on the Edit menu. Choose Edit menu > Hold to save a copy of your scene in a temporary file. Then choose Edit menu > Fetch to discard your current scene and revert to the held scene at any time.

**Managing Files**

3ds Max supports many types of files for working with plug-ins, image maps, models from other programs, rendering images and animations, and of course saving and opening your scene files.
File-management dialogs

File dialogs (such as Open, Save, Save As) uniformly remember the previous path you used, and default to that location.

**Configuring File Paths**

The locations that 3ds Max searches to locate all file types are specified on the Customize menu > Configure Paths dialogs on page 8283.
You can choose to open and save files in any path location. The Configure Paths dialog contains four panels for the general categories of support files.

### Setting General File Paths

The File I/O panel on page 8287 contains paths for most of the standard support files. You can specify one path for each of file types 3ds Max uses.

### Setting Plug-In File Paths

Many features of 3ds Max are implemented as plug-ins. This means you can change and extend 3ds Max functionality by adding new plug-ins from Autodesk Media and Entertainment or from third-party developers.

You tell 3ds Max where to find additional plug-in files by adding path entries on the 3rd Party Plug-Ins panel on page 8296. If you place all of your plug-ins in a single directory, plug-in file management can become messy. That's why 3ds Max supports multiple entries on the 3rd Party Plug-Ins panel.

### Setting Bitmap, FX, and Download File Paths

The External Files panel on page 8289 contains multiple path entries that 3ds Max searches for image files on page 7831, downloaded files (via i-drop on page...
7644), and FX files on page 8589. Image files are used for many purposes, such as material and map definition, light projections, and environment effects.

**Setting XRefs File Paths**

The XRefs panel on page 8292 contains multiple path entries that 3ds Max uses to search for externally referenced files. These are used for sharing files in a workgroup situation.

**Importing, Merging, Replacing, and Externally Referencing Scenes**

You can realize great productivity gains when you reuse work by combining geometry from scenes or other programs. 3ds Max supports this technique with the Import, Merge, and Replace commands. You can also share scenes and objects with others working on the same project using XRef functionality.
Gear model imported to become part of another scene

Importing Geometry from Other Programs

Use Application menu on page 7989 > Import on page 7446 to bring objects from other programs into a scene. The types of files that you can import are listed in the Files Of Type list in the Select File To Import dialog.

Depending on the file type you choose, you might have options available for that import plug-in.

Merging Scenes Together

Use Merge on page 7572 to combine multiple scenes into a single large scene. When you merge a file, you can select which objects to merge. If objects being merged have the same name as objects in your scene, you have the option to rename or skip over the merged objects.
Pipe and ashtray models merged into one scene

**Merging Animation into Scenes**

Use [Merge Animation](#) on page 4126 to merge the animation from one scene into another with the same (or similar) geometry.
Replacing Scene Objects

Use Replace on page 7578 to replace objects in your scene with objects in another scene that have duplicate names. Replace is useful when you want to set up and animate your scene with simplified objects, and then replace the simple objects with detailed objects before rendering.

The Replace dialog looks and functions the same as Merge, except that it lists only objects that have the same name as objects in your current scene.

Using External References

Use XRef Objects on page 7450 and XRef Scenes on page 7477 to use objects and scene setups in your scene that are actually referenced from external MAX files. These functions allow sharing files with others in your workgroup, with options for updating and protecting external files.

Using the Asset Browser

The Asset Browser provides access from your desktop to design content on the World Wide Web. From within 3ds Max you can browse the Internet for texture samples and product models. This includes bitmap textures (BMP, JPG, GIF, TIF, and TGA) and geometry files (MAX, 3DS, and so on).
You can drag these samples and models into your scene for immediate visualization and presentation. You can snap geometry into predefined locations, or drag and drop them interactively in your scene.

You can also use the Asset Browser to browse thumbnail displays of bitmap textures and geometry files on your hard disk or shared network drives. Then you can either view them or drag and drop them into your scene or into valid map buttons or slots.

**NOTE** The thumbnail display of a geometry file is a bitmap representation of a view of the geometry. Since the thumbnail display is not a vector-based representation, you can't rotate it or perform zooms on it.

You can drag and drop most graphic images that are embedded in a Web page into your scene. The exception is images or regions of a Web page that are tagged as hyperlinks or other HTML controls (such as when a bitmap is tagged as a button).
Startup Files and Defaults

When you start 3ds Max, several auxiliary files load, setting things like program defaults and UI layout. You can even create a scene, named `maxstart.max`, that automatically loads when you start or reset 3ds Max. In some cases, 3ds Max updates files when you change settings and when you quit 3ds Max.

**NOTE** 3ds Max comes with several different *market-specific defaults* on page 8246. These set different program defaults on startup, based on the type of files you expect to work on most often. You can load the preset defaults that come with 3ds Max, or you can create your own.

In general, you don’t need to work directly with the auxiliary files, but it’s good to know about them. Among the auxiliary files 3ds Max uses are:

- **3dsmax.ini** on page 60: This file gets updated when you start and exit 3ds Max, as well as when you change most Preferences settings. It contains values relating to program defaults, including the graphics driver, directories used to access external files such as sounds and images, preset render sizes, dialog positions, snap settings, and other preferences and default settings. If you edit this file, be sure to make a copy first, so you can return to the original if anything goes wrong.

  **NOTE** Many program defaults are set in `currentdefaults.ini`, found within the `\defaults` directory. For more information on this file, see *Market-Specific Defaults* on page 8246.

- **maxstart.max**: At startup and when you reset 3ds Max, 3ds Max looks for this file in the `MaxStart` folder specified in Configure User Paths > File I/O panel on page 8287, and if found, loads it. This allows you to specify the default state of the workspace whenever you start or reset 3ds Max. For example, if you always use a ground plane, you can make it the default setup by creating one, and then saving it as `maxstart.max`. If you save a different file over `maxstart.max`, you can return to program defaults by deleting the `maxstart.max` file, and then resetting 3ds Max.
maxstart.cui: This is the default custom user interface file. You can load and save CUI files, and set 3ds Max to use a different default CUI file. See Customize Menu on page 8029.

plugin.ini: This file contains directory paths for plug-ins. Most other paths are kept in 3ds Max INI file, but plugin.ini is maintained as a separate file because third-party plug-ins often add entries to the list at installation.

NOTE It is possible to use multiple plug-in configuration files by nesting additional paths in your plugin.ini file. This can be very useful for allowing an entire network of users to share one plugin.ini file, making the system easier to maintain for the network administrator. For more information, see Network Plug-In Configuration on page 8297.

startup.ms: A MAXScript file that automatically executes at startup time. For more information, see Startup Script on page 8730.

The Initialization File

The file 3ds Max uses to store settings between sessions is named 3dsmax.ini. In most cases, you don’t need to access this file directly. To find it, if necessary, use the Windows Search function.

You can make changes to 3ds Max startup conditions by editing the 3dsmax.ini file in a text editor such as Notepad. If you do edit the file, be sure to maintain the structure and syntax of the original file.

TIP If you encounter unusual and unexplained user-interface problems using 3ds Max, try deleting the 3dsmax.ini file and restarting. 3ds Max writes a new INI file to replace the deleted one. Often this fixes problems related to the state of the user interface.

NOTE Startup scene conditions are defined by the maxstart.max file. To save a particular startup condition, such as a Plane object representing the ground, create a scene file with the condition present and then save it as maxstart.max. 3ds Max automatically opens this file when you start 3ds Max.

The 3dsmax.ini file includes the following categories of settings:

[Directories] Defines the default paths for various file operations.

[Performance] Controls that speed up viewport performance.
[PlugInKeys] Turns on or off the keyboard shortcuts for plug-ins.
[Renderer] Controls for rendering alpha and filter backgrounds.
[RenderPresets] Defines the paths for Rendering Preset files.
[BitmapDirs] Defines the default map paths for bitmaps used by materials.
[Modstack] Controls modifier stack button sets and icon display.
[WindowState] Settings for software display, OpenGL, or Direct3D drivers.
[CustomMenus] Defines path for the .mnu file.
[CustomColors] Defines the path for the .clr file.
[KeyboardFile] Defines the path for the .kbd file.
[ObjectSnapSettings] Settings associated with snaps.
[CommandPanel] Sets number of columns, and controls rollout display in multiple columns.

**Backing Up and Archiving Scenes**

You should regularly back up and archive your work. One convenient method is to save incremental copies of your scenes. This method creates a history of your work process.

**Saving Incremental Files**

If you turn on the Increment On Save option on the Files panel on page 8305 of the Preferences dialog, the current scene is renamed by appending a two-digit number to the end of the file and incrementing the number each time you save. For example, if you open a file named myfile.max and then save it, the saved file is named myfile01.max. Each time you save the file its name is incremented, producing the files myfile02.max, myfile03.max, and so on.

You can also use Save As on page 7441 to increment the file name manually with a two-digit number by clicking the increment button (+) on the Save As dialog.
Using Auto Backup

You can automatically save backup files at regular intervals by setting the Auto Backup options on page 8307 on the Preferences dialog (see File Preferences on page 8305). The backup files are named AutoBackupN.max, where N is a number from 1 to 99, and stored, by default, in the \autoback folder. You can load a backup file like any other scene file.

Archiving a Scene

3ds Max scenes can make use of many different files. When you want to exchange scenes with other users or store scenes for archival purposes, you often need to save more than just the scene file.

Use the Application menu on page 7989 > Archive command on page 7445 to pass the scene file and any bitmap files used in the scene to an archiving program compatible with PKZIP® software.

Crash Recovery System

If 3ds Max encounters an unexpected crash, it attempts to recover and save the file currently in memory. This is fairly reliable, but it does not always work: the recovered scene could be damaged during the crash. The recovered file is stored in the configured Auto Backup path. It is saved as "<filename>_recover.max" in this path. It is also placed in the INI file as the most recently used file in the Application menu on page 7989. This makes it easy to return to the file, if you choose to do so.

The crash recovery system identifies when something in an object's modifier stack is corrupt. In these cases, the corrupt object is replaced with a red dummy object to maintain the object's position and any linked object hierarchy.
NOTE We recommend that you not rely on this file-recovery mechanism as an alternative to good data backup practices:

■ Save your work frequently.

■ Take advantage of automatic incremental file naming: Go to Customize menu > Preferences > Files panel on page 8305 > File Handling group, and turn on Increment On Save.

■ Use Application menu on page 7989 > Save > Save As, and click the Increment button (+) to save incremental copies of work in progress.

■ If you are forgetful about saving, use the Auto Backup feature. Go to Customize menu > Preferences > Files tab > Auto Backup group, and turn on Enable.
Viewing and Navigating 3D Space

Everything in 3ds Max is located in a three-dimensional world. You have a variety of options for viewing this enormous stage-like space, from the tiniest details to the full extent of your scene.

Different viewports can display different angles; on the right, the largest viewport shows a camera view.

Using the view options discussed in this section you move from one view to another, as your work and imagination require. You can fill your screen with a single, large viewport, or set
multiple viewports to track various aspects of your scene. For exact positioning, flat drawing views are available, as are 3D perspective on page 8681 and axonometric views on page 8515.

You navigate 3D space by adjusting the position, rotation and magnification of your views. You have full control over how objects are rendered and displayed on the screen.

You can also use the Grab Viewport command on page 125 to create snapshots of your work as you go.

This section presents brief topics designed to help you quickly start learning how to organize viewports and navigate through 3D space. For details about viewport commands, see Viewport Controls on page 8113.

**General Viewport Concepts**

Viewports are openings into the three-dimensional space of your scene, like windows looking into an enclosed garden or atrium. But viewports are more than passive observation points. While creating a scene, you can use them as dynamic and flexible tools to understand the 3D relationships among objects.
At times you might want to look at your scene through a large, undivided viewport, giving you a “picture-window” view of the world you’re creating. Often you use multiple viewports, each set to a different orientation.

If you want to move an object horizontally in the world space, you might do this in a top viewport, looking directly down on the object as you move it. At the same time, you could be watching a shaded perspective viewport to see when the object you’re moving slides behind another. Using the two windows together, you can get exactly the position and alignment you want.

You also have pan and zoom features available in either view, as well as grid alignment. With a few mouse clicks or keystrokes, you can reach any level of detail you need for the next step in your work.

Another way to use viewports is to place a camera in your scene and set a viewport to look through its lens. When you move the camera, the viewport tracks the change. You can do the same thing with spotlights.
In addition to geometry, viewports can display other views such as Track View and Schematic View, which display the structure of the scene and the animation. Viewports can be extended to display other tools such as the MAXScript Listener and the Asset Browser. For interactive rendering, the viewport can display the ActiveShade window.

**Active Viewport**

One viewport, marked with a highlighted border, is always active. The active viewport is where commands and other actions take effect. Only one viewport can be in the active state at a time. If other viewports are visible, they are set for observation only; unless disabled, they simultaneously track actions taken in the active viewport.

**Saving the Active Viewport**

You can save the view in any active viewport and later restore it with the Views menu's Save Active View on page 127 and Restore Active View on page 128 commands. One view can be saved for each of the following view types: Top, Bottom, Left, Right, Front, Back, Orthographic, Perspective.

For example, while in the Front view, you choose Save Active Front View, and then zoom and pan that view. You then activate the Top viewport, choose Save Active Top View, and then click Zoom Extents. You return to the Front view, and choose Restore Active Front View to return to its original zoom and pan. At any time, you can activate the Top viewport, and then choose Restore Active Top View to restore its saved view.

**Home Grid: Views Based on the World Coordinate Axes**

The grid you see in each viewport represents one of three planes that intersect at right angles to one another at a common point called the origin. Intersection occurs along three lines (the world coordinate axes: X, Y, and Z) familiar from geometry as the basis of the Cartesian coordinate system.
The three planes based on the world coordinate axes are called the home grid; this is the basic reference system of the 3D world.

To simplify the positioning of objects, only one plane of the home grid is visible in each viewport. The figure shows all three planes as they would appear if you could see them in a single perspective viewport.
Axes, Planes, and Views

Two axes define each plane of the home grid. In the default Perspective viewport, you are looking across the XY plane (ground plane), with the X axis running left-to-right, and the Y axis running front-to-back. The third axis, Z, runs vertically through this plane at the origin.
Home Grid and Grid Objects

Above: Inactive grid object in a scene
Below: Activated grid object

The home grid is aligned with the world coordinate axes. You can turn it on and off for any viewport, but you can’t change its orientation.

For flexibility, the home grid is supplemented by grid objects: independent grids you can place anywhere, at any angle, aligned with any object or surface. They function as "construction planes" you can use once and discard or save for reuse. See Precision and Drawing Aids on page 2781.
AutoGrid

The AutoGrid feature lets you create and activate temporary grid objects on the fly. This lets you create geometry off the face of any object by first creating the temporary grid, then the object. You also have the option to make the temporary grids permanent. See AutoGrid on page 2792.

Understanding Views

Each viewport can be set to display either of two types of views: axonometric or perspective.

- Axonometric views on page 8515 show the scene without perspective. All lines in the model are parallel to one another. The Top, Front, Left, and Orthographic viewports are axonometric views.
Perspective views on page 8681 show the scene with lines that converge at the horizon. The Perspective and Camera viewports are examples of perspective views.

Perspective view of the same model

Perspective views most closely resemble human vision, where objects appear to recede into the distance, creating a sense of depth and space. Axonometric views provide an undistorted view of the scene for accurate scaling and placement. A common workflow is to use axonometric views to create the scene, then use a perspective view to render the final output.

Axonometric Views

There are two types of axonometric views you can use in viewports: head-on and rotated.

An orthographic view on page 8668 is often a head-on view of the scene, such as the view shown in the Top, Front, and Left viewports. You can set a viewport to a specific orthographic view using the Point-Of-View (POV) viewport label menu on page 8122, keyboard shortcuts on page 8419, or the ViewCube on page 86. For example, to set an active viewport to Left view, press L.
You can also rotate an orthographic view to see the scene from an angle while retaining parallel projection. However, when viewing the scene from an angle, it’s often more helpful to use a perspective view.

**Perspective Views**

A perspective viewport, labeled Perspective, is one of the startup viewports in 3ds Max. You can change any active viewport to this "eye-like" point of view by pressing P.

**Camera View**

Once you create a camera object in your scene, you can change the active viewport to a camera view by pressing C and then selecting from a list of cameras in your scene. You can also create a camera view directly from a perspective viewport, using the Create Camera from View command.

A camera viewport tracks the view through the lens of the selected camera. As you move the camera (or target) in another viewport, you see the scene move accordingly. This is the advantage of the Camera view over the Perspective view, which can’t be animated over time.

If you turn on Orthographic Projection on a camera’s Parameters rollout, that camera produces an axonometric view. See Cameras on page 5545.
The viewport on the right is seen through a camera in the scene.

Two and Three-Point Perspective and the Camera Correction Modifier

By default, camera views use three-point perspective, in which vertical lines appear to converge with height (in traditional photography this is known as *keystoning*). The Camera Correction modifier on page 5607 applies two-point perspective to a camera view. In two-point perspective, vertical lines remain vertical. A similar effect can be attained by putting a Skew modifier on a camera.

Light View

Light view works much like a targeted camera view. You first create a spotlight or directional light and then set the active viewport to that spotlight. The easiest way is to press the keyboard shortcut $. See Lights on page 5314.
The viewport on the right looks through the lens of a spotlight in the scene.

**Setting Viewport Layout**

3ds Max defaults to a 2 x 2 arrangement of viewports. Thirteen other layouts are available, but the maximum number of viewports on the screen remains four.

Using the Layout panel on page 8379 of the Viewport Configuration dialog, you can pick from the different layouts and customize the viewports in each. The viewport configuration is saved with your work.
Resizing the Viewport

After choosing a layout you can resize the viewports so they have different proportions by moving the splitter bars that separate the viewports. This is available only when multiple viewports are displayed.
Changing the View Type

As you work, you can change the view in any viewport quickly. For example, you can switch from front view to back view. You can use either of two methods: menu or keyboard shortcut.

- Click or right-click the Point-Of-View (POV) viewport label of the viewport you want to change. Then from the POV viewport label menu on page 8122, click the view type that you want.
- Click the viewport you want to change, and then press one of the keyboard shortcuts in the following table.

<table>
<thead>
<tr>
<th>Key</th>
<th>View type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
<td>Top view</td>
<td></td>
</tr>
<tr>
<td>B</td>
<td>Bottom view</td>
<td></td>
</tr>
<tr>
<td>F</td>
<td>Front view</td>
<td></td>
</tr>
<tr>
<td>L</td>
<td>Left view</td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>Camera view. If your scene has only one camera, or you select a camera before using this keyboard shortcut, that camera supplies the view. If your scene has more than one camera, and none are selected, a list of cameras appears.</td>
<td></td>
</tr>
<tr>
<td>P</td>
<td>Perspective view. Retains viewing angle of previous view.</td>
<td></td>
</tr>
<tr>
<td>U</td>
<td>Orthographic User view. Retains viewing angle of previous view. Allows use of Zoom Region on page 8149.</td>
<td></td>
</tr>
<tr>
<td>none</td>
<td>Right view. Use the POV viewport label menu on page 8122.</td>
<td></td>
</tr>
</tbody>
</table>
Controlling Viewport Rendering

You can choose from multiple options to display your scene. You can display objects as simple boxes, or render them with smooth shading and texture mapping. If you want, you can choose a different display method for each viewport.

<table>
<thead>
<tr>
<th>Key</th>
<th>View type</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>Shape view. Use the <strong>POV viewport label menu</strong> on page 8122. Automatically aligns view to the extents of a selected shape and its local XY axes.</td>
</tr>
</tbody>
</table>

- Viewport Layout on page 8379
- Camera Viewport Controls on page 8154
- Spotlight Parameters on page 5439
- Precision and Drawing Aids on page 2781
- Track View on page 3790
Box display, wireframe display, and smooth shading

**TIP** If you want to display and render an individual object as wireframe, you can use a Standard or Raytrace material and set its shader to Wire on page 5971. Or, to display an individual object to display as a box, select the object and choose Display as Box on page 166 on the Display properties rollout on the display panel.

**Using Viewport Rendering Controls**

Viewport rendering options are found on the Shading viewport label menu on page 8130 and on the Rendering Method panel on page 8374 of the Viewport Configuration dialog. Using these controls you can set a rendering level and any options associated with that level. The viewport label menu settings apply to the active viewport only, but the Rendering Method panel lets you apply settings to the active viewport, all viewports, or to all but the active viewport.

The rendering level you choose is determined by your need for realistic display, accuracy, and speed. For example, Bounding Box display level can be much faster than Smooth + Highlights, depending on scene complexity. The more realistic the rendering level, the slower the display speed.

After choosing a rendering level, you can set rendering options. Different options are available for different rendering levels.
You can also use ActiveShade on page 6557 in a viewport. This feature helps you quickly preview changes you make to lighting and materials.

Viewport rendering has no effect on final renderings produced by clicking Render Scene.

Rendering Methods and Display Speed

The rendering methods not only affect the quality of your view display, they can also have a profound effect on display performance. Using higher quality rendering levels and realistic options slows display performance.

After setting a rendering method, you can choose additional options that adjust display performance. One of these controls, Adaptive Degradation, speeds up display performance when you use realistic rendering levels.

See Rendering Method on page 8374.

Controlling Display Performance

3ds Max contains controls to help you adjust display performance: the balance between quality and time in displaying objects.

Depending on your needs, you might give up some display speed to work at higher levels of rendering quality, or you might choose to maximize display speed by using Wireframe or Bounding Box display. Which method you choose depends on your preferences and the requirements of your work.

Display Performance Controls

You use display performance controls to determine how objects are rendered and displayed.

Viewport Preferences

The Customize > Preferences dialog's Viewports panel contains options for fine-tuning the performance of the viewport display software. See Viewport Preferences on page 8308.

How Objects Are Displayed

To see and modify an object's display properties, right-click the object, select Properties, and go to the Display Properties group box; see Object Properties on page 283. These options affect display performance much the same way as
viewport rendering options. For example, turning on Vertex Ticks for an object with a lot of vertices will slow performance.

**NOTE** Display Properties are only available when the By Object/By Layer toggle is set to By Object.

To see and modify how objects are displayed, you can use layers on page 7953. You can then quickly control the visibility and editability of similar objects from the quad menu.

### Which Objects Are Displayed

One way to increase display speed is not to display something. You can use the Hide and Freeze functions on the Display panel, quad menu, Layer Manager on page 7956, and Scene Explorer on page 7888 to change the display state of objects in your scene. The Hide and Freeze features also affect final Rendering and Video Post output. See Hide Rollout on page 161 and Freeze Rollout on page 163.

### Setting Adaptive Degradation

Adaptive Degradation dynamically adjusts viewport rendering levels to maintain a desired level of display speed. You have direct control over how much "degradation" occurs and when it occurs.

The active levels determine which rendering levels 3ds Max falls back to when it cannot maintain the desired display speed. You can choose as many levels as you want but you are advised to choose only one or two levels for each type of degradation.

See Adaptive Degradation on page 8498.

### Using Standard View Navigation

To navigate through your scene, use the view navigation buttons located at the lower-right corner of the 3ds Max window. All view types, except Camera and Light views, use a standard set of view navigation buttons.
Button Operation

Clicking standard view navigation buttons produces one of two results:

- Executes the command and returns to your previous action.
- Activates a view navigation mode.

You can tell that you are in a navigation mode because the button remains highlighted (orange background). This mode remains active until you right-click or choose another command.

While in a navigation mode, you can activate other viewports of the same type, without exiting the mode, by clicking in any viewport. See Viewport Controls on page 8113.

Undoing Standard View Navigation Commands

Use the Undo View Change and Redo View Change commands on page 126 on the Views menu to reset standard view navigation commands without affecting other viewports or the geometry in your scene. Undo View Change also appears on the Point-Of-View (POV) viewport label menu on page 8122. Or you can use the keyboard shortcuts: Shift+Z for Undo View Change and Shift+Y for Redo View Change.

Views menu > Undo View Change and Views menu > Redo View Change are different from Undo and Redo commands on the Edit menu and main toolbar. 3ds Max maintains separate Undo/Redo buffers for scene editing and for each viewport.

The View Change Undo/Redo buffer stores your last 20 view navigation commands for each viewport. You can step back through the Undo View/Redo View buffer until you have undone all of the stored view-navigation commands.
Zooming, Panning, and Rotating Views

When you click one of the view navigation buttons, you can change these basic view properties: zooming, panning, and rotating.

**NOTE** You can also navigate the viewport with the **ViewCube** on page 86 and **SteeringWheels** on page 93 toolsets.

![Zoom](image1.png) **Zoom** Controls zooming in and out.

**Pan View** Controls panning in any direction.

![Orbit](image2.png) **Orbit** Controls rotating in any direction

Before and after zooming a viewport

Before and after rotating a viewport
Zooming a View

Click Zoom on page 8142 or Zoom All on page 8143 and drag in a viewport to change the view magnification. Zoom changes only the active view, while Zoom All simultaneously changes all non-camera views.

If a perspective view is active, you can also click Field of View (FOV) on page 8146. The effect of changing FOV is similar to changing the lens on a camera. As FOV gets larger you see more of your scene and perspective becomes distorted, similar to using a wide-angle lens. As FOV gets smaller you see less of your scene and the perspective flattens, similar to using a telephoto lens.

**WARNING** Be cautious using extreme Field of View settings. These can produce unexpected results.

Zooming a Region

Click Zoom Region on page 8149 to drag a rectangular region within the active viewport and magnify that region to fill the viewport. Zoom Region is available for all standard views.

In a perspective viewport, Zoom Region mode is available from the Field of View flyout on page 8146.

Zooming to Extents

Click the Zoom Extents or Zoom Extents All flyout buttons to change the magnification and position of your view to display the extents of objects in your scene. Your view is centered on the objects and the magnification changed so the objects fill the viewport.

The **Zoom Extents, Zoom Extents Selected buttons** on page 8138 zoom the active viewport to the extents of all visible or selected objects in the scene.
The Zoom Extents All, Zoom Extents All Selected buttons on page 8138 zoom all viewports to the extents of all objects or the current selection.

Panning a View

Click Pan View on page 8150 and drag in a viewport to move your view parallel to the viewport plane. You can also pan a viewport by dragging with the middle mouse button held down while any tool is active.

Rotating a View

Click Orbit, Orbit Selection, or Orbit Sub-Object on page 8152 to rotate your view around the view center, the selection, or the current sub-object selection respectively. When you rotate a head-on viewport, such as a Top view, it is converted to an Orthographic view, as reflected by the viewport label.

With Orbit, objects near the edges of the viewport can rotate out of view.

With Orbit Selected, selected objects remain at the same position in the viewport while the view rotates around them. If no objects are selected, the function reverts to the standard Orbit function.

With Orbit Sub-Object, selected sub-objects or objects remain at the same position in the viewport while the view rotates around them.

NOTE You can rotate a view by holding down the Alt key while you drag in a viewport using middle-button. This uses the current Orbit mode, whether or not the Orbit button is active. You can also activate Orbit by pressing Ctrl+R.

ViewCube

The ViewCube® 3D navigation control provides visual feedback of the current orientation of a viewport, lets you adjust the view orientation, and also switch between standard and isometric views.

Once the ViewCube is displayed, it appears by default in the upper-right corner of the active viewport, superimposed over the scene in an inactive state. It
does not appear in camera, light, or shape viewports, or in other types of views such as ActiveShade or Schematic. While the ViewCube is inactive, its primary function is to show the orientation of the scene based on the North direction of the model.

When you position the cursor over the ViewCube, it becomes active. Using the left mouse button, you can switch to one of the available preset views, rotate the current view, or change to the Home view of the model. Right-clicking opens a context menu with additional options.

**NOTE** If you are using the software display driver on page 8317, the ViewCube doesn’t appear.

**Control the Appearance of the ViewCube**

The ViewCube is displayed in one of two states: inactive and active. When the ViewCube is inactive, it appears transparent over the viewport by default so as not to completely obscure the view of the model. When the ViewCube is active, it is opaque and might obscure the view of objects in the scene.

You can control the opacity level of the ViewCube when it is inactive as well as its size, the viewports it appears in, and the display of the compass. These settings are located on the ViewCube panel on page 8400 of the Viewport Configuration dialog.

**Using the Compass**

The ViewCube compass indicates the North direction for the scene. You can toggle the compass display below the ViewCube and specify its orientation with the Compass settings on page 8402.

**Procedures**

**To display or hide the ViewCube:**

- Do one of the following:
  - Press the default keyboard shortcut: Alt+Ctrl+V.
Open the Viewport Configuration dialog to the **Viewport panel** on page 8400 and toggle the Show The ViewCube check box.

Click or right-click the **General (+) viewport label menu** on page 8117 and choose ViewCube > Show The ViewCube.

**To control the size and inactive opacity of the ViewCube:**

1. Open the Viewport Configuration dialog to the **Viewport panel** on page 8400.
2. In the Display Options group, click the ViewCube Size drop-down list and choose a size. The choices are Large, Normal, Small, and Tiny.
3. Also in the Display Options group, click the Inactive Opacity drop-down list and choose an opacity value. The choices range from 0% (invisible when inactive) to 100% (always fully opaque).
4. Click OK.

**To display the compass for the ViewCube**

1. Open the Viewport Configuration dialog to the **Viewport panel** on page 8400.
2. In the Compass group, turn on Show Compass Below The ViewCube. The compass is displayed below the ViewCube and indicates the North direction in the scene.
3. Click OK.

**Viewport Menu**

Right-click the ViewCube.

The ViewCube menu provides options to define the orientation of the ViewCube, switch between orthographic and perspective projection, define the Home and Front views for the model, and control the appearance of the ViewCube.

The following options can be found on the shortcut menu of the ViewCube:

- **Home**  Restores the Home view saved with the model.
- **Orthographic**  Switches the current view to orthographic projection.
- **Perspective**  Switches the current view to perspective projection.
- **Set Current View as Home**  Defines the Home view of the model based on the current view.
- **Set Current View as Front**  Defines the Front view of the model based on the current view.
- **Reset Front**  Resets the Front view of the scene to its default orientation.
- **Configure**  Opens the Viewport Configuration dialog to the ViewCube panel on page 8400, where you can adjust the appearance and behavior of the ViewCube.
- **Help**  Launches the online Help system and displays the topic on the ViewCube.

**Procedure**

To display the ViewCube menu:

- Right-click the compass, Home icon, or the main area of the ViewCube.

**Change the View of the Scene with the ViewCube**

You can change the view of a model by choosing a preset view or dragging the ViewCube, roll the current view 90 degrees, switch to an adjacent face view, define and restore the Front and Home views, and switch between projection modes.

**Change the Current View**

You can change the current view of a model by clicking predefined areas on the ViewCube or dragging the ViewCube.

The ViewCube provides 26 defined areas you can click to change the current view of a model. The defined areas are categorized into three groups: corner, edge, and face. Of the 26 defined areas, six represent standard orthographic views of a model: top, bottom, front, back, left, and right. You set an orthographic view by clicking one of the faces on the ViewCube.
You access angled views of the scene with the other 20 defined areas. Clicking one of the corners of the ViewCube changes the current view of the model to a three-fourths view, based on a viewpoint defined by three sides of the model. Clicking one of the edges changes the view of the model to a three-fourths view based on two sides of the model.

In addition, you can click and drag the ViewCube to change the view of the scene to a custom angled viewpoint other than one of the predefined viewpoints.

**Roll a Face View**

When you view a model from one of the face views such as Front, two additional icons, called roll arrows, are displayed near the ViewCube. To roll or rotate the current view 90 degrees in the positive or negative directions around the center of the view, click one of the roll arrows.

**Switch to an Adjacent Face**

While viewing a model from one of the face views, you can use the ViewCube to switch to one of the adjacent face views without first changing the view of the model, in order to see the adjacent view. When the ViewCube is active and a face view is current, four triangles are displayed, one on each side of the ViewCube. To rotate the current view to display the face view indicated by one of the triangles, click the triangle.
**Front View**

You can define the Front view of a model. The Front view is used to define the direction of the face views on the ViewCube. Along with the Front view, the Up direction of a model is also used to define the direction of the face views on the ViewCube.

**Procedures**

**To change the current view to a preset view:**

1. Activate the ViewCube.
2. Click one of the faces, edges or corners on the ViewCube.

**To view an adjacent face:**

1. Activate the ViewCube.

   **NOTE** Make sure a face view is current.

2. Click one of the triangles displayed near the edges of the ViewCube.

**To roll a face view:**

1. Activate the ViewCube.

   **NOTE** Make sure a face view is current.

2. Click one of the roll arrows displayed above and to the right of the ViewCube.
   - Click the left roll arrow to rotate the view 90 degrees in a counterclockwise direction or click the right roll arrow to rotate the view 90 degrees in a clockwise direction.

**To change the view interactively:**

- Click the ViewCube, hold down the button on your pointing device and drag to orbit the model.
Drag in the direction that you want to orbit the model.

To define the Front view:
- Right-click on the ViewCube and click Set Current View as Front.

**NOTE** You first need to orient the view using a view tool so that you are looking at what you consider to be the Front of the model with its Top facing upward and then choose Set Current View as Front.

To restore the default Front view:
- Right-click the ViewCube and click Reset Front.

**Set the View Projection Mode**

View projection produces realistic visual effects of a model.

The ViewCube supports two different view projections:

- **Perspective**  Perspective projected views involve foreshortening (closer objects appear larger than more distant ones) and are calculated based on the distance between a theoretical camera and target point. The shorter the distance between the camera and the target point, the more severe the perspective effect appears; greater distances produce less severe affects on the model.

- **Orthographic** Orthographic projected views display all the points of a model being projected parallel to the screen.

The following illustration shows the same model viewed from the same viewing direction, but with different view projections.

When you change the view for a scene, the view is updated using the current projection mode.
Procedure

To change the view projection mode:
➤ Right-click the ViewCube and click one of the following options:
  ■ Orthographic
  ■ Perspective

Define the Home View

You can define a Home view for a model so you can restore a familiar view when using the navigation tools.

The Home view is a special view of the model. The default Home position is the same as that of the Perspective viewport. You can also define a view of the scene as the Home view so you can easily return to the familiar view by clicking the Home icon or by choosing Home from the shortcut menu.

Procedure

To define the Home view, do one of the following:
■ Right-click the ViewCube and click Set Current View as Home.
■ Click or right-click the General (+) viewport label menu on page 8117 and choose ViewCube > Set Current View As Home.

To restore the Home view:

Use one of the following methods to restore the Home view:

■ Click the Home icon located near the active ViewCube.
■ Right-click the ViewCube and then choose Home.

SteeringWheels

The SteeringWheels® 3D navigation controls are tracking menus that allow you to access different 2D and 3D navigation tools from a single tool.
SteeringWheels are divided into different sections known as wedges. Each wedge on a wheel represents a single navigation tool. You can pan, zoom, or manipulate the current view of a scene in different ways.

SteeringWheels, also known as wheels, can save you time by combining many of the common navigation tools into a single interface. Wheels are specific to the context that a scene is being viewed in.

The Full Navigation wheel

NOTE If you are using the software display driver on page 8317, SteeringWheels don’t appear.

First Contact Balloon

By default, the wheel is “pinned” at startup to the lower-left corner of the Perspective viewport. It does not follow the cursor and, when you position the cursor over the wheel, the First Contact balloon for the SteeringWheels opens. The First Contact balloon serves as an introduction to the purpose of the wheels and how you can use them.
Display and Use Wheels

To toggle display of a wheel, use the Views menu > SteeringWheels > Toggle SteeringWheels command or the keyboard shortcut (Shift+W, by default). When a wheel is displayed, you can activate its navigation tools either by clicking one of the wedges on the wheel or clicking and holding down the button on the pointing device. While the button is held down, dragging over the viewport causes the current view to change. Releasing the button returns you to the wheel, and right-clicking at any time closes the wheel.

Not all navigation tools on a wheel support click actions. The following navigation tools support click actions:

- **Zoom** - Adjusts the magnification of the view.
- **Center** - Centers the view based on the position of the cursor over the wheel.
- **Rewind** - Restores the previous view.
- **Forward** - Increases the magnification of the view.

Control the Appearance of Wheels

You can control the appearance of the wheels by changing the current mode, or by adjusting the size and opacity. Wheels are available in two different modes: big and mini. To use a different wheel, choose it from the Wheel menu on a full-size wheel (click the lower-right button on the wheel) or from the Views menu > SteeringWheels submenu.
In addition to changing the current mode, you can adjust the opacity and size for the wheels. The size of a wheel controls how large or small the wedges and labels appear on the wheel; the opacity level controls the visibility of the objects in the viewport behind the wheel. The settings used to control the appearance of the wheels are on the SteeringWheels panel on page 8402 of the Viewport Configuration dialog.

Control Tooltips for Wheels and Messages for Tools

ToolTips are displayed for each wedge and button on a wheel as the cursor hovers over them. The tooltips appear below the wheel and identify the action that is performed if the wedge or button is clicked. You can toggle the display of tooltips on the SteeringWheels panel on page 8402 of the Viewport Configuration dialog.

Similar to tooltips, tool messages are displayed when you use one of the navigation tools from a wheel. Tool messages are displayed over the viewport and provide instructions for using the active navigation tool. Like tooltips, you can turn tool messages on or off on the SteeringWheels panel on page 8402 of the Viewport Configuration dialog. Disabling tool messages affects only messages that are displayed when using the Full Navigation wheel.

Procedures

To close a wheel:

Use one of the following methods to close a wheel:

- Press the Esc key.
- Press Shift+W (this toggles the wheel).
- Click the Close button (the small x in the upper right-hand corner of the wheel).
- Right-click the wheel.

To change the size of the wheels:

1. Display a wheel, if necessary (press Shift+W).
2. Open the SteeringWheels panel on page 8402 of the Viewport Configuration dialog.
3. In the Display Options group, under Big Wheels or Mini Wheels, drag the Wheel Size slider left or right.
Dragging the slider to the left decreases the size of the wheel, while sliding the slider to the right increases the size of the wheel.

4 Click OK.

To change the opacity of the wheels:

1 Display a wheel, if necessary (press Shift+W).

2 Open the SteeringWheels panel on page 8402 of the Viewport Configuration dialog.

3 In the Display Options group, under Big Wheels or Mini Wheels, drag the Wheel Opacity slider left or right.
   Dragging the slider to the left increases the transparency of the wheel, while sliding the slider to the right decreases the transparency of the wheel.

4 Click OK.

To control the startup display of the wheels:

1 Open the SteeringWheels panel on page 8402 of the Viewport Configuration dialog.

2 In the Display Options group, toggle the Always Show Pinned Wheel On Start check box.
   When on, the wheel appears at the cursor position (pinned) whenever you start 3ds Max. When off, you must invoke the wheel explicitly (press Shift+W).

3 Click OK.

Wheel Menu

From the Wheel menu, you can switch among different wheels and change the behavior of some of the navigation tools on the current wheel.

Use the Wheel menu, which is available from the down arrow in the lower-right corner of the wheel, to switch among the big and mini wheels that are available, go to the Home view, change the wheels configuration, and control the behavior of the walk navigation tool. The availability of some items on the Wheel menu depends on the current wheel.
The Wheel menu has the following options:

- **Mini View Object Wheel** Displays the mini version of the View Object wheel.
- **Mini Tour Building Wheel** Displays the mini version of the Tour Building wheel.
- **Mini Full Navigation Wheel** Displays the mini version of the Full Navigation wheel.
- **Full Navigation Wheel** Displays the big version of the Full Navigation wheel.
- **Basic Wheels** Displays the big version of the View Object or Tour Building wheel.
- **Go Home** Restores the Home view saved with the scene.
- **Restore Original Center** Pans the view to the world center (0,0,0).
- **Increase Walk Speed** Doubles the walk speed used for the Walk tool.
- **Decrease Walk Speed** Halves the walk speed used for the Walk tool.
- **Help** Launches the online Help system and displays the topic about the wheels.
- **Configure** Displays the dialog box where you can adjust the preferences for the wheels.

**Procedure**

To display the wheel menu

- Click the down arrow in the lower-right corner of the wheel.

**Navigation Wheels**

You can choose from several different wheels. Each has its own drafting theme, and is designed for a different type of 3D navigation.

Wheels are available in two sizes: big and mini. The big wheel is larger than the cursor. A label is on each wedge in the wheel. The mini wheel is about the same size as the cursor. Labels are not displayed on the wheel wedges.
You can choose from the following wheels:

- View Object
- Tour Building
- Full Navigation

**View Object Wheels**

The View Object wheel is for general 3D navigation; it includes the orbit 3D navigation tool. Use the View Object wheel to examine 3D objects from the outside.

The big View Object wheel is divided into the following wedges:

- **Center** on page 103 Specifies a point on a model to adjust the center of the current view or change the target point used for some of the navigation tools.
- **Zoom** on page 113 Adjusts the magnification of the current view.
- **Rewind** on page 109 Restores the most recent view. You can move backward or forward through previous views.
- **Orbit** on page 107 Rotates the current view around a fixed pivot point.

The mini View Object wheel is divided into the following wedges:

- **Zoom (Top wedge)** on page 113 Adjusts the magnification of the current view.
- **Rewind (Right wedge)** on page 109 Restores the most recent view. You can move backward or forward through previous views.
- **Pan (Bottom wedge)** on page 109 Repositions the current view by panning.
- **Orbit (Left wedge)** on page 107 Rotates the current view around a fixed pivot point.
Procedures

To switch to the big View Objects wheel:
Use one of the following methods:
■ From the Views menu, choose SteeringWheels > View Object Wheel.
■ Click the wheel menu button at the lower-right corner of a big wheel and choose Basic Wheels > View Object Wheel.

To switch to the mini View Objects wheel:
Use one of the following methods:
■ Click the wheel menu button at the lower-right corner of a big wheel and choose Mini View Object Wheel.
■ From the Views menu, choose SteeringWheels > Mini View Object Wheel.

Tour Building Wheels

The Tour Building wheels are designed for 3D navigation within the interior of a model.

The big Tour Building wheel is divided into the following wedges:
■ **Forward on page 104** Adjusts the distance between the current point of view and the defined pivot point of the model.
■ **Look on page 105** Swivels the current view.
■ **Rewind on page 109** Restores the most recent view. You can move backward or forward through previous views.
■ **Up/Down on page 111** Moves the view on the vertical axis of the screen.
The mini Tour Building wheel is divided into the following wedges:

- **Walk (Top wedge) on page 112** Simulates walking through a model.
- **Rewind (Right wedge) on page 109** Restores the most recent view. You can move backward or forward through previous views.
- **Up/Down (Bottom wedge) on page 111** Moves the view on the vertical axis of the screen.
- **Look (Left wedge) on page 105** Swivels the view.

**Procedures**

To switch to the big Tour Building wheel:

- From the Views menu, choose SteeringWheels > Tour Building Wheel.
- Click the wheel menu button at the lower-right corner of a big wheel and choose Basic Wheels > Tour Building Wheel.

To switch to the mini Tour Building wheel:

- Click the wheel menu button at the lower-right corner of a big wheel and choose Mini Tour Building Wheel.
- From the Views menu, choose SteeringWheels > Mini Tour Building Wheel.

**Full Navigation Wheels**

The Full Navigation wheel combines navigation tools found on the View Object and Tour Building wheels.

The big Full Navigation wheel is divided into the following wedges:

- **Zoom on page 113.** Adjusts the magnification of the current view.
Rewind on page 109. Restores the most recent view. You can move backward or forward through previous views.

Pan on page 109. Repositions the current view by panning.

Orbit on page 107. Rotates the current view around a fixed pivot point.

Center on page 103. Specifies a point on a model to adjust the center of the current view or change the target point used for some of the navigation tools.

Walk on page 112 Simulates walking through the scene.

Look on page 105 Swivels the view.

Up/Down on page 111 Moves the view on the vertical axis of the screen.

The mini Full Navigation wheel is divided into the following wedges:

Zoom (Top wedge) on page 113 Adjusts the magnification of the view.

Walk (Upper-right wedge) on page 112 Simulates walking through a model.

Rewind (Right wedge) on page 109 Restores the most recent view. You can move backward or forward through previous views.

Up/Down (Lower-right wedge) on page 111 Moves the view on the vertical axis of the screen.

Pan (Bottom wedge) on page 109 Repositions the current view by panning.

Look (Lower-left wedge) on page 105 Swivels the current view.

Orbit (Left wedge) on page 107 Rotates the current view around a fixed pivot point.

Center (Upper-left wedge) on page 103 Specifies a point on a model to adjust the center of the current view or change the target point used for some of the navigation tools.

Procedures

To switch to the big Full Navigation wheel:

Use one of the following methods:

- From the Views menu, choose SteeringWheels > Full Navigation Wheel.
Click the wheel menu button at the lower-right corner of a big wheel and choose Full Navigation Wheel.

To switch to the mini Full Navigation wheel:
Use one of the following methods:
- Click the wheel menu button at the lower-right corner of a big wheel and choose Mini Full Navigation Wheel.
- From the Views menu, choose SteeringWheels > Mini Full Navigation Wheel.

Navigation Tools

The navigation tools change the current view of the scene.

The availability of a navigation tool depends on the current wheel mode.

Center Tool

The Center tool specifies a point on an object as the center of the current view. It also changes the target point used for some of the navigation tools.

When using the Center tool, you adjust the location of the center of the current view by clicking and dragging. As you do so, the cursor changes to a sphere, indicating where the new center of the view will be established when you release the button on the pointing device. Releasing the button pans the model until the sphere is centered in the view and you are returned to the wheel.

The center point defined by the Center tool is used to constrain the Zoom tool and define the pivot point for the Orbit tool. The Zoom tool is only
constrained to the center point when used from the View Object wheel unless the Ctrl key is held down when using the Zoom tool on the Full Navigation wheel.

**Procedure**

**To specify a point on an object as the center of a view:**

1. Display a wheel that has the Center tool.
2. Click the Center wedge. Hold down the button on your pointing device and drag the cursor to the object.
3. When the cursor changes to an arrow with a sphere at the tip, release the button on your pointing device.
   The viewport is panned until the sphere is centered.

   **NOTE** This also sets the pivot point for the Orbit tool on page 107. Also, in the context of the View Object wheel on page 99, it sets the pivot point for the Zoom tool on page 113.

4. To exit the wheel, right-click.

**Forward Tool**

The Forward tool adjusts the distance between the current point of view and the defined pivot point of the model.

With the Forward tool, you can change the magnification of the model by increasing or decreasing the distance between the current point of view and the pivot point. The distance that you can move forward or backward is limited by the position of the pivot point.
To adjust the distance between the current point of view and the pivot point, you drag the cursor up or down after the pivot point is defined. As you drag the cursor, the current distance from the pivot point is displayed on a graphical element called the Drag Distance indicator. The Drag Distance indicator has two marks on it that show the start and ending distances from the current point of view. While changing the distance with the Drag Distance indicator, the current distance is shown by the bright orange indicator.

**To change a view by moving towards or away from the model**

1. Display a wheel that has the Forward tool.
2. Click the Forward wedge. Hold down the button on your pointing device.
3. When the Drag Distance indicator is displayed, drag the cursor up or down to change the distance from which you view the model.
4. Release the button on your pointing device to return to the wheel.
5. To exit the wheel, right-click.

**Look Tool**

The Look tool rotates the view horizontally and vertically from a fixed point. With the Look tool, you can rotate the current view vertically and horizontally. When rotating the view, the Look tool rotates your line of sight about the current eye position, like turning your head. Look is comparable to standing in a fixed location while looking up, down, left, and right.

When using the Look tool, you adjust the view of the model by dragging the cursor. As you drag the cursor, the cursor icon changes to the Look cursor and the model rotates around the location of the current view.
Walking through a Model

When using the Look tool, you can walk through a model by using the arrow keys on the keyboard. You can adjust the walk speed with the Walk tool settings on page 8404.

Invert Vertical Axis

By default, when you drag the cursor upward, the target point of the view raises; dragging the cursor downward lowers the target point of the view. If you prefer, you can reverse this behavior by turning on the Invert Vertical Axis on page 8404 option.

Procedures

To look around the scene:

1. Display a wheel that has the Look tool.
2. Click the Look wedge. Hold down the button on your pointing device.
3. When the Look cursor is displayed, drag the cursor up, down, left, and right to change the direction in which you are looking.
4. Release the button on your pointing device to return to the wheel.
5. To exit the wheel, right-click.

To look around the view and walk through the model

1. Display the Full Navigation wheel.
2. Click the Look wedge. Hold down the button on your pointing device.
3. When the Look cursor is displayed, drag the cursor up, down, left, and right to change the direction in which you are looking.
4. While holding down the button on your pointing device, press the arrow keys to walk in the model.
5. Release the button on your pointing device to return to the wheel.
6. To exit the wheel, right-click.
**Orbit Tool**

The Orbit tool rotates the current view around a model based on a fixed pivot point.

You use the Orbit tool to change the orientation of a model. The cursor changes to the Orbit cursor. As you drag the cursor, the model rotates around a pivot point while the view remains fixed.

![Orbit Tool](image)

**Specify the Pivot Point**

The pivot point is the base point used when rotating the model with the Orbit tool. You can specify the pivot point in the following ways:

- **Default pivot point** When you first open a model, the target point of the current view is used as the pivot point for orbiting the model.

- **Select objects** With [Selection Sensitivity](page 8405) enabled, you can select objects before using the Orbit tool to calculate the pivot point. The pivot point is calculated based on the center of the extents of the selected objects.

- **Center tool.** You can specify a point on the model to use as the pivot point for orbiting with the [Center tool](page 103) on page 103.

**Maintain Up Direction**

You can control how the model orbits around the pivot point by choosing to maintain the Up direction of the model. When the Up direction is maintained, orbiting is constrained to the XY plane and along the Z axis. If you drag the cursor horizontally, the camera moves parallel to the XY plane. If you drag the cursor vertically, the camera moves along the Z axis. To control if the Up direction is maintained for the Orbit tool, use the [Keep the Scene Upright](page 8404) on page 8404 option.
Procedures

To orbit around the center of the view:

1. Display a wheel that has the Orbit tool.
2. Click the Orbit wedge. Hold down the button on your pointing device.
3. When the cursor changes to the Orbit cursor, drag the cursor to rotate the model.

**NOTE** If you need to change the part of the model that is displayed in the center of the view, use the Center tool.

4. Release the button on your pointing device to return to the wheel.
5. To exit the wheel, right-click.

To orbit around a selection set:

1. Press Esc to make sure no commands are active.
2. Make sure Selection Sensitivity on page 8405 is on.
3. Select the objects in the scene that are to define the pivot point location.
4. Display a wheel that has the Orbit tool.
5. Click the Orbit wedge. Hold down the button on your pointing device.
6. When the cursor changes to the Orbit cursor, drag the cursor to rotate the model.
7. Release the button on your pointing device to return to the wheel.
8. To exit the wheel, right-click.

To maintain the up direction for the Orbit tool:

1. Display a wheel that has the Orbit tool.
2. On the SteeringWheels panel on page 8402 of the Viewport Configuration dialog, make sure the Orbit Tool > Keep the Scene Upright on page 8404 check box is on.
   Orbiting the model is constrained to the XY plane and Z axis.
3. Click OK.
Pan Tool

The Pan tool adjusts the viewpoint of the model by moving it within the screen plane.

When the pan tool is active, the cursor changes to a four-sided arrow. As you drag the cursor, the direction you drag moves the scene in the same direction. For example, dragging upward moves the scene up while dragging the cursor downward moves the scene down.

TIP If the cursor reaches the edge of the screen, you can continue panning by dragging the cursor further to force it to wrap around the screen.

Procedure

To pan the view with the wheel Pan tool:

1. Display a wheel that has the Pan tool.
2. Click the Pan wedge. Hold down the button on your pointing device and drag to reposition the model.
3. Release the button on your pointing device to return to the wheel.
4. To exit the wheel, right-click.

Rewind Tool

The Rewind tool restores the most recent view. You can also move backward and forward through a series of saved views.

As you pan, zoom, orbit, and use the other navigation tools (including the ViewCube) to change the view of a scene, each previous view is saved automatically to the navigation history. The navigation history holds the previous views along with a thumbnail image for each. A separate navigation
history is maintained for each viewport; the histories are not saved with the scene.

With the Rewind tool, you can retrieve the navigation history of a model. You can restore the previous view or you can scroll through any of the views saved to the navigation history.

When you hold down the button on the pointing device over the Rewind tool on the wheel, the Rewind interface is displayed as a horizontal strip of thumbnails showing each stored view. You can scroll through the navigation history. To restore one of the previous views in the navigation history, drag the bracket horizontally in the Rewind interface. Dragging to the left goes to previous views, and if you’ve rewound but haven’t changed the view, you can restore later stored views by “unwinding” to the right.

If you rewind to a previous view and then use a navigation tool, 3ds Max deletes the history after the current frame. However, it still remembers all saved views prior to the current frame.

Procedures

To restore the previous view:

1. Display a wheel.
2. Click the Rewind wedge.
3. Click Close to exit the wheel.

To restore a previous view with the Rewind interface:

1. Display a wheel.
2. Click the Rewind wedge. Hold down the button on your pointing device. The Rewind interface is displayed.
3. While holding down the button on your pointing device, drag to the left or to the right to restore a previous view.
Dragging to the left restores an older previous view. Dragging to the right restores one of the more-recent previous views. The current position in the navigation history is indicated by the orange box that is dragged along the Rewind UI.

4 To exit the wheel, click Close.

Up/Down Tool

The Up/Down tool slides the current view of a model along the vertical screen axis.

Unlike the Pan tool, the Up/Down tool does not significantly displace the model being viewed because the view is sliding along the vertical axis of the screen. You can think of the Up/Down tool as similar to looking in a fixed direction while riding in a glass elevator.

To adjust the vertical elevation of the current view, drag the cursor up or down. As you drag, the current elevation and the allowed range of motion are shown on a graphical element called the Vertical Distance indicator. This indicator has two marks that show the highest (Top) and lowest (Bottom) elevation the view can have. While changing the elevation with the Vertical Distance indicator, the current elevation is shown by the bright orange indicator while the previous elevation is shown by the dim orange indicator.

Procedure

To change the elevation of a view:

1 Display a wheel that has the Up/Down tool.
2 Click the Up/Down wedge. Hold down the button on your pointing device.

3 When the Vertical Distance indicator is displayed, drag the cursor up or down to change the elevation of the view.

4 Release the button on your pointing device to return to the wheel.

5 To exit the wheel, click Close.

Walk Tool

The Walk tool simulates walking through a model.

With the Walk tool, you can navigate through a model as if you were walking through it. Once you start the Walk tool, the Center Circle icon is displayed near the center of the view and the cursor changes to display a series of arrows. To walk through the model, you drag the cursor in the direction that you want to move in.

Constrain the Walk Angle

When walking through a model, you can constrain the movement angle to the ground plane. If the Constrain Walk Movement Angle to Ground Plane on page 8404 option is on (the default setting), you can look around freely while the current view moves parallel to the ground plane. If the walk angle is not constrained, you “fly” in the direction you are looking.

Movement Speed

As you walk or “fly” through a model, you can control the movement speed. You control the walk speed by the distance you move the cursor from the Center Circle icon. To set the base movement speed, you use the Speed Factor on page 8404 setting or the Increase Walk Speed and Decrease Walk Speed options on the Wheel menu.
Change the Elevation of the View

As you use the Walk tool, you can adjust the elevation of the view by holding down the Shift key. You switch temporarily to the Up/Down tool on page 111. To change the current elevation of the view for the model, you drag up and down.

Procedure

To use the Walk tool to move through the model:

1. Display a wheel that has the Walk tool.
2. Click the Walk wedge. Hold down the button on your pointing device.
3. When the Center Circle icon is displayed, drag the cursor in the direction that you want to walk.
4. Release the button on your pointing device to return to the wheel.
5. Click Close to exit the wheel.

Zoom Tool

The Zoom tool adjusts the magnification of the current view of a model.

With the Zoom tool, you can change the zoom magnification of a model in the following ways:

- **Click** If you click the Zoom tool on a wheel, the current view is zoomed in by a factor of 25 percent. If you are using the Full Navigation wheel, Incremental Zoom-in on page 8404 must be enabled on the SteeringWheels panel of the Viewport Configuration dialog.

- **Shift + click** If you hold down the Shift key before you click the Zoom tool on a wheel, the current view is zoomed out by a factor of 25 percent.

- **Ctrl+click** If you hold down the Ctrl key before you click the Zoom tool on a wheel, the current view is zoomed in by a factor of 25 percent.

- **Click and drag** If you click the Zoom tool and hold down the button on your pointing device, you can adjust the magnification of the model by dragging up and down.
Ctrl+click and drag When using the Full Navigation wheel, you can control the target point used by the Zoom tool. By holding down Ctrl, the Zoom tool uses the center point defined by the Center tool.

NOTE When you invoke the Zoom tool from the Full Navigation Wheel, Ctrl+click causes zooming to occur about the current pivot point rather than the current cursor position. Click and Shift+click perform incremental zooming only if Incremental Zoom-in on page 8404 is enabled on the SteeringWheels panel of the Viewport Configuration dialog.

Zoom Constraints

When changing the magnification of a model with the Zoom tool, you cannot zoom in any further than the focus point or out past the extents of the model. The direction you can zoom in and out is controlled by the center point set by the Center tool.

NOTE Unlike the Zoom tool on the View Object wheels, the Zoom tool on the Full Navigation wheels is not constrained.

Procedures

To zoom the view with a single click:

To use this function with the Full Navigation wheel, you must enable the Incremental Zoom-in option on page 8404.

1 Display a wheel that has the Zoom tool.

2 Click the Zoom wedge.

The magnification of the model is increased and you are zoomed in closer to the model. If you hold down the Shift key while clicking the Zoom wedge, the model is zoomed out or you can hold down the Ctrl key to zoom in.
3 Click Close to exit the wheel.

**To zoom a view in and out by dragging:**
1 Display a wheel that has the Zoom tool.
2 Click the Zoom wedge. Hold down the button on your pointing device and drag vertically to zoom in and out.
3 Release the button on your pointing device to return to the wheel.
4 To exit the wheel, right-click.

## Using Walkthrough Navigation

Walkthrough navigation lets you move through a viewport by pressing a set of shortcut keys, including the arrow keys, much as you can navigate a 3D world in many video games.

When you enter the walkthrough navigation mode, the cursor changes to a hollow circle that shows a directional arrow while you are pressing one of the directional keys (forward, back, left, or right).

This feature is available for perspective and camera viewports. It is not available for orthographic views or for spotlight viewports.

### Animating a Walkthrough

When you use walkthrough navigation in a Camera viewport, you can animate the camera walkthrough using either Auto Key on page 8090 or Set Key on page 3376. In either case, to get an animated camera you have to change the frame number manually (the easiest way is to use the Time Slider on page 8068), and in the case of Set Key, you have to change the frame number and click Set Keys.

**TIP** Select the camera before you animate it. If the camera isn't selected, its keys won't appear in the Track Bar on page 8071.

### Procedures

**To begin using walkthrough navigation, do one of the following:**

1 Press the Up Arrow key.
Click the **Walk Through button** on page 8140 to turn it on. This button is found on the **Pan/Truck And Walkthrough flyout** on page 8140.

**To stop using walkthrough navigation, do one of the following:**

1. Right-click.
2. Activate a different viewport.
3. Change the active viewport to a different type.
4. Turn on a different viewport navigation tool (such as Zoom or Pan).
5. Turn on Select Object or one of the transform tools.

**NOTE** You do not exit walkthrough mode when you select an object or change the viewport shading type (between shaded and wireframe, for example).

**Interface**

The Walk Through button is the only graphical element of the interface to walkthrough navigation. The other features are provided by mouse actions or by keyboard shortcuts. The following table shows the keyboard actions:

<table>
<thead>
<tr>
<th>Command</th>
<th>Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accelerate Toggle</td>
<td>Q</td>
</tr>
<tr>
<td>Back</td>
<td>S, Down Arrow</td>
</tr>
<tr>
<td>Decelerate Toggle</td>
<td>Z</td>
</tr>
<tr>
<td>Decrease Rotation Sensitivity</td>
<td></td>
</tr>
<tr>
<td>Decrease Step Size</td>
<td>[</td>
</tr>
<tr>
<td>Down</td>
<td>C, Shift+Down Arrow</td>
</tr>
<tr>
<td>Forward</td>
<td>W, Up Arrow</td>
</tr>
<tr>
<td>Command</td>
<td>Shortcut</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>Increase Rotation Sensitivity</td>
<td></td>
</tr>
<tr>
<td>Increase Step Size</td>
<td>]</td>
</tr>
<tr>
<td>Invert Vertical Rotation Toggle</td>
<td></td>
</tr>
<tr>
<td>Left</td>
<td>A, Left Arrow</td>
</tr>
<tr>
<td>Level</td>
<td>Shift+Spacebar</td>
</tr>
<tr>
<td>Lock Horizontal Rotation</td>
<td></td>
</tr>
<tr>
<td>Lock Vertical Rotation</td>
<td>Spacebar</td>
</tr>
<tr>
<td>Reset Step Size</td>
<td>Alt+[</td>
</tr>
<tr>
<td>Right</td>
<td>D, Right Arrow</td>
</tr>
<tr>
<td>Up</td>
<td>E, Shift+Up Arrow</td>
</tr>
</tbody>
</table>

If nothing appears in the Shortcut column, no default key is assigned to this command. You can set custom keystrokes using the Keyboard panel on page 8250 of the Customize User Interface dialog.

**Forward, Backward, and Sideways Movement**

For movement, you can use either the arrow keys, or letters at the left of the keyboard pad.

**TIP** When you are in a Perspective viewport, you can use Undo View Change and Redo View Change (Shift+Z, Shift+Y) to undo or redo your navigation. However, when you are in a Camera viewport, walkthrough animation transforms the camera object, so you must use Edit > Undo and Edit > Redo (Ctrl+Z and Ctrl+Y).

Holding down any of these keys causes the motion to be continuous.

**Forward** W or the Up Arrow. Moves the camera or the viewpoint forward.
NOTE If you are not already in walkthrough navigation mode, pressing Up Arrow enters it.

Back S or Down Arrow. Moves the camera or the viewpoint backward.
When you are in a camera viewport, Forward and Back are equivalent to dollying in or out.

Left A or Left Arrow. Moves the camera or the viewpoint to the left.
Right D or Right Arrow. Moves the camera or the viewpoint to the right.
When you are in a camera viewport, Left and Right are equivalent to trucking left or right.

Up E or Shift+Up Arrow. Moves the camera or the viewpoint up.
Down C or Shift+Down Arrow. Moves the camera or the viewpoint down.

Acceleration and Deceleration

Accelerate Toggle and Decelerate Toggle Pressing Accelerate (Q) causes motion to be quicker. Pressing Decelerate (Z) causes movement to be slower. These controls are toggles: pressing the key a second time restores the default motion rate (and pressing the alternate key turns off the first). They are especially useful when you are navigating by holding down keys.
The acceleration and deceleration toggles are independent of the step size.

Adjusting Step Size

Increase Step Size and Decrease Step Size Pressing Increase Step Size (]) increases the motion increments when you move the camera or viewpoint. Pressing Decrease Step Size ([) reduces them. You can press either of these shortcuts repeatedly, to increase the effect. Changing the step size is apparent when you navigate either by single clicks, or by holding down keys. Step size changes are useful for adjusting movement to the scale of the scene. They are saved with the MAX file.

Reset Step Size Pressing Reset Step Size (Alt+]) restores the step size to its default value.
The step size is independent of acceleration or deceleration.

Rotation (Tilting)

Tilt View Click+drag to tilt the camera or viewpoint.
When you are in a camera viewport, Tilt View is equivalent to panning the camera.

**Increase Rotation Sensitivity and Decrease Rotation Sensitivity** Pressing Increase Rotation Sensitivity (no default key) increases the motion increments when you use Tilt View. Pressing Decrease Rotation Sensitivity (no default key) decreases them. You can press either of these shortcuts repeatedly, to increase the effect. They are useful for adjusting movement to the scale of the scene. They are saved with the MAX file.

**Lock Horizontal Rotation** Pressing Lock Horizontal Rotation (no default key) locks the horizontal axis, so the camera or viewpoint tilts only vertically.

**Lock Vertical Rotation** Pressing Lock Vertical Rotation (Spacebar) locks the vertical axis, so the camera or viewpoint tilts only horizontally.

**Invert Vertical Rotation Toggle** Pressing Invert Vertical Rotation (no default key) inverts the tilt direction when you drag the mouse. When this toggle is off, dragging up causes scene objects to descend in the view, and dragging down causes them to rise (this is like tilting a physical camera). When this toggle is on, objects in the view move in the same direction you are dragging the mouse.

**Level** Pressing Level (Shift+Spacebar) removes any tilt or roll the camera or viewpoint might have, making the view both level and vertical.

### Navigating Camera and Light Views

The Camera and Light view navigation buttons are the same with a few exceptions. The buttons are visible when a viewport with a Camera or Light view is active. The Camera and Light view navigation buttons do more than adjust your view. They transform and change the parameters of the associated camera or light object.

![The camera navigation buttons](image)

Light views treat the light (spotlight or directional light) as if it were a camera. The light falloff is treated the same as the camera field of view.
Keep in mind the following:

■ Using the Camera and Light viewport navigation buttons is the same as moving or rotating the camera or Light, or changing their base parameters.

■ Changes made with Camera or Light view navigation buttons can be animated the same as other object changes.

### Zooming a Camera or Light View

![Zooming a camera](image)

You zoom a camera view by clicking FOV on page 8146 and then dragging in the Camera viewport.

The field of view defines the width of your view as an angle with its apex at eye level and the ends at the sides of the view. The effect of changing FOV is exactly like changing the lens on a camera. As the FOV gets larger you see more of your scene and the perspective becomes distorted, similar to using a wide-angle lens. As the FOV gets smaller you see less of your scene and the perspective flattens, similar to using a telephoto lens. See Cameras on page 5545.
Click **Light Hotspot** on page 8169 for a light viewport to achieve the same effect as zooming.

The hotspot is the inner of the two circles or rectangles visible in a light viewport. Objects inside the hotspot are illuminated with the full intensity of the light. Objects between the hotspot and falloff are illuminated with decreasing intensity as objects approach the falloff boundary. See **Using Lights** on page 5318.

**Moving a Camera or Light View**

You move a camera or light view by clicking one of the following buttons and dragging in the camera or light viewport.

- **Dolly** on page 8155 moves the camera or light along its line of sight.
- **Truck** on page 8161 moves the camera or light and its target parallel to the view plane.
- **Pan** on page 8162 moves the target in a circle around the camera or light. This button is a flyout that shares the same location with Orbit.
- **Orbit** on page 8162 moves the camera or light in a circle around the target. The effect is similar to Orbit for non-camera viewports.
Rolling a Camera or Light View

Click Roll on page 8159, and drag in a camera or a light viewport to rotate the camera or light about its line of sight. The line of sight is defined as the line drawn from the camera or light to its target. The line of sight is also the same as the camera’s or the light’s local Z axis.
Changing Camera Perspective

Click **Perspective** on page 8157, and drag in a camera viewport to change the Field of View (FOV) and dolly the camera simultaneously. The effect is to change the amount of perspective flare while maintaining the composition of the view.

Adaptive Degradation

Status bar > Adaptive Degradation button
Views menu > Adaptive Degradation
Keyboard > O (the letter O)

Adaptive degradation can improve viewport performance when you transform geometry, change the view, or play back an animation. It does so by decreasing the visual fidelity of certain objects temporarily; for example, by drawing...
larger objects or those closer to the camera as bounding boxes instead of wireframes.

Without adaptive degradation, the geometry is displayed as usual, even if that slows down viewport display and animation playback. Animation playback might drop frames if the graphics card cannot display the animation in real time.

Turn on adaptive degradation if you have large models you need to navigate around and if you are finding performance sluggish.

The Adaptive Degradation button on the status bar has three states:

- **Off**: No degradation occurs.
- **On**: Degradation can occur under the specified conditions. This is the default setting.
- **Active**: Degradation is being applied currently.

You can change the display options and set other adaptive degradation parameters, on the Viewport Configuration dialog (Customize menu > Viewport Configuration > Adaptive Degradation panel on page 8384). Also, you can toggle adaptive degradation for individual objects with the Object Properties > Never Degrade setting on page 291.

**Procedures**

To toggle adaptive degradation, do one of the following:

- Choose Views menu > Adaptive Degradation.
- Press O (the letter O).

To change the level of adaptive degradation in the viewports:

1. Click or right-click the General viewport label (“[ + ]”). On the General viewport label menu on page 8117, choose Configure.
   
3ds Max opens the Viewport Configuration dialog.
2 On the Viewport Configuration dialog, open the Adaptive Degradation panel and adjust the settings.

Grab Viewport

Tools menu > Grab Viewport

Grab Viewport creates a snapshot of the active viewport in the Rendered Frame Window on page 6513, where you can save it as an Image file on page 7831.

Procedures

To create a snapshot of a viewport:

1 Activate the viewport you want to capture.
2 Choose Tools menu > Grab Viewport.
   A dialog appears that allows you to add a label to your snapshot.
3 Enter a label for your snapshot, if desired.
   The label appears in the lower-right corner of the image as you enter it into the dialog.
4 Click Grab.
   The Rendered Frame Window opens to display a snapshot of your viewport.
5 Use the controls in the Rendered Frame Window to save your image.

Interface

![Grab Active Viewport](image.png)
Label  Enter text here to add a label to your screenshot. The text you enter is displayed in the lower-right corner of your screenshot.

Grab  Opens the Rendered Frame Window with a snapshot of the active viewport.

Cancel  Cancels the Grab Viewport command.

**View-Handling Commands**

Most viewport-handling commands are found on the Views menu on page 8006 and on the viewport label menus on page 8117.

See also:

- Viewing and Navigating 3D Space on page 65
- Quad Menu on page 8052

**Undo View Change / Redo View Change**

Views menu > Undo View Change or Redo View Change

Keyboard > Shift+Z (Undo) or Shift+Y (Redo)

Undo View Change cancels the last change made to the current viewport. Redo View Change cancels the last Undo in the current viewport.

These commands act like Undo and Redo on the main toolbar and Edit menu, but operate on a different list of events. They affect changes made to the viewport, rather than changes made to objects in the viewport.

Use Undo View Change and Redo View Change when you have inadvertently made a view unusable by zooming in too close, or rotating the wrong way. You can keep stepping back until a useful view appears. The keyboard shortcuts are handy for multiple commands.

You can also access Undo View Change by right-clicking the Point-Of-View viewport label and choosing Undo View Change from the POV viewport label menu on page 8122. This menu choice shows the last change you made in that viewport: for example, “Undo View Zoom.” Each viewport has its own independent undo/redo stack.
Camera and Spotlight viewports use object-based Undo and Redo, because the viewport change is actually a change to the camera or spotlight object. In these viewports, use Edit > Undo (Ctrl+Z) or Edit > Redo (Ctrl+Y).

Interface

**Undo View Change** Cancels viewport changes. The name of the change you're undoing is displayed in the View menu beside the command.

Undo is useful when you are working with a background image in the viewport. You can zoom into the geometry to adjust it, then use Undo Viewport Zoom to restore the original alignment of the geometry with the background.

**Redo View Change** Cancels the previous Undo View Change. The name of the change you're redoing appears in the View menu beside the command.

Save Active View

Views menu > Save Active View (the name of the active viewport is part of the command)

Save Active View stores the active view to an internal buffer. If you have framed a shot in any view other than a camera, use Save Active View to preserve the viewport’s appearance. The saved active view is saved with the scene file. Once saved, you can retrieve it using Restore Active View on page 128.

The viewport that will be restored is displayed in the menu item (for example, "Save Active Perspective View"). You can save and restore up to eight different views (Top, Bottom, Left, Right, Front, Back, Orthographic, Perspective).

Viewport changes that are saved include viewport shading type and point of view (POV): perspective or orthographic, zoom and rotations, and field-of-view (FOV).

Show Safe Frames and Viewport Clipping settings are not saved. If these settings are important to the view, make a note of what they are so you can reset them after restoring the view.

**Procedures**

To save an active view:

1. Activate the viewport with the view you want to save.
2. Choose Views menu > Save Active View. The view is now saved and can be recalled using Restore Active View.
Restore Active View

Views menu > Restore Active View (the name of the active viewport is part of the command.)

Restore Active View displays the view previously stored with Save Active View on page 127.

The viewport to be restored is displayed in the menu item (for example, "Restore Active Perspective View").

The active view is restored if the same viewport and layout are active.

If an active view won’t restore with this command, check the following:

■ Be sure the viewport is active.

■ Make sure the layout is the same as before. Use Viewport Configuration (right-click any viewport label and choose Configure) and choose Layout.

■ If the layout and active viewport are the same, be sure Viewport Clipping on the Point-Of-View (POV) viewport label menu on page 8122 is set the same as it was when the viewport was saved.

Procedures

To restore a saved view:

1. Activate the viewport where you saved the view.

2. Choose Views menu > Restore Active View. This option is available only in a viewport with a saved view.

3. The viewport returns to the saved view.

   If you’re not sure whether a viewport has a saved view, check the Views menu. Restore Active View is unavailable unless a view is saved in the active viewport.

Viewport Background Dialog

Views menu > Viewport Background > Viewport Background dialog
Click or right-click the Shading viewport label. > Shading viewport label menu on page 8130 > Viewport Background > Viewport Background > Viewport Background dialog

Keyboard > Alt+B

The Viewport Background dialog controls display of an image or animation as the background for one or all viewports. You can use this for modeling, for example, by placing front, top or side view sketches in the corresponding viewports. Or use Viewport background to match 3D elements with digitized camera footage, or for rotoscoping on page 8702.

You select the image or animation to display in the active viewport, set the frame synchronization between the animated image file and the current scene, and turn the assigned image on and off. These changes do not affect the rendered scene.

To place an image in the background of the rendered scene, use the Environment And Effects dialog > Environment panel on page 7162, accessed from the Rendering menu.

NOTE When safe frames are displayed in a viewport, and the Aspect Ratio options are set to either Match Viewport or Match Rendering Output, the assigned viewport background image is confined to the Live area of the safe frames and will correctly match the rendered background bitmap.

TIP If you are using a viewport driver with hardware acceleration (OpenGL or Direct3D), the viewport background might not appear. If this happens, choose Customize > Preferences. In the Viewports preferences on page 8308, click Configure Driver. Then in the Configure OpenGL dialog on page 8319 or the Configure Direct3D dialog on page 8325, go to the Background Texture Size group and turn on Match Bitmap Size As Closely As Possible (do not change the numeric setting). Click OK in both dialogs to accept your change.

See also:

■ Select Background Image Dialog on page 137
■ Update Background Image on page 142
■ Reset Background Transform on page 143
Procedures

To assign an image to one or all viewports:

1. Activate the viewport that is to display the background image.
2. Choose Views menu > Viewport Background > Viewport Background or press Alt+B.
   This opens the Viewport Background dialog.
3. In the Background Source group, click the Files button.
   This opens the Select Background Image dialog.
4. Use the dialog to open the image or animation to use.
5. To display the image in all viewports, choose All Views in the Apply Source And Display To group.
6. Click OK.
   The image is displayed in a single viewport or all viewports.

To update the image or map in the viewport:

Because of the time it takes to render the image or map in the viewport, the map is not automatically updated when you alter the bitmap or assign a new bitmap.

- Choose Views menu > Viewport Background > Update Background Image.
  The revised image or map is displayed in the viewport.

To display the environment map in a viewport:

1. In the Environment dialog, assign an environment map. (See the procedure “To choose an environment map.” on page 7163)
2. In the Environment dialog > Background group, be sure Use Map is turned on (the default).
3. Activate the viewport where you want the map displayed.
4. Choose Views menu > Viewport Background > Viewport Background.
5 In the Viewport Background dialog > Background Source group, turn on Use Environment Background.

6 Click OK.
   The map is displayed in the viewport.

To display an animated background:

1 Assign an animation file (AVI, MOV, or IFL file) as the viewport background.

2 Turn on Animate Background.

3 Choose Customize > Preferences. On the Viewports panel, turn on Update Background While Playing.
   Now the background plays when you click Play, or when you drag the time slider.

   **TIP** If you follow these steps and the background still doesn't appear to animate, open the Time Configuration dialog on page 8106 and in the Playback group, turn off Real Time.

To use the environment map with animation controls:

This procedure is useful if you’ve assigned an animated environment map and want access to the animation controls on the Viewport Background dialog.

1 In the Viewport Background dialog > Background Source group, turn off Use Environment Background.

2 In the same group, click File.

3 Choose the same map you’re using as the environment map.

4 Set parameters in the Animation Synchronization group.

5 Click OK.
   The environment map appears in the viewport. The image is renderable.

To match the viewport background with the rendered background:

1 Activate the viewport to render.

2 Click or right-click the General viewport label (“[ + ]”). On the General viewport label menu on page 8117. choose Show Safe Frame.
This turns on Safe Frames on page 8380 in the viewport.

**NOTE** You can also use Views menu > Configure > Safe Frame tab. In the Application group, turn on Show Safe Frames In Active View.

3 In the Material Editor, create a material that contains the bitmap for your rendered background.

4 At the bitmap level of the Material Editor, on the Coordinates rollout, choose Environ.
   The Mapping control is automatically set to Screen. This is the only mapping type that works for this purpose.

5 On the main menu, choose Rendering > Environment.

6 Drag the map from the Material Editor > Maps rollout to the Environment Map button on the Environment dialog. Click OK on the Instance (Copy) Map dialog.

7 In the Viewport Background dialog > Background Source group, click Files to assign the same bitmap.

8 In the Aspect Ratio group, turn on either Match Viewport or Match Rendering Output. Click OK.

9 Render the viewport.
   The background displayed in the rendered scene should exactly match the background displayed in the Live area of the safe frames.

**NOTE** When you use the Match Bitmap option, the bitmap reverts to its original aspect ratio and does not match the rendered scene, unless you're rendering to the same aspect ratio.

**To remove a background image:**

1 Activate the viewport in which the background image is visible.

2 On the Views menu, choose Viewport Background > Viewport Background.
   Notice that the name and path of the background file is displayed in the Current field in the Background Source group

3 In the Background Source group, click Devices.
4  On the Select Image Input Device dialog, choose No I/O Handlers from
the drop-down list, then click OK.

5  On the Bitmap Manager Error dialog, click OK.
   The current field no longer displays the background file name. Instead
   No I/O Handler is listed in the Current field.

6  Click OK to close the Viewport Background dialog.
   Next time you open up the Viewport Background dialog, no file name
   will be displayed in the Current field.

TIP  This technique will work only on systems that don’t have any other Image
Input Devices installed.
Interface

Background Source group

Options let you select the background image, either from a bitmap image file on page 8523, a video file, or from a device such as a video recorder.

Files Displays the Select Background Image dialog on page 137, which lets you select a file or sequence of files for your background.
Devices Displays the Select Image Input Device dialog. This lets you use a background from a digital device. (No device is supported by the default 3ds Max installation.)

Use Environment Background Lets you display in the viewports the map you’ve assigned as your environment background. If no environment map has been assigned in the Environment dialog, or Use Map in that dialog is off, then the Use Environment Background check box is not available.

Animation Synchronization group

Controls how sequences of images (for example, from IFL on page 7841, AVI on page 7832, or MOV on page 7849 files) are synchronized to the viewport for rotoscoping on page 8702.

Use Frame The first field sets the first frame of the incoming sequence that you want to use, and the second field sets the last one.

Step Sets the interval between the frames you want to use. For example, if this spinner is set to 7, 3ds Max uses every seventh frame.

Start At Specifies the frame number at which you want the first input frame to appear. What happens in the viewport before the start frame depends on the option you choose for "Start Processing," below.

Sync Start To Frame Determines which frame from your incoming sequence is displayed at the Start At frame. For example, you could have a 30-frame IFL sequence that starts in your scene at frame 10, but you could use the 5th frame from the IFL on frame 10 by setting Sync Start to 5.

Start Processing group

Determines what happens in the viewport background before the start frame.

Blank Before Start Makes the viewport background blank before the start frame.

Hold Before Start Specifies that the viewport background will contain the start frame.

End Processing group

Determines what happens in the viewport background after the last input frame.

Blank After End Makes the viewport background blank after the last input frame.
Hold After End Specifies that the viewport background will contain the last input frame until the last frame in the animation.

Loop After End Specifies that the viewport background will loop from the end frame back to the start frame, ad infinitum.

Aspect Ratio group

Controls the proportions of the viewport background by matching it to the bitmap, rendering output, or to the viewport itself.

Match Viewport Changes the aspect ratio on page 8511 of the image to match the aspect ratio of the viewport.

Match Bitmap Locks the aspect ratio of the image to the native aspect ratio of the bitmap.

Match Rendering Output Changes the aspect ratio of the image to match the aspect ratio of the currently chosen rendering output device.

NOTE When the Match Bitmap or Match Rendering Output option is chosen, 3ds Max centers the image and clears the edges of the viewport to the background color.

Display Background

Turns on display of the background image or animation in the viewport.

Lock Zoom/Pan

Locks the background to the geometry during zoom and pan operations in orthographic or user viewports. When you Zoom or Pan the viewport, the background zooms and pans along with it. When Lock Zoom/Pan is turned off, the background stays where it is, and the geometry moves independently of it. Use Match Bitmap or Match Rendering Output to enable Lock Zoom/Pan. This control is disabled if you choose Match Viewport.

Keyboard shortcut: Ctrl+Alt+B

WARNING If you zoom in too far, you can exceed the limit of virtual memory, and crash 3ds Max. When you perform a zoom that requires more than 16 megabytes of virtual memory, an alert asks if you want to display the background during the zoom. Choose No to perform the zoom and turn off the background. Choose Yes to zoom with the background image. Your machine might run out of memory as a result.
Animate Background

Turns on animation of the background. Shows the appropriate frame of the background video in the scene.

Apply Source And Display To group

All Views Assigns the background image to all viewports.
Active Only Assigns the background image to only the active viewport.

Viewport

The name of the currently active viewport appears in a list to the left of the OK and Cancel buttons. This reminds you which viewport you're working with and lets you change the active viewport by selecting its name from the list.

NOTE When you use different images for different viewports, the settings for each viewport are stored separately. Each time you display the Viewport Background dialog, the settings of the currently active viewport are displayed. If you switch the viewport using the list, the settings remain the same. This is useful for copying settings from one viewport to another.

Select Background Image Dialog

Views menu > Viewport Background > Viewport Background > Viewport Background dialog > Background Source group > Files > Select Background Image dialog

The Select Background Image dialog allows you to choose a file or sequence of files for a viewport background.
You can also convert a set of sequentially numbered files to an Image File List (IFL) on page 7841. This is the same process used by the IFL Manager Utility on page 7845.

**Procedures**

To select a background image for a viewport:

1. Activate the viewport where you want the image.
2. Choose Views menu > Viewport Background > Viewport Background.
3. Under Background Source in the dialog that displays, click Files.
4. In the Look In field, navigate to the directory containing the file you want to use for the background.
   
   **NOTE** The Select Background Image File dialog uses the last location where a bitmap was chosen, rather than the default bitmap path defined on the Configure User Paths dialog on page 8284.

5. Highlight the file name in the file list window.
6. Click Open to select the image and close the dialog.
7 Click OK to close the Viewport Background dialog and display the background image.

**To select a set of still images as a viewport background:**

1 Activate the viewport where you want the image.
2 Choose Views menu > Viewport Background > Viewport Background.
3 Under Background Source, click Files.
4 In the Look In field, navigate to the directory containing the sequence of files.
The files must be sequentially numbered (for example, `image01.bmp`, `image02.bmp`, `image03.bmp`).

**TIP** If necessary, change Files Of Type to match the file extension of the sequence, or choose All Formats.

5 Turn on Sequence, and choose the name of the first sequential file (for example, `image01.bmp`).

**TIP** Click the Setup button to display the Image File List Control dialog on page 7844.

6 In the Image File List Control dialog, use the Browse button to set the Target Path to a directory on your hard disk. Do not set this path to a CD-ROM drive, because you cannot save the file there.

7 Choose the options you want, and then click OK.
The Image File List (IFL) file is saved to the target directory.
Interface

History Displays a list of the directories most recently searched.

Look In Opens a navigation window to move to other directories or drives.

Up One Level Move up a level in the directory structure.

Create New Folder Lets you create a new folder while in this dialog.

List Displays the contents of a directory by file name.
Details Displays the contents of a directory including all the file details.

List Window When Details is on, the contents of the directory are displayed with Name, Size, Type, Date Modified, and Attributes. You can sort the files by clicking the label of each parameter.

File Name Displays the name of the file selected in the list.

Files of Type Displays all the file types that can be displayed. This serves as a filter for the list.

Open Selects the highlighted file and closes the dialog.

Cancel Cancels the selection and closes the dialog.

Devices Lets you select a background image from a digital device. (No device is supported by the default 3ds Max installation.)

Setup Displays the Image File List Control dialog on page 7844 to create an IFL file. Available only when Sequence is on and there are sequentially numbered files in the displayed directory.

Info Displays expanded information about the file, such as frame rate, compression quality, file size, and resolution. The information here is dependent on the type of information that is saved with the file type.

View Displays the file at its actual resolution. If the file is a movie, the Media Player is opened to play the file.

Gamma group

Selects the type of gamma to be used for the selected file. Available only when Enable Gamma Selection is turned on in the Gamma panel on page 8330.

Use Image's Own Gamma Uses the gamma of the incoming bitmap.

Use System Default Gamma Ignores the image's own gamma and uses the system default gamma instead, as set in the Gamma panel on page 8330.

Override Defines a new gamma for the bitmap that is neither the image's own, nor the system default.

Sequence Creates an "Image File List" to your specifications. Each selected image is checked to see if a valid IFL sequence can be created. If the selected image doesn’t yield a list, this option is still available, but doesn’t do anything.
**Preview** Displays the image as a thumbnail in the Image Window.

**Image Window** Displays a thumbnail of the selected file if Preview is on.

---

**Statistics** Displays the resolution, color depth, file type and number of frames of the selected file.

**Location** Displays the full path for the file. With this information at the bottom of the dialog, you always know exactly where you are.

**Update Background Image**

Views menu > Viewport Background > Update Background Image (available only when a viewport background is displayed)

This command updates the background image displayed in the active viewport. If the active viewport is not displaying a background image, this command is unavailable.

Use this command to update the background for changes that are not updated automatically, such as the following:

- Reassigning the map, or changing any parameters affecting the map in the Materials Editor, the Environment dialog, or the Viewport Background dialog.

- Changing the rendering resolution and aspect ratio. The following changes update the viewport background image automatically:
  - Changing the camera view.
  - Undo (for views).
  - Undo (for objects).
  - Assigning a different view type.
  - Toggling Safe Frames display on or off.
  - Changing the rendering parameters.
  - Moving the time slider when the viewport contains an animated background image.
NOTE Viewports can use the current Environment Map (set on the Environment panel on page 7163 of the Environment and Effects dialog) as the background image.

Procedures

To update the background image displayed in a viewport:

1. Activate a viewport that contains a background image.
2. Choose Views menu > Update Background Image.

Reset Background Transform

Views menu > Reset Background Transform (available only when a viewport background image is displayed and Lock Zoom/Pan is turned on)

Reset Background Transform rescales and recenters the current background to fit an orthographic or user viewport. Use this command when you want to reset the background to the new position of your geometry. See Procedure for detailed requirements.

Procedures

To reset the background to fit the viewport:

1. Activate an orthographic or user viewport that has a background image.
2. Press Alt+B.
3. Turn on either Match Bitmap or Match Rendering Output, and then turn on Lock Zoom/Pan.
4. Click OK.
5. Choose Views menu > Reset Background Transform. The background image readjusts in the viewport.

Show Transform Gizmo

Views menu > Show Transform Gizmo

Keyboard > X
Show Transform Gizmo toggles the display of the Transform gizmo axis tripod on page 905 for all viewports when objects are selected and a transform is active.

Additional controls for the Transform gizmo are found on the Gizmo Preferences settings on page 8354.

When the Transform gizmo is turned off, Show Transform Gizmo controls the display of the axis tripod on selected objects.

The state of Transform gizmo is saved in 3dsmax.ini, so it's maintained between scenes and sessions.

The related entries in the 3dsmax.ini file are:

- INI: Transformgizmo=1 (for Transform Gizmo visibility, controlled by Preferences)
- INI: ShowAxisIcon=1 (for Axis Icon visibility, controlled in Views menu)

The visibility of the Axis tripod overrides the visibility of the Transform Gizmo. If you turn off the Transform Gizmo in Preferences, the Axis tripod remains on the selected object. If you then turn off the Show Transform Gizmo in the Views menu, it actually turns off the Axis tripod. When the Axis tripod is disabled, the Transform Gizmo is also hidden.

**TIP** The converse is not true. If the transform gizmo is turned off, turning on the axis tripod visibility does not display the transform gizmo.

### Procedures

**To scale the transform gizmo, do one of the following:**

1. Press – (hyphen) to shrink the Transform gizmo.
2. Press = (equal sign) to enlarge the Transform gizmo.

### Show Ghosting

**Views menu > Show Ghosting**

Ghosting is a method of displaying wireframe "ghost copies" of an animated object at a number of frames before or after the current frame. Use it to analyze and adjust your animation. Ghosts that overlap indicate slower motion; ghosts that are spread further apart show faster motion.
When this command is active, ghosting is displayed for selected objects in the scene. Only currently selected objects display the ghosting.

![Ghosting helps to visualize animation.](image)

To change Ghosting parameters choose Customize > Preferences. On the Viewport panel of the Preferences dialog you can determine the number of ghosting frames, whether to ghost before or after the current frame, or both, and you can also show frame numbers with the ghosts.

**Procedures**

To show wireframe ghost copies of an animated object:

- Choose Views menu > Show Ghosting.

**Show Key Times**

Select an object with animation. > Views menu > Show Key Times
Key Times shows the frame numbers along a displayed animation trajectory on page 3411. Key times correspond to the settings in Time Configuration on page 8106 for Frames or SMPTE on page 8725. By default, key times are shown as frame numbers.

**Procedures**

**To display trajectory time values in the viewport:**

1. Select an object with animation.

2. On the Display panel > Display Properties rollout, turn on Trajectory.

   **TIP** If the rollout controls are unavailable, right-click the object in the active viewport, choose Object Properties, and in the Display Properties group, click By Layer to change to By Object. This will make the Trajectory option become available.

3. Choose Views menu > Show Key Times.

   The time values are displayed as white numbers along the trajectory. They remain displayed in red when the animated object is deselected.
Shade Selected

Select an object to be shaded. > Views menu > Shade Selected
Shade Selected shades only the selected objects in the scene when the viewport is set to Wireframe or Other. When Smooth + Highlights is on, all objects are shaded whether they are selected or not.
Shade Selected lets you work with a wireframe scene and shade only the selected objects when you want to visualize them more clearly. All other objects in the scene will appear in wireframe.
Selected objects shaded in a wireframe viewport.

**Procedures**

**To shade only selected objects in a scene:**

1. Choose Views menu > Shade Selected.
2. Click or right-click the Shading viewport label and choose Wireframe from the Shading viewport label menu on page 8130.
3. Select the object.
   Only the selected object is shaded.

**Show Dependencies**

Views menu > Show Dependencies

While you are using the Modify panel, this command toggles viewport highlighting of objects dependent on the currently selected object.
When Show Dependencies is on and the Modify panel is active, any object that is dependent upon the currently selected object in any way appears magenta. This includes instances on page 8611, references on page 8699, and shared modifiers on page 8643. Default=off.

You can also see similar dependencies in Schematic View on page 7922.

Procedures

To show dependencies between objects:

1. Select an object with an instanced modifier on page 1063.
2. On the Modify panel, choose the instanced modifier in the modifier stack.
3. Choose Views menu > Show Dependencies
   Other objects with instances of the same modifier appear in a different color.
Example: To use Show Dependencies when animating with Linked XForm:

1. Select the sub-object geometry you want to animate, and apply a Linked XForm modifier on page 1484.
2. On the Parameters rollout, click Pick Control Object.
3. Click an object to be the control object. Choose a dummy object if you want to keep the control hidden in final rendering.
4. The chosen object is now linked as parent to the sub-object selection and its name is listed on the Parameters rollout.
5. Choose Views menu > Show Dependencies to make the link visible when the control object is selected.
6. Use any of the transforms to animate the control object. The selection is animated in parallel with the control object.

Create Camera From View

Activate a Perspective viewport. > Views menu > Create Camera From View
Activate a Perspective viewport. > Create menu > Cameras > Create Camera From View
Activate a Perspective viewport. > Keyboard > Ctrl+C

Create Camera From View creates a Target camera on page 5556 whose field of view matches an active Perspective viewport. At the same time, it changes the viewport to a Camera viewport on page 8154 for the new camera object, and makes the new camera the current selection.
Alternatively, if the scene already contains a camera and the camera is selected, then Create Camera From View does not create a new camera from the view. Instead, it simply matches the selected camera to the active, Perspective viewport. This functionality was adopted from the Match Camera to View command, which is now available only as an assignable main user interface shortcut (see Keyboard Shortcuts on page 8419).

**NOTE** Create Camera From View is available only when a Perspective viewport is active.

To create a camera from a view, assuming any existing cameras are unselected:

1. Activate a Perspective viewport.
2. If necessary, adjust the viewport using Pan, Zoom, and Orbit, or the ViewCube, until you have a view you like.
3. Leaving the viewport active, on the Views menu choose Create Camera From View or press Ctrl+C.

3ds Max creates a new camera, matching its view to that of the Perspective viewport, and then switches the Perspective viewport to a Camera viewport, showing the view from the new camera.
Add Default Lights to Scene

Click or right-click the General viewport label (“[ + ]”). > General viewport label menu on page 8117 > Configure > Viewport Configuration dialog > Lighting And Shadows panel > Illuminate Scene With group > Choose Default Lighting and then choose 2 Lights (to activate the Add Default Lights To Scene menu item) > Click OK. > Create menu > Lights > Standard Lights > Add Default Lights To Scene

This command opens the Add Default Lights To Scene dialog, which provides options that let you convert the default scene lighting into actual light objects on page 5314.

The default lighting for viewports consists of a key light, positioned in front and to the left of the scene, which behaves as an omni light on page 5410.

This command is unavailable unless you use the Viewport Configuration dialog on page 8374 to configure the active viewport to use two lights. When viewports use two lights, and you invoke this command, the lights are added to the scene as omni lights. You can add either the key light, the fill light, or both.

Two default lights are placed opposite to each other.
A, the key light is in front of the object, on the upper left side, while B, the fill light is behind on the lower right side.

You can add either the key light, the fill light, or both. The omni light objects have the names DefaultKeyLight and DefaultFillLight.

If you have already added one or both default lights, a warning prompts you to rename or delete the previous default light object before you add another.

**Procedures**

**To add the default lights as objects:**

1. Click or right-click the General viewport label (“[ + ]”).
   3ds Max opens the General viewport label menu on page 8117.
2. Choose Configure.
3. On the Viewport Configuration dialog > Rendering Method tab, in the Rendering Options group, turn on Default Lighting and choose 2 Lights. Click OK to close the dialog.
5. On the Add Default Lights To Scene dialog, toggle Add Default Key Light, Add Default Fill Light, or both. Click OK.

   ![Add Default Lights to Scene](image)

6. Activate the Top viewport, and on the status bar, click Zoom Extents.
   The lights are now visible in the viewport.
Interface

Add Default Key Light When on, adds the default key light to the scene. The key light is in front of the scene and to the left. The key light becomes an omni light on page 5410 with the name, DefaultKeyLight. Default=on.

Add Default Fill Light When on, adds the default fill light to the scene. The fill light is behind the scene and to the right. The fill light becomes an omni light on page 5410 with the name, DefaultFillLight. Default=on.

Distance Scaling Affects how far the lights are placed from the origin (0,0,0). The default value leaves the scene's lighting unchanged. Larger values move the lights farther away, dimming the scene, and smaller values move them closer, brightening the scene. Default=1.0. Range=0.0 to 1000.0.

Redraw All Views

Views menu > Redraw All Views

Keyboard > ` (accent grave)

Redraw All Views refreshes the display in all viewports. When you move, rotate, scale, or otherwise manipulate geometry, the viewports may display the scene with some irregularities, or with objects or parts of objects missing. Use Redraw All Views to redisplay your scene with all lines and shading restored.
Show Materials in Viewport As

Views menu > Show Materials in Viewport As > Standard Display
Views menu > Show Materials in Viewport As > Standard Display with Maps
Views menu > Show Materials in Viewport As > Hardware Display
Views menu > Show Materials in Viewport As > Hardware Display with Maps
Material Editor > Material menu > Show Materials in Viewport As > Standard Display
Material Editor > Material menu > Show Materials in Viewport As > Standard Display with Maps
Material Editor > Material menu > Show Materials in Viewport As > Hardware Display
Material Editor > Material menu > Show Materials in Viewport As > Hardware Display with Maps

These commands turn on and off display of all maps in the viewports, using software or hardware rendering. Software rendering applies to all maps and materials, but tends to be less accurate. Hardware rendering is highly accurate, showing highlights very close to the way they render, but applies primarily to the Arch & Design material on page 5858, although it also supports the Standard material on page 5962.

NOTE Hardware viewport rendering is not available on computers with older graphics systems. Also, hardware viewport rendering is supported only by the Direct3D display driver on page 8325.

NOTE These commands do not apply to XRef materials on page 6183, including materials from XRef objects on page 7450 and XRef scenes on page 7477.

See also:
- Show Standard/Hardware Map in Viewport on page 5696

Interface

Standard Display Uses the legacy software shader, which works on a per-face basis, and turns off viewport display of all maps at the material level. This applies only to materials used in the scene.
**Standard Display with Maps** Uses the legacy software shader, which works on a per-face basis, and turns on viewport display of all maps.

**Hardware Display** Uses the hardware viewport shader, which works on a per-pixel basis, and turns off viewport display of all maps at the material level. The hardware shader applies only to the Standard on page 5962 and Arch & Design on page 5858 materials; when it’s active, 3ds Max still uses the software shader to display all other materials.

**Hardware Display with Maps** Uses the hardware viewport shader, which works on a per-pixel basis, and turns on viewport display of all maps at the material level. This switch applies only to the Standard on page 5962 and Arch & Design on page 5858 materials; when it’s active, 3ds Max still uses the software shader to display all other materials. Also, it doesn’t affect viewport display of maps for materials other than those two.

### Update During Spinner Drag

Views menu > Update During Spinner Drag

When Update During Spinner Drag is on, dragging a spinner (such as a Radius spinner for a sphere) updates the effects in real time in the viewports. Default=on.

When Update During Spinner Drag is off, the effect is updated after the drag, when you release the mouse. Use this option when you're adjusting processor-intensive controls.

### Diagnose Video Hardware

Help menu > Diagnose Video Hardware

This command runs a MAXScript script that displays information about your system’s graphic display configuration. This can be useful for telling you whether some interactive viewport features such as shadows on page 5335 are supported.
Expert Mode

Views menu > Expert Mode

Keyboard > Ctrl+X

When Expert mode is on, the title bar, toolbar, command panel, status bar, and all of the viewport navigation buttons are removed from the display, leaving only the menu bar, time slider, and viewports. Use Expert mode when you need to view your composition alone without the rest of the interface.

With the ability to customize the user interface in 3ds Max, you can create your own versions of Expert mode by hiding whatever you want item-by-item. Expert mode is only a quick way to hide everything that can be hidden at once.

You can assign keyboard shortcuts to hide and unhide the command panel, toolbars, and so on and then use these while in Expert mode. You can also use the quad menu to access tools quickly in Expert mode as well.

Procedures

To turn on Expert mode, do one of the following:

- Choose Views menu > Expert Mode.
- Press Ctrl+X.
To turn off Expert mode and return to full display, do one of the following:

- Click the Cancel Expert Mode button to the right of the time slider.
- Press Ctrl+X.
- Choose Views menu > Expert Mode.

**Controlling Object Display**

You use the Display panel, *layers* on page 7953, and *Scene Explorer* on page 7888 to control how objects are displayed in viewports, and to hide or freeze objects. This section covers usage of the Display panel controls.

*TIP* You can also use the *Isolate Selection command* on page 198 to hide everything except your selection set.

**See also:**

- *Object Display Properties* on page 288

**Display Color Rollout**

Display panel > Display Color rollout

The Display Color rollout specifies whether 3ds Max displays objects using their wireframe colors (also known as object colors) or their diffuse material colors on page 8552, when the objects have their display properties set to By Object. If the display properties of an object is set to By Layer, the layer color is used for viewport display. You can choose one method for wireframe display and a different one for shaded display. In each shading mode you can specify whether the material or the object color is used.

By default, all new objects have their display properties set to By Object. You can change this default by turning on *Default to By Layer for New Nodes* on page 8304. When this switch is off (the default), all new objects created in 3ds Max display in the viewports using the settings on the Display Color rollout. A toggle for switching individual objects between By Object and By Layer is available in the Object Properties dialog > *Display Properties group* on page 288.
If the object color box displays black and white rectangles, this indicates that the object has its display properties set to By Layer.

Interface

![Display Color](image)

**Wireframe** Controls the color of objects when the viewport is in wireframe display mode.
- **Object Color** Displays the wireframes in object color.
- **Material Color** Displays the wireframes using the material color.

**Shaded** Controls the color of the object when the viewport is in any shaded display mode.
- **Object Color** Displays the shaded objects using the object color.
- **Material Color** Displays the shaded objects using the material color.

**Hide By Category Rollout**

Display panel > Hide By Category rollout

The Hide By Category rollout toggles the display of objects by category (objects, cameras, lights, and so on).

By default, 3ds Max displays all objects in the scene. Objects hidden by category aren’t evaluated in the scene, so hiding objects by category improves performance.

You can use any of the default display filters provided, or add new display filters for fast selection of objects to hide.
Interface

Turn on the check boxes to hide objects of that category. You can use the All, None, and Invert buttons to quickly change the settings of the check boxes.

The Display Filter box gives you finer control in creating categories to hide. Click the Add button to display a list of display filters. Hold down the Ctrl key and click the filter name to select whatever category you'd like to hide.

Geometry Hides all geometry in the scene.
Shapes Hides all shapes in the scene.
Lights Hides all lights in the scene.
Cameras Hides all cameras in the scene.
Helpers Hides all helpers in the scene.
Space Warps Hides all space warps in the scene.
Particle Systems Hides all particle systems in the scene.
Bone Objects Hides all bones in the scene.
Bones Hides all bones in the scene.
IK Chain Hides all IK chains in the scene.
Point Hides all points in the scene.
All Hides everything in the scene.
None Unhides everything in the scene
Invert Hides everything that is visible and unhides everything currently hidden.
Add Adds a display filter category to the list.
Remove Removes a display filter category.
None Deselects all highlighted display filters in the list.

Hide Rollout

Display panel > Hide rollout

The Hide rollout provides controls that let you hide and unhide individual objects by selecting them, regardless of their category.

You can also hide and unhide objects using the Display Floater on page 8218.

See also:

| Hide By Category Rollout on page 159 | Hide Rollout | 161 |
Interface

Hide Selected  Hides the selected objects.

Hide Unselected  Hides all visible objects except the selected ones. Use this to hide all objects except the one you're working on. Objects hidden by category aren’t affected.

Hide by Name  Displays a dialog you use to hide objects you choose from a list. See Select From Scene on page 206, which describes nearly identical controls.

Hide by Hit  Hides any object you click in the viewport. If you hold the Ctrl key while selecting an object, that object and all of its children are hidden. To exit Hide by Hit mode, right-click, press Esc, or select a different function. This mode is automatically turned off if you hide all objects in the scene.

Unhide All  Unhides all hidden objects. The unhide buttons are available only when you have specifically hidden one or more objects. They won’t unhide objects hidden by category.

NOTE  If you click Unhide All in a scene with hidden layers, a dialog will pop up prompting you to unhide all layers. You cannot unhide an object on a hidden layer.

Unhide by Name  Displays a dialog you use to unhide objects you choose from a list. See Select From Scene on page 206, which describes nearly identical controls.

NOTE  If you select an object on a hidden layer, a dialog will pop up prompting you to unhide the object’s layer. You cannot unhide an object on a hidden layer.
Hide Frozen Objects  Hides any frozen objects. Turn it off to display hidden frozen objects.

Freeze Rollout

Display panel > Freeze rollout

The Freeze rollout provides controls that let you freeze or unfreeze on page 8587 individual objects by selecting them, regardless of their category.

Frozen objects remain on the screen, but you can’t select, transform, or modify them. By default, frozen objects turn dark gray. Frozen lights and cameras, and their associated viewports, continue to work as they normally do.

You can choose to have frozen objects retain their usual color or texture in viewports. Use the Show Frozen In Gray toggle in the Object Properties dialog on page 283.

Interface

Freeze Selected  Freezes the selected object(s).

Freeze Unselected  Freezes all visible objects except the selected ones. Use this to quickly freeze all the objects except the one you’re working on.

Freeze by Name  Displays a dialog that lets you choose objects to freeze from a list. See Select From Scene on page 206, which describes nearly identical controls.
**Freeze by Hit**  Freezes any object you click in a viewport. If you press Ctrl while selecting an object, that object and all of its children are frozen. To exit Freeze by Hit mode, right-click, press Esc, or select a different function. This mode is automatically turned off if you freeze all objects in the scene.

**Unfreeze All**  Unfreezes all frozen objects.

**NOTE**  If you click Unfreeze All in a scene with frozen layers, a dialog opens prompting you to unfreeze all layers. You cannot unfreeze an object on a frozen layer.

**Unfreeze by Name**  Displays a dialog that lets you choose objects to unfreeze from a list. See Select From Scene on page 206, which describes nearly identical controls.

**NOTE**  If you unfreeze by name an object on a frozen layer, a dialog opens prompting you to unfreeze the object's layer. You cannot unfreeze an object on a frozen layer.

**Unfreeze by Hit**  Unfreezes any object you click in the viewport. If you press Ctrl while selecting an object, that object and all of its children are unfrozen. If you select an object on a frozen layer, a dialog will pop up prompting you to unfreeze the object's layer. You cannot unfreeze an object on a frozen layer.

**Display Properties Rollout**

Display panel > Display Properties rollout

The Display Properties rollout provides controls for altering the display of selected objects.

**See also:**

- Link Display Rollout on page 169

**Procedures**

To display trajectories using the Display panel:

1. Select one or more animated objects.
2. Right-click the selection, and choose Properties.
3 In the Display properties group, click By Layer to change it to By Object, and then click OK.

4 Expand the Display Properties rollout in the Display panel.

5 Turn on Trajectory.

   By default, object trajectories appear with the following properties:
   ■ The trajectory curve is drawn in red.
   ■ Frame increments display as white dots on the curve.
   ■ Position keys display as red boxes surrounding the appropriate frame dot on the curve. The boxes are white when the object is selected.
   ■ If Views > Show Key Times is turned on, the keyframe numbers are displayed along side the keys on the trajectory.

   Trajectories can also be displayed through Object Properties. Right-click any object and choose Properties, then in the Display properties group change By Layer to By Object. Turn on Trajectories when it becomes available in the Display Properties group.

   You can change the colors for these items on the Colors panel on page 8272 of the Customize User Interface dialog.

You can also use object properties to display trajectories: right-click any object and choose Properties, then turn on Trajectory.

**Interface**

![Display Properties Rollout](image-url)
The first three options reduce the displayed geometric complexity of selected objects in a scene, resulting in faster response time because the computer has less to calculate. These options are also available in the Display Properties group of the Object Properties dialog > General panel on page 283 and the Display floater on page 8218.

**Display as Box** Toggles the display of selected objects, including 3D objects and 2D shapes, as bounding boxes on page 8528. Produces minimum geometric complexity.

Particle systems appear as bounding boxes when adaptive degradation takes effect. Because particle systems exist in world space, their bounding box is always oriented parallel to the world planes.

![Bounding Boxes](image)

**Backface Cull** Toggles the display of faces, edges, and vertices with normals on page 8654 pointing away from the point of view. When off, all entities are visible. Default=off.

![Backface Cull](image)

**Edges Only** Toggles the display of hidden edges and polygon diagonals on page 8551. When on, only outside edges appear. When off, all mesh geometry appears. Applies to Wireframe viewport display mode, as well as other modes with Edged Faces turned on.
**Vertex Ticks** Displays the vertices in the selected geometry as tick marks. If the current selection has no displayed tick marks, the check box is clear. If some of the vertices in the current selection display tick marks, the check box contains a gray X. If all vertices in the current selection display tick marks, the check box contains a black X.

**Trajectory** Toggles trajectory on page 8746 display for the selected object so its trajectory is visible in viewports.
See-Through  Makes the object or selection translucent in viewports. This setting has no effect on rendering: it simply lets you see what’s behind or inside an object in a crowded scene, and is especially useful in adjusting the position of objects behind or inside the See-Through object. This is very handy when you have objects within other objects in your scene.

This option is also available from Object Properties dialog on page 283 and the Tools > Display Floater on page 8218.

You can customize the color of see-through objects by using the Colors panel on page 8272 of the Customize > Customize User Interface dialog on page 8249.

Keyboard shortcut (default): Alt+X

Ignore Extents  When turned on, the object is ignored when you use the display control Zoom Extents. Use this on distant lights.

Show Frozen in Gray  When on, the object turns gray in viewports when you freeze it. When off, viewports display the object with its usual color or texture even when it is frozen. Default=on.

Never Degrade  When on, the object is not subject to adaptive degradation on page 8498.

Vertex Colors  Displays the effect of assigned vertex colors. You assign vertex colors using the Assign Vertex Color utility, or the VertexPaint modifier. Once vertex colors have been assigned they can also be edited in the Vertex Properties rollout in the editable mesh or editable poly in vertex or face sub-object level.

The Shaded button determines whether the object with the assigned vertex colors appears shaded in the viewport. When this button is off, the colors are unshaded and appear in their pure RGB values, looking a little like self-illuminated materials. When the Shaded button is on, the colors appear like any other assigned color in the viewports.
Link Display Rollout

Display panel > Link Display rollout

The Link Display rollout provides controls that alter the display of hierarchical linkages on page 8599.

Interface

![Link Display Rollout]

**Display Links** Displays a wireframe representation of any hierarchical links affecting the selected object.

**NOTE** Display Links must be turned on in order to see Joint Limits on a inverse kinematics chain.

**Link Replaces Object** Replaces the selected object with the wireframe representation of the hierarchical link. This option offers another way to reduce the geometric complexity of selected objects in a scene. See also Display Properties rollout on page 164.

The Draw Links As Lines option on the Viewports panel on page 8308 of the Preference Settings dialog further reduces the display of links to a single line.
Selecting Objects

In most cases, before you can perform an action on an object or objects in your scene, you must first select them. Thus, the act of selection is an essential part of the modeling and animation process.

A battlefield scene

Below: Different selections in a wireframe viewport
3ds Max provides you with a variety of selection tools, which are covered in this chapter. Besides the basic techniques of selecting single and multiple objects using mouse and keyboard, the topics here discuss the use of named selection sets and other features that help you manage object selection, such as hiding and freezing objects and layers. Also included is an introduction to sub-object selection, essential to working with an object's underlying geometry.

Lastly, a technique for grouping objects is presented. Grouping lets you create more permanent selections that have many of the characteristics of independent objects.

**Introducing Object Selection**

3ds Max is an object-oriented program. This means that each object in the 3D scene carries instructions that tell 3ds Max what you can do with it. These instructions vary with the type of object. Because each object can respond to a different set of commands, you apply commands by first selecting the object and then selecting the command. This is known as a noun-verb interface, because you first select the object (the noun) and then select the command (the verb).

**Identifying the Selection Interface**

In the user interface, selection commands or functions appear in the following areas:

- Main toolbar
- Edit menu
- Quad menu (while objects are selected)
- Tools menu
- Track View
- Display panel
- Schematic View

The buttons on the main toolbar provide a direct means of selection. The Select From Scene dialog on page 206 is easy to use, while the Edit menu provides more general selection commands, plus methods of selecting objects by property. Perhaps the most powerful selection tool is Scene Explorer on page 7888, which lets you select objects by various methods, and also edit object
hierarchies and properties. Track View and Schematic View let you select objects from a hierarchical list.

**Selecting From the Quad Menu**

The quickest way to select an object is from the Transform quadrant of the quad menu, where you can easily switch among the Move, Rotate, Scale, and Select modes. Choose any of these and click the object you want to select in the viewport.

**Selecting by Name**

Another quick way to select an object is to use the keyboard shortcut for the Select By Name command. Press H on the keyboard to open the Select From Scene dialog on page 206 and then select the object by name from the list. This is a foolproof way to ensure you select the correct object when the scene contains many overlapping objects.

**Selection Buttons**

Another way to select an object is to click one of these buttons, and then click the object.

- ![Select Object](image)
- ![Select by Name](image)
- ![Select And Move](image)
- ![Select And Rotate](image)
- ![Select And Scale](image)
- ![Select And Manipulate](image)
The main toolbar has several selection-mode buttons. When any of the selection buttons is active, 3ds Max is in a state where you can select objects by clicking them.

Of the selection buttons, you use Select Object when you want selection only. The remaining buttons let you both select and transform or manipulate your selection. Use transforms to move, rotate, and scale your selection. See Moving, Rotating, and Scaling Objects on page 885 and Select and Manipulate on page 2838.
Crossing Versus Window Selection

Above: Window selection selects the trash can and bench, but not the streetlight.
Below: Crossing selection selects all three: trash can, bench, and streetlight.

One way to select multiple objects simultaneously is to drag a region, such as a rectangle, around them. The Window/Crossing toggle, available from the main toolbar, switches between Window and Crossing modes when you select by region. In Window mode, you select only the objects within the selection. In Crossing mode, you select all objects within the region, plus any objects crossing the boundaries of the region.

**Edit Menu Commands**

The Edit menu contains selection commands that operate globally on your objects.

Edit menu selection commands include:

- **Select All** on page 227
- **Select None** on page 227
- **Select Invert** on page 228
- **Select Similar** on page 228
- **Select By > Color** on page 229
- **Select By > Name** on page 229 (also a toolbar button)
- **Select By > Layer** on page 230
- **Selection Region > Rectangular Region** on page 230
- **Selection Region > Circular Region** on page 231
- **Selection Region > Fence Region** on page 232
- **Selection Region > Lasso Region** on page 233
- **Selection Region > Paint Selection Region** on page 234
- **Selection Region > Window** on page 235 (also a toolbar button)
- **Selection Region > Crossing** on page 237 (also a toolbar button)
- **Edit Named Selection Sets** on page 219

176 | Chapter 4  Selecting Objects
Tools Menu Commands

The Tools menu provides the Scene Explorer commands as well as access to modeless selection dialogs or "floaters." You can place them anywhere on the screen, or minimize them by right-clicking the title bar and choosing Minimize:

- **New Scene Explorer (and related commands)**  See Scene Explorer on page 177.
- **Display Floater**  Provides options for hiding and freezing selections as well as some display options. See Display Floater on page 8218.
- **Layer Manager**  This modeless dialog lets you select objects individually and by layer, and change display properties such as Hide and Freeze. See Layer Manager on page 7956.

Scene Explorer

Scene Explorer on page 7888 gives you a modeless dialog for selecting and linking objects as well as changing object properties such as the name and display characteristics. You can manipulate hierarchical relationships via drag-and-drop techniques, and use various search methods including a powerful Boolean editor to fine-tune your selection. You can also edit properties for multiple objects at once simply by selecting them and then changing one of them.

Track/Schematic View Selection

Track View on page 3790 is primarily designed as an animation tool, but you can also use its Hierarchy List window as an alternative method of selecting objects by name and hierarchy. This works in both the Curve Editor and Dope Sheet modes of Track View.

Schematic View on page 7922 is specifically designed to let you navigate your scene efficiently, presenting a hierarchical view and letting you select objects and their properties by name.
Display Panel Selection

The Display panel provides options for hiding and freezing objects. These techniques exclude objects from other selection methods, and are useful in simplifying complex scenes. Frozen objects are still visible, but hidden objects are not.

Basics of Selecting Objects

The most basic selection techniques use either the mouse, or the mouse in conjunction with a keystroke.
Bed selected in wireframe

Bed selected in smooth and shaded view
Procedures

To select an object in the viewport:

1. Click one of the selection buttons on the toolbar: Select Object, Select And Move, Select And Rotate, Select And Scale, or Select And Manipulate. Alternatively, right-click in a viewport to open the quad menu, and from the Transform menu choose Move, Rotate, Scale, or Select.

2. In any viewport, move the cursor over the object you want to select. The cursor changes to a small cross when it’s positioned over an object that can be selected.

   The valid selection zones of an object depend on the type of object and the display mode in the viewport. In shaded mode, any visible surface of an object is valid. In wireframe mode, any edge or segment of an object is valid, including hidden lines.

3. While the cursor displays the selection cross, click to select the object (and to deselect any previously selected object).

   A selected wireframe object turns white. A selected shaded object displays white brackets at the corners of its bounding box.

   **NOTE** When you use the mouse to select overlapping objects or sub-objects, the first click selects the object under the mouse cursor closest to your point of view; the second click selects the next-closest object, and so on. If you move the mouse more than five pixels at any point in the sequence, the next click begins again with the closest object. And with the farthest object selected, clicking selects the closest object again.

To select all objects do one of the following:

- Choose Edit menu > Select All.
  
  This selects all objects in your scene.

- On the keyboard press Ctrl+A.

To invert the current selection do one of the following:

- Choose Edit menu > Select Invert.
  
  This reverses the current selection pattern. For example, assume you begin with five objects in your scene, and two of them are selected. After choosing Invert, the two are deselected, and the remaining objects are selected.

- On the keyboard press Ctrl+I.
To extend or reduce a selection:

- Hold down Ctrl while you click to make selections. This toggles the selection state of the objects you select. Use this method to select or deselect objects. For example, if you have two objects selected and Ctrl+click to select a third, the third object is added to the selection. If you now Ctrl+click any of the three selected objects, that object is deselected.

  **TIP** You can also hold down Alt while you click to remove objects from selections.

To lock a selection:

1. Select an object.

2. Click the Selection Lock Toggle on page 8079 on the status bar to turn on locked selection mode.

   While your selection is locked, you can drag the mouse anywhere on the screen without losing the selection. The cursor displays the current selection icon. When you want to deselect or alter your selection, click the Lock button again to turn off locked selection mode. The keyboard toggle for locked selection mode is Spacebar.

To deselect an object, do any of the following:

- Hold down the Alt key, and either click an object, or drag a region around the object to deselect it.

- Hold down the Ctrl key and click to deselect a selected object. This is a toggle; it also selects non-selected objects.

- To deselect all objects in the scene, choose Edit menu > Select None, or click an empty area of a viewport anywhere outside the current selection.

**Selecting by Region**

The region-selection tools let you use the mouse to select one or more objects by defining an outline or area.
Region Selection

By default, when you drag the mouse a rectangular region is created. When you release the mouse all objects within and touched by the region are selected. The remainder of this topic describes how you can change each of these settings.

NOTE If you hold down Ctrl while specifying a region, the affected objects are added to the current selection. Conversely, if you hold down Alt while specifying a region, the affected objects are removed from the current selection.
Setting Region Type

The type of region you define when you drag the mouse is set by the Region flyout button to the right of the Select By Name button. You can use any of five types of region selection:

- **Rectangular Region** Dragging the mouse selects a rectangular region. See Rectangular Selection Region on page 230.

- **Circular Region** Dragging the mouse selects a circular region. See Circular Selection Region on page 231.

- **Fence Region** Draw an irregular selection-region outline by alternating between moving the mouse and clicking (begin with a drag). See Fence Selection Region on page 232.

- **Lasso Region** Dragging the mouse outlines an irregular selection region. See Lasso Selection Region on page 233.

- **Paint Region** Drag the mouse over objects or sub-objects to be included in the selection. See Paint Selection Region on page 234

Setting Region Inclusion

This option lets you specify whether to include objects touched by the region border. It applies to all region methods.
Choose Edit menu > Region to display a submenu of the following two items. Only one can be active at a time. The option is also available on the main toolbar.

■ **Window**  Selects only objects that are completely within the region. See Select Region Window on page 235.

■ **Crossing**  Selects all objects that are within the region and crossing the boundaries of the region. This is the default region. See Select Region Crossing on page 237.

The Window/Crossing toggle on page 239 on the main toolbar also switches between these two modes. You can set up a preference to switch automatically between Window and crossing based on the direction of your cursor movement. See Auto Window/Crossing by Direction on page 8303 in General Preferences.

**Procedures**

**To make a region selection using defaults:**

1. Click Select Object on page 204.

2. Drag the mouse to define a region. A rubber-band rectangle appears.

3. Release the mouse button to select all objects within or touching the region.
   The selected objects turn white.

You can also use the Select and Transform buttons on the main toolbar to select by region. You must start defining the region over an unselectable area of the viewport. Otherwise, you'll transform the object beneath your mouse when you begin to drag.

**Using Select By Name**

The Select By Name command opens the Select From Scene dialog, which lets you select objects by their assigned names without having to click in the viewports.
Procedures

To select objects by name:

1 Do one of the following:

- On the main toolbar, click Select By Name.
- Choose Edit menu > Select By > Name.
- Press H.

The Select From Scene dialog opens. By default, this dialog lists all objects in the scene. Any selected objects are highlighted in the list.

2 Use the mouse to highlight one or more objects in the list. To select multiple objects, drag vertically in the list or use Ctrl to add to the selection.

3 Click OK to make the selection.

The dialog closes and the objects are selected.

4 Alternatively, to select a single object and close the dialog at the same time, double-click the object name.

For more information, see Select From Scene on page 206.

Using Named Selection Sets

You can assign a name to the current selection, and then later reselect those objects by choosing their selection name from a list.

You can also edit the contents of named sets from the Named Selection Sets dialog on page 219.
**Editing Named Selections**

As you model and create a scene, you’re likely to rearrange the objects making up your named selection sets. If you do, you’ll need to edit the contents of those sets.

**Procedures**

**To assign a name to a selection set:**

1. Select one or more objects or sub-objects using any combination of selection methods.
2. Click in the Named Selection field on the main toolbar.
3. Enter a name for your set. The name can contain any standard ASCII characters, including letters, numerals, symbols, punctuation, and spaces. 
   
   **NOTE** Names are case-sensitive.
4. Press Enter to complete the selection set.

You can now select another combination of objects or sub-objects and repeat the process to create another named selection set.

**To retrieve a named selection set:**

1. In the Named Selection field, click the arrow.
   
   **NOTE** If you’re working with a sub-object selection set, you must be at the same level at which you created the selection set (for example, editable mesh > vertex) for it to appear on the list.
2. On the list, click a name.

**To edit named selection sets:**

1. On the main toolbar, click Edit Named Selection Sets to open the Named Selection Sets dialog.
Using Selection Filters

You can use the Selection Filter list on the main toolbar to deactivate selection for all but a specific category of object. By default, all categories can be selected, but you can set the Selection Filter so that only one category, such as lights, can be selected. You can also create combinations of filters to add to the list.

For greater ease of use while working with animations, you can choose filters that let you select only Bones, objects in IK chains, or Points.

Using Combos

The Combos feature allows you to combine two or more categories into a single filter category.

Procedures

To use the selection filter:

- Click the Selection Filter arrow and click a category from the Selection Filter list.
  Selection is now limited to objects defined in this category. The category remains in effect until you change it.
  The following categories are available:
    - All
      All categories can be selected. This is the default setting.
    - Geometry
      Geometry
Only geometric objects can be selected. This includes meshes, patches, and other kinds of objects not specifically included in this list.

**Shapes**
Only shapes can be selected.

**Lights**
Only lights (and their targets) can be selected.

**Cameras**
Only cameras (and their targets) can be selected.

**Helpers**
Only helper objects can be selected.

**Warps**
Only space warps can be selected.

**Combos**
Displays a Filter Combinations dialog on page 215 that lets you create custom filters.

**Bone**
Only bones objects can be selected.

**IK Chain**
Only objects in IK chains can be selected.

**Point**
Only point objects can be selected.

**To create a combination category:**

1. From the drop-down list, choose Combos to display the Filter Combinations dialog on page 215.
   All single categories are listed.

2. Select the categories you want to combine.

3. Click Add.
   The combination appears in a list to the right, abbreviated by the first letter of each category. Click OK.

   For example, if you selected Geometry, Lights, and Cameras, the Combo would be named GLC. This name appears below Combo on the drop-down list. For more information, see Selection Filters List on page 214.
Selecting with Track View

Track View provides sophisticated methods to edit your animation tracks. In addition, its Hierarchy list displays all objects in the scene by name and hierarchy. Using Track View, you can select any object in the scene by clicking its object icon in the Hierarchy list.

Procedures

You can use Track View selection functionality in both the Curve Editor Introduction on page 3804 and the Dope Sheet on page 3805. This procedure illustrates usage of the Curve Editor; the same methods work in the Dope Sheet.
To open Track View and display and select objects:

1. On the main toolbar, click Curve Editor (Open).
2. Click any cube icon in the list to select the named object.

You can make the following kinds of selections:

- Select several adjacent objects in the list. Click the first object, hold down Shift, and click another object elsewhere in the list.
- Modify the selection by pressing Ctrl while clicking. Ctrl lets you toggle individual items on and off without deselecting others in the list.
- Select an object and all its descendants. Press and hold Alt, right-click the object’s cube icon (keep the right mouse button held down), and choose Select Children from the menu.

You can open a Track View window for the sole purpose of selecting objects by name. Shrink the window until only a portion of the Hierarchy appears, and then move the window to a convenient area on your screen.

Selecting with Schematic View

Schematic view is a window that displays the objects in your scene in a hierarchical view. It gives you an alternate way to select and choose the objects in your scene and navigate to them.

When the Modify panel is open, double-clicking an object modifier in Schematic view navigates the modifier stack to that modifier for quick access to its parameters.

Procedures

To open Schematic View and display and select objects:

1. Click Open Schematic View on the main toolbar.
2. Click the rectangle containing the name of your object.
You can select any number of objects in Schematic View using standard methods, including dragging a region. For more information, see Using Schematic View on page 7926.

**Freezing and Unfreezing Objects**

You can freeze any selection of objects in your scene. By default, frozen objects, whether wireframe or rendered, turn a dark gray. They remain visible, but can’t be selected, and therefore can’t be directly transformed or modified. Freezing lets you protect objects from accidental editing and speeds up redraws.

Above: No layers frozen
Below: Trash can and streetlight are frozen, and displayed in gray

You can choose to have frozen objects retain their usual color or texture in viewports. Use the Object Properties dialog > General panel > Display Properties > Show Frozen In Gray toggle on page 291.
Frozen objects are similar to hidden objects. Linked, instanced, and referenced objects behave when frozen just as they would if unfrozen. Frozen lights and cameras and any associated viewports continue to work as they normally do.

For more information, see Freeze Rollout on page 163.

**Freezing Objects**

You can freeze one or more selected objects. This is the usual method to put objects "on hold."

You can also freeze all objects that are not selected. This method lets you keep only the selected object active, useful in a cluttered scene, for example, where you want to be sure no other objects are affected.

**IMPORTANT** Objects on a frozen layer cannot be unfrozen. If you try to unfreeze an object on a frozen layer (with Unfreeze All or Unfreeze By Name), you are prompted (by default on page 8304) to unfreeze the object’s layer.

**Procedures**

To access Freeze options, select one or more objects and then do one of the following:

- Open a scene explorer on page 7888 and use the check boxes in the Frozen column to freeze and unfreeze objects.

- Open the Display panel and then expand the Freeze rollout.

- Choose Tools menu > Display Floater. This modeless dialog has the same options as the Freeze rollout. It also contains Hide options.

- Access the Object Properties dialog on page 283 from either the right-click (quad) menu or the Edit menu. Turn on Hide and/or Freeze.

- In the Layer Manager, click in the Freeze column to freeze/unfreeze each layer in the list.

- Right-click in the active viewport and choose a Freeze or Unfreeze command from the quad menu > Display quadrant.
Hiding and Unhiding Objects by Selection

You can hide any selection of individual objects in your scene. They disappear from view, making it easier to select remaining objects. Hiding objects also speeds up redraws. You can then unhide all objects at once or by individual object name. You can also filter the list contents by category, so only hidden objects of a certain type are listed.

**NOTE** Hiding a light source doesn't alter its effect; it still illuminates the scene.

Hiding objects is similar to freezing objects. Linked, instanced, and referenced objects behave when hidden just as they would if unhidden. Hidden lights and cameras and any associated viewports continue to work normally.

For more information, see [Hide Rollout](#) on page 161.
Hiding Objects

Hiding objects is similar to freezing objects. See Freezing and Unfreezing Objects on page 191. You can hide one or more selected objects. You can also hide all objects that are not selected.

Another option is to hide objects by category. See Hiding and Unhiding Objects by Category on page 195.

Unhiding Objects

You can unhide objects in either of two ways:

- Use Unhide All to unhide all objects at the same time.
- Use All On to display all objects at the same time.
- Use Unhide By Name to unhide object selectively. When you click Unhide By Name, the same dialog is displayed as for hiding, now called Unhide Objects.

The Unhide buttons are unavailable when no object in the scene is hidden.

Objects that were first hidden by selection and then hidden by category do not reappear. Although they are unhidden at the selection level, they are still hidden at the category level. For details, see Hiding and Unhiding Objects by Category on page 195.

IMPORTANT Objects on a hidden layer cannot be unhidden. If you try to unhide an object on a hidden layer (with Unhide All or Unhide By Name), you are prompted (by default on page 8304) to unhide the object's layer.

Procedures

To access Hide options, do one of the following:

- Open a scene explorer on page 7888 and use the check boxes in the Hidden column to hide and unhide objects.
- Open the Layer Manager on page 7956.
  In the Layer Manager, you can easily hide groups of objects or layers.
- Open the Display panel. Click Hide, if necessary, to expand the rollout.
Choose Tools menu > Display Floater. This modeless dialog has the same options as the Hide rollout. It also contains Freeze options.

Access the **Object Properties dialog** on page 283 from either the right-click (quad) menu or the Edit menu. Turn on Hide, Freeze, or both. If the button is unavailable because By Layer is turned on, click By Layer to change it to By Object.

Right-click in the active viewport and choose a Hide or Unhide command from the quad menu > Display quadrant.

**Hiding and Unhiding Objects by Category**

You can hide objects by category, the basic types of objects. For example, you can hide all lights in your scene at one time, or all shapes, or any combination of categories. By hiding all categories, your scene appears empty. Hidden objects, while not displayed, continue to exist as part of the geometry of your scene but cannot be selected.
Above: All objects displayed
Below: Lights and shapes are hidden
Hiding Geometry and Particle Systems

Geometry and particle systems have separate categories, even though particle systems are also geometry.

- Selecting Geometry hides all geometry in the scene, including particle systems. The option for particle systems becomes unavailable.
- Selecting Particle Systems hides only these objects, leaving the other geometry unaffected.

Effects of Hiding by Category

- If you create an object in a category that is hidden, 3ds Max turns off hiding for that category and unhides the objects within the category.
- Unhiding by category has no effect on objects hidden with the controls on the Hide rollout (see Hiding and Unhiding Objects by Selection on page 193). These objects remain hidden. You need to use the controls on that rollout to unhide them.
- Unhiding by category has no effect on objects that are on a layer that is turned off. These objects remain invisible. You need to turn on their layer to display them.
- Unhiding by selection does not return a hidden object to the scene if the category of the object is hidden. The Unhide All and Unhide By Name controls continue to work, but the effect is not seen until the category is cleared.
- Lights hidden by category continue to shine. Views through cameras and targeted lights are still active.
- Linked, instanced, and referenced objects behave when hidden just as they would if visible.

Procedures

To hide a category of objects:

1. Open the Display panel.
2. Click Hide by Category, if necessary, to expand the rollout. By default, all categories are off (unhidden) on this rollout.
Choose the category you want to hide. All objects of that category disappear from your scene as soon as you make the choice.

The same Hide By Category options appear on the Object Level panel of the Display Floater (Tools menu > Display Floater).

**To unhide a category of objects:**

- Deselect the category.

All objects in the category reappear, unless some have been hidden by selection. See Effects of Hiding by Category on page 197.

---

**Isolate Selection**

Tools menu > Isolate Selection

Right-click to open the quad menu. > Display (upper-right) quadrant > Isolate Selection

Keyboard > Alt + Q

The Isolate Selection tool lets you edit a single object or selection set of objects while hiding the rest of the scene on a temporary basis. This guards against selecting other objects while working on a single selection. It allows you to focus on the objects you need to see, without the visual distraction of the surroundings. It also reduces the performance overhead that can come from displaying other objects in the viewports.

When you turn on Isolate Selection, the active viewport (Perspective and axonometric on page 8515 only) performs the Zoom Extents on page 8138 action on the isolated objects. When you exit Isolate Selection mode, Perspective viewports return to the previous zoom level, but axonometric viewports do not.

When an isolated selection includes multiple objects, you can select a subset of these, and choose Isolate Selection once again. This isolates the subset. However, clicking Exit Isolation unhides the entire scene. You can’t “step back” through individual levels of isolation.

---

**NOTE** Isolate Selection works only at the object level. You can’t choose it while at the sub-object level. If you go to a sub-object level while working with an isolated object, you can click Exit Isolation, but you can’t isolate sub-objects.
Interface

While the Isolate tool is active, a dialog labeled Warning: Isolated Selection appears.

**Exit Isolation Mode** Click to end isolation, close the dialog, and unhide the rest of the scene.

The views are restored to what they showed before you chose Isolate Selection.

## Introduction to Sub-Object Selection

This is a general introduction to sub-object selection. For specific information, see [Editable Mesh](#) on page 2192, [Editable Patch](#) on page 2360, [Editable Poly](#) on page 2240, and [Editable Spline](#) on page 620; for a discussion of NURBS sub-object selection, see [Sub-Object Selection](#) on page 2428.

When you model an object, often you edit a portion of its underlying geometry, such as a set of its faces or vertices. Or when you are working with a model, you may want to apply mapping coordinates to a portion of its underlying geometry. Use the methods described in this topic to make sub-object selections.
You can access sub-object geometry through a variety of methods. The most common technique is to convert an object into "editable" geometry such as a mesh, spline, patch, NURBS, or poly object. These object types let you select and edit geometry at the sub-object level.

If you have a primitive object and want to retain control of its creation parameters, you can apply a modifier such as Edit Mesh on page 1321, Edit Poly on page 1332, Edit Spline on page 1424, Edit Patch on page 1329, or Mesh Select on page 1500.

The Line Spline on page 584 and NURBS curves and surfaces are the exception: you can edit their sub-objects as soon as you create these kinds of objects.
sub-object level appears to the right of both its name and the name of the top-level object.

Stack display shows the sub-object hierarchy, letting you choose a sub-object level.

**Editing at the Sub-Object Level**

When you edit an object at the sub-object level, you can select only components at that level: vertices, edges, polygons, and so on. You can’t deselect the current object, nor can you select other objects. To leave sub-object editing and return to object-level editing, click the top-level name of the object in the modifier stack, or click the highlighted sub-object level.
Click the top-level object name to exit sub-object editing.

**TIP** You can also access sub-object levels from the buttons at the top of the Selection rollout on the Modify panel.

### Procedures

**To make a sub-object selection:**

These methods assume the object has sub-object levels. If the object has no sub-object levels (for example, a primitive such as a sphere), the + icon is not present. In that case, you need to collapse the object or apply an Edit modifier before you can edit its sub-object geometry.

**TIP** When working with an editable poly or Edit Poly object, we highly recommend that you use the Graphite Modeling tools on page 2025 instead of the Modify panel.

1. Select the object you want to edit.
2. If the object doesn’t already have sub-object levels, apply an Edit ... modifier such as Edit Mesh.
3. Open the Modify panel.
4. On the modifier stack display, click the + icon to expand the object’s hierarchy.
5. On the stack display, click a sub-object level such as Vertex, Edge, or Face.
For a detailed selection, you might want to zoom in on the object.

6 Click one of the toolbar selection buttons, and then use the same selection methods you’d use on objects to select the sub-object components. Or from the quad menu > Transform quadrant, choose one of the selection methods and select the sub-object components.

There are two alternative ways to go to a sub-object level:

■ Select the object and go to the Modify panel. Then right-click the object, and use the quad menu > Tools 1 (upper-left) quadrant > Sub-objects submenu.

■ Choose the selection level using buttons on the Modify panel’s Selection rollout, if one is present for the type of object you’re editing.

Once you’re at a sub-object level, the Insert key cycles through the levels of other kinds of sub-objects.

To exit a sub-object level, do one of the following:

■ In the stack display, click the highlighted sub-object name or the top-level name of the object.

■ If the object has a Selection rollout, click the button of the active sub-object level to turn it off.

■ Right-click the object, and then in the Tools 1 (upper-left) quadrant of the quad menu, choose Top-level.

■ Access a different command panel. This turns off sub-object editing.

If you think you’ve turned off sub-object editing but top-level object selection is still not restored, it might be due to the following reasons:

■ Your selection is locked. Click the Lock Selection Set button on the prompt line to turn it off.
You’ve set the Selection Filter on page 187 on the main toolbar to a specific category of object, so you can’t select any of the other categories. To fix this, select All in the Selection Filter list.

**Selection Commands**

Selection commands appear on the quad menu, on the main toolbar, on the Edit menu, and on the status bar.

**Main toolbar** By default, important selecton commands appear on the main toolbar.

**Edit menu** The Edit menu contains selection commands that operate globally on your objects. **Status bar** The Selection Lock Toggle on page 8079 is located on the status bar. Locking a selection is useful when you are doing a lot of editing on a selection, and don’t want to select something else by mistake.

The simplest method of selection is to turn on Select Object mode on page 204, and then click an object in a viewport (or drag to surround the object). While the method is simple, it is not effective for selecting multiple objects, especially in a crowded scene. Other tools let you select objects by name, filter out the kinds of objects you want to select, and to create named selection sets you can select repeatedly.

**See also:**
- Introducing Object Selection on page 172
- Basics of Selecting Objects on page 178
- Isolate Selection on page 198
- Scene Explorer on page 7888

**Select Object**

Main toolbar > Select Object
Right-click to open quad menu. > Transform quadrant > Select
Select Object lets you select an objects and sub-objects for manipulation.
Object selection is affected by several other controls:

- The active Selection Region type: Rectangular on page 230, Circular on page 231, Fence on page 232, Lasso on page 233, or Paint on page 234.
- The active selection filter on page 214 (All, Geometry, Shapes, Lights, and so forth).
- The state of the crossing selection tool (which determines whether completely surrounded objects or surrounded and crossing objects are selected).

You can also select objects by name with the Select From Scene dialog Select From Scene on page 206 list; press the H key to access the dialog.

A number of objects selected together is called a selection set on page 185. You can name selection sets in the Named Selection Sets field on the main toolbar and then recall them for later use.

**NOTE** The Smart Select command activates the Select Object function and, with repeated invocations, cycles through the available Selection Region methods. By default, Smart Select is assigned to the Q key; you can use Customize User Interface on page 8249 to assign it to a different keyboard shortcut, a menu, etc.

**Procedures**

**To add or remove individual objects from a selection set:**

1. Hold down the Ctrl key and select the objects to add or remove.
2. Hold down the Alt key and select objects to remove from the current selection set.

**NOTE** Adding and removing objects doesn't change a named selection set.

**To toggle the selected/deselected state of multiple objects in the selection set:**

- Hold down the Shift key and drag to region-select the objects to toggle.
To select objects and move, rotate, or scale them:

- Use Select And Move, Select And Rotate, or Select And Scale, available from the main toolbar and the quad menu > Transform quadrant.

When you rotate a selection set, the pivot of rotation depends on which option is selected on the Use Center flyout on page 930 on the toolbar.

These tools are restricted to a specific axis or plane, which you can choose from the Axis Constraints toolbar on page 8039 or specify with the transform gizmo on page 889.

Select From Scene

main toolbar > Select By Name

Keyboard > H

Edit menu > Select By > Name

This dialog, named Select From Scene or Select Objects in most contexts, lets you select or designate objects by choosing them from a list of all objects currently in the scene. Select From Scene is a modal on page 8641, read-only version of Scene Explorer on page 7888; you can’t use it to change object properties such as name and color. Other differences between Select From Scene and Scene Explorer include:

- No hierarchy manipulation; you can’t link or unlink objects.
- Hidden and frozen objects don’t appear in the list.
- Because the dialog is modal, you must close it before continuing.
- To select an object and close the dialog, double-click the object’s list entry.
- All toggle settings such as Select Dependents, Display > Children, and the Display buttons persist. That means they survive Reset operations and even quitting and restarting 3ds Max. This also applies to the position and size of the dialog. To return all dialog settings to their defaults, delete this file: [program folder]\plugcfg\DefaultModalSceneExplorer.ini.

206 | Chapter 4  Selecting Objects
NOTE The Select From Scene dialog name and functionality are context dependent. When a transform such as Select And Move is active, the dialog lets you choose from all objects in the scene. But when certain modes are active, the choices in the dialog are more limited. For example, when Select and Link on page 3631 is active, the dialog is entitled Select Parent, and shows linkable objects but not the child object already selected. Similarly, if Group > Attach is active, the dialog is named Attach To Group and lists groups but not solitary objects.

TIP If you prefer to use the legacy Select Objects dialog instead of Select From Scene, it’s available as an option. Open the CurrentDefaults.ini file (see Market-Specific Defaults on page 8246), find the [Scene Explorer] section, and change SelectByNameUsesSceneExplorer setting. If set to 1, then Select By Name and related commands use the Select From Scene dialog. If set to 0, then Select By Name and related commands use the legacy Select Objects dialog. The latter’s functionality is essentially the same as the Selection Floater on page 209, except that it’s modal, not modeless.

See also:

■ Selection Floater on page 209
Procedures

To select objects by name:

1. Do one of the following:
   - Click the Select By Name button on the main toolbar.
   - Choose Edit menu > Select By > Name.
   - Press H.

   The Select From Scene dialog opens. By default, it lists all objects in
   the scene, displaying any hierarchies as collapsible branches. Currently
   selected objects are highlighted in the list.

2. Choose one or more objects in the list by doing one of the following:
   - To select a single object and close the dialog, double-click the object
     name.
   - Drag, or click and then Shift+click to select a contiguous range of
     objects and Ctrl+click to select noncontiguous objects.
   - In the field above the list, type a search phrase. As you type, all
     matches for the current phrase are highlighted in the list. To highlight
     only objects whose case matches the search phrase exactly, turn on
     Find Case Sensitive (from the Select menu).

   **NOTE** In some cases, such as when linking objects, you can select only one
   object.

3. Click Select.

   The selection is made as the dialog closes.

To highlight a single item from among multiple highlighted items:

Clicking one list item among several highlighted items does not unhighlight
the rest. When several items are highlighted, but you want to highlight only
one of them, do either of the following:

- If any items are not highlighted, click one of them to remove highlighting
  from the rest, and then highlight the one you want.
If all items are highlighted, the preceding method isn't practical. In that case, on the upper toolbar click Select None, and then highlight the one you want.

Selection Floater

[Available only as a CUI action]

This modeless dialog lets you select objects in the scene. You can keep the dialog open while you work in your scene, making it easier to select objects.

IMPORTANT The Selection Floater command is available only as a Customize User Interface on page 8249 action; to use it you must first add it explicitly to the user interface.

See also:

- Scene Explorer on page 7888
Interface

[select objects field] Enter a name to highlight objects in the list whose names begin with the text you specify.

Find Case Sensitive When on, the select objects field above the list is case-sensitive. For example, if the list contains objects named apple and Apple and Find Case Sensitive is on, typing “a” will highlight only the apple entry. Also, sorts the list so uppercase names come before lowercase.

[objects list] Lists objects according to the current Sort and List Types choices. Does not display hidden and frozen objects.
To highlight an object name in the list, click with the mouse. To highlight multiple object names, drag, or click and then Ctrl+click or Shift+click, or use the search field above the list. To select highlighted objects, click the Select button.

Alternatively, you can highlight and select a single object in the list by double-clicking its name.

After selecting objects, the dialog remains open until you close it explicitly.

**All/None/Invert** These buttons alter the pattern of selection in the list window.

**Influences** When you highlight an object in the list window and then click the Influences button, the selected object’s influences on page 8609 are highlighted as well.

**Display Subtree** Displays each item in the list so that its hierarchical branch on page 8599 is included (for example, Thigh/Shin/Foot). Hierarchical branches are indented.

**Display Influences** When this is on and you select an item in the list window, all of its influences are shown in blue. If you want to highlight these influences, click Influences.

**Select Subtree** When this is on and you select an item in the list window, all of its hierarchical children are selected as well.

**Select Dependents** When this is on and you select an item in the list window, all of its dependent on page 8549 objects are selected as well. Dependents include instances, references, and objects sharing a common modifier (the same objects that appear green when Show Dependencies is on in the View menu).

When both Select Subtree and Select Dependents are on, the subtree of any newly selected node is first selected, and then the dependents are selected. In other words, dependents of the subtree are selected, but not the subtrees of all dependents.

**Sort group**

Lets you choose the sort order of the items displayed in the list. This option is unavailable when Display Subtree is on; in that case, sorting is always alphabetical.

**Alphabetical** Sorts from numeric characters at the top, then A to Z at the bottom. When Find Case Sensitive is on, all upper-case names come before lower-case names.
By Type Sorts by category, using the same order as the check boxes in the List Types group.

By Color Sorts by object wireframe color. The sorting order is arbitrary; the value of this option is that objects of the same color are grouped together.

By Size Sorts based on the number of faces in each object. The object with the least number of faces is listed first, followed by objects with successively greater number of faces.

List Types group

Determines the types of objects to display in the list.

All/None/Invert These buttons alter the pattern of activation of the List Types options.

Selection Sets group

Lists any named selection sets on page 217 that you have defined in the scene. When you choose a selection set from the drop-down list, 3ds Max highlights its component objects in the main list.

Selection Region Flyout

Main toolbar > Selection Region flyout

The Selection Region flyout provides access to five methods you can use to select objects by region. Clicking the Selection Region button displays a flyout containing the Rectangle on page 230, Circular on page 231, Fence on page 232, Lasso on page 233, and Paint on page 234 Selection Region buttons.
For the first four methods, you can select either objects that are completely within the selection region (window method), or objects that are within or touched by the selection shape (crossing method). Toggle between the window and crossing selection methods by using the Window/Crossing Selection button on page 237 on the main toolbar.

**NOTE** If you hold down Ctrl while specifying a region, the affected objects are added to the current selection. Conversely, if you hold down Alt while specifying a region, the affected objects are removed from the current selection.

**NOTE** The Smart Select command activates the Select Object on page 204 function and, with repeated invocations, cycles through the available Selection Region methods. By default, Smart Select is assigned to the Q key; you can use Customize User Interface on page 8249 to assign it to a different keyboard shortcut, a menu, etc.

**Procedures**

**To select using a region (general method):**

1. Choose a Selection Region method from the flyout.

2. Drag in a viewport, then release the mouse. The first location you click is one corner of the rectangle, and where you release the mouse is the opposite corner.
**IMPORTANT** If you’re using Select Object on page 204, you can start dragging anywhere to select a region: on an object or off. However, if you’re using one of the transform tools, such as Select and Move on page 914, start the drag operation away from an object; that is, in an empty part of the viewport. Otherwise, if you start dragging on an object, most likely 3ds Max will assume you intend to select where you click and will begin the transform operation immediately.

To cancel the selection, right-click before you release the mouse.

## Selection Filter List

Main toolbar > Selection Filter

The Selection Filter list lets you restrict to specific types and combinations of objects that can be selected by the selection tools. For example, if you choose Cameras, you can select only cameras with the selection tools. Other objects do not respond. When you need to select objects of a certain type, this is useful as a quick method of freezing all other objects.

![Selection Filter List](image)

Use the drop-down list to select a single filter. Choose Combos from the drop-down list to use multiple filters from the Filter Combinations dialog on page 215.
Filter Combinations Dialog

Main toolbar > Selection Filter list > Combos > Filter Combinations dialog

Use the Filter Combinations dialog to create your own custom combinations of categories to add to the Selection Filters list on page 214.

You can also add specific types of objects, or Class IDs, to the list. For example, you can set a filter that lets you select only Sphere primitives.

Procedures

To create a combination filter:

1. Open the Selection Filter list and choose Combos.
   The Filter Combinations dialog appears.

2. Turn on one or more of the check boxes in the Create Combination group.

3. Click the Add button.
   The specified combination appears in the Current Combinations list to the right as a combination of the first letters of each selected category.

4. Click OK.
   The new combo item appears at the bottom of the Select Filter list.
   Combos are stored in the 3dsmax.ini on page 60 file, so they remain in effect for all scenes through all sessions.

To delete a combination filter:

1. Open the Selection Filter list and choose Combos.
   The Filter Combinations dialog appears.

2. Choose one or more of the combos in the Current Combinations list.

3. Click the Delete button.

4. Click OK.
Chapter 4   Selecting Objects
Create Combination group

**Geometry, Shapes, Lights, Cameras, Helpers, Space Warps** Choose the category or categories you want included in the combination.

**Add** After choosing the categories to include in a combination, click this button to place the categories, labeled with the categories’ initials, in the Current Combinations list, as well as at the bottom of the Selection Filter list.

Current Combinations group

**Current Combinations list** Lists current combinations. To delete one or more combinations, choose them, and then click **Delete**.

**Delete** After choosing one or more combinations in the Current Combinations list, click this button to delete them.

All Class ID group

**Class ID list** Lists all the available categories that can be added to custom filters for display and selection. Highlight a category to add, then click **Add**.

**Add** After choosing a class to include in the filter list, click this button to place the class in the Current Class ID Filter list, as well as at the bottom of the Selection Filter list.

Current Class ID Filter group

**Class ID list** Lists current classes to filter. To delete a class, choose it, and then click **Delete**.

**Delete** After choosing a class in the Current Class ID Filter list, click this button to delete the class.

Named Selection Sets

Main toolbar > Edit Named Selection Sets and the Named Selection Sets text field and drop-down list

The Named Selection Sets list allows you to name a selection set and recall the selection for later use. It supports selection sets both at the object level and at sub-object levels. You edit named object-level selection sets with the
Named Selections Sets dialog on page 219 and sub-object level sets with the Edit Named Selections dialog on page 224.

A named selection set is removed from the list if all of its objects have been deleted from the scene, or if all of its objects have been removed from the named set in the Named Selections Sets dialog.

Selection set names are case sensitive at both the object level and at sub-object levels.

You can transfer sub-object named selections from one level in the stack to another. The Copy and Paste buttons let you copy named selections from one modifier to another.

While at a specific sub-object level, such as Vertex, you can make selections and name those selections in the Named Selection Sets field of the toolbar. The named sets are specific to both the selection level and the level on the stack.

Keep in mind the following restrictions:

- You can transfer named selections only between the same type of sub-object level. In other words, you can transfer named selections from vertex sub-object to another vertex sub-object, but you can't transfer it to face or edge sub-object level.

- You must transfer the selection between modifiers that handle like geometry. You can copy and paste between an editable mesh and a mesh select modifier, but you can't copy and paste between a mesh select modifier and an editable spline.

- You can copy and paste between two modifiers in two different objects, as long as you're at the same level and both modifiers handle the same type of geometry.

- If you change the topology of a mesh after creating a named selection (such as deleting some vertices), the named selections will probably no longer select the same geometry.

Procedures

To create a named selection set:

1. Select the objects you want to be in a set.
2 Type the name of the set in the Named Selection Sets field, and then press Enter.

3 Whenever you want to access the selection, choose its name from the Named Selection Sets drop-down list.

**To select a named selection set, do one of the following:**

1 To select a single item, click it in the list.

2 To select more than one item in the list, select one, and then select others while holding down the Ctrl key.

3 To deselect single items after you’ve selected multiple items, hold down the Alt key.

---

### Named Selection Sets Dialog

Edit menu > Manage Selection Sets

Main toolbar > Edit Named Selection Sets

The Named Selection Sets dialog, available from the Edit menu and the toolbar, is a modeless dialog on page 8641 that lets you create named selection sets or select objects to add to (or remove from) a selection set, directly from the viewport. The dialog also lets you organize your current named selection sets, browse their members, delete or create new sets, or identify which named selection sets a particular object belongs to.

**NOTE** This dialog applies to objects only. For editing sub-object named selection sets, see Edit Named Selections Dialog on page 224.

**See also:**

- Named Selection Sets on page 217
- Using Named Selection Sets on page 185
- Edit Named Selections Dialog on page 224
Procedures

To create a named selection:

1. In the viewport, select the objects you want to gather as a selection set.

2. Click the Edit Named Selection Sets button on the main toolbar, or choose Edit > Manage Selection Sets.

3. On the Named Selection Sets dialog, click Create New Set.

4. Enter a name for the new selection set.

To add objects to a named selection set:

1. Click the Edit Named Selection Sets button on the main toolbar, or choose Edit > Manage Selection Sets.

2. Choose the named selection set in the dialog.

3. Select one or more objects in the viewport.

4. In the dialog, click Add Selected Objects.

To remove objects from a named selection set:

1. Click the Edit Named Selection Sets button on the main toolbar, or choose Edit > Manage Selection Sets.

2. Choose the named selection set in the dialog.

3. In the viewport, select the objects you want to remove.

4. In the dialog, click Subtract Selected Objects.
NOTE You can also remove objects by selecting them in the Named Selection Sets dialog, then clicking Remove or pressing Delete.

To move an object from one set to another:

1. Click the Edit Named Selection Sets button on the main toolbar, or choose Edit > Manage Selection Sets.
2. In the Named Selection Sets dialog, expand the selection sets.
3. Drag an object from one set to another.
   The object is moved into the second set. If you use Ctrl+drag, the object will be copied into the second set.

   TIP You can also copy the contents of an entire set into another, by dragging them into the desired selection set.

To select objects in a set:

1. Highlight the set in the Named Selection Sets dialog.
2. Click Select Objects In Set to select all of the objects in the highlighted set.
Interface

In the Named Selection Sets dialog, all of the current named selection sets are displayed. By clicking the plus (+) or minus (-) icon, you can expand or collapse (respectively) the object list for each set.

The buttons along the top of the dialog let you create or delete sets, add or remove objects from a set, select objects (independently or as a selection set), and see which named selection set(s) a particular object belongs to.

![Create New Set][1] Creates a new selection set, including any currently selected objects as members.

**NOTE** If no objects are selected, an empty set is created.
Remove  Removes the selected object or selection set.

**NOTE** Deleting an object or its selection set does not delete the object; it only destroys the named set.

Add Selected Objects  Adds the currently selected objects to the selected named selection set.

Subtract Selected Objects  Removes currently selected objects from the selected named selection set.

Select Objects in Set  Selects all members of the current named selection.

Select Objects by Name  Opens the Select Objects dialog on page 206, where you can select a group of objects. The selected objects can then be added to or removed from any named selection set.

Highlight Selected Objects  Highlights all of the named selection sets that contain the current scene selection.

Status Bar  Displays the current named selection set, as well as what’s currently selected in the scene. If more than one object is selected, the number of selected objects is displayed.

**Right-click menu**

Additional commands are available when you right-click in the Named Selection Sets dialog.

Rename  Lets you rename the selected set or object.

**TIP** You can rename objects or sets by pressing F2.

Cut  Removes the selected object or set and stores it in a buffer for reuse with the Paste command, similar to the Cut command in Windows.
Tip: You can cut an object or set by pressing Ctrl+X.

Copy copies the selected object or set and stores it in a buffer for reuse with the Paste command, similar to the Copy command in Windows.

Tip: You can copy an object or set by pressing Ctrl+C.

Paste adds a Cut or Copied object or set into another set.

Tip: You can paste an object or set by pressing Ctrl+V.

Collapse All collapses all expanded selection sets.

Expand All expands all collapsed selection sets.

Create New Set creates a new selection set, including any currently selected objects as members.

Remove removes the selected object or selection set.

Add Selected Objects adds currently selected objects to the selected named selection set.

Subtract Selected Objects removes currently selected objects from the selected named selection set.

Select Objects in Set selects all members of the current named selection.

Select Objects by Name opens the Select Objects dialog on page 206, and adds all objects selected there to the current named selection set.

Highlight Selected Objects highlights all of the named selection sets that contain the current scene selection.

Find Next toggles through selection sets containing the selected object, when used in collaboration with the Highlight Selected Objects command.

Tip: You can use Ctrl+G to toggle through the sets.

Edit Named Selections Dialog

Make a sub-object selection. > Edit menu > Manage Selection Sets

Make a sub-object selection. > Main toolbar > Edit Named Selection Sets
Edit Named Selections displays the Edit Named Selections dialog, letting you manage named selection sets of *sub-objects on page 199*. Unlike the *Named Selection Sets dialog* on page 219, which applies to *objects only*, it is a modal dialog, which means that you must close it in order to work in other areas of 3ds Max. Also, you can work only with existing named sub-object selections; you cannot use the dialog to create new selections.

**Procedures**

To edit named sub-object selections:

1. At a sub-object level, create one or more *named selection sets* on page 217.

2. Click the Edit Named Selection Sets button on the main toolbar, or choose Edit > Manage Selection Sets. The Edit Named Selections dialog opens, listing all named selection sets for the current sub-object level.

3. Use the dialog controls to edit the named selection sets.
The dialog window lists all named selections at the current sub-object level. The buttons beneath the windows let you delete, merge, and edit the listed items. Use standard mouse-plus-keyboard methods (using Ctrl or Shift) to highlight list items and designate them for subsequent operations.
To rename a set, click it in the list, and then edit its name in the one-line window immediately below the list.

**Combine** Merges all objects from the highlighted selection sets into a single, new selection set. Select two or more selection sets, and then click Combine and enter a new name for the selection set. Use Delete to delete the original sets.

**Delete** Deletes all highlighted items from the Named Selections window. This affects only selection sets, not the sub-objects they refer to.

**Subtract (A-B)** Removes the sub-objects contained in one selection set from another. Select one item in the Named Selections window, and then select the other. The top highlighted item in the window is operand A, and the bottom is operand B (regardless of the order of their selection). Click Subtract (A-B) to subtract the sub-objects in the bottom item from those in the top item. There must be some overlap between the two selection sets for this command to have any effect.

**Subtract (B-A)** Subtracts the sub-objects in the top selected item from those in the bottom item.

**Intersection** Creates a selection set that consists only of sub-objects that all highlighted selection sets have in common. Highlight two or more items in the Named Selections window, and then click Intersection. In the dialog that appears, enter a new set name and click OK.

### Select All

- **Edit menu > Select All**
- **Keyboard > Ctrl+A**

This command selects all objects in the scene matching the current selection filter type on page 214 on the main toolbar.

### Select None

- **Edit menu > Select None**
- **Keyboard > Ctrl+D**

This command deselects all objects in the scene conforming to the current selection filter type on page 214 on the main toolbar.
Select Invert

Edit menu > Select Invert

Keyboard > Ctrl+I

This command inverts the current selection set. All objects not currently selected are selected, and all objects currently selected are deselected, respecting the current selection filter type on page 214 on the main toolbar.

Select Similar

Select one or more objects. > Edit menu > Select Similar

Select one or more objects. > Right-click > quad menu > Transform quadrant > Select Similar

Select one or more objects. > Ctrl+Q

Select Similar automatically selects all items that are “similar” to the current selection. In general, this means that the objects must be on the same layer, and have the same material (or no material) applied. The specific functionality depends on the objects’ source:

- Selects all items imported in the DWG format in the selected object’s or objects’ layer that have the same style(s) on page 7535 or categories as defined in AutoCAD Architecture (formerly known as ADT, or Architectural Desktop), or the same families and types as defined in Revit. For example, if you’ve imported or linked to a DWG file that contains walls in several different styles, such as CMU-8, Concrete-8, and Stud-4, you could select all CMU-8 wall segments in the same layer by selecting one and then invoking Select Similar.
  
  If you start by selecting multiple objects with different styles, Select Similar will select all objects with those styles.

- This command also applies to objects native to 3ds Max. It selects all objects of the same type. This includes primitives and editable object types. For example, if you add some boxes and cylinders, select one of the cylinders, and then invoke Select Similar, all of the cylinders will be selected, but not the boxes. If you then convert all of the objects to Editable Poly format and repeat the test, all of the objects will be selected. If you then apply a material to one of the objects or move it to a different layer, it’s no longer “similar” to the rest and won’t be selected by Select Similar.
Select By

Edit menu > Select By

The Select By submenu on the Edit menu provides commands for selecting objects in the scene by color, name, and other characteristics. It also gives quick access to the various Region selection options.

See also:
■ Selection Tab on page 2180

Select By Color

Edit menu > Select By > Color

Select By Color lets you select all objects having the same color as the selected object. Selection is made by wireframe color (see Object Color Dialog on page 368), rather than by any materials associated with the objects.

After you choose this command, click any object in the scene to determine the color for the selection set.

TIP To select objects by material, use Schematic View on page 7926.

Select By Name (Edit Menu)

Edit menu > Select By > Name

Keyboard > H

Select By Name lets you select objects by choosing them from a list of all objects in the scene.

For a full description of the Select By Name function, see Select From Scene on page 206.

TIP To select objects by material, use Select By Material on page 5686.
Select By Layer

Edit menu > Select By > Select By Layer

Select By Layer lets you select all objects in one or more layers by picking them from a list of all layers in the scene. Choosing this command opens the Select By Layer dialog; use standard methods to highlight one or more layers, and then click OK. The dialog closes, and all objects in the highlighted layer or layers are selected.

Selection Region

Edit Menu > Selection Region

The Selection Region submenu on the Edit menu provides quick access to the various region selection options.

See also:
- Selecting by Region on page 181

Rectangular Selection Region

main toolbar > Rectangular Selection Region (Selection Region flyout)

Edit menu > Selection Region > Rectangular Region

The Rectangular Selection Region option, available from the Selection Region flyout on page 212 and the Edit menu, provides one of five methods you can use to select objects by region. The other methods are Circular on page 231, Fence on page 232, Lasso on page 233, and Paint on page 234.

You can use Rectangular to select either objects that are completely within the selection region (window method), or objects that are either within or touched by the selection shape (crossing method). Toggle between the window and crossing selection methods by using the Window/Crossing Selection button on page 237 on the main toolbar.

NOTE If you hold down Ctrl while specifying a region, the affected objects are added to the current selection. Conversely, if you hold down Alt while specifying a region, the affected objects are removed from the current selection.
Procedures

To select using a rectangle:

1. Click the Rectangular Selection Region button.

2. Drag in a viewport, then release the mouse. The first location you click is one corner of the rectangle, and where you release the mouse is the opposite corner.

   To cancel the selection, right-click before you release the mouse.

Circular Selection Region

main toolbar > Circular Selection Region (Selection Region flyout)

Edit menu > Selection Region > Circular Region

The Circular Selection Region option, available from the Selection Region flyout on page 212 and the Edit menu, provides one of five methods you can use to select objects by region. The other methods are Rectangular on page 230, Fence on page 232, Lasso on page 233, and Paint on page 234.

You can use Circular to select either objects that are completely within the selection region (window method), or objects that are either within or touched by the selection shape (crossing method). Toggle between the window and crossing selection methods by using the Crossing Selection button on page 237 on the main toolbar.

NOTE If you hold down Ctrl while specifying a region, the affected objects are added to the current selection. Conversely, if you hold down Alt while specifying a region, the affected objects are removed from the current selection.

Procedures

To select using a circle:

1. Click the Circular Selection Region button.
2 Drag in a viewport, then release the mouse. The first location you click is the center of the circle, where you release the mouse defines the circle's radius.

To cancel the selection, right-click before you release the mouse.

**Fence Selection Region**

Main toolbar > Fence Selection Region (Selection Region flyout)

Edit menu > Selection Region > Fence Region

The Fence Selection Region option, available from the Selection Region flyout on page 212 and the Edit menu, provides one of five methods you can use to select objects by region. The other methods are Rectangular on page 230, Circular on page 231, Lasso on page 233, and Paint on page 234.

You can use Fence to select either objects that are completely within the selection region (window method), or objects that are either within or touched by the selection shape (crossing method). Toggle between the window and crossing selection methods by using the Window/Crossing button on page 239 on the main toolbar.

**NOTE** If you hold down Ctrl while specifying a region, the affected objects are added to the current selection. Conversely, if you hold down Alt while specifying a region, the affected objects are removed from the current selection.

**Procedures**

To select using a fence:

1. Click the Fence Selection Region button.

2. Drag to draw the first segment of a polygon, then release the mouse button.

   A "rubber-band line" is now attached to the cursor, anchored at the point of release.

3. Move the mouse and click to define the next segment of the fence. You can make as many steps as you want.

4. To complete the fence, either click the first point, or double-click.
A pair of cross hairs appears when you're near enough to click the first point. This creates a closed fence.

Double-clicking creates an open fence, which can select objects only by the crossing method.

To cancel the selection, right-click before you release the mouse.

---

**Lasso Selection Region**

Main toolbar > Lasso Selection Region (Selection Region flyout)

Edit menu > Selection Region > Lasso Region

The Lasso Selection method lets you select multiple objects within a complex or irregular region with a single mouse action.

The Lasso Selection Region option, available from the Selection Region flyout on page 212 and the Edit menu, provides one of five methods you can use to select objects by region. The other methods are Rectangular on page 230, Circular on page 231, Fence on page 232, and Paint on page 234.

You can use Lasso to select either objects that are completely within the selection region (window method), or objects that are either within or touched by the selection shape (crossing method). Toggle between the window and crossing selection methods by using the Window/Crossing button on page 239 on the main toolbar.

---

**NOTE** If you hold down Ctrl while specifying a region, the affected objects are added to the current selection. Conversely, if you hold down Alt while specifying a region, the affected objects are removed from the current selection.

---

**Procedures**

**To select using a lasso:**

1. Click the Lasso Selection Region button.

2. Drag to draw a shape around the object(s) that should be selected, then release the mouse button.

   **NOTE** To cancel the selection, right-click before you release the mouse.
Paint Selection Region

main toolbar > Paint Selection Region (Selection Region flyout)

Edit menu > Selection Region > Paint Region

The Paint Selection method lets you select multiple objects or sub-objects by dragging the mouse over them. To change the brush size, right-click the Paint Selection Region button, and then, on the Preference Settings dialog > General tab > Scene Selection group, change the Paint Selection Brush Size value on page 8303.

If you hold down Ctrl while specifying a region, the affected objects are added to the current selection. Conversely, if you hold down Alt while specifying a region, the affected objects are removed from the current selection.

TIP You can also create custom tools for changing the brush size; choose Customize menu > Customize User Interface and set keyboard shortcuts or other user interface items for the actions Paint Selection Size Up and Paint Selection Size Down.

NOTE Paint Selection Region respects the Window/Crossing selection toggle on page 239 setting. If the toggle is set to Select Region Window on page 235 and the brush is smaller than an object or sub-object to be selected, you won’t be able to select the item. To resolve this, enlarge the brush or choose Select Region Crossing on page 237.

NOTE With editable poly on page 2240 and Edit Poly on page 1332 objects, you can also paint soft selections on page 2021 and deformation on page 2245.

The Paint Selection Region button, available from the Selection Region flyout on page 212, provides one of five methods you can use to select objects by region. The other methods are Rectangular on page 230, Circular on page 231, Lasso on page 233, and Fence on page 232.

Procedures

To select by painting a region:

1 Choose Paint Selection Region from the flyout.
2 Drag over the object(s) to select, then release the mouse button. As you drag, a circle showing the brush radius appears attached to the mouse.

**NOTE** To cancel the selection, right-click before you release the mouse.

3 To change the brush size, right-click the Paint Selection Region button, and then, on the Preference Settings dialog > General tab > Scene Selection group, change the Paint Selection Brush Size value on page 8303.

You can also set keyboard shortcuts for changing the brush size. To do so, use the Paint Selection Size Up and Paint Selection Size Down action items. See Keyboard Panel on page 8250.

---

**Select Region Window**

Edit menu > Selection Region > Window
main toolbar > Window/Crossing Selection

Select Region Window selects objects within a [selection region](#) on page 212.

After you choose this command, draw a selection region around any objects in the scene. Only those objects that are entirely inside the region boundary are selected.
Select Region Window selects only those objects completely inside the window: the trash can and bench.

Procedures

To select objects within a selection region:

1. Do one of the following:
   - Choose Edit > Selection Region > Window.
   - Click the Window/Crossing Selection Toggle on page 239 to display the Window icon.

2. On the main toolbar, click the Selection Region flyout on page 212 and choose a method: Rectangular, Circular, Fence, or Lasso Selection region.

   **NOTE** This setting also applies to Paint Selection Region, but in this case the boundary is that of the brush, not the region. In other words, when painting a selection region, the brush must completely encompass an object or sub-object to select it.

3. Drag to specify the region and select the objects.
Region

Edit menu > Region
main toolbar > Window Selection or Crossing Selection

When dragging the mouse to select one or more objects, the Region options let you switch between selecting objects within, or crossed by, a window region that you draw with the mouse. Choose the appropriate Selection Region submenu command, or use the Window/Crossing Selection Toggle on page 239 on the main toolbar.

You can automatically switch between Window and Crossing Region Selection based on cursor movement direction. To set this up, choose Customize > Preferences and on the General tab in the Scene Selection group turn on Auto Window/Crossing Selection by Direction.

See also:

- Select Region Window on page 235
- Select Region Crossing on page 237

Select Region Crossing

Edit menu > Selection Region > Crossing
main toolbar > Crossing Selection

Select Region Crossing selects objects within and crossed by a selection region on page 212 boundary.
Select Region Crossing selects objects within the window and also objects it crosses: the trash can, bench, and streetlight.

After you choose this command, draw a selection region around or crossing objects in the scene. Objects within the region boundary as well as those that intersect the boundary are selected.

Procedures

To select objects within and crossed by a selection region:

1. Do one of the following:
   - Choose Edit > Selection Region > Crossing.
   - Click the Window/Crossing Selection Toggle on page 239 to display the Crossing icon.

2. From the main toolbar, click the Selection Region flyout on page 212 and choose a method: Rectangular, Circular, Fence or Lasso Selection region.
NOTE This setting also applies to Paint Selection Region, but in this case the boundary is that of the brush, not the region. In other words, when painting a region in Crossing mode, the brush selects every object or sub-object it touches or encompasses.

3 Drag to specify the region and select the objects.

Window/Crossing Selection Toggle

main toolbar > Crossing Selection or Window Selection from the Window/Crossing toggle
Edit menu > Region > Window or Crossing
The Window/Crossing Selection toggle switches between window and crossing modes when you select by region.
- In Window mode on page 235, you select only the objects or sub-objects within the selection.
- In Crossing mode on page 237, you select all objects or sub-objects within the region, plus any objects or sub-objects crossing the boundaries of the region.

TIP If you’re making sub-object selections of faces and you select more faces than you want, make sure you’re in Window mode.

The Selection Region flyout on page 212 on the toolbar allows you to create different-shaped boundaries.
3ds Max automatically saves the Window/Crossing setting in the 3dsmax.ini file.

Edit Commands

These commands on the Edit menu on page 7999 are for basic edit manipulations of selections.
Undo and Redo work as in standard Windows applications. These commands are available on the default main toolbar as well. 3ds Max also provides a history of commands. Right-clicking the Undo or Redo buttons displays a list of commands you can undo or redo. Not all operations are reversible using Undo.

**NOTE** Viewport changes such as panning and zooming have a separate Undo and Redo. See View-Handling Commands on page 126.

The Hold and Fetch command pair serves as an alternative to Undo and Redo. Hold saves the current state of the scene. After using Hold, you can restore that state at a later point by using Fetch. Sometimes, when you are about to perform a risky operation, an alert prompts you to first use Hold.

3ds Max does not have the Cut or Paste functions found in many Windows applications. The Delete command simply removes the selection from the scene.

---

**Undo/Redo**

Quick Access toolbar on page 7995 > Undo button or Redo button
Edit menu > Undo or Redo
Keyboard > Ctrl+Z (Undo) or Ctrl+Y (Redo)

The Undo command reverses the last operation, including selection actions and those performed on selected objects. Redo reverses the last Undo operation.

Some actions cannot be undone: for example, applying the Collapse utility or Reset Transform utility, or saving a file, which overwrites the previous version. When you know an action cannot be undone, use Hold on page 242 first. Then if you want to undo it, use Fetch. Hold and Fetch are also commands on the Edit menu on page 7999.

After you perform an action that is undoable, the Undo command on the Edit menu shows the name of the function to be undone. After you undo an action, the Redo command Edit menu shows the name of the function you can redo.

Undo and Redo are also available as buttons on the Quick Access toolbar. You can click the Undo or Redo down-arrow to display a drop-down list that shows the last operations performed. You can highlight and reverse any number of these operations in sequence with the respective Undo or Redo command. By
default, there are 20 levels of Undo. You can change the number of levels with the Customize > Preferences > General tab on page 8299 > Scene Undo group.

**Undo/Redo and Object Creation**

When you create an object, the Create operation is recorded by 3ds Max and displayed next to the activated Undo command in the Edit menu. If you undo the Create operation, the Create operation appears next to the activated Redo command in the Edit menu. The Undo and Redo commands in the Edit menu are unavailable when no valid operation was performed or recorded.

**Procedures**

To undo the most recent action:

Do one of the following:

- Click Undo.
- Choose Edit menu > Undo.
- Press Ctrl+Z.

To undo several actions:

1. Click the Undo drop-down arrow.
2. From the list, select the level where you want to return. You must choose a continuous selection; you can’t skip over items in the list.
3. Click the Undo button.
   To exit the list without performing an action, click the Cancel button, or click somewhere outside of the list.

To redo an action, do one of the following:

1. Click Redo.
2. Edit menu > Redo.
3. Press Ctrl+Y.
To redo several actions:

1. Click the Redo drop-down arrow.

2. From the list, click the action to return to.
   Your selection must be continuous: you can't skip over any items in the list.

3. Click the Redo button.
   To exit the list without performing an action, click the Cancel button or click somewhere outside of the list.

Hold/Fetch

Edit menu > Hold or Fetch

Hold saves the scene and its settings to a disk-based buffer. Fetch restores the contents of the buffer stored by the previous Hold command. The information stored includes geometry, lights, cameras, the viewport configuration, and selection sets.

Use Hold before you perform an operation that might not work as expected, that is new or unfamiliar to you, or that cannot be undone. If the results aren’t as expected, you can use Fetch to return to the point where you chose Hold.

TIP Also use Save or Save As before you perform an operation that cannot be undone: for example, applying the Reset Transform utility.

If you experience an unexpected end of operation or crash after you perform Hold, you can retrieve your scene from the buffer with the Fetch command after you restart 3ds Max.

Additional Details

- The Hold buffer is a temporary file (maxhold.mxx) in the directory specified by the AutoBackup path on the Configure User Paths dialog > File I/O panel on page 8287.
- Fetch also deletes all operations recorded in the Undo and Redo History lists.
Delete

Make a selection. > Edit menu > Delete
Make a selection. > Keyboard > Delete
The Delete command deletes the current selection from the model.
The Undo command on page 240 can restore the deleted selection to the model.
(Undo is also available as a button on the Quick Access toolbar on page 7995.)

NOTE Actively file-linked objects on page 7538 cannot be deleted.

Groups and Assemblies

You use groups and assemblies in 3ds Max to combine arbitrary sets of scene entities into a single, non-hierarchical object that you can then manipulate as one. Grouping works best when you don’t need to manipulate components of the group; assemblies are best for articulated models such as light fixtures; character assemblies are specifically for modeling bipedal characters.

See also:
- Container on page 7395

Using Groups

Grouping lets you combine two or more objects into a single grouped object. The grouped object is given a name, and then treated much like any other object.
Object on the right is a group and treated as a single entity.

Group names are similar to object names, except that they're carried by the group object. In lists like the one in the Selection Floater on page 209, group names appear in square brackets. For example: [Group01]. In Scene Explorer on page 7888 and related dialogs, the square brackets enclose the group object icon instead.

The commands to manage groups are on the default Group menu on page 8005.

**General Features of Groups**

Once you group objects, you can treat them as a single object in your scene. You can click any object in the group to select the group object.

When you create a group, all of its member objects are rigidly linked to an invisible dummy object. The group object uses the pivot point and the local transform coordinate system of this dummy object.

Groups can be nested. That is, groups can contain other groups, up to any level.
Transforming and Modifying a Group

You can transform and modify a group as if it were a single object, and you can animate the transforms and the modifiers.

When you apply a modifier to the group, this applies an instance of the modifier to each object in the group. A grouped object retains its modifier instance, even if you later remove it from the group.

When you apply a transform to the group, on the other hand, this applies only to the group as a whole. More precisely, 3ds Max applies transforms to the dummy object that represents the group.

You can transform and animate individual objects within a group independently from the group itself. However, when you transform the group itself, the transform affects all grouped objects equally. The group transform is uniformly added to objects that have independent motions. An analogy is a cage of birds, each flying around on its own, while the cage itself is being moved. In the case of groups, the "cage" (the dummy object) expands to surround all objects in the group, wherever the objects' independent transforms take them.

Accessing Objects in a Group

You can open and close groups to access the individual objects contained in them without dissolving the group. These commands maintain the integrity of the group.

- **Open** on page 260: Temporarily opens the group so that you can access its member objects. While a group is open, you can treat the objects (or nested groups) as individuals. You can transform them, apply modifiers, and access their modifier stacks.

- **Close** on page 260: Restores the group when you’re finished working with the individual objects.

Dissolving Groups

You can permanently dissolve groups by either ungrouping or exploding them. Both commands dissolve groups, but to different levels.

- **Ungroup** on page 261: Goes one level deep in the group hierarchy. It separates the current group into its component objects (or groups), and deletes the group dummy object.
■ **Explode** on page 261: Similar to Ungroup, but dissolves all nested groups as well, leaving independent objects.

When you Ungroup or Explode a group, the objects within the group lose all group transforms not on the current frame. However, objects retain any individual animation.

To transform or modify the objects within a group, you must first remove them from the group, either temporarily or permanently. The Open command lets you do this.

**Comparing Groups with Other Selection Methods**

Compared to the other methods you can use to combine objects in 3ds Max, grouping is more permanent than selection sets, but less permanent than attaching objects.

■ **Selection sets** on page 178: Form a temporary collection of objects to which you apply the current commands. As soon as you select another object, the selection set is gone.

■ **Named selection sets** on page 185: Let you reselect the same pattern of objects, but the positional relationship between those objects (their transforms) might be different each time you recall the named set.

■ Grouped objects: Maintain their positional relationships unless you open the group and rearrange them. A group also keeps its identity as an individual object.

Each object in a group retains its modifier stack, including its base parameters. At any time, you can open the group to edit an object, and then close the group to restore the group identity.

■ Attached objects (see **Editable Mesh (Object)** on page 2200): Attached objects form a single object. The modifier stacks of the original objects are lost, including their base parameters. You can regain the form of the original objects by detaching them, but they become plain meshes.

■ **Assemblies** on page 247 are useful for creating combinations of geometry and light objects that act as lighting fixtures.
Using Assemblies

Assemblies are useful for creating combinations of geometry and light objects that act as lighting fixtures; you use them to represent the housing of a lamp and its light source or sources. You can use assemblies to represent lighting fixtures such as simple desk lamps, lighting strips, track systems, wall sconces with fluorescent or incandescent lights, chandelier systems, line voltage cable systems, and so on.

Object on the right is an assembly and is treated as a single entity.

When you create light assemblies, first you create your objects and build a hierarchy, then set joint parameters and assign inverse kinematics (IK) on page 3661. As a final step, you assemble the object hierarchy. The lights you use in the assembly have light-multiplier and filter color controls. You wire on page 3610 the Dimmer and Filter Color parameters of the Luminaire helper object to the parameters of the light sources that are members of the light assembly.
NOTE In order to wire the Luminaire controls to the light parameters, you must first open on page 267 the assembly; then, after wiring, you close on page 268 it.

You can use IK to point a luminaire’s beam by simply moving the light’s target object.

Assemblies and Groups

Assembly functionality is a superset of grouping on page 243. Like grouping, creating an assembly lets you combine two or more objects and treat them as a single object. The assembled object is given a name, and then treated much like any other object.

The main difference with assemblies is that, when you assemble on page 263 the member objects, you specify a head object on page 271: a Luminaire helper object on page 271. The head object acts as a front end for the assembly, and its parameters appear in the Modify panel when the assembly is selected. You can use these parameters to control the light sources in the assembly via parameter wiring on page 3610. You can create other types of head objects with MAXScript; for further information, open the MAXScript Help, available from the Help menu, and look in Creating MAXScript Tools > Scripted Plug-ins > Scripted Helper Plug-ins.

Assembly names are similar to object names, except that they’re carried by the assembly. In lists like the one in the Selection Floater on page 209, assembly names appear in square brackets; for example: [Assembly01]. In Scene Explorer on page 7888 and related dialogs, the square brackets enclose the assembly object icon instead.
**TIP** After you’ve created one fixture and assembled the parts, use instancing on page 8611 to copy on page 981 the fixture, and then distribute them in your scene. That way, if you change the attributes for a light source in an assembly, the change will be reflected in all the instanced light sources. For example, in the early design stages, you might use shadow maps, but later you might want to switch to advanced ray-trace shadows for greater accuracy in rendering. Using instancing makes it easier to change such settings globally.

### General Features of Assemblies

Once you assemble objects, you can treat them as a single object in your scene. You can click any object in the assembly to select the entire assembly.

When you create an assembly, all of its member objects are rigidly linked to an invisible Luminaire helper object. The assembly uses the pivot point and the local transform coordinate system of this helper object.

You can nest assemblies. That is, assemblies can contain other assemblies (or groups), up to any level.

The head object parameters appear in the Modify panel when the assembly is selected. You can use the 3ds Max Wire Parameters on page 3610 functionality to connect these parameters to those of light objects in the assembly. For a step-by-step procedure, see To wire a head object to a light source on page 265.

---

**Luminaire types**

- **Left:** Fixed
- **Middle:** Orientable
- **Right:** Multiple lights
Transforming and Modifying an Assembly

You can transform or modify an assembly as if it were a single object, and you can animate the transforms.

Unlike a group, when you apply a modifier to the assembly, only the luminaire receives the modifier. Thus, deforming modifiers such as Bend don’t have any effect on assemblies.

When you apply a transform to the assembly, it applies to the assembly as a whole. More precisely, 3ds Max applies transforms to the dummy object that represents the assembly. To modify member objects, you must first open the assembly, select the objects, and then apply modifiers. Such modifiers do not appear in the modifier stack when the assembly is closed.

You can transform and animate individual objects within an assembly independently from the assembly itself. However, when you transform the assembly itself, the transform affects all assembled objects equally. The assembly transform is uniformly added to objects that have independent motions. An analogy is a cage of birds, each flying around on its own, while the cage itself is being moved. In the case of assemblies, the "cage" (the dummy object) expands to surround all objects in the assembly, wherever the objects’ independent transforms take them.

Accessing Objects in an Assembly

You can open and close assemblies to access the individual objects contained in them without dissolving the assembly. These commands maintain the integrity of the assembly.

- Open on page 267: Temporarily opens the assembly so that you can access its member objects. While an assembly is open, you can treat the objects (or nested assemblies/groups) as individuals. You can transform them, apply modifiers, and access their modifier stacks.

- Close on page 268: Restores the assembly when you’re finished working with the individual objects.

Using Make Unique with Assemblies

When you clone assemblies using instancing, and then make the clones unique, it’s important to consider how this affects parameter wiring. Consider the following typical usage case:

1. Drag an assembly, such as a light fixture, into the scene.
2 Clone the assembly several times using the Instance option and position the instances in the scene.

3 To make the scene look more realistic, giving the appearance of randomness to the objects in the scene, make some of the assembly instances unique and adjust their parameters to differ from the rest of the instances.

When you clone-instance an assembly, all objects in the assembly, along with all the parameter wires, are instanced. So if you change a wired luminaire parameter, all instanced assemblies are affected.

When the modifier stack displays an assembly head that is an instance or reference, the Make Unique button is active. By clicking it, the assembly head object is made unique with respect to its instances and all the assembly members are also made unique.

The parameter wiring between the unique assembly head and its members is de-coupled from the other instances of the assembly. Changing the parameters of the unique assembly head object affects only the parameters of its own members, not the members of the other instances of the assembly.

When multiple assembly instances are selected, the Make Unique command works the same as when multiple instances of an object are selected. You’re asked whether you want to make the selected assemblies unique one with respect to each other.

- If you answer Yes, 3ds Max makes the assemblies unique one with respect to another and parameter wires are reconnected inside each unique assembly. That is, the parameters of each unique assembly head drives only the parameters of its own members, not that of the members in any other assembly instances.

- If you answer No, then the selected assemblies are made unique only with respect to the other assembly instances. The parameters of unique assembly heads drive only the parameters of their members, not the members of the other assembly instances.

**NOTE** If you chose to instance the controllers when you instanced the assembly, the Modify panel > Make Unique command does not make the controllers unique. You can make them unique by doing the following: Open Track View, select the Transform track for object whose controller you want to make unique, and click the Make Unique button in the Track View toolbar.
Dissolving Assemblies

You can permanently dissolve assemblies by either *disassembling* or *exploding* them. Both commands dissolve assemblies, but to different levels.

- **Disassemble** on page 269: Goes one level deep in the assembly hierarchy. It separates the current assembly into its component objects (or assemblies/groups), and deletes the assembly head object.
- **Explode** on page 269: Similar to Disassemble, but dissolves all nested assemblies and groups as well, leaving independent objects.

When you disassemble or explode an assembly, any transform animation applied to the assembly is lost, and objects remain as they were in the frame at which the dissolution is performed. However, objects retain any individual animation.

To transform or modify the objects within an assembly, you must first remove them from the assembly, either temporarily or permanently. The Open command lets you do this.

Comparing Assemblies with Other Selection Methods

Compared to the other methods you can use to combine objects in 3ds Max, assembling is more permanent than selection sets, but less permanent than attaching objects.

- **Selection sets** on page 178: Form a temporary collection of objects to which you apply the current commands. As soon as you select another object, the selection set is gone.
- **Named selection sets** on page 217: Let you reselect the same pattern of objects, but the positional relationship between those objects (their transforms) might be different each time you recall the named set.
- **Assembled and grouped** on page 243 objects: Maintain their positional relationships unless you open the assembly and rearrange them. An assembly also keeps its identity as an individual object. Each object in an assembly retains its modifier stack, including its base parameters. At any time, you can open the assembly to edit an object, and then close the assembly to restore the assembly identity.
- **Attached objects** (see *Editable Mesh (Object)* on page 2200): Attached objects form a single object. The modifier stacks of the original objects are lost, including their base parameters. You can regain the form of the original objects by detaching them, but they become plain meshes.

- Lights on page 5314

Procedures

To insert and place an existing assembly:

1. Turn on AutoGrid on page 2792.

2. Drag the assembly from a Web page (if it's an i-drop object on page 7644) or from your local disk and drop it into your scene, placing it on any existing surface.

3. On the main toolbar, click Use Pivot Point Center on page 931.

4. Position the assembly as you would any other object to aim it in a specific direction.

5. If necessary, wire on page 265 the assembly luminaire to its light source or sources.

6. Select the assembly, and then use the Modify panel settings to adjust the intensity of the light with the Dimmer control.

To create your own luminaire:

1. Create the geometry of the lighting fixture.

2. Create a light source on page 5314 or on the Create panel, click Lights to add a standard or photometric light to the geometry of the lighting fixture you just made.

3. Select all the objects in the assembly, including geometrical objects and lights.

   **NOTE** If using IK, leave the light targets out of the assembly so that you can manipulate them independently.

4. Choose Assembly menu > Assemble.
   A dialog appears requesting a name for the assembly and that you specify a head object. The only head object type available by default is Luminaire on page 271.
5 Enter a name for the assembly and click OK.
6 Wire on page 265 the assembly luminaire to its light source or sources. More information on parameter wiring is available at the link in this step. If more than one light source is present inside the assembly, create a chain of wired parameters. Then enter the desired relationship expression in the expression text box.

To adjust the pivot location of an assembly:
- When you adjust the pivot point of a closed group or assembly, the pivot point of all group and assembly members are affected, not only the pivot point of the group or assembly head object. Therefore, we recommend that you open the assembly, adjust the pivot of the head object, and then close the assembly.

To use an assembly with radiosity:
- Right-click the Luminaire, choose Properties, and on the Object Properties dialog on page 283 choose the Radiosity tab. You can exclude and control radiosity parameters of the geometry and lights independently.

To adjust the properties of an assembly:
1 After wiring the Dimmer and Filter Color parameters, select the Luminaire, and then go to Modify panel to display the luminaire parameters.
2 Adjust the parameters.
The effect is visible in the viewport.

Character Assembly

A character assembly is a special type of group for objects particular to a character setup: the character mesh, bones, IK chains, helper objects, controllers, and other objects used to animate characters. Once the objects are grouped (assembled), you can perform various functions on the group as a whole, such as saving and loading animation for the entire bone/mesh set.
The objects that make up a typical character assembly

Unlike an ordinary group, there is no need to open a character assembly to work with its individual members.

When a character assembly is created, it is designated by a placeholder object called a *node*, placed near the bottom of the character assembly. Selecting the node gives access to special tools for working with character models and animation.
A character assembly will not create a character mesh or bone structure for you. The character assembly tool is designed for use on character structures that have already been set up using other tools.

Although the character assembly feature was designed for use with character structures, it will work equally well with any type of hierarchy or related set of objects.

**Adding Character Assembly Commands to the UI**

By default, the character-assembly commands described here are not part of the 3ds Max user interface. To add them, choose Customize menu > Customize User Interface, click the tab representing the part of the UI to which you'll add the commands (Keyboard, Toolbars, etc.) and then, from the Category drop-down list, choose Characters. Use standard CUI functionality on page 8249 to add the commands.

**TIP** To add a fully populated Character menu to the menu bar, on the Customize User Interface dialog, scroll the Menus list to Character, and then drag the Character item over to the Main Menu Bar list on the right side of the dialog.
Creating a Character Assembly

To create a character assembly, first select the objects that will make up the assembly. Next, you need to add any character-assembly commands you wish to use to the user interface; see Adding Character Assembly Commands to the UI on page 256. Last, choose the Create Character command.

All selected objects become members of the assembly, and the character assembly node is created. Other objects can be manually added to the assembly after it has been created.

Once the character assembly has been created, you can work with it in a variety of ways. For information about the Modify panel options available after a character assembly is created, see Create Character on page 274.

Linked Objects in Character Assemblies

Any or all members of the character assembly can be linked to a single object outside the assembly, but no more than one. For example, ThighLeft and ThighRight, which are both part of the assembly, can both be linked to Pelvis, which is not part of the assembly. However, if ThighLeft and ThighRight are each linked to different objects outside the assembly, the creation of the assembly will fail, and will show the following error message:

![Error Message]

A character assembly cannot be created since more than one object is parented to objects outside of current selection.

Error Nodes:
- ThighRight
- ThighLeft

Ok
Parameter Wiring and Animation

If you plan to wire parameters between two objects, create the assembly first and then set up the wiring. Be sure to include both objects in the assembly.

Because wiring should be done after the assembly is created, you will probably find it easiest to create the character assembly before animating the character.

- Merge Animation on page 4126

Group Commands

The commands to manage groups are on the Group menu on page 8005.

See also:
- Using Groups on page 243

Group

Group menu > Group
Scene Explorer on page 7888 > Highlight one or more entries. > Right-click a highlighted entry. > Groups > Group

The Group command combines a selection set of objects or groups into a single group.

Once you group objects, you can treat them as a single object in your scene. You can click any object in the group to select the group object. You can
transform the group as a single object, and you can apply modifiers as if it were a single object.

Groups can contain other groups, up to any level.

Group names are similar to object names, except that they’re carried by the group object. In lists like the one in the Selection Floater on page 209, group names appear in square brackets. For example: [Group01]. In Scene Explorer on page 7888 and related dialogs, the square brackets enclose the group object icon instead.

A group in Scene Explorer

If a group is selected, its name will appear in “bolded” text in the Name And Color rollout.

All members of a group inherit the visibility of the parent when a visibility controller is assigned to the parent.

Groups are considered whole objects in the Light Exclude/Include dialog, so you can exclude (or include) all objects in a group by selecting the group in the list. If a group is nested within another group, only the "outer" group is available in the list. To exclude only certain objects in a group, open the group before displaying the Exclude/Include dialog.

**Procedures**

**To define a group:**

1. Select two or more objects.
2. Choose Group menu > Group.
   
   A dialog appears requesting a name for the group.
3. Enter a name for the group and click OK.

**To define a nested group:**

1. Select two or more groups or any combination of groups and objects.
2. Choose Group > Group.
A dialog appears requesting a name for the group.

3 Enter a name for the new group object and click OK.

**Open**

Select one or more groups. > Group menu > Open

*Scene Explorer* on page 7888 > Right-click a group entry. > Groups > Open Group

The Open command lets you ungroup a group temporarily, and access objects within a group.

You can transform and modify the objects within the group independently from the rest of the group, then restore the original group using the Close command.

**Procedures**

**To open a group:**

1 Select one or more groups.

2 Choose Group > Open. A pink bounding box appears, and the objects in the group are now accessible.

**To open nested groups:**

1 Select the group within the opened group.

2 Choose Group > Open.

**Close**

Select the pink dummy object of an opened group. > Group menu > Close

*Scene Explorer* on page 7888 > Right-click a group entry. > Groups > Close Group

The Close command regroups an opened group. For nested groups, closing the outermost group object closes all open inner groups.

When you link an object to a closed group, the object becomes a child of the group parent rather than of any member of the group. The entire group flashes to show that you’ve linked to the group.
Procedures

To close all opened groups nested within a main group:
1 Select the pink bounding box representing the main group.
2 Choose Group > Close.

To close a nested group:
1 Select any object in the nested group or its dummy.
2 Choose Group > Close.

Ungroup

Select one or more groups. > Group menu > Ungroup

Scene Explorer on page 7888 > Right-click a group entry. > Groups > Ungroup

Ungroup separates the current group into its component objects or groups.
The Ungroup command ungroups one level, unlike Explode on page 261, which ungroups all levels of nested groups.
When you Ungroup a group, the objects within the group lose all group transforms that were applied on nonzero frames, but they retain any individual animation.
All ungrouped entities remain in the current selection set.

Procedures

To ungroup a group:
1 Select one or more groups.
2 Choose Group > Ungroup.
   All components of the group remain selected, but are no longer part of the group. The group dummy is deleted.

Explode

Select one or more groups. > Group menu > Explode
The Explode command ungroups all objects in a group, regardless of the number of nested groups, unlike Ungroup on page 261, which ungroups one level only.

As with the Ungroup command, all exploded entities remain in the current selection set.

**WARNING** Ungroup and Explode remove all transform animations that have been applied to the group as a whole. As with the Ungroup command, all exploded entities remain in the current selection set.

### Procedures

**To explode a group:**

1. Select one or more groups.
2. Choose Group > Explode.
   
   All objects in the groups remain selected but no longer belong to groups. All nested groups are exploded. All group dummies in the selection are deleted.

### Detach

Select a group. > Group menu > Open > Select one or more objects detach. > Group menu > Detach

Scene Explorer on page 7888 > Right-click a member of an open group. > Groups > Exclude From Group

The Detach (or, in Scene Explorer, Exclude From Group) command detaches the selected object from its group.

This command becomes available when you select a member of an open group.

### Procedures

**To detach an object from a group:**

1. Open the group.
2. Choose Group > Detach.
   
   The selected objects are now separate, independent objects, no longer members of the group.
**Attach**

Select one or more objects. > Group menu > Attach

The Attach command makes the selected object part of an existing group. With an object selected, choose this command, and then click a group in the scene.

**Procedures**

To attach an object to a group:

1. Select one or more objects to attach.
2. Choose Group > Attach.
3. Click any member of a closed group.
   The selected objects become part of the group, which is now selected.

**NOTE** To attach an object to an open group, click the pink bounding box.

---

**Assembly Commands**

The commands to manage assemblies are available from the Group > Assembly submenu.

**See also:**

- Using Assemblies on page 247

---

**Assemble**

Select the objects to assemble. > Group menu > Assembly > Assemble

The Assemble command combines a selection set of objects, assemblies, and/or groups into a single assembly, and adds a Luminaire helper object on page 271 as a head object on page 271.

Once you assemble objects, you can treat them as a single object in your scene. You can click any object in the group to select the entire assembly. You can...
transform the assembly as a single object, and you can apply modifiers as if it were a single object.

Assemblies can contain other assemblies and/or groups, up to any level.

Assembly names are similar to object names, except that they’re carried by the assembly. In lists like the one in the Selection Floater on page 209, assembly names appear in square brackets; for example: [Assembly01]. In Scene Explorer on page 7888 and related dialogs, the square brackets enclose the assembly object icon instead.

Each member of an assembly inherits the visibility of the parent when a visibility controller is assigned to the parent, providing its Object Properties > Rendering Control group > Inherit Visibility check box is turned on, or if its Rendering Control is set to By Layer and Inherit Visibility is turned on for its layer.

Assemblies are considered whole objects in the Light Exclude/Include dialog, so you can exclude (or include) all objects in an assembly by selecting the assembly in the list. If an assembly is nested within another assembly, only the "outer" assembly is available in the list. To exclude only certain objects in an assembly, open the assembly before displaying the Exclude/Include dialog.

See also:

- Using Assemblies on page 247

Procedures

To define an assembly:

1. Select two or more objects.

2. Choose Group menu > Assembly > Assemble.
   
   The Create Assembly dialog appears. It requests you to specify a name for the assembly and a head object on page 271. The default head object type is Luminaire on page 271.

3. Enter a name for the assembly, choose Luminaire on page 271 from the list, and click OK.
   
   The selected objects are assembled. The assembly head object position and orientation is determined as follows:

   - If there are multiple immediate children of the assembly head (for example, you’re assembling several non-hierarchical objects), the head
object is aligned with center of bottom face of the assembly bounding box.

- If there's only one immediate child of the assembly head, the assembly head pivot point is aligned with that object's pivot point. For example, if you're assembling a single hierarchy, the topmost object in the hierarchy would be the single immediate child of the assembly head.

To define a nested assembly:

1. Select two or more assemblies or any combination of assemblies and objects.
2. Choose Group menu > Assembly > Assemble. The Create Assembly dialog appears. It requests a name for the assembly, and a head object.
3. Enter a name for the new assembly object and click OK.

To wire a head object to a light source:

1. Create a hierarchy of lights and geometrical objects that models a lighting fixture. Sets up all the necessary IK chains and other constraints that make the model behave properly when the user interacts with it (orients, positions, aims, etc.).

   **IMPORTANT** For any photometric lights that you want to control with the head object, be sure to turn on the Multiplier check box on the Intensity/Color/Distribution rollout.

2. Select all objects in the fixture and define them as an assembly. When the assembly is selected, the luminaire parameters Dimmer and Filter Color appear in the Modify panel.
3. From the Animation menu, choose Wire Parameters > Parameter Wire Dialog.
4. The Parameter Wiring dialog appears.
5. On one side of the dialog, find the assembly and expand the branch titled Object (LuminaireHelper). Click the Dimmer item to highlight it.
6. On the other side, find the assembly and expand its hierarchy branch (click the + symbol in the square box). Find and expand the branch for
the light source, and then expand its Object branch. Click the Multiplier item to highlight it.

7 Between the two hierarchy lists, click the Control Direction arrow button that points from the selected Dimmer item to the selected Multiplier item.

8 If you're wiring a photometric light, skip this step. If you're wiring a standard light, or any light whose default Multiplier setting is 1.0, do this:

- The Expression box below the selected Multiplier item contains the word "Dimmer." Edit this to read "Dimmer/100". This divides the Dimmer value by 100, giving a 1:1 value ratio between it and the Multiplier setting.

9 Click the Connect button.

Now, when you change the luminaire’s Dimmer setting, the light source intensity changes as well.

10 If you like, use the same method to wire the luminaire to any additional light sources in the light fixture.

You can also use this method to wire the luminaire's Filter Color parameter to any light sources' color settings.
Interface

Name Specifies the name of the new assembly. The default name is "Assembly" followed by a two-place number starting with 01 and incremented by one for each new assembly.

Choose Head Object Lets you choose the type of object to serve as the assembly head object.

Open Assembly

Select one or more assemblies. > Group menu > Assembly > Open

The Open command lets you temporarily disassemble an assembly and access its head and member objects individually.
You can transform and modify the head and member objects within the assembly independently from the rest of the assembly, then restore the original assembly using the Close command on page 268.

Procedures

To open nested assemblies:

1. Select an assembly within the opened assembly.
2. Choose Group menu > Assembly > Open.

Close Assembly

Select the luminaire. > Group menu > Assembly > Close

The Close command reassembles an opened assembly. For nested assemblies, closing the outermost assembly object closes all open inner assemblies.

When you link an object to a closed assembly, the object becomes a child of the assembly parent rather than of any member of the assembly. The entire assembly flashes to show that you've linked to the assembly.

Procedures

To close all opened assemblies nested within a main assembly:

1. Select any object in the main assembly or its luminaire head object.

   **NOTE** If you select an object within an opened inner assembly, using Close will close only that assembly.

2. Choose Group menu > Assembly > Close.

To close a nested assembly:

1. Select any object in the nested assembly or its luminaire.
2. Choose Group menu > Assembly > Close.
Disassemble

Select one or more assemblies. > Group menu > Assembly > Disassemble

Disassemble separates the current assembly into its component objects or assemblies.

The Disassemble command separates one level, unlike Explode on page 269, which separates all levels of nested assemblies.

When you disassemble an assembly, all components of the assembly remain selected, but are no longer part of the assembly. Any transform animation applied to the assembly is lost, and objects remain as they were in the frame at which the dissolution is performed. However, objects retain any individual animation.

All disassembled entities remain in the current selection set.

**NOTE** If you have wired the luminaire head to any other parameters, those parameters are still controlled by the wiring setup after disassembly and are not adjustable until you apply a standard controller, such as Bezier Float. Use Track View to do this.

Explode Assembly

Select one or more assemblies. > Group menu > Assembly > Explode

The Explode command separates all objects in an assembly, regardless of the number of nested assemblies and/or groups, unlike Disassemble on page 269, which separates one level only.

When you explode an assembly, all components of the assembly remain selected, but are no longer part of the assembly. Any transform animation applied to the assembly is lost, and objects remain as they were in the frame at which the dissolution is performed. However, objects retain any individual animation.

**NOTE** If you have wired the luminaire head to any other parameters, those parameters are still controlled by the wiring setup after exploding and are not adjustable until you apply a standard controller, such as Bezier Float. Use Track View to do this.
**Detach Assembly**

Select an assembly. > Group menu > Assembly > Open > Select one or more objects to detach. > Assembly > Detach

Select one or more objects to detach in an open assembly. > Group menu > Assembly > Detach

The Detach command detaches the selected object from its assembly. If the object is a member of a nested assembly, after you detach it, it is no longer a member of any assembly.

This command becomes active when you open the assembly by choosing **Open** on page 267 from the Assembly menu.

**Attach Assembly**

Select one or more objects. > Group menu > Assembly > Attach

The Attach command makes the selected object part of an existing assembly.

With an object selected, choose this command, and then click either a closed assembly in the scene, or the head object of an open assembly.

**Procedures**

To attach an object to an assembly:

1. Select one or more objects to attach.
2. Choose Group menu > Assembly > Attach.
3. Click any member of an assembly.
   The selected objects become part of the assembly, which is now selected.

**Assembly Head Helper Objects**

Assembly head helper objects are for controlling the assembly.
**Assembly Head Helper Object**

When you create an assembly on page 247, 3ds Max automatically adds a special type of helper object called a head object, or assembly head. This object serves as the fulcrum of the assembly and also exposes parameters, available in the Modify panel when the assembly is selected, that you can wire to properties of objects inside the assembly. Thus, you can change and animate parameters of assembly member objects without having to open the assembly, as you would with a group.

**Luminaire Helper Object**

Create panel > Helpers > Assembly Heads > Object Type rollout > Luminaire

The Luminaire helper object serves primarily as a head, or control, object for light fixtures. When you assemble on page 263 a set of objects into a light fixture, you specify that a new luminaire object should be used as the assembly head object. The luminaire's parameters, available from the Modify panel, let you control the light sources in the fixture. See Using Assemblies on page 247 for more information.

You can also add a Luminaire object separately from the Create panel, but in general it's not necessary.
A luminaire object groups and manages the components as a whole.

**Interface**

When a selected assembly is closed, the Modify panel displays the Luminaire parameters. However, when you open an assembly, 3ds Max shows you the parameters of the whichever object is selected. The Luminaire object provides Dimmer and Filter Color parameters. You wire these to the light objects that are part of the assembly.
**Luminaire rollout**

**Dimmer** Emulates the dimmer switch of a real-world lighting fixture. The setting determines the percentage of the default light intensity is emitted by the light source of a lighting fixture. You wire this parameter to one or more light sources' Multiplier settings.

**Filter Color** An RGB color parameter that you link to a light source's color or filter color.

The Dimmer option can control the intensity of all the lights in the luminaire.
Character Assembly Commands

A character assembly is a special type of group for objects particular to a character setup: the character mesh, bones, IK chains, helper objects, controllers, and other objects used to animate characters. Once the objects are grouped (assembled), you can perform various functions on the group as a whole, such as saving and loading animation for the entire bone/mesh set.

By default, the character-assembly commands listed here are not part of the 3ds Max user interface. To add them, choose Customize menu > Customize User Interface, click the tab representing the part of the UI to which you’ll add the commands (Keyboard, Toolbars, etc.) and then, from the Category drop-down list, choose Characters. Use standard CUI functionality on page 8249 to add the commands.

TIP  To add a fully populated Character menu to the menu bar, on the Customize User Interface dialog, scroll the Menus list to Character, and then drag the Character item over to the Main Menu Bar list on the right side of the dialog.

See also:

- Merge Animation on page 4126

Create Character

See Adding Character Assembly Commands to the UI on page 256.

This command creates a character assembly on page 254.

See also:

- Destroy Character on page 278
- Lock/Unlock Character on page 279
- Save Character on page 279
- Merge Animation on page 4126
Procedures

To create a character assembly:

1. Create a linked structure of bones or other objects. The structure can have several chains. You can also use the linked structure with the Skin modifier, and/or set up character rigs and controllers as needed.

2. Select all objects that will become members of the assembly.

3. Use this method on page 256 to add the character-assembly commands to the user interface, and then choose the Create Character command. The character-assembly node is created at the bottom of the entire selection, as viewed in the Front viewport.

4. On the Modify panel, use the character assembly tools to work with the character structure.

The character assembly is given the default name of Character01, which can be changed. All members of the assembly are listed in the Character Members rollout.
Interface

To work with the character assembly, select the character assembly node and work with the parameters on the Modify panel.

Character Assembly rollout

![Character Assembly rollout]

Skin Pose group

The *Skin pose* is the bone structure pose used by the Skin modifier for associating bones with the mesh. When the Skin modifier is first applied, the
current bone structure pose is used as the Skin pose. The Skin pose can sometimes be accidentally altered by animating the bone structure on frame 0. If this occurs, you can use these options to fix the Skin pose.

You can use these options both before and after applying the Skin modifier. You can also invoke these options when any member of the character assembly is selected.

**Set as Skin Pose** Sets the Skin pose to the current bone structure's pose. The Skin modifier's envelopes and vertex weighting are automatically recalculated to work with the new pose.

**Assume Skin Pose** Causes the bone structure to take on the Skin pose. This feature can be useful during the animation phase. For example, if you have animated the character on various keyframes and want the character to animate back to its Skin pose at frame 50, you can turn on Auto Key at frame 50 and click Assume Skin Pose.

**Skin Pose Mode** Poses the character in its Skin pose and allows the Skin pose to be refined. Changes to the bone structure when Skin Pose Mode is on will affect only the Skin pose and not the animation. When Skin Pose Mode is turned off, the bone structure returns to its pose at the current frame.

**Display group**

When a high resolution character model is animated, redraw time can slow the animation process. To speed up your work, a low resolution version of the model can be used for the animation process, then switched for the full resolution version at render time. Character assembly objects can be designated as Full Res or Low Res on the Character Members rollout.

**Low Res Objects** Displays only the objects checked in the Low Res display in the Character Members rollout.

**Full Res Objects** Displays only the objects not checked in the Low Res display in the Character Members rollout.

**All Objects** Displays all objects in the character assembly.

**Animation group**

Animation for the character assembly can be saved or reset in this group. Previously saved animation from another character can also be inserted to the current character assembly.

**Insert Animation** Displays the Merge Animation dialog on page 4126, and prompts for a previously saved animation file.
**Save Animation** Saves the character assembly animation in an ANM or XML file. Both file types contain the character assembly and its animation. An ANM file is a proprietary format that can be read and saved only by 3ds Max. An XML file formats the information as XML code, and can be edited with a text editor.

Animation saved as an ANM file loads and saves faster than an XML file. Saving and editing an XML animation file is recommended only for users who are familiar with the XML language, and who have a specific need for editing the file.

**Reset All Animation** Removes all animation from the character assembly.

**Character Members rollout**

**Add** Allows you to select individual objects to add to the character assembly.

**Add List** Displays the Pick Character Members dialog, where you can select multiple objects from a list and add them to the character assembly.

**Remove** Removes highlighted object(s) from the assembly. Bones and objects upon which other assembly objects depend, cannot be removed.

**Low Res** All members of the character assembly are displayed on this list. By default, all members are designated as Full Res objects. To designate a member as Low Res, check the object on the list. The Full Res and Low Res designations are used in conjunction with the Display group selection in the Character Assembly rollout.

**Destroy Character**

See Adding Character Assembly Commands to the UI on page 256.

Destroying a character deletes the character assembly node.

This command is available only when a character assembly node is selected.

See also:

- **Character Assembly** on page 254
- **Lock/Unlock Character** on page 279
Lock/Unlock Character

See Adding Character Assembly Commands to the UI on page 256.

Locking a character assembly prevents the character from being animated. Use these commands when you want to prevent accidental animation of the character, such as when the animation process is complete.

Unlocking a locked character assembly allows you to animate the character. These commands are available only when a character-assembly node is selected.

See also:

■ Character Assembly on page 254

Insert Character

See Adding Character Assembly Commands to the UI on page 256.

Choose this command to insert a previously saved character into the current scene.

You save a character assembly as a CHR file with Save Character on page 279. A CHR file contains the character assembly node, all members of the assembly and any animation on the members.

When a character is inserted into the scene, it is placed at the same world-space location it had when saved.

See also:

■ Character Assembly on page 254
■ Save Character on page 279

Save Character

See Adding Character Assembly Commands to the UI on page 256.

Saving a character saves a character assembly on page 254 at its current location, including its node, all members, and any animation on its members. Use this
command for storing a character assembly to disk prior to inserting it into another scene.

Saving a character with this command saves the assembly as a CHR file. You can then insert the CHR file into a scene with Insert Character on page 279. This option is available only when a character assembly node is selected.

**Skin Pose Commands**

Animation menu > Set as Skin Pose

Animation menu > Assume Skin Pose

Animation menu > Skin Pose Mode

When the Skin modifier is first applied to a mesh, the bone structure's current pose is used as the skin pose. Subsequent animation of the bone structure on frame 0 can cause the skin pose to be altered. The skin pose commands allow you to change and set the skin pose either before or after you apply the Skin modifier.

The skin pose stores a specific position, rotation and scale for an object. Its intended use is for storing a character assembly's pose for the Skin modifier. However, a skin pose can be used for any object to store its current transforms for later retrieval.

These commands work on any object, regardless of whether the structure is part of a character assembly, or whether the bones have been assigned to a mesh with the Skin modifier.

**Set as Skin Pose** Stores the selected objects' current position, rotation and scale as the skin pose. If the selected objects are assigned as bones for the Skin modifier, the envelopes and vertex weighting are automatically recalculated to work with the new pose.

**Assume Skin Pose** Causes the selected objects to take on the stored skin pose. This feature can be useful during the animation phase. For example, if you have animated the character on various keyframes and want the character to animate back to its skin pose at frame 50, you can turn on Auto Key at frame 50 and click Assume Skin Pose.

**Skin Pose Mode** Poses the character in its skin pose and allows the skin pose to be refined. Changes to the objects when Skin Pose Mode is on will affect only the skin pose and not the animation. When Skin Pose Mode is turned off, the structure returns to its pose at the current frame.
See also:

- Character Assembly on page 254
The Object Properties dialog, available from the Edit and right-click menus, lets you view and edit parameters for how selected objects behave in viewports and renderings. Note that you cannot necessarily edit all properties; parameters that apply to renderable geometry are unavailable for non-renderable objects. However, parameters that apply to any object, such as Hide/Unhide, Freeze/Unfreeze, Trajectory, and so on, remain available for these non-renderable objects.

With the Object Properties dialog you can specify settings per object or by layer on page 8530. Object settings affect only the object or objects selected. When an object is set to By Layer, it inherits its properties from the layer settings, which you set with the Layer Properties dialog on page 7966.

The Object Properties dialog panels are:

- General Panel (Object Properties Dialog) on page 283
- Advanced Lighting Panel (Object Properties Dialog) on page 295
- mental ray Panel (Object Properties Dialog) on page 300
- User Defined Panel (Object Properties Dialog) on page 303

Object Properties Dialog Panels

The Object Properties dialog has four panels for managing properties.

General Panel (Object Properties Dialog)

Edit menu > Object Properties > Object Properties dialog > General panel
Select object or objects. > Right-click. > Transform (lower-right) quadrant of the quad menu > Object Properties > Object Properties dialog > General panel
Layer manager > Click the icon next to an object's name. > Object Properties dialog > General panel
This panel of the Object Properties dialog displays general object information, as well as controls for rendering the object and displaying it in viewports.
Interface
Object Information group

This group displays information about the selected object, including the following:

**Name** Shows the name of the object. When a single object is selected, you can edit this field to give the object a new name. When multiple objects are selected, this field shows "Multiple Selected," and cannot be edited.

**Color** The color swatch shows the object's color. You can click it to display the Object Color dialog on page 368 and select a different color.

**Dimensions** Displays the X, Y, and Z dimensions of the object's extents on page 8567.

**Vertices and Faces** Display the number of vertices and faces in the object. For shapes on page 572, these values are the values used if you have made the shape renderable. Faces for renderable shapes are generated only at rendering time.

**Shape Vertices and Shape Curves** Appear only for shape objects. Shape Vertices is the number of vertices in the shape, and Shape Curves is the number of polygons. (Shape Curves is the value that appeared as "Polygons" in previous releases.)

These values can change over time: they are valid only for the current frame and the current view.

**Parent** Displays the name of the object's parent in a hierarchy. Shows "Scene Root" if the object has no hierarchical parent.

**Material Name** Displays the name of the material assigned to the object. Displays "None" if no material is assigned.

**Num. Children** Displays the number of children hierarchically linked to the object.

**In Group/Assembly** Displays the name of the group or assembly to which the object belongs. Displays "None" if the object is not part of a group.

**Layer** Displays the name of the layer which the object is assigned to.

Interactivity Group

**Hide** Hides the selected object or objects. Hidden objects exist in the scene, but do not appear in the viewports or rendered images. To unhide hidden objects, use the Display panel on page 8217 or choose Tools > Display Floater on page 8218.
NOTE Objects residing on a hidden layer are automatically hidden, regardless of this setting.

TIP The Layer Manager on page 7956 is the easiest way to hide groups of objects or layers.

Freeze Freezes the selected object or objects. Frozen objects appear in the viewports, but cannot be manipulated. To unfreeze frozen objects, use the Display panel on page 8217 or choose Tools > Display Floater on page 8218.

NOTE Objects residing on a frozen layer are automatically frozen, regardless of this setting.

TIP The Layer Manager on page 7956 is the easiest way to freeze groups of objects or layers.

Display Properties group

NOTE Most of these options are also available on the Display panel on page 8217 and by choosing Tools > Display Floater on page 8218.

By Object/By Layer Toggles between setting display properties on a per-object basis and at the layer level. When set to By Layer, the object display properties are unavailable; set the layer properties on the Layer Properties dialog on page 7966.

NOTE If multiple objects are selected and have different values for this setting, this button reads “Mixed.”

See-Through Makes the object or selection translucent in viewports. This setting has no effect on rendering: it simply lets you see what is behind an object in a crowded scene, and especially to adjust the position of objects behind the see-through object. Default=off.

You can customize the color of see-through objects by using the Colors panel on page 8272 of the Customize > Customize User Interface dialog on page 8249.

Keyboard shortcut (default): Alt+X
**Display as Box** Toggles the display of selected objects, both 3D objects and 2D shapes, as *bounding boxes* on page 8528. Produces minimum geometric complexity for rapid display in viewports. Default=off.

**Backface Cull** Toggles the display of faces with *normals* on page 8654 that point away from the view. When on, you see through the wireframe to the backfaces. Applies only to wireframe viewports. Default=off.

**Edges Only** Toggles the display of hidden edges and polygon *diagonals* on page 8551. When on, only outside edges appear. When off, all mesh geometry
appears. Applies to Wireframe viewport display mode, as well as other modes with Edged Faces turned on.

**NOTE** This option is also available in the Display panel on page 8217 and by choosing Tools > Display Floater on page 8218.

**Vertex Ticks** Displays the object's vertices as tick marks. Default=off.

**Trajectory** Displays the object's trajectory on page 8746. Default=off.
Ignore Extents When on, this object is ignored when you use the display controls Zoom Extents on page 8144 and Zoom Extents All on page 8138. Keyboard shortcut: No default, but you can customize it using the Keyboard panel on page 8250 of the Customize > Customize User Interface dialog on page 8249.

Show Frozen in Gray When on, the object turns gray in viewports when you freeze it. When off, viewports display the object with its usual color or texture even when it is frozen. Default=on.

Never Degrade When on, the object is not subject to adaptive degradation on page 8498.

Vertex Channel Display For editable mesh on page 2192, editable poly on page 2240, and editable patch on page 2360 objects, displays the assigned vertex colors in viewports. The drop-down list lets you choose to display Vertex Color, Vertex Illumination, Vertex Alpha, Map Channel Color, or Soft Selection Color. Default=off.

You can assign vertex colors at all sub-object levels except Edge.

Map Channel Sets the map channel for the vertex color. Available only when the Map Channel Color option is active.

Shaded When on, shaded viewports add shading to the vertex coloring. When off, colors are unshaded. Default=off.

Rendering Control group

By Object/By Layer Toggles between setting rendering controls on a per-object basis and at the layer level. When set to By Layer, the object rendering control settings are unavailable; set the layer properties on the Layer Properties dialog on page 7966.

NOTE If multiple objects are selected and have different values for this setting, this button reads “Mixed.”
Visibility** Controls the rendered visibility of the object. At 1.0, the object is fully visible. At 0.0, the object is completely invisible when rendered. Default=1.0.

You can animate this parameter. Animating Visibility assigns a visibility controller to the object. By default this is a Bezier float controller on page 3432.

**Renderable** Makes an object or selected objects appear or disappear from rendered output. Nonrenderable objects don’t cast shadows or affect the visual component of the rendered scene. Like dummy objects, nonrenderable objects can manipulate other objects in the scene.

For lights, this is the only available control in the Rendering Controls group. Making a light non-renderable effectively turns it off.

**Shape** on page 572 objects have the Renderable option turned on by default. In addition, each shape has an Enable In Renderer parameter. When both check boxes are on, the shape appears in rendered output. If the Renderable object properties setting is off, the shape is not renderable, regardless of the state of its local Enable In Renderer check box.

If you apply a modifier that converts the shape into a mesh object, such as a Lathe modifier on page 1474 or Extrude modifier on page 1425, the shape automatically becomes renderable regardless of the state of its local Enable In Renderer setting.

**Inherit Visibility** Causes the object to inherit a percentage of the visibility of its parent (as determined by the parent’s Visibility track in Track View). When a group parent is assigned a visibility track, Inherit Visibility is automatically turned on for all children in the group. The children will have the maximum visibility of the parent. Transparent materials and hidden objects have no effect on this function.

**Visible to Camera** When on, the object is visible to cameras in the scene. When off, cameras do not view this object; however, its shadows and reflections are rendered. Default=on.

**Visible to Reflection/Refraction** When on, the object has “secondary” visibility: it appears in rendered reflections and refractions. When off, the object does not appear in rendered reflections or refractions. Default=on.

**NOTE** An object can have Visible To Camera on but Visible To Reflection/Refraction off, in which case the object renders in the scene but does not appear in reflections or refractions.

**Receive Shadows** When on, the object can receive shadows. Default=on.

**Cast Shadows** When on, the object can cast shadows. Default=on.
Apply Atmospherics  When on, atmospheric effects are applied to the object. When off, atmospheric effects do not change the rendered appearance of this object. Default=on.

Render Occluded Objects  Allows special effects to affect objects in the scene that are occluded by this object. The special effects, typically applied by plug-ins on page 8687 such as Glow on page 7073, use G-buffer on page 8589 layers to access occluded objects. Turning on this control makes the object transparent for the purposes of special effects. This makes no difference when you render to most image files. When you render to either the RLA on page 7873 or RPF on page 7875 file format, however, occluded objects appear with the effect applied on their designated G-buffer layer. Default=off.

G-Buffer group

Allows you to tag an object as a target for a render effect on page 7057 based on the G-buffer on page 8589 channel. Assigning the object a nonzero ID creates a G-buffer channel that can be associated with a render effect.

The Object ID property is also used with the Multi/Sub-Map shader on page 6414, and can be displayed in the Rendered Frame Window when rendering to RLA on page 7873 and RPF on page 7875 formats.

WARNING  The mental ray renderer on page 6675 does not recognize Z-depth with G-buffers. G-buffer data is saved on a single layer. Also, the mental ray renderer does not support the following effects:

- Glow lens effect on page 7073 (rendering effect)
- Ring lens effect on page 7080 (rendering effect)
- Lens effects Focus filter on page 7339 (Video Post)

Object ID  Setting Object ID to a nonzero value means that the object will receive the rendering effects associated with that channel in Render Effects and the post-processing effects associated with that channel in Video Post. To save the channel data with the rendering, render to either the RLA on page 7873 or RPF on page 7875 file format.

Motion Blur group

By Object/By Layer  Toggles between setting motion blur properties on a per-object basis and at the layer level. When set to By Layer, the motion blur settings are unavailable; set the layer properties on the Layer Properties dialog on page 7966.
If multiple objects are selected and have different values for this setting, this button reads “Mixed.”

**Multiplier** Affects the length of the motion-blur streak.

If you choose either form of motion blur here in the Object Properties dialog, you must also choose to apply that type of blur in the Render Setup dialog on page 6506.

The rendering speed of object motion blur depends on the complexity of the geometry to which it’s assigned. The rendering speed of image motion blur depends on the amount of rendered screen space taken up by the blurring object. In most cases image motion blur renders more quickly. Object motion blur renders more quickly when applied to very simple objects, and image motion blur renders more slowly when the object takes up a lot of screen space, and moves all the way across the screen in a single frame.

**Changing the Object Blur Multiplier value.**

**Enabled** When on, enables motion blur for this object. When off, motion blur is disabled regardless of the other blur settings. Default=on.

You can animate the Enabled check box. The main use of animating Enable is to apply motion blur over only a limited range of frames. This can save a tremendous amount of time when you are rendering an animation.

You can enable motion blur for lights and cameras. With the mental ray renderer, moving lights and cameras can generate motion blur. However, they do not generate motion blur with the default scanline renderer.

**None** Turns off the state of motion blur for the object.
- **Object**  
  Object motion blur on page 8658 provides a time-slice blur effect.

- **Image**  
  Image motion blur on page 8606 blurs the object's image based on the velocity of each pixel.

**Advanced Lighting Panel (Object Properties Dialog)**

Select object or objects. > Edit menu > Object Properties > Object Properties dialog > Advanced Lighting panel

Select object or objects. > Right-click. > Transform (lower-right) quadrant of the quad menu > Object Properties > Object Properties dialog > Advanced Lighting panel

Layer manager > Click the icon next to an object's name. > Object Properties dialog > Advanced Lighting panel

This panel of the Object Properties dialog lets you customize how objects behave under advanced lighting (the Light Tracer on page 6601 or radiosity on page 6615).
Chapter 5  Object Properties

Selection Information rollout

Num. Geometric Objects The number of geometric objects present in the current selection.

Num. Light Objects The number of lights present in the current selection.

Geometric Object Radiosity Properties rollout

Exclude from Adv. Lighting Calculations When on, the current selection is excluded from advanced lighting (radiosity or light tracing). Objects excluded from advanced lighting will not contribute to indirect illumination.

By Object/By Layer Toggles between object settings and object layer settings. Object settings affect only the object or objects selected. Object layer settings affect all objects on the same layer as the selected object. Most settings on this rollout are available only when this toggle is set to By Object. Default=By Object.

NOTE If multiple objects with different settings are selected, this button will read “Mixed.”

Adv. Lighting General Properties group

Cast Shadows Determines whether objects will cast shadows in the radiosity solution.

NOTE When disabling Cast Shadows, you should also turn off Diffuse (reflective & translucent) and Specular (transparent) in the Radiosity-only Properties group. If these switches are left turned on, objects will still generate light that can produce artifacts in the solution.

Receive Illumination Determines whether objects will receive indirect illumination.

Num. Regathering Rays Multiplier Lets you adjust the number of rays cast by this object, per pixel. If an object looks “blotchy” after rendering, Increasing this value can improve its appearance. Default=1.0.

TIP Increasing this setting is most useful for objects with large, smooth surfaces. More complex geometry tends not to show advanced lighting artifacts as much as smooth surfaces do.
Radiosity-only Properties group

Diffuse (reflective & translucent) When on, the radiosity solution will process diffuse reflection and translucency on page 8751 of the selected objects.

Specular (transparent) When on, radiosity will process transparency of the selected objects.

Exclude from Regathering When on, objects are excluded from the regathering process when rendering.

For more information on the Radiosity-only Properties group, see Radiosity Control Panel on page 6634.

Object Subdivision Properties group

Use Global Subdivision Settings When on, the object’s meshing settings correspond to the global subdivision settings on the Radiosity Control Panel. When off, you can change the meshing settings for each object. Default=on.

Subdivide When on, a radiosity mesh is created for the objects regardless of the global meshing state. The subdivision that is performed is determined by the Use Adaptive Subdivision switch. When off, the settings in the Mesh Settings group are unavailable. Default=on.

Use Adaptive Subdivision Toggles adaptive subdivision. Default=on.

TIP Adaptive meshing is computed for an object only if Shoot Direct Lights is turned on in the Radiosity Meshing Parameters rollout on page 6645.

NOTE The Mesh Settings group parameters Contrast Threshold, Min Mesh Size, and Initial Mesh Size are available only when Use Adaptive Subdivision is turned on.

Mesh Settings group

Max Mesh Size The size of the largest faces after adaptive subdivision. Default=36” for imperial units and 100cm for metric units.

When Use Adaptive Subdivision is off, Max Mesh Size sets the size of the radiosity mesh in world units.

Min Mesh Size Faces are not divided smaller than the minimum mesh size. Default=3 inches for Imperial units and 10cm for metric units.

Contrast Threshold Faces that have vertex illuminations that differ by more than the Contrast Threshold setting are subdivided. Default=75.0.
Initial Mesh Size When improving the face shape, faces that are smaller than the Initial Mesh Size are not subdivided. The threshold for deciding whether a face is poorly shaped also gets larger as the face size is closer to the Initial Mesh Size. Default=12 inches for Imperial units and 30cm for metric units.

Radiosity Refine Iterations The number of refine iterations in the radiosity process for the current selection.

Iterations Done The number of refine iterations performed on the current selection.

Light Object Radiosity Properties rollout

These options are available only for light objects.

Exclude from Radiosity Processing When on, the current selection is excluded from the radiosity solution. When lights are excluded from radiosity, their direct contribution is only used for rendering. This option is available only when By Object is selected.

By Object/By Layer Toggles between object settings or object layer settings. Object settings affect only the object or objects selected. Object layer settings affect all objects on the same layer as the selected object.

NOTE If multiple objects are selected and have different settings, this button reads “Mixed.”

Store Direct Illumination in Mesh When on, the light’s direct illumination is added to the radiosity mesh, even if the global rendering mode is Render Direct Illumination. This is comparable to the Re-Use Direct Illumination option when rendering radiosity, but only for this particular light.

When off, the light’s direct illumination is used only when you render the scene. This is comparable to the Render Direct Illumination option.

for more information about the Re-Use Direct Illumination and Render Direct Illumination options, see Rendering Parameters Rollout (Radiosity) on page 6653. In general, re-using direct illumination stored in the radiosity mesh improves render time, but shadows appear coarse and inaccurate unless the mesh is very fine. Rendering direct illumination and shadows (using the radiosity mesh to provide only indirect light) takes more time but gives you a more finished and accurate image.
mental ray Panel (Object Properties Dialog)

Edit menu > Object Properties > Object Properties dialog > mental ray panel

Select object or objects. > Right-click. > Transform (lower-right) quadrant of the quad menu > Object Properties > Object Properties dialog > mental ray panel

Layer manager > Click the icon next to an object's name. > Object Properties dialog > mental ray panel

This panel of the Object Properties dialog supports mental ray rendering; specifically, the indirect illumination features caustics on page 6700 and global illumination on page 6706. They control whether objects generate or receive caustics or global illumination.

These settings are ignored where they aren't appropriate. For example, lights can be set to generate caustics, but for a light, the Receive Caustics setting has no effect, as lights aren't renderable. Similarly, these settings have no meaning for cameras.

Also available on this panel are controls for setting displacement parameters on a per-object basis.

TIP Most of these settings, as well as additional rendering-related settings, are also available on the quad menu that opens when you Alt+Ctrl+right-click a selected object.
**Interface**

The mental ray panel contains object properties for the mental ray renderer.

**Final Gather group**

These settings let you specify how an object interacts with the final gather process.

**When Object is Hit by a Final Gather Ray**

- **Return Object Color (Physically Correct)** Returns the object’s material color at the point that the final gather ray intersects it, and contributes to final gather illumination. This is the default mode.
■ **Return Black**  Blocks final gather rays, returning no color, thus not shading the object at all.

■ **Pass through (Invisible to FG)**  Prevents the final gather process from seeing the object during ray casting. This is useful for ignoring the light contribution from small, complex objects like blades of grass. The final gather rays pass through and strike the underlying object, such as a ground plane that is easier to shade.

**Receive Illumination from Final Gather**  When on, the object is subject to illumination from final gather rays. When off, the object is not illuminated by final gather rays. Default=on.

### Caustics and Illumination group

These settings determine whether and how the object participates in the simulation of caustics and global illumination (photons). To use these capabilities, the respective check boxes must also be enabled on the Render Setup dialog’s Caustics And Global Illumination rollout on page 6771.

**Exclude from Caustics**  When on, the object does not participate in the caustics solution. When off, the additional caustics-related object properties are available. Default=off.

**Generate Caustics**  When on, the object can generate caustics. When off, the object does not generate caustics. Default=off.

**Receive Caustics**  When on, the object can receive caustics. That is, caustic effects are cast onto this object. When off, the object does not receive caustics. Default=on.

**Exclude from GI**  When on, the object does not participate in the global-illumination solution. When off, the additional global-illumination-related object properties are available. Default=off.

**Generate Global Illumination**  When on, the object can generate global illumination. When off, the object does not generate global illumination. Default=off.

**Receive Global Illumination**  When on, the object can receive global illumination. That is, reflected light is cast onto this object. When off, the object does not receive global illumination. Default=on.

### Displacement group

These settings let you apply displacement parameters on a per-object basis.
Use Global Settings When on, applies to all objects the Displacement settings on the Render Setup dialog > Renderer panel > Shadows and Displacement rollout on page 6756. Turn off to make settings on a per-object basis. Default=on.

View-Dependent defines the space for displacement. When View-Dependent is on, the Edge Length setting specifies the length in pixels. When off, Edge Length is specified in world-space units. Default=on.

Smoothing Turn off to have the mental ray renderer correctly render height maps. Height maps can be generated by normal mapping; see Creating and Using Normal Bump Maps on page 6856.

When on, mental ray simply smoothes the geometry using the interpolated normals, making the geometry look better. This result, however, cannot be used for height map displacement because smoothing affects geometry in a way that is incompatible with height mapping.

Edge Length Defines the smallest allowable edge length. The mental ray renderer will stop subdividing an edge once it reaches this size. Default=2.0 pixels.

Max. Displace Controls the maximum offset, in world units, that can be given to a vertex when displacing it. This value can affect the bounding box of an object. Default=20.0.

TIP If displaced geometry appears to be “clipped,” try increasing the value of Maximum Displace.

NOTE When using placeholders (see the Translator Options rollout on page 6787), if this value is larger than it needs to be, it can reduce performance. If you experience slow times while displaced objects when Use Placeholder Objects is on, try lowering the Max. Displace value.

Max. Level Controls how many times a triangle can be subdivided. Default=6.

User Defined Panel (Object Properties Dialog)

Edit menu > Object Properties > Object Properties dialog > User Defined panel

Select object or objects. > Right-click. > Transform (lower-right) quadrant of the quad menu > Object Properties > Object Properties dialog > User Defined panel

Layer manager > Click the icon next to an object’s name. > Object Properties dialog > User Defined panel

User Defined Panel (Object Properties Dialog) | 303
This panel of the Object Properties dialog lets you enter properties or comments that you define yourself.
Interface

User Defined Panel (Object Properties Dialog)
**User Defined Properties** In this text box, you can enter properties for the object, or comments about it, that you define yourself. 3ds Max doesn't use these properties, but it saves them with the scene, and they reappear whenever you view the Object Properties dialog for the object.

**Rename Objects Tool**

Tools menu > Rename Objects

The Rename Objects tool helps you rename several objects at once.

**Interface**

![Rename Objects interface](image)

- **Selected** or **Pick**
- **Base Name**: 
- **Prefix**: 
- **Remove First**: 
- **Suffix**: 
- **Remove Last**: 
- **Numbered**: 
  - **Base Number**: 
  - **Step**: 

  Rename
Selected When chosen, renaming affects currently selected objects.

Pick Click to open the Pick Objects To Rename dialog, which lets you choose the objects to rename. This dialog has the same controls as Select From Scene on page 206.

Base Name Enter a base name for all objects. The toggle enables or disables this name.

Prefix When on, lets you enter a string that will be a prefix to the name of all renamed objects.

Remove First N Digits When on, the first N characters in the base name are removed from object names. The spinner sets the value of N.

Suffix When on, lets you enter a string that will be a suffix to the name of all renamed objects.

Remove Last N Digits When on, the last N characters in the base name are removed from object names. The spinner sets the value of N.

Numbered When on, lets you number object names incrementally.

- **Base Number** The base number appended to the name of the first renamed object.

- **Step** The step by which the base number is incremented in succeeding renamed objects.

Rename Click to rename the affected objects and have your changes take effect.

### Custom Attributes

Animation menu > Parameter Editor

Keyboard > Alt+1

Use the Parameter Editor to assign custom attributes to objects, modifiers, materials, and animation tracks. A custom attribute is an additional, abstract parameter; abstract in the sense that it does not directly extend the functionality of the object by default. It affects an object only after wire parameters on page 3610, reaction controllers on page 3527, or expression controllers on page 3456 are set up to connect the custom attribute to another parameter in the scene. You can also use custom attributes to store job-specific notes and data.
Custom attributes behave like other object parameters in several ways:

- They are saved and loaded in the scene file along with the object.
- They can be animated and keyframed.
- They are displayed in Track View along with the base parameters.

Each custom attribute parameter can be one of a number of different data types, including integers, floating numbers, Booleans, arrays, nodes, colors, and texture maps. Parameters added to an object or modifier appear on a Custom Attributes rollout on the Modify panel. For each custom attribute parameter you create, you can specify the name, layout, value range, default value, and UI type: spinner or slider for floats and integers, check box for Booleans, etc.

As you customize an attribute, the result is displayed on the Testing Attribute rollout at the bottom of the dialog.

See also:
- Parameter Collector on page 325
- Attribute Holder Modifier on page 1163

Custom Attributes Special Features

The Custom Attributes feature offers an array of workflow-enhancing functionality, including:

- the ability to add custom attributes to specific animation tracks.
- the ability to edit existing custom attributes.
- 13 available data types.
- a variety of available UI options, such as ComboBox and ListBox for the Array data type.
- the ability to position UI elements precisely with X and Y Offset controls.
- the ability to preserve custom attributes on page 8205 when collapsing the stack.
- A special Attribute Holder modifier on page 1163 that lets you collect attributes from different entities and access them in one place on the Modify panel.
Procedures

To add a parameter to an object:

1. Select the object.
2. Choose Animation menu > Parameter Editor.
   The Parameter Editor opens.
3. Change settings as desired.
4. Click Add.
   The parameter is added to the level specified in the Add To Type list. If an object has no custom attributes, Parameter Editor first adds a Custom Attributes entry to the current Add To Type level, and then adds the parameter to the Custom Attributes entry. If an object has more than one Custom Attributes entry as a result of collapsing its stack, the parameter is added to the first Custom Attributes entry.
   If a custom attribute parameter is assigned to an object or modifier, you can see and edit its value on the Modify panel after adding it by activating the entity to which the attribute is assigned. If the custom attribute is assigned to a material, it’s available for that material in the Material Editor, on the Custom Attributes rollout. To access a parameter that’s assigned to an animation track, open Track View, highlight the track's Custom Attributes entry, and then right-click and choose View Attribute Dialog.

To edit a parameter or custom attribute:

1. Select the object.
2. Choose Animation menu > Parameter Editor.
   The Parameter Editor opens.
310 | Chapter 5  Object Properties

3. From the Add To Type drop-down list, choose the type of parameter to edit, and then click Edit/Delete. The Edit Attributes/Parameters dialog opens.
NOTE: If you chose Add To Type > Picked Track, the Track View Pick dialog might open first to prompt you to choose the animation track whose attribute to edit.

4. In the Edit Attributes/Parameters dialog, highlight the parameter to edit. Its settings appear in the Parameter Editor.

5. Change the settings in the Parameter editor, and then click Accept Parameter changes.

6. With multiple parameters or custom attributes, to change the ordering, click the entity to move, and then use the up and down arrow buttons to move the entity in the list. Moving a Custom Attributes entry also moves its parameters.

NOTE: You cannot rename a Custom Attributes entry.
7 When finished editing, click Apply Changes, and then exit the dialog by clicking the Close or Cancel button.

To delete a custom attribute or parameter:

1 Select the object.

2 Choose Animation menu > Parameter Editor. The Parameter Editor opens.

3 From the Add To Type drop-down list, choose the type of parameter to delete, and then click Edit/Delete. The Edit Attributes/Parameters dialog opens.

   **NOTE** If you chose Add To Type > Picked Track, the Track View Pick dialog might open first to prompt you to choose the animation track from which to delete the attribute.

4 In the Edit Attributes/Parameters dialog, highlight the parameter to delete, and then click Delete Parameter. Alternatively, to delete all parameters under the same Custom Attributes heading as the highlighted parameter, click Delete All Parameters.

   To delete one or more custom attributes instead, click a Custom Attributes heading, and then click Delete Attribute or Delete All Attributes. Multiple attributes can result from collapsing an object’s stack with Preserve Custom Attributes on. For example, one set of custom attributes might be applied to an object and a second set of attributes assigned to one of its modifiers. Collapsing such an object results in two sets of custom attributes.

5 Click Apply Changes, and then close the dialog by clicking its Close box or the Cancel button.

**Interface**

The Parameter Editor takes the form of a dialog with several rollouts: The first rollout sets general options for the attribute; the central rollout sets options for the current parameter type; and the third lets you preview the attribute user interface (UI).
Add to Type group

Add to Type list Choose whether the custom attribute is assigned to the selected object, its active modifier (as highlighted in the modifier stack), its
material, or a picked track. Also use this drop-down list to choose the attribute type to delete or edit.

If the text “Pick Explicit Track” appears in the box below the drop-down list before you choose Picked Track, the Track View Pick dialog appears showing the Track View hierarchy. Expand the hierarchy as necessary, click the track to add the attribute to, and then click OK.

**NOTE** If you choose Selected Object’s Current Modifier and multiple modifiers are highlighted in the stack when you click Add, Parameter Editor applies the custom attribute to the first modifier you highlighted and removes the highlighting from the other modifiers.

[pick explicit track] Click this button to open a Track View hierarchy window from which to choose an animation track. Navigate the hierarchy to find the desired track, highlight the track, and then click OK. The controller information for the track then appears in the text box to the right of the button, and the Parameter Editor will then use this track for adding or editing custom attributes and parameters.
Add/Edit/Delete group

Add Applies the custom attribute parameter to the current object, modifier, material, or track, depending on the current choice in the Add To Type list. If a custom attribute parameter is assigned to an object or modifier, you can see and edit its value on the Modify panel after adding it by activating the entity to which the attribute is assigned. If the custom attribute is assigned to a material, it's available for that material in the Material Editor. To access a parameter that's assigned to an animation track, open Track View, highlight the track's Custom Attributes entry, and then right-click and choose View Attribute Dialog.

Edit/Delete Opens the Edit Attributes/Parameters dialog.
This dialog displays a list of all of the custom attribute parameters assigned to the currently object at the current level. Dialog behavior is described in these two procedures: To edit a parameter or custom attribute: on page 309 and To delete a custom attribute or parameter: on page 312.
Parameter Type group

Parameter Type Use the drop-down list to choose the data type for the current parameter. The following list includes links to the sections describing the UI settings for each parameter’s data type:

- Angle: Spinner on page 317 or Slider on page 317
- Array on page 320
- Boolean: CheckBox on page 319 or CheckButton on page 319
- Color on page 322
- Float: Spinner on page 317 or Slider on page 317
- fRGBA on page 322
- Integer: Spinner on page 317 or Slider on page 317
- Material on page 323
- Node on page 322
- Percent: Spinner on page 317 or Slider on page 317
- String on page 324
- TextureMap on page 323
- WorldUnits: Spinner on page 317 or Slider on page 317

UI Type group

UI Type Selects the type of UI element that controls the parameter. The UI types available depend on which parameter type you specify. For example, float and integer values are controlled by spinners or sliders, and Boolean values by check boxes or check buttons. Array values are always controlled by drop-down lists, node values by pick buttons, color values by color pickers, and texture map values by map buttons.

Full descriptions of each UI Options rollout follow, and the list of parameter types, above, includes links to the respective UI Options rollout descriptions.

Name The name of the parameter. Parameter Editor gives the parameter the default name Param#, with # being a number. Change the name by editing this field.
Angle/Float/Integer/Percent/WorldUnits UI Options rollout: Spinner

This is a numeric value that the user can set with a standard 3ds Max spinner.

Size group

Width Sets the width of the spinner.

Range group

From Sets the minimum value of the spinner.
To Sets the maximum value of the spinner.
Default Sets the default value of the spinner.

Alignment group

Left/Right/Center Sets the alignment of the spinner in the rollout.
Offsets X/Y Fine-tune the position of the spinner on the horizontal and vertical axes.

Angle/Float/Integer/Percent/WorldUnits UI Options rollout: Slider

This is a numeric value that the user can set with a standard 3ds Max slider.
Size group

**Width** Sets the width of the slider.

Range group

**From** Sets the minimum value of the slider.
**To** Sets the maximum value of the slider.
**Default** Sets the default value of the slider.

Alignment group

**Left/Right/Center** Sets the alignment of the slider in the rollout.

**Offsets X/Y** Fine-tune the position of the slider on the horizontal and vertical axes.

Orientation And Ticks group

**Vertical** When on, the slider will be displayed vertically. When off, the slider is displayed horizontally.

**Ticks** Sets the number of ticks along the slider. The ticks are distributed evenly along the length of the slider.
Boolean UI Options rollout: Check Box

This is a standard 3ds Max check box that the user can turn on and off by clicking it with the mouse.

Size group

Width Sets the width of the check box.

Height Sets the height of the check box.

Alignment group

Left/Right/Center Sets the alignment of the check box in the rollout.

Offsets X/Y Fine-tune the position of the check box on the horizontal and vertical axes.

Boolean UI Options rollout: Check Button

This is a standard 3ds Max check button that the user can turn on and off by clicking it with the mouse.
Size group

Width Sets the width of the check button.
Height Sets the height of the check button.

Alignment group

Left/Right/Center Sets the alignment of the check button in the rollout.
Offsets X/Y Fine-tune the position of the check button on the horizontal and vertical axes.

Check Button Options group

Highlight Color Sets the color of the button when it is pressed.

Array UI Options rollout: Drop-Down List/ComboBox/ListBox

This lets the user of the custom attribute choose a named option from a list. The options for the three Array UI types are the same; they differ in how they appear on the Custom Attributes rollout. The types are:

- Drop-Down List: Only the current choice is visible by default. The user clicks the field to open the list and then clicks to choose a different item.
- ComboBox: Displays an editable field above a list box. The user clicks to choose from the list, or edits the field.
- ListBox: Displays a list. The user clicks the desired item; the highlighting indicates the current choice.
**Size group**

*Width* Sets the width of the list.

*Height* Sets the height of the list.

**Alignment group**

*Left/Right/Center* Sets the alignment of the drop-down list in the rollout.

*Offsets X/Y* Fine-tune the position of the array list on the horizontal and vertical axes.

**Array group**

*Item name* Lets you enter a name into the list.

Click Add Item to add the name to the array list. To remove an item, highlight its name and click Delete Item. Click Clear Array to remove all items from the list.
[array list] Displays the contents of the list. The item at the top of the array list is the default selection.

**Node UI Options rollout: Pick Button**

A node is any object in the 3ds Max scene. The Node UI element creates a button that, when clicked, lets the user pick a scene node other than the one to which the attribute is attached. After selecting the node, its name appears on the button.

### Size group

**Width** Sets the width of the pick button.  
**Height** Sets the height of the pick button.

### Alignment group

**Left/Right/Center** Sets the alignment of the pick button in the rollout.  
**Offsets X/Y** Fine-tune the position of the pick button on the horizontal and vertical axes.

**Color UI Options rollout: Color Picker**

This creates a color swatch that displays the current color and lets the user click it to choose a new color with the Color Selector dialog.
**Size group**

- **Width** Sets the width of the color picker.
- **Height** Sets the height of the color picker.

**Alignment group**

- **Left/Right/Center** Sets the alignment of color picker in the rollout.
- **Offsets X/Y** Fine-tune the position of the color picker on the horizontal and vertical axes.

**ColorPicker Default Color group**

- **Default Color** Sets the default color of the color picker.

**Material/TextureMap Options rollout: MaterialButton/MapButton**

The options for the Material UI type (MaterialButton) and TextureMap UI type (MapButton) are the same. The difference is that, when the user clicks the resulting button to open the Material/Map Browser, the former displays only materials and the latter displays only maps.
Size group

**Width** Sets the width of the material/map button.

**Height** Sets the height of the material/map button.

Alignment group

**Left/Right/Center** Sets the alignment of the material/map button in the rollout.

**Offsets X/Y** Fine-tune the position of the material/map button on the horizontal and vertical axes.

String Options rollout: EditText

The String parameter type creates a text box that the user can edit with the keyboard, with optional default text.

Size group

**Width** Sets the width of the material/map button.

**Height** Sets the height of the material/map button.

Alignment group

**Left/Right/Center** Sets the alignment of the text box in the rollout.

**Offsets X/Y** Fine-tune the position of the text box on the horizontal and vertical axes.
Label group

**Label above text box** When off, the label (parameter name) appears to the left of the text box. When on, the label appears above the text box.

EditText Default Text group

**Default Text** Enter any default text that should appear in the box before the user edits it.

Testing Attribute rollout

This rollout displays the UI layout for the custom attribute that you are working on. It updates continuously so that you can see how different settings in the various rollouts affect the UI display of the attribute.

The UI element is operational in this rollout in the sense that it can be moved, clicked, toggled, and so on.

Parameter Collector

Animation menu > Parameter Collector

Keyboard > Alt+2

Parameter Collector lets you sort and present animatable parameters so that you can access and key selected parameter sets with a click or two. It takes the form of a resizable dialog that regenerates dynamically as parameters change. The dialog supports drag-and-drop rollout reordering. Collections are saved with their scenes and can be merged into other scenes.

One of Parameter Collector's most powerful features is the ability to change all parameters in a collection simultaneously, in an absolute or relative mode. For example, if you're animating a character's hand, you can use Parameter Collector to easily make all the fingers curl up together to form a fist.

**NOTE** Parameter Collector does not support parameters of externally referenced objects on page 7450 or objects in externally referenced scenes on page 7477.
Procedures

Example: To use Parameter Collector:

This exercise demonstrates some basic Parameter Collector functions.

In general, start with a scene containing one or more objects whose parameters you'll collect. Ideally, they should be animated, but it's not absolutely necessary.

1 For this example, reset 3ds Max and then add a sphere.
2 Open Parameter Collector from the Animation menu, or press Alt+2.
3 On the Parameter Collector toolbar, click the Add To New Rollout button.
The Track View Pick dialog opens. This lets you specify parameters to collect.
4 On the Track View Pick dialog, expand Objects > Sphere01 > Transform: Position/Rotation/Scale > Position: Position XYZ.
5 Click X Position: Bezier Float.
The parameter highlights.
6 Click OK to close the dialog.
A new rollout named Parameters 1 appears, containing the X Position parameter.

NOTE A parameter in Parameter Collector can contain only a single value (for example: float, integer, color), so 3ds Max doesn't let you add parameters such as Position: Position XYZ, which contains three distinct values.

7 Click Add To Selected Rollout and then use the same method to add the Y Position and Z Position parameters: Highlight both parameters on the Track View Pick dialog and then click Add To Selected Rollout to add both at once to the Parameters 1 rollout.
8 Drag each spinner in turn to move the sphere on the respective axis. As you change each parameter value, the sphere moves in real time in the viewports.

9 Set all three parameters to 0.0.

10 Click the check button next to each parameter to select all three.

11 On the toolbar, turn on Multiple Edits.

12 Drag one of the spinners. All three change by the same amount, so that the sphere moves diagonally in the scene.

13 Use the keyboard to change the Y Position value to 30.0. Again, the other two change.

14 Click the Absolute/Relative button to turn on Relative mode. All the values display 0.0, as with Offset mode on the status bar coordinate display.

15 Use the spinner to set Y Position to 0.65. The three change in unison, and then reset back to 0.0 when you release the mouse button. This has added the value you set to each of the three positions, as you'll see in the next step.

16 Click the Absolute/Relative button to return to Absolute mode. The values are all set to 30.65, reflecting the relative change that you made.

17 Click the Y Position check button to deselect the parameter.

18 From the Edit menu, choose Select Invert.
The Y Position parameter is now selected, and the other two are deselected.

19 Click the Move Parameters Up button.
The Y Position parameter now sits above the X Position parameter.

20 Click the Move Parameters Down button.
The Y Position returns to its position below the X Position parameter.

21 Choose Edit > Edit Notes.
The Notes dialog opens. Here you can change the parameter name, set a URL or file location with further information about the parameter, and enter comments.

22 In the box below Parameter Name, type Sphere Y Loc., and then press Enter.
The new name replaces the old one on the rollout. You can see the original name by hovering the mouse cursor over the parameter name; it appears on a tooltip.
To conclude this exercise, you'll use Parameter Collector to set and edit animation keyframes.

23 On the Collection menu, turn on Show Keys In Track Bar if necessary.

24 On the 3ds Max status bar, turn on Auto Key.

25 Change the Sphere Y Loc. (the old Y Position) parameter value to 20.0.
Because you're at frame 0, no key is set. This is the same way Auto Key works normally.

26 Go to frame 20 and then set Sphere Y Loc. to 30.0.
This sets animation keys at frames 0 and 20.

27 Right-click the key at frame 20.
The menu shows that a key exists at frame 20 only for Y Position. Normally, 3ds Max would create keys for all three axes, even if you moved the sphere only on one axis.
Parameter Collector can set keys for unselected objects as well.
28 Click in an empty area of the active viewport to deselect the sphere, and then go to frame 30 and change the Sphere Y Loc. value to 40.0. This sets another key for Y Position at frame 30.

29 In Parameter Collector, select the X Position and Z Position parameters, and then click Key Selected. This button is available only when Auto Key is on.

30 Check the track bar key again. Now there are keys for all three parameters, as demonstrated by the red brackets on the spinners in Parameter Collector.

31 Click the Properties button to the right of the Sphere Y Loc. parameter. This opens a Key Info dialog on page 3418 for the parameter, with the ability to edit the key time and value as well as interpolation with other keys. The dialog is also available from the track bar right-click menu, but it’s much easier to access the data for a specific key from Parameter Collector.
Parameter Collector takes the form of a dialog with a menu bar, a toolbar, and rollouts that you create and modify using the dialog tools. You can resize the dialog horizontally and vertically; expanding it lets you see all rollouts simultaneously.
Menu Bar

The menu bar provides a range of functions for using Parameter Collector. See Parameter Collector Menu Bar on page 334 for details. Also, you can open the Spinner Right-Click menu on page 338 by right-clicking a numeric field in Parameter Collector.

Toolbar

The Parameter Collector toolbar provides button access to the most commonly used functions.

[collection name] If empty, enter a name for the current collection, or choose a different collection from the drop-down list. If a name appears and you edit it, pressing Enter duplicates the current collection with the new name.

New Collection Creates a new, empty collection, clearing the current collection name and the rollout area. You can restore any existing collection by choosing it from the drop-down list. This button is unavailable if you have not entered a name for the collection.

Duplicate Collection Creates a new, unnamed collection containing the same data as the current collection. Enter a name for the duplicate selection in the editable field. This button is unavailable if you have not entered a name for the collection.

TIP You can also duplicate a collection and name it at the same time by editing the name of an existing collection and then pressing Enter.

Delete Collection Removes the current collection from memory. This button is unavailable if you have not entered a name for the collection.

Multiple Edits Enables multiple editing, in which changing the value of any selected parameter simultaneously changes all selected parameters of Parameter Collector | 331
the same type by the same amount. This applies to both Absolute and Relative modes (see following).

**Absolute/Relative** Works the same way as the Absolute/Offset mode toggle on the Coordinate Display on page 8081. When Absolute is chosen, modifying a value changes it to the exact amount you specify. When Relative is chosen, the displayed value is 0, and modifying the parameter adds the specified change to the original value. The actual value appears only in Absolute mode.

This applies to numeric values only; any changes to other values, such as color, are always absolute.

**NOTE** With multiple parameters selected, and Multiple Edits on, changing the value of a selected parameter changes the other selected parameter values by the same amount, not to the same amount. This happens in both Absolute and Relative modes.

**Key Selected** Sets keys on page 8616 for selected parameters only at the current frame. Available only when Auto Key on page 8090 is on.

**Reset Selected** Sets all selected numeric parameters to 0. Has no effect on other parameter types.

**Move Parameters Down** Moves each selected parameter down one position within its rollout, if possible.

**Move Parameters Up** Moves each selected parameter up one position within its rollout, if possible.

**Add to Selected Rollout** Lets you add new parameters to the selected rollout. Click this button to open the Track View Pick dialog, and then choose the parameters from the dialog.

**NOTE** You can add several parameters at once by highlighting them in the dialog before clicking OK.
Add to New Rollout  Lets you add new parameters to a new rollout. Click this button to open the Track View Pick dialog, and then choose the parameter from the dialog. Parameter Collector creates a new rollout to hold the parameters.

NOTE You can add several parameters at once by highlighting them in the dialog before clicking OK.

Delete Selected  Deletes all selected parameters.

Delete All  Deletes all parameters and rollouts.

Rollouts

Rollouts work the same way in Parameter Collector as they do on the command panel on page 47. You can expand and collapse a rollout by clicking its title bar, and move it to another location by dragging the title bar. You can resize the dialog to be able to see all rollouts at once.

Only one rollout can be selected at a time. You select a rollout by clicking the horizontal bar beneath the title; when selected, this bar is orange-yellow in color, and angle brackets surround the rollout title (for example, “> Hand Parameters <”).

The interface for each parameter on a rollout is as follows:

[Select Parameter] A small check button on the left side of the rollout. Click it to toggle the parameter's selection status. When selected, the button appears pressed in and is colored yellow-orange.

[parameter name] By default, the parameter has the same name as is shown in Track View, but you can change it with the Edit menu > Edit Notes command. You can see the default name for a parameter as well as the object it controls, if any, by hovering the mouse over the parameter name; the information appears on a tooltip.

[parameter value] Shows the current value of the parameter. The parameter type determines how this appears: numeric field/spinner, color swatch, etc. You can edit the value the same way as on the command panel or a dialog. If a key exists for the value at the current frame, the spinner or swatch appears with red brackets at the corners.
[Properties] Opens a Key Info dialog on page 3418 for the parameter. Available only if the parameter has an animation controller. Use the Key Info dialog to edit an animation key's value, time, and interpolation methods.

Parameter Collector Menu Bar

Animation menu > Parameter Collector > Parameter Collector menu bar
Keyboard > Alt+2 > Parameter Collector menu bar

The Parameter Collector dialog menu bar provides access to a number of important commands. Some of these commands are replicated on the dialog toolbar; others, such as the Select tools, are available only from the menus. Also, you can open the Spinner Right-Click menu on page 3380 by right-clicking a numeric field in Parameter Collector.

Interface

Collection menu

The first three items in this menu are unavailable until you enter a name for the current collection in the editable field (drop-down list) just below the menu bar.

New Collection Creates a new, empty collection, clearing the current collection name and the rollout area. You can restore any existing collection by choosing it from the drop-down list.

Duplicate Collection Creates a new, unnamed collection containing the same data as the current collection. Enter a name for the duplicate selection in the editable field.

Delete Collection Removes the current collection from memory.

Show Keys in Track Bar Displays in the track bar on page 8071 animation keys for all objects with parameters in the current collection, whether or not the objects are selected in the scene.

Isolate Keys in Track Bar The track bar displays only keys for parameters in the Parameter Collector.
Show Selected Keys in Track Bar Displays in the track bar on page 8071 animation keys for all objects with selected parameters in the current collection, whether or not the objects are selected in the scene.

Isolate Selected Keys in Track Bar The track bar displays only keys for selected parameters in the Parameter Collector.

Put to Object Stores the current collection as part of an object in the scene. Opens the Put To Object dialog; highlight an object in the list, and then click Pick.

Although parameter collections are stored with the scene in which they're created, you can use this function to transfer a collection to a different scene. After putting the collection to an object, save the scene. Open or create another scene, merge the object from the saved scene to the new one, and then use Get from Object.

You can also back up, organize and streamline parameter collections by putting and getting different collections to and from various objects in your scene. Just remember that if you add, reorder, or remove parameters or rollouts to a collection that has been put to an object, you must then put it to the object again so the changes are saved to the collection.

Link to Object Stores the current collection using a live link as part of an object in the scene. Any change to the collection instantly updates the version of the collection stored in the object. Opens the Link To Object dialog; highlight an object in the list, and then click Pick.

Link to Object has basically the same function as Put To Object (see previous entry), except that it guarantees an up-to-date stored version of the collection, especially when merging the object into another scene that is a common production workflow.

NOTE Only one “linked-to” object can be active in a scene, but you can use Put To Object on any number of objects at a time.

Get from Object Retrieves a collection that you stored with Put To Object or Link To Object.

Remove from Object Deletes a collection that you stored with Put To Object or Link To Object.

Edit menu

Parameter Collector lets you select parameters in any combination, but you can select no more than one rollout at a time. To select or deselect a parameter, click the small button on its left side. To select or deselect a rollout, click the
A wide horizontal button just below the rollout title. Selecting a rollout deselects any other selected rollout.

**Select All** Selects all parameters and rollouts.

**Select All Rollout** Selects all parameters on the current rollout. Unavailable if no rollout is selected.

**Select None** Deselects all parameters.

**Select Invert** Inverts the current selection of parameters.

**Delete Selected** Deletes all selected parameters.

**Delete All** Deletes all parameters and rollouts.

**Multiple Edits** Enables multiple editing, in which changing any parameter simultaneously changes all selected parameters of the same or similar type.

---

**NOTE** The changed parameter need not be selected.

**Absolute/Relative** This works the same as the Absolute/Offset mode toggle on the Coordinate Display on page 8081. When Absolute is chosen, modifying a value changes it to the exact amount you specify. When Relative is chosen, the displayed value shows 0, and modifying the parameter adds the specified change to the original value. This applies to numeric values only; changes to any other value types such as color are always absolute.

**Edit Notes** Opens a single Notes dialog on page 337 for all selected parameters. You can open the Notes dialog for a single parameter by right-clicking its Select Parameter button.

**Parameters menu**

**Add to Selected** Lets you add new parameters to the selected rollout.

**Add to New Rollout** Lets you add new parameters to a new rollout.

**Move Up** Moves selected parameters up one position within their rollout, if possible.

**Move Down** Moves selected parameters down one position within their rollout, if possible.

**Move Up By Rollout** Moves selected parameters to the rollout above, if possible. If the same parameter already exists in the rollout above, the selected parameter is simply deleted.
**Move Down By Rollout** Moves selected parameters to the next rollout, if possible. If the same parameter already exists in the next rollout, the selected parameter is simply deleted.

**Key All** Sets keys on page 8616 for all parameters at the current frame. Available only when Auto Key on page 8090 is on.

**Key Selected** Sets keys on page 8616 for selected parameters only at the current frame. Available only when Auto Key on page 8090 is on.

**Reset All** Sets all numeric parameters to 0. Has no effect on other parameter types.

**Reset Selected** Sets all selected numeric parameters to 0. Has no effect on other parameter types.

**Rollout menu**

*NOTE* While there are no menu commands for moving rollouts, you can do so simply by dragging the rollout title bar to a new location.

**New Rollout** Creates a new, empty rollout.

**New Rollout Selected Parameters** Creates a new rollout and populates it with copies of any selected parameters.

**Rename Rollout** Opens a small dialog that lets you rename the selected rollout.

**Delete Rollout** Deletes the selected rollout.

**Delete Rollout Move Up** Deletes the selected rollout and moves its parameters to the rollout above.

**Delete Rollout Move Down** Deletes the selected rollout and moves its parameters to the rollout below.

**Notes Dialog (Parameter Collector)**

Parameter Collector > Select one or more parameters. > Parameter Collector menu bar > Edit menu > Notes

Parameter Collector > Right-click a Parameter Select button.

The Notes dialog lets you enter a name, URL, and comments for one or more selected parameters in Parameter Collector.
Choosing Notes from the Edit menu with multiple parameters selected opens a single dialog common to all selected parameters. Right-clicking a Parameter Select button opens a dialog for that parameter only.

When you open Notes from the Edit menu with multiple parameters selected, if the text contents for a box in all selected parameters are the same (or null), its check box is on, indicating that changes to the text will apply to all selected parameters. If a text box has different contents for different selected parameters, the check box is off, and the corresponding text box is empty and unavailable, preventing any changes. If you turn on a check box, you can edit the text, and changes will be applied to all selected parameters.

**Interface**

![Notes dialog interface](image)

The Notes dialog interface comprises three text boxes, each with its respective check box, and a button. By default, the text boxes are empty; you can enter any text into each box, although each has a specific purpose, as described below.

**Parameter Name** Lets you change the parameter name shown in Parameter Collector.

338 | Chapter 5  Object Properties
By default, the parameter name displayed in Parameter Collector is the same as the name that appeared in the Track View Pick dialog when you added it to Parameter Collector. If you enter a different name in the Notes dialog, Parameter Collector then displays that name. The changed name is used only in Parameter Collector; elsewhere, such as the Modify panel, it remains the same as before.

You can see the original parameter name, as well as the object to which it’s attached, by hovering the mouse over the parameter name in Parameter Collector; the information appears in a tooltip.

**URL** Lets you enter a URL, such as www.discreet.com. This could be a link to a Web or intranet page, or even a network location or file pertaining to the selected parameter. To access the link, click the Go button.

**Go** If the URL text box contains a valid URL, clicking Go opens the URL in a separate browser window.

**Notes** Contains any comments on the parameters. This field is strictly for informational purposes.

### Expression Techniques

In 3ds Max, you can use mathematical expressions (rather than constant numbers) to express parameter values. For example, you could use the expression $24 \times 6$ to represent the number 144.

You can use mathematical expressions to control the following object properties:

- Object parameters, such as length, width, and height
- Transform and modifier values, such as an object’s position coordinates

*Parameter wiring* on page 3610, the *expression controller* on page 3456, and the *numerical expression evaluator* on page 49 all use expressions, which are described in this topic.
An expression is a mathematical function that returns a value. You can use expressions to control the following scene elements:

<table>
<thead>
<tr>
<th>Scene element</th>
<th>Calculatable property</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creation parameters</td>
<td>Any numeric creation parameter</td>
</tr>
<tr>
<td>Transforms</td>
<td>Position [X, Y, Z]</td>
</tr>
<tr>
<td></td>
<td>X Rotation</td>
</tr>
<tr>
<td></td>
<td>Y Rotation</td>
</tr>
<tr>
<td></td>
<td>Z Rotation</td>
</tr>
<tr>
<td></td>
<td>Scale [X%, Y%, Z%]</td>
</tr>
<tr>
<td>Modifiers</td>
<td>Any numeric modifier parameter (including creation parameters)</td>
</tr>
<tr>
<td>Materials</td>
<td>Colors [R, G, B]</td>
</tr>
<tr>
<td></td>
<td>Any numeric material parameter</td>
</tr>
</tbody>
</table>

**NOTE** Expressions only work with the individual XYZ components of Euler rotation. You can't assign an expression to TCB rotation or other kinds of rotation controllers.

The links below are to the sections that follow in this topic.

- Expression Return Types on page 341
- Operators on page 341
- Variables on page 344
- Functions on page 346

**See also:**
- Trigonometric Functions on page 349
- Vectors on page 352
- Expression Controller Techniques on page 3463
Expression Return Types

The type of value returned by an expression depends on the kind of controller:

- Float expressions return a floating-point scalar value (For example, 5.617). Scalars are used in the animation controllers of numeric parameters. If the parameter has an integer value, the expression rounds the float value to the nearest integer.

- Position, Scale, and Point3 expressions return a three-component vector. For example, [5, 18, 24]. The vector can represent an object’s X,Y,Z location, percent scaling in X, Y, and Z, or a color (RGB values) in a material.

Operators

In the following tables, p and q are any scalar value or expression, V and W are any vector value or expression. (The character “x” is used as the vector cross-product operator.)

Scalar Operators

These are the arithmetic operators for scalar values:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Use</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>p+q</td>
<td>Addition</td>
</tr>
<tr>
<td>-</td>
<td>p-q</td>
<td>Subtraction</td>
</tr>
<tr>
<td>-</td>
<td>-p</td>
<td>Additive inverse</td>
</tr>
<tr>
<td>*</td>
<td>p*q</td>
<td>Multiplication</td>
</tr>
<tr>
<td>/</td>
<td>p/q</td>
<td>Division</td>
</tr>
<tr>
<td>^</td>
<td>p^q</td>
<td>power (p to the power of q)</td>
</tr>
<tr>
<td>**</td>
<td>p**q</td>
<td>^ and ** are the same operation</td>
</tr>
</tbody>
</table>
You can also use logical (Boolean) operators with scalar values. These operators all return 1 if true, 0 otherwise:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Use</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>p=q</td>
<td>equal to</td>
</tr>
<tr>
<td>&lt;</td>
<td>p&lt;q</td>
<td>less than</td>
</tr>
<tr>
<td>&gt;</td>
<td>p&gt;q</td>
<td>Greater than</td>
</tr>
<tr>
<td>&lt;=</td>
<td>p&lt;=q</td>
<td>less than or equal to</td>
</tr>
<tr>
<td>&gt;=</td>
<td>p&gt;=q</td>
<td>Greater than or equal to</td>
</tr>
<tr>
<td></td>
<td>p</td>
<td>q</td>
</tr>
<tr>
<td>&amp;</td>
<td>p&amp;q</td>
<td>Logical AND, returns 1 if p and q are both nonzero; otherwise, returns 0</td>
</tr>
</tbody>
</table>

**TIP** Logical operators are useful with the "if" function.

**Vector Operators**

For vectors that have a variable name, you can use a special component operator (.) to refer to the three scalar components of the vector:

<table>
<thead>
<tr>
<th>Use</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>V.x</td>
<td>first component (X)</td>
</tr>
<tr>
<td>V.y</td>
<td>second component (Y)</td>
</tr>
<tr>
<td>V.z</td>
<td>third component (Z)</td>
</tr>
</tbody>
</table>
These are the operators for vector arithmetic:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Use</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>V+W</td>
<td>Addition</td>
</tr>
<tr>
<td>-</td>
<td>V-W</td>
<td>subtraction</td>
</tr>
<tr>
<td>*</td>
<td>p*V</td>
<td>scalar multiplication</td>
</tr>
<tr>
<td>*</td>
<td>V*p</td>
<td>scalar multiplication</td>
</tr>
<tr>
<td>*</td>
<td>V*W</td>
<td>dot product</td>
</tr>
<tr>
<td>X</td>
<td>VxW</td>
<td>cross product</td>
</tr>
<tr>
<td>/</td>
<td>V/p</td>
<td>scalar division</td>
</tr>
</tbody>
</table>

**Operator Precedence**

Expressions have eight levels of precedence. The higher the operator is on the list, the earlier it is evaluated.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Level of Precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>- +</td>
<td>as unary operators, as in -8, +25</td>
</tr>
<tr>
<td>.</td>
<td>the component operator, as in V.x</td>
</tr>
<tr>
<td><strong>^</strong></td>
<td></td>
</tr>
<tr>
<td>X</td>
<td>cross product</td>
</tr>
<tr>
<td>* /</td>
<td></td>
</tr>
<tr>
<td>+ -</td>
<td></td>
</tr>
<tr>
<td>Operator</td>
<td>Level of Precedence</td>
</tr>
<tr>
<td>----------</td>
<td>---------------------</td>
</tr>
<tr>
<td>= &lt; &gt; &lt;=</td>
<td></td>
</tr>
<tr>
<td>&gt;=</td>
<td></td>
</tr>
<tr>
<td></td>
<td>&amp;</td>
</tr>
</tbody>
</table>

Parentheses are a special case. They are a grouping or subexpression operator that is provided so you can override the precedence order of the other operators.

**Variables**

In expressions you write for expression controllers on page 3456, variables are represented by symbolic names. You create them to contain constant or variable values in your expressions. Several predefined variables are also provided. Some of these have a constant value, others can vary.

In expressions used for parameter wiring on page 3610 and the numerical expression evaluator on page 49, you can use predefined variables with constant values.

**Predefined Variables with Constant Values**

These are the predefined variables that have a constant value (variable names are case-sensitive):

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Constant Value</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>pi</td>
<td>3.14159</td>
<td>Ratio of a circle's circumference to its diameter.</td>
</tr>
<tr>
<td>e</td>
<td>2.71828</td>
<td>Base of natural logarithms.</td>
</tr>
<tr>
<td>TPS</td>
<td>4800</td>
<td>Ticks per second. The tick is the basic time unit of 3ds Max animation.</td>
</tr>
</tbody>
</table>
Predefined Variables with Variable Values

These are the predefined variables that have a variable, time-based value (variable names are case-sensitive).

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>Frame number. For each frame, F equals the current frame number, counting from zero. The range of frames can vary depending on the number of frames in the active time segment.</td>
</tr>
<tr>
<td>NT</td>
<td>Normalized time. By definition, normalized time (NT) ranges from 0 to 1 over the active time segment, regardless of how many frames are in the segment. If you base an expression on NT, its effect happens exactly once over the range. You can also multiply NT by a factor for the expression's effect to occur a certain number of times (for example, 2*NT causes the expression's effect to occur twice). Expressions based on NT speed up or slow down if you change the length of the time segment.</td>
</tr>
<tr>
<td>S</td>
<td>Seconds (elapsed time in seconds). Elapsed time is measured from the first frame to the current frame. The range of seconds can vary depending on the total time of the active time segment.</td>
</tr>
<tr>
<td>T</td>
<td>Ticks (elapsed time in ticks). There are 4800 ticks per second. Elapsed time is measured from the first frame to the current frame. The range of ticks can vary depending on the total time of the active time segment.</td>
</tr>
</tbody>
</table>
Rules for Variable Names

- Variable names can contain as many alphanumeric characters as you like. Their length is not limited.
- Variable names cannot contain spaces.
- The variable name must begin with a letter. Numbers are valid within a variable name (as in "Pos1" or "M23").
- Variable names are case-sensitive. For example, "pos", "Pos", and "POS" designate three different variables.
- You can’t create a variable with a name that duplicates another name, including the variable names that are predefined.

Functions

Following is a list of the functions provided for expressions. In this list, p, q, and r represent scalar values or scalar expressions. V and W represent vector values or vector expressions.

To use a function in an expression, enter the name of the function and appropriate arguments to it.

Trigonometric Functions

The sine, cosine, and tangent functions take an angle in degrees and return a floating-point value. The arc functions take a floating-point value and return a value in degrees.

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>sin(p)</td>
<td>sine</td>
</tr>
<tr>
<td>cos(p)</td>
<td>cosine</td>
</tr>
<tr>
<td>tan(p)</td>
<td>tangent</td>
</tr>
<tr>
<td>asin(p)</td>
<td>arc sine</td>
</tr>
<tr>
<td>acos(p)</td>
<td>arc cosine</td>
</tr>
</tbody>
</table>
### Hyperbolic Functions

Hyperbolic functions take a floating-point value and return a floating-point value.

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>sinh(p)</td>
<td>hyperbolic sine</td>
</tr>
<tr>
<td>cosh(p)</td>
<td>hyperbolic cosine</td>
</tr>
<tr>
<td>tanh(p)</td>
<td>hyperbolic tangent</td>
</tr>
</tbody>
</table>

### Conversion Between Radians and Degrees

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>radToDeg(p)</td>
<td>takes p in radians and returns the same angle in degrees</td>
</tr>
<tr>
<td>degToRad(p)</td>
<td>takes p in degrees and returns the same angle in radians</td>
</tr>
</tbody>
</table>

### Rounding Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ceil(p)</td>
<td>smallest integer greater than or equal to p</td>
</tr>
<tr>
<td>floor(p)</td>
<td>largest integer less than or equal to p</td>
</tr>
</tbody>
</table>
## Standard Calculations

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ln(p)</td>
<td>natural (base e) logarithm</td>
</tr>
<tr>
<td>log(p)</td>
<td>common (base 10) logarithm</td>
</tr>
<tr>
<td>exp(p)</td>
<td>exponential function exp(p)=e^p</td>
</tr>
<tr>
<td>pow(p,q)</td>
<td>p to the power of q (p^q)</td>
</tr>
<tr>
<td>sqrt(p)</td>
<td>square root</td>
</tr>
<tr>
<td>abs(p)</td>
<td>absolute value</td>
</tr>
<tr>
<td>min(p,q)</td>
<td>minimum returns p or q, depending on which is smaller</td>
</tr>
<tr>
<td>max(p,q)</td>
<td>maximum returns p or q, depending on which is greater</td>
</tr>
<tr>
<td>mod(p,q)</td>
<td>remainder of p divided by q</td>
</tr>
</tbody>
</table>

## Conditional Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>if(p,q,r)</td>
<td>works like the common spreadsheet &quot;if&quot; (If p is nonzero then &quot;if&quot; returns q, otherwise &quot;if&quot; returns r.)</td>
</tr>
<tr>
<td>vif(c,V1,V2)</td>
<td>&quot;Vector If&quot; (Value is V1 if c is true, else V2.)</td>
</tr>
</tbody>
</table>
Vector Handling Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>length(V)</td>
<td>length of V</td>
</tr>
<tr>
<td>comp(V,i)</td>
<td>i'th component (i=0,1,2):</td>
</tr>
<tr>
<td></td>
<td>comp([5,6,7],1)=6</td>
</tr>
<tr>
<td>unit(V)</td>
<td>returns a unit vector in the same direction as V</td>
</tr>
</tbody>
</table>

**NOTE** The comp function is an alternative to the notation V.x, V.y, V.z.

Special Animation Function

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>noise(p,q,r)</td>
<td>3D noise: returns a randomly generated position</td>
</tr>
</tbody>
</table>

The arbitrary values p, q and r, are used as a random-generation seed. You can reuse these values to ensure that noise() returns the same value.

Trigonometric Functions

This topic is a quick review for readers who need a reminder about this area of mathematics. If you’re familiar with trigonometry, you can skip this topic. If you find this topic difficult to follow, you might consult a more basic reference on mathematics.

Trigonometric functions are principally used to model or describe:

- The relation between angles in a triangle (hence the name).
- Rotations about a circle, including locations given in polar coordinates.
- Cyclical or periodic values, such as sound waves.
The three basic trigonometric functions are derived from an angle rotating about a unit circle.

![Diagram of a unit circle with trigonometric functions](image)

**Trigonometric functions based on the unit circle**

\[
\sin \theta = \frac{y}{r} \quad \cos \theta = \frac{x}{r} \quad \tan \theta = \frac{y}{x}
\]

The tangent function is undefined for \(x=0\). Another way to define the tangent is:

\[
\tan \theta = \frac{\sin \theta}{\cos \theta}
\]

Because \(XYR\) defines a right-angled triangle, the relation between the sine and cosine is:

\[
(\cos \theta)^2 + (\sin \theta)^2 = 1
\]

The graphs of the basic trigonometric functions illustrate their cyclical nature.
Graphs of basic trigonometric functions

The sine and cosine functions yield the same values, but the phase differs along the X axis by $\pi/2$: in other words, 90 degrees.

The inverse functions for the trigonometric functions are the arc functions; the inverse only applies to values of x restricted by $-\pi/2 \leq x \leq \pi/2$. The graphs for these functions appear like the basic trigonometric function graphs, but turned on their sides.

Graphs of basic arc functions

The hyperbolic functions are based on the exponential constant $e$ instead of on circular measurement. However, they behave similarly to the trigonometric functions and are named for them. The basic hyperbolic functions are:
The topic is a quick review for readers who need a reminder about vector arithmetic. If you’re familiar with vectors and vector calculations, you can skip this topic. If this topic is difficult to follow, you might consult a more basic reference on mathematics.

A vector expresses a length and a direction in a particular space. The vector is expressed as a point; for example, [5, 5, 7]. The length is the distance from the origin to that point, and the direction is similarly from the origin to (and through) the point.

In 3ds Max, vectors have three values and describe positions in three-dimensional space. They can also represent percent scaling in X, Y, and Z; and (more abstractly) describe locations in RGB color space.
**Unit Vectors and Basic Vectors**

A unit vector has a length of one. Unit vectors are often used to express direction only. The three basic vectors are unit vectors that describe the three axes (X, Y, and Z) of 3D space.

![Basic vectors and the XYZ axes](image)

**Adding and Subtracting Vectors**

Adding two vectors creates a new vector that combines the length and direction of the original two. Vector addition is commutative: $V + W = W + V$.

![Adding two vectors](image)
\[ \mathbf{V} + \mathbf{W} = [v_1 + w_1, v_2 + w_2, v_3 + w_3] \]

Subtracting two vectors gives the vector between the two points.

\[ \mathbf{V} - \mathbf{W} = [v_1 - w_1, v_2 - w_2, v_3 - w_3] \]

**Scalar Multiplication and Division**

Multiplying a vector by a scalar changes the vector's length, as does dividing the vector by a scalar.

\[ y \mathbf{V} = \mathbf{V} y = [yv_1, yv_2, yv_3] \]
\[ \mathbf{V} / y = [v_1 / y, v_2 / y, v_3 / y] \]

**Vector Length and Direction**

The length of a vector is obtained from the Pythagorean theorem.

\[ |\mathbf{V}| = \sqrt{v_1^2 + v_2^2 + v_3^2} \]
In 3ds Max expressions, the length() function returns this value.
The direction of the vector is the vector divided by its length; this gives you a unit vector with the same direction.

\[ \frac{\mathbf{V}}{|\mathbf{V}|} \]

The distance between two points is the length of the vector between them.

\[ |\mathbf{VW}| = |\mathbf{W} - \mathbf{V}| \]

*Subtracting vectors to obtain a distance*
The solid 3D objects in the scene, and the objects used to create them, are known as *geometry*. Usually, geometry comprises the subject of your scene and the objects that you render.

Villa with a swimming pool was created using a variety of geometry.

This section describes the types of geometry you can create using the *Create panel* on page 8182.

**See also:**
- [Surface Modeling](#) on page 2013
Basics of Creating and Modifying Objects

This section provides an introduction to techniques for creating and modeling objects.

The Create panel contains controls for creating new objects, the first step in building a scene. Despite the variety of object types, the creation process is consistent for most objects.

The Modify panel provides controls to complete the modeling process. You can rework any object, from its creation parameters to its internal geometry. Both object-space and world-space modifiers let you apply a wide range of effects to objects in your scene. The modifier stack allows editing of the modifier sequence.

In 3ds Max, you model basic parametric objects into more complex ones by:
- Changing parameters
- Applying modifiers
- Directly manipulating sub-object geometry

Varying the Parameters

Unlike physical objects, with a fixed shape and size, you can change the creation parameters of objects and shapes to dramatically alter topology. Here are some examples of changes you can make:
- Turn a cone into a four-sided pyramid by reducing the number of sides and turning the Smooth option off.
- Slice any circular object as if it were a pie.
- Animate almost all creation parameters, and interactively change their settings during animation playback.
- Render splines directly at any assigned width.
- Break, detach, and divide wall segments.
- Change the number of risers without affecting the overall rise of the stairs.

**Collapsing Primitives to Base Geometry**

You can collapse a geometric primitive or shape to one of a variety of base geometric types once you no longer need access to its creation parameters. For example, you can convert any standard primitive to an **editable mesh** on page 2192, **editable poly** on page 2240, **editable patch** on page 2360, or **NURBS** on page 2440 object, and you can convert a spline shape to an **editable mesh**, **editable spline** on page 620, or NURBS object. The easiest way to collapse an object is to select it, right-click it, and choose a "Convert to" option from the quad menu > Transform quadrant. This lets you use explicit editing methods with the object, such as transforming vertices. You can also use the Modify panel to collapse a primitive.

**Mapping Coordinates**

Most Geometry objects have an option for generating mapping coordinates. Objects need these mapping coordinates if you plan to apply a mapped material to them. Mapped materials include a wide range of rendered effects, from 2D bitmaps to reflections and refractions. See **Mapping Coordinates** on page 5636 and **Using Maps to Enhance a Material** on page 5627. If mapping coordinates have already been applied to an object, the check box for this feature is turned on.

**See also:**
- Using the Modify Panel on page 1041
- Using the Modifier Stack on page 1045
- Editing the Stack on page 1049
- Modifying at the Sub-Object Level on page 1054
- Using the Stack at the Sub-Object Level on page 1057
- Modifying Multiple Objects on page 1059
- How Instanced Modifiers Work on page 1063
- Transforms, Modifiers, and Object Data Flow on page 1034
Using the Create Panel

The Create panel provides the controls for creating objects and adjusting their parameters.

To access the Create panel:

1. Click the Create tab in the command panels on page 8181.
   By default, this panel is open when you start 3ds Max. If the command panel isn't visible, choose it from the Customize Display right-click menu on page 8239.
2. Click an object type to display its Parameters rollout.

The Creation Process

The actual creation of objects is accomplished with a single click of the mouse, a drag, or some combination, depending on the object type. This is the general sequence:

- Choose an object type.
- Click or drag in a viewport to create an object of approximate size and location.
- Adjust the object's parameters and position, either immediately or later.

See Creating an Object on page 364.

Create Panel Interface

Controls in the Create panel vary depending on the kind of object you are creating. However, certain controls are always present, and others are shared by nearly all object types.

**Category** Buttons at the top of the panel access the seven main categories of objects. Geometry is the default category.

**Subcategory** A list lets you select subcategories. For example, subcategories under Geometry include Standard Primitives, Extended Primitives, Compound Objects, Particle Systems, Patch Grids, NURBS Surfaces, and Dynamics Objects.

**Object Type** A rollout contains labeled buttons for creating objects in a particular subcategory, plus the AutoGrid on page 2792 check box.
Name and Color  The Name shows the automatically assigned name of the object. You can edit this name or replace it with another. (Different objects can have the same name, though this is not recommended.) Clicking the square color swatch brings up an Object Color dialog on page 368 to change the color of the object as it appears in viewports (the wireframe color).

Creation Method  This rollout provides a choice of how you use the mouse to create an object. For example, you can use either the center (radius) or edge (diameter) to define the size of a Circle shape.

A default creation method is always selected when you access the tool. If you want to use an alternate method, choose the option before you create the object. The creation method has no effect on a finished object; the options are for your convenience during creation.

Keyboard Entry  This rollout lets you enter creation parameters from the keyboard for geometric primitive and shape objects.

Parameters  This rollout shows creation parameters: the defining values for an object. Some parameters can be preset, while others are only for adjustment after an object has been created.

Other rollouts  Additional rollouts can appear on the Create panel, depending on what kind of object you create.

Identifying the Basic Building Blocks

On the Create panel, the categories for Geometry and Shapes supply the "building blocks" to combine and modify into more sophisticated objects. These parametric on page 8675 objects are ready to use. By adjusting values and turning some buttons on or off, you can create dozens of "new" building blocks from the ones listed here.

You can choose these types from the sub-categories list on the Create panel.

Geometry Types

Standard Primitives  Relatively simple 3D objects such as Box, Sphere, and Cylinder, as well as Torus, Plane, Cone, GeoSphere, Tube, Teapot, and Pyramid.

Extended Primitives  More complex 3D objects such as Capsule, OilTank, Spindle, Hedra, Torus Knot, and Prism.

Compound Objects  Compound objects include Scatter, Connect, ShapeMerge, Booleans, Morph, BlobMesh, Terrain, and Loft. Booleans combine the geometry
of two objects using union, intersection, and difference operations. Morphys
are animated objects that change one geometric shape into other shapes over
time. ShapeMerge lets you embed a spline shape into a geometric mesh. Loft
on page 742 uses shapes as cross sections along a path to produce a 3D object.

**Particle Systems** Animated objects that simulate spray, snow, blizzard, and
similar collections of small objects.

**Patch Grids** Simple 2D surfaces ready for modeling or repairing existing
meshes.

**NURBS Surfaces** Analytically generated surfaces especially suited for modeling
surfaces with complicated curves.

**AEC Extended** Elements useful for AEC design, including Terrain, Foliage
(plants and trees), Railing, for creating custom railings, and Wall, for the
production of Wall objects.

**Stairs** Four types of stairs: Spiral, L-Type, Straight, and U-Type.

**Doors** Parametric door styles include Pivot, BiFold, and Sliding.

**Windows** Parametric window styles include Awning, Fixed, Projected,
Casement, Pivoted, and Sliding.

**NOTE** Default materials are automatically applied to Foliage, as well as to the
following object types: Railing, Stairs, Doors, and Windows.

**Dynamics Objects** Objects designed for use in dynamics simulations.

**Shape Types**

**Splines** Common 2D shapes such as a Line, Rectangle, Circle, Ellipse, Arc,
Donut, NGon, and Star. Text shapes support TrueType fonts. Section creates
a spline from the cross-section of an object. Helix is a 3D shape.

**NURBS Curves** A Point Curve and CV Curve provide the starting points for
complex surfaces. See *Introduction to NURBS Modeling* on page 2416.

**Extended Splines** More complex 2D shapes including Walled Rectangle,
Channel Spline, Angle Spline, Tee Spline, and Wide Flange Spline. Extended
splines can be used in architectural and similar applications.
Varying the Parameters

Unlike physical building blocks, with fixed shape and size, you can change the parameters of objects and shapes to dramatically alter topology. Here are some examples of changes you can make:

- Turn a cone into a four-sided pyramid by reducing the number of sides and turning the Smooth option off.
- Slice any circular object as if it were a pie.
- Animate almost all creation parameters, and interactively change their settings during animation playback.
- Render splines directly at any assigned width.
- Break, detach, and divide wall segments.
- Change the number of risers without affecting the overall rise of the stairs.

Collapsing Primitives to Base Geometry

You can collapse a building-block object to one of a variety of base geometric types once you no longer need access to its creation parameters. For example, you can convert any standard primitive to an editable mesh on page 2192, editable poly on page 2240, editable patch on page 2360, or NURBS on page 2440 object, and you can convert a spline shape to an editable mesh, editable spline on page 620, or NURBS object. The easiest way to collapse an object is to select it, right-click it, and choose a "Convert to" option from the quad menu > Transform quadrant. This lets you use explicit editing methods with the object, such as transforming vertices. You can also use the Modify panel to collapse a primitive.

Mapping Coordinates

Most Geometry objects have an option for generating mapping coordinates. Objects need these mapping coordinates if you plan to apply a mapped material to them. Mapped materials include a wide range of rendered effects, from 2D bitmaps to reflections and refractions. See Mapping Coordinates on page 5636 and Using Maps to Enhance a Material on page 5627. If mapping coordinates have already been applied to an object, the check box for this feature is turned on.
Creating an Object

With some variations, the steps shown in the following images apply to creating any type of object on the Create panel. For specific examples, see the Procedures section in any object’s topic.

1. Radius defined
2. Height defined
3. Sides increased
4. Height Segments increased

To choose an object category:

1. Click the Create tab to view the Create panel.
2. Click one of the buttons at the top of the Create panel. For example, Geometry.
3. Choose the subcategory Standard Primitives from the list. A number of buttons appear on the Object Type rollout.

To choose an object type:

- Click the button for the type of object you want to create. The button highlights, showing that it is active. Four rollouts appear: Name and Color, Creation Method, Keyboard Entry, and Parameters.
To choose a creation method (optional):
You can accept the default method and skip this step.
■ Choose a method in the Creation Method rollout.

To preset the creation parameters (optional):
You can adjust all creation parameters after you create an object. Skip this step if you prefer.
■ In the Parameters rollout, you can set parameters before you create an object. However, the values of parameters you set by dragging the mouse (for example, the Radius and Height of a cylinder) have no effect until after you create the object.

To create the object:
1 Put the cursor at a point in any viewport where you want to place the object, and hold the mouse button down (do not release the button).
2 Drag the mouse to define the first parameter of the object; for example, the circular base of a cylinder.
3 Release the mouse button. The first parameter is set with this release. In some cases, such as Sphere, Teapot, and Plane, this completes the object. You can skip the remaining steps.
4 Move up or down without touching the mouse button. This sets the next parameter; for example, the height of a cylinder.
   If you want to cancel! Until you complete the next step, you can cancel the creation process with a right-click.
5 Click when the second parameter has the value you want, and so on.
The number of times you press or release the mouse button depends on how many spatial dimensions are required to define the object. (For some kinds of objects, such as Line and Bones, the number is open-ended.)

When the object is complete, it is in a selected state and ready for adjustments.

To name the object (optional):
■ Highlight the default object name in the Name and Color rollout, and then enter a name. This option is available only when a single object is selected.
Naming objects is a good practice for organizing your scenes. To name a set of selected objects, see Named Selection Sets on page 185.

**To change the object’s display color (optional):**

- The color swatch next to the object name field displays the selected object’s color and lets you select a new one. The color is the one used to display the object in viewports. Click the color swatch to display the Object Color dialog on page 368. You can also change object colors with Layers on page 7956.

**To adjust the object’s parameters:**

- You can change the creation parameters immediately after you complete an object, while it’s still selected. Or, you can select the object later and adjust its creation parameters on the Modify panel.

While making adjustments, you can use viewport navigation controls like Zoom, Pan, and Orbit to change your view of the selected object. You can also adjust the time slider.

**To end the creation process:**

While the object type button remains active, you can continue creating objects of the same type until you do one of the following:

1. Select an object other than the one you created most recently.
2. Transform an object.
3. Change to another command panel.
4. Use commands other than viewport navigation or the time slider.

After you end the creation process, changing parameters on the Create panel will have no effect on the object; you must go to the Modify panel to adjust the object’s parameters. See Using the Modify Panel on page 1041.

---

**Assigning Colors to Objects**

3ds Max is a truecolor program. When you pick a color in 3ds Max, you are specifying 24 bits of color data, which provide a range of over 16 million colors.
Object wireframe colors are used primarily as an organizational tool. Object naming strategies, named selection sets, and object wireframe color strategies provide a rich set of tools for organizing even the most complex scenes.

You can use two dialogs to specify colors:

- The Object Color dialog on page 368 contains two preset palettes of colors that you use to set an object’s wireframe color. This is also the surface color you see in a rendered viewport. The two color palettes are Default palette and AutoCAD ACI palette.

- The Color Selector on page 371 is a generic dialog that you use to define any color in the 24-bit color range. For the purpose of defining colors to assign to objects, it is available only through the Default palette.

The Layers functionality lets you organize your scene and can also be used for assigning object colors. For more information, see Layer Manager on page 7956.

**Object Color Dialog**

Click the color swatch by the object's name in any command panel.

The Object Color dialog contains two preset palettes of colors that you use to set an object’s wireframe color. This is also the surface color you see in a shaded viewport.

**Using Random Color Assignment**

By default, 3ds Max assigns colors randomly as objects are created. The colors are chosen from the current palette in the Object Color dialog. If you turn on Customize > Preferences > General panel on page 8299 > Default to By Layer for New Nodes, new objects are assigned the color set by the layer.

For individual objects, you can click the By Layer/By Object button on the Object Color dialog to change the method used to set the object color.

**Defining Custom Colors**

When using the 3ds Max palette, the Object Color dialog contains a palette of 16 custom color swatches. You can define any color for each of the 16 color swatches by selecting a swatch from the Custom Colors group, then clicking Add Custom Colors.
Switching Between Palettes

You can alternate between two versions of the Object Color dialog at any time by clicking the appropriate Basic Colors toggle:

- **3ds Max palette**: Contains a fixed palette of 64 colors, plus a custom palette of 16 user-defined custom colors.
  Use this version when you want to work with a smaller palette of colors or when you want to define custom object wireframe colors.

- **AutoCAD-compatible version**: Contains a fixed palette of 256 colors matching the colors in the AutoCAD Color Index (ACI).
  Use this version when you want to assign object colors that match the AutoCAD Color Index. Using ACI colors is useful if you plan to export objects to AutoCAD and want to organize them by object color, or when you want a wide selection of colors to choose from.

Procedures

To set object color:

This is the general procedure for selecting object color.

1. Select one or more objects.
2. On any command panel, click the color swatch to the right of the Object Name field to display the Object Color dialog.
3. On the Object Color dialog, click the By Layer / By Object toggle to set it to By Object.
4. Click a color swatch from the palette, and then click OK to apply the color to the selection.

To create objects of the same color:

- Choose the color you want to use and turn off Assign Random Colors. Newly created objects appear in this color until you change the setting.

To define a custom color:

1. With the 3ds Max palette option active, click one of the 16 custom color swatches.
2. Click Add Custom Colors to display the Color Selector on page 371.
Define a custom color and click Add Color.
The custom color is stored in the selected color swatch of the Object
Color dialog and is set as the current color.

To copy a custom color from an object in your scene to one of your custom
color swatches:

- Drag the Active Color swatch up to one of the custom color swatches.
The Active Color swatch is in the Object Color dialog, to the left of the
OK button.

To select objects by color:

- Click Select By Color. This displays the Select Objects dialog on page
206. All objects that have the same color as the current object are highlighted
in the list. Click Select.

Interface

Palette Choose one of these:

- **3ds Max palette** When chosen, the dialog displays Basic Colors and
  Custom Colors groups, and you have the option to add custom colors.
AutoCAD ACI palette

When chosen, the AutoCAD ACI palette is shown. When you click a color, its ACI# is displayed at the bottom of the dialog.

Basic Colors

A set of 64 default colors, available only when 3ds Max Palette is active.

Custom Colors

Displays 16 custom colors when 3ds Max Palette is active. To choose a custom color, click its swatch. To define or change a custom color, click its swatch and then click Add Custom Colors.

Add Custom Colors

Available only when 3ds Max Palette is active. Clicking this option displays the Color Selector on page 371, which allows you to modify the currently selected custom color. If you click Add Custom Colors with a basic color chosen, the dialog switches to the first custom color before opening the Color Selector.

By Layer/By Object

Sets the object’s color by layer or by object. If color is set by object, choosing a new color on the Object Color dialog changes the object’s wireframe color in viewports.

ACI# Displays the ACI number for the selected color. Available only when AutoCAD ACI palette is active.

Select by Color

Opens the Select Objects dialog on page 206 listing all objects that use the current color as their wireframe color.

NOTE

This button is available only if at least one object in the scene has the Current Color as its wireframe color.

Assign Random Colors

When on, 3ds Max will assign a random color to each object created. When off, 3ds Max will assign the same color to every object created until the color swatch is changed. This setting affects wireframe colors only when By Object is turned on as the color method.

Active/Current Color

Displays the active color (if no object is selected) or current color. When you click the color swatch, the Color Selector dialog on page 371 opens, where you can mix a custom color.

Color Selector Dialog

Any command panel > Name and Color fields > Click color swatch. > Object Color dialog > Add Custom Colors button or Current Color swatch.
Material Editor > Click any color swatch.
Select or add a light object. > Modify panel >
Intensity/Color/(Distribution/Attenuation) rollout > Click color or Filter Color swatch.

Rendering menu > Environment > Environment and Effects dialog > Click color swatch for Background, Tint, and Ambient components of Global Lighting, and various components of atmospheric effects such as Fire, Fog, and so on..

The Color Selector dialog lets you specify a custom color parameter in 3ds Max. You can work simultaneously with three different color models to help you zero in on the exact color you want.

You can use the Color Selector to specify many color parameters, such as light colors, material colors, background colors, and custom object colors. (Another way to choose an object's viewport color is to use the predefined colors in the Object Color dialog on page 368.)

In most contexts, the Color Selector is modeless on page 8641; that is, it remains on the screen until you dismiss it, and you can use other controls or work in a viewport while the dialog is still visible. In other contexts, the Color Selector is modal, and you must close the dialog before proceeding.

The dialog is divided into three different color selection models. You can use the controls for any model to define a color. The three color models are:

- **Hue/Blackness/Whiteness (HBW)**
  The most prominently displayed and intuitive color model is the HBW model. This model represents a natural, pigment-based way of mixing color by starting with a pure color (hue) and then making it darker by adding black, or lighter by adding white.
  The main feature of the HBW model is a large square box displaying the color spectrum. Across the top of this box you have the spectrum of pure colors, or hue. Down the side of the box you see increasing levels of blackness, making the color dark as you approach the bottom.
  To the right of the color spectrum box is the Whiteness box, which controls the amount of white in the color. Use higher positions to decrease the whiteness, or lower positions to increase the whiteness.

- **Red/Blue/Green (RGB)**
  The RGB model adjusts the mix of Red, Green, and Blue to define a color. This model represents the way colored light can be mixed. This is additive color mixing, as opposed to the subtractive color mixing for paint and other pigments. You can adjust values using the color sliders, the numeric
fields to their right (via the keyboard), or the spinners to the right of the numeric fields.

■ Hue/Saturation/Value (HSV)
The HSV color model adjusts Hue, Saturation, and Value. Hue sets the color; Saturation (labeled "Sat") sets the color's purity; and Value sets the color's brightness, or intensity. You can adjust values using the color sliders, the numeric fields to their right (via the keyboard), or the spinners to the right of the numeric fields.

As you adjust the controls of one color model, the controls of the other two models change to match. The color defined by the color model is displayed in the right half of the Color Output box. The original color, before you began making changes, is displayed in the left half.

Procedures

To display the Color Selector:

1. Click the color swatch of a color parameter such as the color of a light or of a material component.

   **NOTE** The object color displayed next to an object's name on command panels uses the Object Color dialog on page 368. On the Object Color dialog, clicking the Active (or Current) Color swatch or the Add Custom Colors button displays a Color Selector.

2. Make a color selection and click OK or Cancel, or the Close button (X).
   If using the Add Color version of the Color Selector, be sure to click Add Color first.

3. To revert to the original color, click Reset.

To choose the hue of a color, do one of the following:

1. Click anywhere in the Hue rainbow (the large, multicolored square).
2. Drag the Hue slider at the top of the rainbow.
3. Drag the Red, Green, and Blue sliders.
4. Drag the Hue slider.
5. Use the Red, Green, Blue, or Hue spinners.
To make a color lighter, do one of the following:

1. Drag the vertical Whiteness slider (at the right of the Hue rainbow) downward.
2. Drag the vertical Blackness slider (at the left of the Hue rainbow) upward.
3. Drag the Saturation (Sat.) slider to the left.
4. Use the Saturation spinner to decrease saturation.
5. Drag the Value slider to the right.
6. Use the Value spinner to increase the value.

To make a color darker, do one of the following:

1. Drag the vertical Whiteness slider (at the right of the Hue rainbow) upward.
2. Drag the vertical Blackness slider (at the left of the Hue rainbow) downward.
3. Drag the Saturation (Sat.) slider to the right.
4. Use the Saturation spinner to increase saturation.
5. Drag the Value slider to the left.
6. Use the Value spinner to decrease the value.

To return to the original color:

- Click Reset.
  The new color is replaced by the original color, and all parameter values are reset.

To dismiss the Color Selector, do one of the following:

1. Click Close.
2. Click OK or Cancel.
3. Click the dialog's Close (X) button.
Interface

Hue Define a pure color by dragging the hue pointer across the top of the box.

Blackness Drag the blackness pointer down the side to darken the pure color by adding black. You can also click or drag inside the box to change hue and blackness at the same time.

Whiteness The vertical bar to the right controls the amount of whiteness. The color set by the hue and blackness pointers is displayed at the top of the bar and pure white at the bottom. Drag the whiteness pointer down to lighten the color by adding white.

Red, Green, and Blue When a red, green, or blue slider is all the way to the left, its numeric field contains 0; none of the color controlled by that slider is used. If the slider is all the way to the right, the field reads 255; the maximum amount of that color is being used.

The spinners to the right of each slider are another way of setting the red, blue, or green component.

The colors in the sliders change to show an approximation of what the color result will be if you move the slider to that location, without adjusting any other color parameter.

Hue Sets the pure color. Locating the slider all the way to the left gives you pure red. As you drag the slider to the right you move through the spectrum of Red, Yellow, Green, Cyan, Blue, Magenta, and back to Red again. Hue is more accurately represented as a color wheel rather than a linear slider. That is why the Hue slider is red at both ends. Think of the hue range from 0 to
255 as being points on a circle where the numbers 0 and 255 are right next to each other.

**Saturation ("Sat")** Sets the purity or strength of the color. A weak color, with a saturation near 0, is dull and gray. A strong color, with a saturation near 255 is very bright and pure.

**Value** Sets the lightness or darkness of a color. Low values darken the color toward black. High values lighten the color toward white. A value in the middle, at a setting of 127, gives you the color defined only by hue and saturation.

**Color Output** This pair of color swatches, below the Value slider, lets you compare the new color, shown on the right, to the original color, shown on the left.

**Sample Screen Color** Lets you pick a new color from anywhere on the screen. After clicking this button, the mouse cursor changes to the eyedropper icon shown on the button. While this cursor appears, use any of these methods:

- Click anywhere on the screen to replace the current color with the color of the pixel under the lower-right corner of the cursor.
- Drag to continually update the current color with the color of the pixel under the lower-right corner of the cursor. This makes it easier to make sure you get the right color if the desired color area is small (say, a one-pixel-thick line).
- At any time, press and hold Shift to average the current color with colors the cursor moves over. Instead of replacing the current color with the new sampled color, smoothed sampling gradually mixes the sampled color with the current color, giving a smoothed color transition during sampling. This is useful for sampling noisy areas, where the variations in colors are accumulated to provide a representative general color.

Unlike the other methods, releasing the left mouse button only does not exit the sampler mode; you can move the mouse elsewhere (without sampling) and then start dragging again to continue smoothed sampling in other areas. Releasing Shift only returns to regular sampling. Releasing both Shift and the left mouse button exits the sampler mode, returning the mouse cursor and behavior to normal.

Sampling can occur under any conditions anywhere within any windows that belong to the current instance of 3ds Max. To sample anywhere outside of
3ds Max (for example, the desktop), drag the mouse from within one of these 3ds Max windows.

The color sampler tool compensates for any gamma applied to the color selector using the Customize > Preferences > Gamma And LUT on page 8330 > Affect Color Selectors option. This means that the color-corrected, displayed sampled visual color in the color selector always matches the on-screen visual color of the sampled location. If the gamma of the color selector does not match the gamma of the sampled location, the true color values (RGB/HSV) of the sampled color will differ from the true color values of the sampled location. This behavior applies to both regular gamma and Autodesk LUT gamma correction modes.

Reset Click to restore color settings to the original color.

OK Accepts any changes and closes the dialog.

NOTE If you opened the dialog by clicking Add Custom Colors on the Object Color dialog, the button label reads “Add Color.”

Cancel Restores the original color and closes the dialog.

**Color Selector for mental ray Materials and Shaders**

When you click a color swatch in the interface for a mental ray material on page 5772 or mental ray shader on page 6385, or a DirectX material on page 6175, you see a variant of the Color Selector.
This dialog differs from the standard Color Selector in two ways:

- The RGB and HSV values appear as normalized values between 0.0 and 1.0, rather than as 8-bit integers (0–255).
- An additional Alpha slider and spinner let you explicitly set the alpha value for this color. This value is also normalized, where 0.0 represents fully transparent, and 1.0 represents fully opaque.

This version of the Color Selector also appears when you use the DirectX Shader material on page 6175 and the mental ray renderer's Sampling Quality rollout on page 6735.

Color Clipboard Utility

Tools menu > Color Clipboard

Utilities panel > Utilities rollout > Color Clipboard button

The Color Clipboard utility stores color swatches for copying from one map or material to another.

For example, if in the Material Editor, you want to copy a color from a swatch in one level of a material to a swatch in another level (or from another material), there would be no way to do it with drag and drop. This is because you can't have two materials/maps visible at the same time. However, you can drag the color from one material to the color clipboard, switch to the other material, and then drag the color from the clipboard to the swatch in the new material.

You can save and load color clipboard files. The saved file, which is given a .ccb (color clipboard) extension, is an ASCII file that contains a palette description. The first 12 lines of the file consist of three RGB numbers, so you can easily edit or create your own clipboard files. This file format is also used by the VertexPaint modifier on page 1959.

Procedures

To copy a color from a swatch to the color clipboard:

1. On the Utilities panel, click Color Clipboard.
2. Open the Material Editor.
3. Select a color from any swatch in a material.
4 Drag the color to a swatch in the color clipboard.

5 A dialog appears asking if you want to copy or swap the material. Choose copy to replace the swatch in the color clipboard with the swatch from the material you selected. Choose swap to swap colors on the Color Clipboard swatch and material swatch.

Interface

**Color swatches** Click a color swatch to edit its value with the Color Selector.

**NOTE** The Color Selector invoked by this utility uses decimal numbers in the range 0.0 to 1.0, instead of integers in the range 0 to 255 as with other color-selection dialogs in 3ds Max.

**New Floater** Displays a floating clipboard with 12 slots, plus buttons for opening and saving color clipboard files. You can open up as many of these floaters as you want and you can minimize them. If you exit the Utilities panel or select the Close button to exit the Color Clipboard utility, any visible floaters remain open. When you close a floater, any changed values are lost.
Adjusting Normals and Smoothing

In general, you adjust normals and smoothing to prepare objects for rendering. A normal is a unit vector that defines which way a face or vertex is pointing. Smoothing groups define whether a surface is rendered with sharp edges or smooth surfaces.

The direction in which a normal points represents the front, or outer surface of a face or vertex, which is the side of the surface that is normally displayed and rendered. You can manually flip or unify face normals to fix surface errors caused by modeling operations or by importing meshes from other programs.

Smoothing groups are numbers assigned to the faces of an object. Each face can carry any number of smoothing groups, up to the maximum of 32. If two faces share an edge and share the same smoothing group, they render as a smooth surface. If they don’t share the same smoothing group, the edge between them renders as a corner. You can change and animate smoothing group assignments manually. Changing smoothing groups does not alter geometry in any way: it simply changes the way faces and edges are shaded.

Viewing and Changing Normals

When you create an object, normals are generated automatically. Usually objects render correctly using these default normals. Sometimes, however, you need to adjust the normals.
Left: The normals shown as spikes indicate the orientation of faces on the pyramid.
Right: Flipping normals can make faces invisible (or visible) in shaded viewports and renderings.

Undesired normals can appear in these objects:

- Meshes imported from other applications.
- Geometry generated by complex operations such as Boolean objects, lathe objects, or lofts.

Normals are used to define which side of a face or vertex is considered the "out" side. The out side of a face or vertex is the side that gets rendered unless you are using two-sided materials, or turn on the Force 2-Sided option in the Render Setup dialog > Common panel > Common Parameters rollout on page 6568.

Do one of the following to view or change face normals:

- Apply a Normal modifier on page 1551. If a Face sub-object selection is active, Normal applies to the selected faces. If no faces are selected, Normal applies to the entire object.
Apply an Edit Mesh modifier on page 1321, enable Face, Polygon or Element sub-object mode, and then use the features on the Surface Properties rollout to change the directions in which normals point.

Convert the object to an editable mesh on page 2192, enable Face, Polygon or Element sub-object mode, and use the features on the Surface Properties rollout.

**Viewing Normals**

The easiest way to view normals is to look at an object in a shaded viewport. In this case, you are not viewing the normal arrows themselves, but rather their effects on the shaded surface. If the object looks as if it is inside-out, or has holes, then some of the normals might be pointing in the wrong direction.

You can display the normal vectors for selected faces or vertices by enabling Show Normals on the Selection rollout of an editable mesh object or the Edit Mesh modifier.

**Unifying Normals**

Use Unify Normals to make normals point in a consistent direction. If an object has normals that are inconsistent (some point outward and others inward) the object will appear to have holes in its surface.

Unify Normals is found on the Surface Properties rollout and on the Normal modifier.

If you are animating the creation of a complex object such as a nested Boolean or a loft, and you think the operation might result in inconsistent faces, apply a Normal modifier on page 1551 to the result, and turn on Unify Normals.

**Flipping Normals**

Use Flip Normals to reverse the direction of all selected faces. Flipping the normals of an object turns it inside-out.

Flip Normals is found on the Surface Properties rollout and on the Normal modifier.

The Lathe modifier on page 1474 sometimes creates an object with normals pointing inward. Use the Flip Normals check box on the Lathe modifier's Parameters rollout to adjust the normals. You can also use the Normal modifier with both Unify and Flip turned on to fix inside-out lathed objects.
Viewing and Changing Smoothing

Smoothing blends the shading at the edges between faces to produce the appearance of a smooth, curved surface. You can control how smoothing is applied to a surface so your objects can have both smooth surfaces and sharp, faceted edges where appropriate.

The face labeled “1-2” shares smoothing groups with adjacent faces, so the edges between them are smoothed over in renderings.

The face labeled “3” does not share a smoothing group, so its edge is visible in renderings.

Smoothing does not affect geometry. It affects only the way geometry is colored when rendered.

Smoothing is controlled by smoothing groups, which are numbered groups ranging from 1 to 32. You can assign each face to one or more smoothing groups. When a scene is rendered, the renderer checks each adjacent pair of faces to see if they share a smoothing group, and renders the object as follows:

- If faces have no smoothing groups in common, the faces are rendered with a sharp edge between them.
If faces have at least one smoothing group in common, the edge between the faces is “smoothed”, meaning it is shaded in such a way that the area where the faces meet appears smooth.

Because each face has three edges, only three smoothing groups can be in effect for any face. Extra smoothing groups assigned to a face are ignored.

Do one of the following to view or change smoothing group assignments:

■ Turn on the Smooth check box on the Parameters rollout of a parametric object to set default smoothing for the object.

■ Turn on the Auto Smooth check box on the Rendering rollout of a spline shape to turn on smoothing.

■ Apply a Smooth modifier on page 1733. If a Face sub-object selection is active, Smooth applies to the selected faces. If no faces are selected, Smooth applies to the entire object.

■ Convert the object to editable poly on page 2240 format or apply the Edit Poly modifier on page 1332, access the Polygon or Element sub-object level, then use the features on the Polygon: Smoothing Groups rollout.

■ Convert the object to editable mesh on page 2192 format or apply the Edit Mesh modifier on page 1321, access the Face (or Polygon or Element) sub-object level, then use the features on the Surface Properties rollout.

**Viewing Smoothing Groups**

The easiest way to view smoothing is to look at an object in a shaded viewport. In this case, you are not viewing the smoothing groups themselves but rather their effects on the shaded surface.

You can see the smoothing group numbers for selected faces of an editable mesh object or the Edit Mesh modifier by looking at the Smoothing Group buttons on the Surface Properties rollout, or of an editable poly object on the Polygon Properties rollout.

Smoothing Group buttons appear as follows:

■ Group numbers not used by any face in the selection, appear normal.

■ Group numbers used by all faces in the selection, appear selected.

■ Group numbers used by some, but not all, faces in the selection, appear blank.
Automatically Smoothing an Object

Click Auto Smooth to assign smoothing automatically. You set a Threshold angle to determine whether to smooth adjacent faces.

- If the angle between face normals is less than or equal to the threshold, the faces are assigned to a common smoothing group.
- If the angle between face normals is greater than the threshold, the faces are assigned to separate groups.

Auto Smooth is found on the Surface Properties rollout and on the Smooth modifier.

Manually Applying Smoothing Groups

You manually assign smoothing groups to a selection of faces by clicking Smoothing Group buttons on the Surface Properties rollout or the Smooth modifier. The smoothing group of each button you click is assigned to the selection.

Selecting Faces by Smoothing Group

You can also select faces according to the assigned smoothing groups. Click Select By SG on the Surface Properties rollout (editable mesh) or Polygon Properties rollout (editable poly) and then click the smoothing group of the faces to select.

This is a convenient way to examine smoothing groups on an object someone else created.

Geometric Primitives

Geometric primitives are basic shapes that 3ds Max provides as parametric objects on page 8675. Primitives are divided into two categories: standard primitives and extended primitives.

See also:

- Basics of Creating and Modifying Objects on page 358
- Creating an Object on page 364
Creating Primitives from the Keyboard

You can create most geometric primitives from your keyboard using the Keyboard Entry rollout. In a single operation, you define both the initial size of an object and its three-dimensional position. 3ds Max automatically assigns the object’s name and color. See Object Name and Wireframe Color on page 8182.

This method is generally the same for all primitives; differences occur in the type and number of parameters. The Hedra primitive, a complex and highly visual family of objects, is unsuited to this method and has no keyboard entry.

Procedures

To open the Keyboard Entry rollout:

1. On the Create panel for Standard or Extended Primitives, click any of the primitive Object Type rollout buttons, except Hedra, RingWave, or Hose.
2. Click the Keyboard Entry rollout to open it. This rollout is closed by default.

   **NOTE** The buttons on the Creation Method rollout have no effect on keyboard entry.

To create a primitive from the keyboard:

1. On the Keyboard Entry rollout, select a numeric field with the mouse and then enter a number.
2. Press Tab to move to the next field. You do not have to press Enter after entering a value. Press Shift+Tab to reverse direction.
3. When you have all fields set, click Create.
4. The object appears in the active viewport.

Once created, a new primitive is unaffected by the numeric fields in the Keyboard Entry rollout. You can adjust parameter values on the Parameters rollout, either immediately after creation or on the Modify panel.
Interface

The Keyboard Entry rollout contains a common set of position fields, labeled X, Y, and Z. The numbers you enter are offsets along the axes of the active construction plane; either the home grid or a grid object. Plus and minus values correspond to positive and negative directions for these axes. Defaults=0,0,0; the center of the active grid.

The location set by X,Y is equivalent to the first mouse-down position in the standard method of creating objects.

Each standard primitive has the following parameters on its Keyboard Entry rollout.

<table>
<thead>
<tr>
<th>Primitive</th>
<th>Parameters</th>
<th>XYZ point</th>
</tr>

Creating Primitives from the Keyboard | 387
Standard Primitives

Geometric primitives are familiar as objects in the real world such as beach balls, pipes, boxes, doughnuts, and ice cream cones. In 3ds Max, you can model many such objects using a single primitive. You can also combine primitives into more complex objects, and further refine them with modifiers.

A collection of standard primitive objects
3ds Max includes a set of 10 basic primitives. You can easily create the primitives with the mouse in the viewport, and most can be generated from the keyboard as well. These primitives are listed in the Object Type rollout and on the Create menu on page 8008.

Also available from the Object Type rollout is the AutoGrid option on page 2792.

You can convert standard primitive objects to editable mesh objects on page 2192, editable poly objects on page 2240, and NURBS surfaces on page 2483. You can also convert primitives to patch objects; see the path annotation at Editable Patch on page 2360 (the information at the start of the topic that tells you how to create this type of object).

All primitives have name and color controls, and allow you to enter initial values from the keyboard. See these topics:

Object Name and Wireframe Color on page 8182
Creating Primitives from the Keyboard on page 386

The remaining rollouts are covered in the topic for each primitive.

**Box Primitive**

Create panel > Geometry button > Standard Primitives > Object Type rollout > Box button

Create menu > Standard Primitives > Box

Box produces one of the simplest of the primitives. Cube is the only variation of Box. However, you can vary the scale and proportion to make many different kinds of rectangular objects, from large, flat panels and slabs to tall columns and small blocks.
Examples of boxes

Procedures

To create a box:

1. On the Object Type rollout, click Box.
2. In any viewport, drag to define a rectangular base, then release to set length and width.
3. Move the mouse up or down to define the height.
4. Click to set the finished height and create the box.

To create a box with a square base:

- Hold down Ctrl as you drag the base of the box. This keeps length and width the same. Holding the Ctrl key has no effect on height.

To create a cube:

1. On the Creation Method rollout, choose Cube.
2 In any viewport, drag to define the size of the cube.
3 As you drag, a cube emerges with the pivot point at the center of its base.
4 Release to set the dimensions of all sides.

Interface

Creation Method rollout

**Cube** Forces length, width, and height to be equal. Creating a cube is a one-step operation. Starting at the center of the cube, drag in a viewport to set all three dimensions simultaneously. You can change a cube's individual dimensions in the Parameters rollout.

**Box** Creates a standard box primitive from one corner to the diagonally opposite corner, with different settings for length, width, and height.

Parameters rollout

The defaults produce a box with one segment on each side.

**Length, Width, Height** Sets the length, width, and height of the Box object. These fields also act as readouts while you drag the sides of the box. Default=0,0,0.

**Length, Width, Height Segments** Sets the number of divisions along each axis of the object. Can be set before or after creation. By default, each side of
the box is a single segment. When you reset these values, the new values become the default during a session. Default=1,1,1.

**TIP** Increase the Segments settings to give objects extra resolution for being affected by modifiers. For example, if you're going to bend on page 1165 a box on the Z axis, you might want to set its Height Segments parameter to 4 or more.

**Generate Mapping Coords** Generates coordinates for applying mapped materials to the box. Default=on.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

### Cone Primitive

Create panel > Geometry button > Standard Primitives > Object Type rollout > Cone button

Create menu > Standard Primitives > Cone

The Cone button on the Creation command panel lets you produce round cones, either upright or inverted.
Examples of cones

Procedures

To create a cone:

1 On the Create menu choose Standard Primitives > Cone.

2 In any viewport, drag to define a radius for the base of the cone, then release to set it.

3 Move to up or down to define a height, either positive or negative, then click to set it.

4 Move to define a radius for the other end of the cone. Decrease this radius to 0 for a pointed cone.

5 Click to set the second radius and create the cone.
Interface

Creation Method rollout

Edge Draws a cone from edge to edge. You can change the center location by moving the mouse.

Center Draws a cone from the center out.

Parameters rollout

The defaults produce a smooth, round cone of 24 sides with five height segments, one cap segment, and the pivot point at the center of the base. For improved rendering of smoothly shaded cones, particularly those with pointed tips, increase the number of height segments.

Radius 1, Radius 2 Set the first and second radii for the cone. The minimum value for both is 0.0. If you enter a negative value, 3ds Max converts it to 0.0. You can combine these settings to create pointed and flat-topped cones, upright or inverted. The following combinations assume a positive height:

<table>
<thead>
<tr>
<th>Radius Combinations</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>Radius 2 is 0</td>
<td>Creates a pointed cone</td>
</tr>
</tbody>
</table>
### Radius Combinations

<table>
<thead>
<tr>
<th>Radius Combinations</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>Radius 1 is 0</td>
<td>Creates an inverted pointed cone</td>
</tr>
<tr>
<td>Radius 1 is larger than Radius 2</td>
<td>Creates a flat-topped cone</td>
</tr>
<tr>
<td>Radius 2 is larger than Radius 1</td>
<td>Creates an inverted flat-topped cone</td>
</tr>
</tbody>
</table>

If Radius 1 and 2 are the same, a cylinder is created. If the two radius settings are close in size, the effect is similar to applying a Taper modifier to a cylinder.

### Effect of Radius settings

- **Height** Sets dimension along the central axis. Negative values create the cone below the construction plane.

- **Height Segments** Sets the number of divisions along the cone’s major axis.

- **Cap Segments** Sets the number of concentric divisions around the center of the cone’s top and bottom.

- **Sides** Sets the number of sides around the cone. Higher numbers shade and render as true circles with Smooth selected. Lower numbers create regular polygonal objects with Smooth off.

- **Smooth** Blends the faces of the cone, creating a smooth appearance in rendered views.

- **Slice On** Enables the Slice function. Default=off.
  
  When you create a slice and then turn off Slice On, the complete cone reappears. You can use this check box to switch between the two topologies.

- **Slice From, Slice To** Sets the number of degrees around the local Z axis from a zero point at the local X axis.
  
  For both settings, positive values move the end of the slice counterclockwise; negative values move it clockwise. Either setting can be made first. When the ends meet, the whole cone reappears.
**Generate Mapping Coords** Generates coordinates for applying mapped materials to the cone. Default=on.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

---

**Sphere Primitive**

Create panel > Geometry button > Standard Primitives > Object Type rollout > Sphere button

Create menu > Standard Primitives > Sphere

Sphere produces a full sphere, or a hemisphere or other portion of a sphere. You can also "slice" a sphere about its vertical axis.

![Examples of spheres](image)

---

396 | Chapter 6  Creating Geometry
Procedures

To create a sphere:

1  On the Create menu choose Standard Primitives > Sphere.
2  In any viewport, drag to define a radius.
   As you drag, a sphere emerges with its center at the pivot point.
3  Release the mouse to set the radius and create the sphere.

To create a hemisphere:

You can reverse the order of the following steps, if you like.

1  Create a sphere of desired radius.
2  Type 0.5 in the Hemisphere field.
   The sphere is reduced to exactly the upper half, a hemisphere. If you use
   the spinner, the sphere changes in size.

Interface

Creation Method rollout

Edge  Draws a sphere from edge to edge. You can change the center location
   by moving the mouse.

Center  Draws a sphere from the center out.
Parameters rollout

The defaults produce a smooth sphere of 32 segments with the pivot point at its center.

**Radius** Specifies the radius of the sphere.

**Segments** Sets the number of polygonal divisions for the sphere.

**Smooth** Blends the faces of the sphere, creating a smooth appearance in rendered views.

**Hemisphere** Increasing values progressively will "cut off" the sphere, starting at the base, to create a partial sphere. Values range from 0.0 to 1.0. The default is 0.0, producing a full sphere. A setting of 0.5 produces a hemisphere, and 1.0 reduces the sphere to nothing. Default=0.0.

Chop and Squash toggle creation options for Hemisphere.

**Chop** Reduces the number of vertices and faces in the sphere by "chopping" them out as the hemisphere is cut off. Default=on.

**Squash** Maintains the number of vertices and faces in the original sphere, "squashing" the geometry into a smaller and smaller volume toward the top of the sphere.
Effects of Chop and Squash during hemisphere creation

**Slice On** Uses the From and To angles to create a partial sphere. The effect is similar to lathing a semicircular shape fewer than 360 degrees.

**Slice From** Sets the start angle.

**Slice To** Sets the stop angle.

For both settings, positive values move the end of the slice counterclockwise; negative values move it clockwise. Either setting can be made first. When the ends meet, the whole sphere reappears.

Smoothing groups are assigned to sliced spheres as follows: The surface of the sphere is always assigned group 1; the bottom, when Smooth is on, gets group 2. Facing the pie-slice surfaces, the cut on the left gets group 3, and the cut on the right gets group 4.

Material IDs are assigned to sliced spheres as follows: The bottom is 1 (when Hemisphere is greater than 0.0), the surface is 2, and the slice surfaces are 3 and 4.

**Base To Pivot** Moves a sphere upward along its local Z axis so the pivot point is at its base. When off, the pivot point is on the construction plane at the center of the sphere. Default=off.

Turning on Base To Pivot lets you place spheres so they rest on the construction plane, like pool balls on a table. It also lets you animate a hemisphere so it appears to grow out of the construction plane or sink into it.
Effect of using Base To Pivot setting

**Generate Mapping Coords** Generates coordinates for applying mapped materials to the sphere. Default=on.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material’s Coordinates rollout on page 6201. Default=off.
GeoSphere Primitive

Create panel > Geometry button > Standard Primitives > Object Type rollout > GeoSphere button

Create menu > Standard Primitives > GeoSphere

Use GeoSphere to make spheres and hemispheres based on three classes of regular polyhedrons.

Examples of geospheres

Geospheres produce a more regular surface than standard spheres. They also render with a slightly smoother profile than a standard sphere given the same number of faces. Unlike a standard sphere, a geosphere has no poles, which can be an advantage when you apply certain modifiers such as Free-Form Deformation (FFD) modifiers on page 1436.

Procedures

To create a geosphere:

2 In any viewport, drag to set the center and radius of the geosphere.
3 Set parameters such as Geodesic Base Type and Segments.

To create a geo-hemisphere:

1 Create a geosphere.
2 In the Parameters rollout, turn on the Hemisphere check box. The geosphere is converted to a hemisphere.

Interface

Creation Method rollout

Diameter Draws a geosphere from edge to edge. You can change the center location by moving the mouse.
Center Draws a geosphere from the center out.

Parameters rollout

Radius Sets the size of the geosphere.
Segments Sets the total number of faces in the geosphere. The number of faces in a geosphere is equal to the sides of the base polyhedron times the segments squared.
Lower segment values work best. Using the maximum segment value of 200 can generate up to 800,000 faces, impairing performance.

**Geodesic Base Type group**

Lets you choose one of three types of regular polyhedrons for the geosphere's basic geometry.

- **Tetra** Based on a four-sided tetrahedron. The triangular facets can vary in shape and size. The sphere can be divided into four equal segments.

- **Octa** Based on an eight-sided octahedron. The triangular facets can vary in shape and size. The sphere can be divided into eight equal segments.

- **Icosa** Based on a 20-sided icosahedron. The facets are all equally sized equilateral triangles. The sphere can be divided into any number of equal segments, based on multiples and divisions of 20 faces.

**Smooth** Applies smoothing groups to the surface of the sphere.

**Hemisphere** Creates a half-sphere.

**Base To Pivot** Sets the pivot point location. When on, the pivot is at the bottom of the sphere. When off, the pivot is at the center of the sphere. This option has no effect when Hemisphere is on.

**Generate Mapping Coords** Generates coordinates for applying mapped materials to the geosphere. Default=on.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

**Cylinder Primitive**

Create panel > Geometry button > Standard Primitives > Object Type rollout > Cylinder button

Create menu > Standard Primitives > Cylinder

Cylinder produces a cylinder, which you can "slice" around its major axis.
Examples of cylinders

Procedures

To create a cylinder:

2. In any viewport, drag to define the radius of the base, then release to set the radius.
3. Move up or down to define a height, either positive or negative.
4. Click to set the height and create the cylinder.

Interface

Creation Method rollout

Edge Draws a cylinder from edge to edge. You can change the center location by moving the mouse.

Center Draws a cylinder from the center out.
The defaults produce a smooth cylinder of 18 sides with the pivot point at the center of the base. There are five height segments and one cap segment. If you don't plan to modify the cylinder's shape, such as with a Bend modifier, set Height Segments to 1 to reduce scene complexity. If you plan to modify the ends of the cylinder, consider increasing the Cap Segments setting.

**Radius** Sets the radius of the cylinder.

**Height** Sets the dimension along the central axis. Negative values create the cylinder below the construction plane.

**Height Segments** Sets the number of divisions along the cylinder's major axis.

**Cap Segments** Sets the number of concentric divisions around the center of the cylinder's top and bottom.

**Sides** Sets the number of sides around the cylinder. With Smooth on, higher numbers shade and render as true circles. With Smooth off, lower numbers create regular polygonal objects.

**Smooth** The faces of the cylinder are blended together, creating a smooth appearance in rendered views.

**Slice On** Enables the Slice function. Default=off.
When you create a slice and then turn off Slice On, the complete cylinder reappears. You can use this check box to switch between the two topologies.

**Slice From, Slice To** Sets the number of degrees around the local Z axis from a zero point at the local X axis.

For both settings, positive values move the end of the slice counterclockwise; negative values move it clockwise. Either setting can be made first. When the ends meet, the whole cylinder reappears.

**Generate Mapping Coords** Generates coordinates for applying mapped materials to the cylinder. Default=on.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

---

**Tube Primitive**

Create panel > Geometry button > Standard Primitives > Object Type rollout > Tube button

Create menu > Standard Primitives > Tube

Tube produces both round and prismatic tubes. The tube is similar to the cylinder with a hole in it.
Examples of tubes

Procedures

To create a tube:
2. In any viewport, drag to define the first radius, which can be either the inner or outer radius of the tube. Release to set the first radius.
3. Move to define the second radius, then click to set it.
4. Move up or down to define a height, either positive or negative.
5. Click to set the height and create the tube.

To create a prismatic tube:
1. Set the number of sides for the kind of prism you want.
2. Turn Smooth off.
3. Create a tube.
**Interface**

**Creation Method rollout**

*Edge* Draws a tube from edge to edge. You can change the center location by moving the mouse.

*Center* Draws a tube from the center out.

**Parameters rollout**

The defaults produce a smooth, round tube of 18 sides with the pivot point at the center of the base. There are five height segments and one cap segment. If you don’t plan to modify the cylinder’s shape, such as with a Bend modifier, set Height Segments to 1 to reduce scene complexity. If you plan to modify the ends of the cylinder, consider increasing the Cap Segments setting.

**Radius 1, Radius 2** The larger setting specifies the outside radius of the tube, while the smaller specifies the inside radius.

**Height** Sets the dimension along the central axis. Negative values create the tube below the construction plane.

**Height Segments** Sets the number of divisions along the tube’s major axis.
**Cap Segments** Sets the number of concentric divisions around the center of the tube's top and bottom.

**Sides** Sets the number of sides around the tube. Higher numbers shade and render as true circles with Smooth on. Lower numbers create regular polygonal objects with Smooth off.

**Smooth** When on (the default), faces of the tube are blended together, creating a smooth appearance in rendered views.

**Slice On** Enables the Slice feature, which removes part of the tube's circumference. Default=off.

When you create a slice and then turn off Slice On, the complete tube reappears. You can therefore use this check box to switch between the two topologies.

**Slice From, Slice To** Sets the number of degrees around the local Z axis from a zero point at the local X axis.

For both settings, positive values move the end of the slice counterclockwise; negative values move it clockwise. Either setting can be made first. When the ends meet, the whole tube reappears.

**Generate Mapping Coords** Generates coordinates for applying mapped materials to the tube. Default=on.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

---

**Torus Primitive**

Create panel > Geometry button > Standard Primitives > Object Type rollout > Torus button

Create menu > Standard Primitives > Torus

Torus produces a torus, or a ring with a circular cross section, sometimes referred to as a doughnut. You can combine three smoothing options with rotation and twist settings to create complex variations.
Examples of tori

Procedures

To create a torus:

1. From the Create menu, choose Standard Primitives > Torus.
2. In any viewport, drag to define a torus.
3. As you drag, a torus emerges with its center at the pivot point.
4. Release to set the radius of the torus ring.
5. Move to define the radius of the cross-sectional circle, then click to create the torus.

Interface

Creation Method rollout

Edge: Draws a torus from edge to edge. You can change the center location by moving the mouse.
Center Draws a torus from the center out.

Parameters rollout

The defaults produce a smooth torus with 12 sides and 24 segments. The pivot point is at the center of the torus on the plane, cutting through the center of the torus. Higher settings for sides and segments produce a more dense geometry that might be required for some modeling or rendering situations.

Radius 1 Sets the distance from the center of the torus to the center of the cross-sectional circle. This is the radius of the torus ring.

Radius 2 Sets the radius of the cross-sectional circle. This value is replaced each time you create a torus. Default = 10.
Rotation 1 and Rotation 2

**Rotation** Sets the degree of rotation. Vertices are uniformly rotated about the circle running through the center of the torus ring. Positive and negative values for this setting “roll” the vertices in either direction over the surface of the torus.

**Rotation and Twist**

**Twist** Sets the degree of twist. Cross sections are progressively rotated about the circle running through the center of the torus. Beginning with twist, each successive cross section is rotated until the last one has the number of degrees specified.

Twisting a closed (unsliced) torus creates a constriction in the first segment. You can avoid this by either twisting in increments of 360 degrees, or by turning Slice on and setting both Slice From and Slice To to 0 to maintain a complete torus.

**Segments** Sets the number of radial divisions around the torus. By reducing this number, you can create polygonal rings instead of circular ones.

**Sides** Sets the number of sides on the cross-sectional circle of the torus. By reducing this number, you can create prism-like cross sections instead of circular ones.

**Smooth group**

Choose one of four levels of smoothing:

- **All** (default) Produces complete smoothing on all surfaces of the torus.
- **Sides** Smooths the edges between adjacent segments, producing smooth bands running around the torus.
- **None**  Turns off smoothing entirely, producing prism-like facets on the torus.

- **Segments**  Smooths each segment individually, producing ring-like segments along the torus.

**Slice On**  Creates a portion of a sliced torus rather than the entire 360 degrees.

**Slice From**  When Slice On is on, specifies the angle where the torus slice begins.

**Slice To**  When Slice On is on, specifies the angle where the torus slice ends.

**Generate Mapping Coords**  Generates coordinates for applying mapped materials to the torus. Default=on.

**Real-World Map Size**  Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

**Pyramid Primitive**

Create panel > Geometry button > Standard Primitives > Object Type rollout > Pyramid button

Create menu > Standard Primitives > Pyramid

The Pyramid primitive has a square or rectangular base and triangular sides.
Examples of pyramids

Procedures

To create a Pyramid:

2. Choose a creation method, either Base/Apex or Center.

   NOTE Hold the Ctrl key while using either creation method to constrain the base to a square.

3. In any viewport, drag to define the base of the pyramid. If you're using Base/Apex, define the opposite corners of the base, moving the mouse horizontally or vertically to define the width and depth of the base. If you're using Center, drag from the center of the base.
4. Click, and then move the mouse to define the Height.
5. Click to complete the pyramid.
Interface

Creation Method rollout

**Base/Apex** Creates the pyramid base from one corner to the diagonally opposite corner.

**Center** Creates the pyramid base from the center out.

Parameters rollout

![Parameters rollout](image)

**Width, Depth and Height** Sets the dimension of the corresponding side of the pyramid.

**Width, Depth and Height Segs** Sets the number of segments to the corresponding sides of the pyramid.

**Generate Mapping Coords** Generates coordinates for applying mapped materials to the pyramid. Default=on.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.
Teapot Primitive

Create panel > Geometry button > Standard Primitives > Object Type rollout > Teapot button

Create menu > Standard Primitives > Teapot

Teapot produces a teapot. You can choose to make the whole teapot at once (the default), or any of its parts. Since the Teapot is a parametric object, you can choose which parts of the teapot to display after creation.

Examples of teapots

History of the Teapot

This teapot derives from the original data developed by Martin Newell in 1975. Beginning with a graph-paper sketch of a teapot that he kept on his desk, Newell calculated cubic Bezier splines on page 8519 to create a wireframe model. James Blinn, also at the University of Utah during this period, produced early renderings of exceptional quality using this model.
The teapot has since become a classic in computer graphics. Its complexly curved and intersecting surfaces are well suited to testing different kinds of material mappings and rendering settings on a real-world object.

**Procedures**

**To create a teapot:**

2. In any viewport, drag to define a radius.
   As you drag, a teapot emerges with the pivot point at the center of its base.
3. Release the mouse to set the radius and create the teapot.

**To create a teapot part:**

1. In Parameters rollout > Teapot Parts group, turn off all parts except the one you want to create.
2. Create a teapot.
   The part you left on appears. The pivot point remains at the center of the teapot's base.
3. In Parameters rollout > Teapot Parts group, turn off all parts except the one you want.

The teapot has four separate parts: body, handle, spout, and lid. Controls are located in the Teapot Parts group of the Parameters rollout. You can check any combination of parts to create at the same time. The body alone is a ready-made bowl, or a pot with optional lid.

**To turn a part into a teapot:**

1. Select a teapot part in the viewport.
2. On the Modify panel > Parameters rollout, turn on all parts. (This is the default.)
   The whole teapot appears.

You can apply modifiers to any separate part. If you later turn on another part, the modifier affects the additional geometry as well.
Interface

Creation Method rollout

Edge Draws a teapot from edge to edge. You can change the center location by moving the mouse.

Center Draws a teapot from the center out.

Parameters rollout

Radius Sets the radius of the teapot

Segments Sets the number of divisions for the teapot or its individual parts.

Smooth Blends faces of the teapot, creating a smooth appearance in rendered views.

Teapot Parts group

Turn check boxes on or off for teapot parts. By default, all are on, producing a complete teapot.

Generate Mapping Coords Generates coordinates for applying mapped materials to the teapot. Default=on.
Real-World Map Size  Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

Plane Primitive

Create panel > Geometry button > Standard Primitives > Object Type rollout > Plane button
Create menu > Standard Primitives > Plane

The Plane object is a special type of flat polygon mesh that can be enlarged by any amount at render time. You can specify factors to magnify the size or number of segments, or both. Use the Plane object for creating a large-scale ground plane that doesn't get in the way when working in a viewport. You can apply any type of modifier to the plane object, such as Displace on page 1313 to simulate a hilly terrain.

Example of plane
Procedures

To create a plane:

2. In any viewport, drag to create the Plane.

Interface

Creation Method rollout

Rectangle: Creates the plane primitive from one corner to the diagonally opposite corner, interactively setting different values for length and width.

Square: Creates a square plane where length and width are equal. You can change dimensions in the Parameters rollout subsequent to creation.

Parameters rollout

<table>
<thead>
<tr>
<th>Parameters</th>

</tr>
</tbody>
</table>

Render Multipliers:

| Scale: 1.0          |
| Density: 1.0        |
| Total Faces: 32     |

Generate Mapping Coords: 

Real-World Map Size: 

Length, Width: Sets the length and width of the plane object. These fields act also as readouts while you drag the sides of the box. You can revise these values. Defaults= 0.0, 0.0.
Length Segs, Width Segs Sets the number of divisions along each axis of the object. Can be set before or after creation. By default, each side of the plane has four segments. When you reset these values, the new values become the default during a session.

Render Multipliers group

Render Scale Specifies the factor by which both length and width are multiplied at render time. Scaling is performed from the center outward.

Render Segs Specifies the factor by which the number of segments in both length and width are multiplied at render time.

Generate Mapping Coords Generates coordinates for applying mapped materials to the plane. Default=on.

Real-World Map Size Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

Extended Primitives

Extended Primitives are a collection of complex primitives for 3ds Max. The topics that follow describe each type of extended primitive and its creation parameters.
A collection of extended primitive objects

These primitives are available from the Object Type rollout on the Create panel and from the Create menu on page 8008 > Extended Primitives.

All primitives offer AutoGrid. They all have name and color controls, and allow you to enter initial values from the keyboard. See these topics:

AutoGrid on page 2792
**Hedra Extended Primitive**

Create panel > Geometry button > Extended Primitives > Object Type rollout > Hedra button

Create menu > Extended Primitives > Hedra

Use Hedra to produce objects from several families of polyhedra.

**Procedures**

**To create a polyhedron:**

1. From the Create menu, choose Extended Primitives > Hedra.
2 In any viewport, drag to define a radius, then release to create the polyhedron.
   As you drag, a polyhedron emerges from the pivot point.

3 Adjust the Family Parameter and Axis Scaling spinners to vary the Hedra's appearance.

**Interface**
Family group

Use this group to select the type of polyhedron to create.

Tetra Creates a tetrahedron.

Cube/Octa Creates a cubic or octahedral polyhedron (depending on parameter settings).

Dodec/Icos Creates a dodecahedron or icosahedron (depending on parameter settings).

Star1/Star2 Creates two different star-like polyhedra.

TIP You can animate between Hedra types. Turn on the Auto Key button, go to any frame, and change the Family check box. There is no interpolation between types; the model simply jumps from a star to a cube or tetrahedron, and so on.

Family parameters group

P, Q Interrelated parameters that provide a two-way translation between the vertices and facets of a polyhedron. They share the following:

■ Range of possible values is 0.0 through 1.0.

■ The combined total of the P and Q values can be equal to or less than 1.0.

■ Extremes occur if either P or Q is set to 1.0; the other is automatically set to 0.0.

■ Midpoint occurs when both P and Q are 0.

In the simplest terms, P and Q change the geometry back and forth between vertices and facets. At the extreme settings for P and Q, one parameter represents all vertices, the other represents all facets. Intermediate settings are transition points, with the midpoint an even balance between the two parameters.

Axis Scaling group

Polyhedra can have as many as three kinds of polygonal facets, such as triangle, square, or pentagon. These facets can be regular or irregular. If a polyhedron has only one or two types of facet, only one or two of the axis scaling parameters are active. Inactive parameters have no effect.
P, Q, R Controls the axis of reflection for one of the facets of a polyhedron. In practice, these fields have the effect of pushing their corresponding facets in and out. Defaults=100.

Reset Returns axes to their default setting.

**Vertices group**

Parameters in the Vertices group determine the internal geometry of each facet of a polyhedron. Center and Center & Sides increase the number of vertices in the object and therefore the number of faces. These parameters cannot be animated.

**Basic** Facets are not subdivided beyond the minimum.

**Center** Each facet is subdivided by placing an additional vertex at its center, with edges from each center point to the facet corners.

**Center & Sides** Each facet is subdivided by placing an additional vertex at its center, with edges from each center point to the facet corners, as well as to the center of each edge. Compared to Center, Center & Sides doubles the number of faces in the polyhedron.

**NOTE** If you scale the axis of the object, the Center option is used automatically, unless Center & Sides is already set.

To see the internal edges shown in the figure, turn off Edges Only on the Display command panel.

**Radius** Sets the radius of any polyhedron in current units.

**Generate Mapping Coords** Generates coordinates for applying mapped materials to the polyhedron. Default=on.

**Torus Knot Extended Primitive**

Create panel > Geometry > Extended Primitives > Object Type rollout > Torus Knot button

Create menu > Extended Primitives > Torus Knot

Use Torus Knot to create a complex or knotted torus by drawing 2D curves in the normal planes around a 3D curve. The 3D curve (called the Base Curve) can be either a circle or a torus knot.

You can convert a torus knot object to a [NURBS surface](#) on page 2483.
Example of torus knot

Procedures

To create a Torus Knot:

1. On the Create menu, choose Extended Primitives > Torus Knot.
2. Drag the mouse to define the size of the torus knot.
3. Click, then move the mouse vertically to define the radius.
4. Click again to finish the torus.
5. Adjust the parameters on the Modify panel.

Interface

Creation Method rollout

Diameter Draws the object from edge to edge. You can change the center location by moving the mouse.

Radius Draws the object from the center out.
Parameters rollout > Base Curve group

Provides parameters that affect the base curve.

**Knot/Circle** With Knot, the torus interweaves itself, based on various other parameters. With Circle, the base curve is a circle, resulting in a standard torus if parameters such as Warp and Eccentricity are left at their defaults.

**Radius** Sets the radius of the base curve.

**Segments** Sets the number of segments around the perimeter of the torus.

**P and Q** Describes up-and-down (P) and around-the-center (Q) winding numbers. (Active only when Knot is chosen.)

**Warp Count** Sets the number of "points" in a star shape around the curve. (Active only when Circle is chosen.)

**Warp Height** Sets the height of the "points" given as a percentage of the base curve radius.
Parameters rollout > Cross Section group

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Radius</td>
<td>Sets the radius of the cross section.</td>
</tr>
<tr>
<td>Sides</td>
<td>Sets the number of sides around the cross section.</td>
</tr>
<tr>
<td>Eccentricity</td>
<td>Sets the ratio of the major to minor axes of the cross section. A value of 1 provides a circular cross section, while other values create elliptical cross sections.</td>
</tr>
<tr>
<td>Twist</td>
<td>Sets the number of times the cross section twists around the base curve.</td>
</tr>
<tr>
<td>Lumps</td>
<td>Sets the number of bulges in the torus knot. Note that the Lump Height spinner value must be greater than 0 to see any effect.</td>
</tr>
<tr>
<td>Lump Height</td>
<td>Sets the height of the lumps, as a percentage of the radius of the cross section. Note that the Lumps spinner must be greater than 0 to see any effect.</td>
</tr>
<tr>
<td>Lump Offset</td>
<td>Sets the offset of the start of the lumps, measured in degrees. The purpose of this value is to animate the lumps around the torus.</td>
</tr>
</tbody>
</table>

Parameters rollout > Smooth group

Provides options to alter the smoothing displayed or rendered of the torus knot. This smoothing does not displace or tesselate the geometry, it only adds the smoothing group information.
All Smoothes the entire torus knot.

Sides Smoothes only the adjacent sides of the torus knot.

None The torus knot is faceted.

**Parameters rollout > Mapping Coordinates group**

![Mapping Coordinates]

Provides methods of assigning and adjusting mapping coordinates.

**Generate Mapping Coords** Assigns mapping coordinates based on the geometry of the torus knot. Default=on.

**Offset U/V** Offset the mapping coordinates along U and V.

**Tiling U/V** Tile the mapping coordinates along U and V.

**ChamferBox Extended Primitive**

Create panel > Geometry button > Extended Primitives > Object Type rollout > ChamferBox button

Create menu > Extended Primitives > Chamfer Box

Use ChamferBox to create a box with beveled or rounded edges.
Examples of chamfered boxes

Procedures

To create a standard chamfered box:

1. From the Create menu, choose Extended Primitives > Chamfer Box.

2. Drag the mouse to define the diagonal corners of the base of the chamfered box. (Press Ctrl to constrain the base to a square.)

3. Release the mouse button, and then move the mouse vertically to define the height of the box. Click to set the height.

4. Move the mouse diagonally to define the width of the fillet, or chamfer (toward the upper left increases the width; toward the lower right decreases it).

5. Click again to finish the chamfered box.

To create a cubic chamfered box:

1. On the Creation Method rollout, click Cube.
2 Beginning at the center of the cube, drag in a viewport to set all three dimensions simultaneously.

3 Release the button, and move the mouse to set the fillet or chamfer.

4 Click to create the object.

You can change a cube’s individual dimensions in the Parameters rollout.

Interface

Creation Method rollout

Cube Forces length, width, and height to be equal. You can change a cube’s individual dimensions in the Parameters rollout.

Box Creates a standard chamfered box primitive from one corner to the diagonally opposite corner, with individual settings for length, width, and height.

Parameters rollout

<table>

</tr>
</tbody>
</table>

- Smooth
- Generate Mapping Coords.
- Real-World Map Size

Length, Width, Height Sets the corresponding dimensions of the chamfered box.
**Fillet** Slices off the edges of the chamfered box. Higher values result in a more refined fillet on the edges of the chamfered box.

**Length, Width, Height Segs** Sets the number of divisions along the corresponding axis.

**Fillet Segs** Sets the number of segments in the filleted edges of the box. Adding fillet segments increases the edge roundness.

**Smooth** Blends the display of the faces of the chamfered box, creating a smooth appearance in rendered views.

**Generate Mapping Coords** Generates coordinates for applying mapped materials to the chamfered box. Default=on.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

---

**ChamferCyl Extended Primitive**

Create panel > Geometry button > Extended Primitives > Object Type rollout > ChamferCyl button

Create menu > Extended Primitives > Chamfer Cylinder

Use ChamferCyl to create a cylinder with beveled or rounded cap edges.
Examples of chamfered cylinders

Procedures

To create a chamfered cylinder:

1. From the Create menu, choose Extended Primitives > Chamfer Cylinder.
2. Drag the mouse to define the radius of the base of the chamfered cylinder.
3. Release the mouse button, and then move the mouse vertically to define the height of the cylinder. Click to set the height.
4. Move the mouse diagonally to define the width of the fillet, or chamfer (toward the upper left increases the width; toward the lower right decreases it).
5. Click to finish the cylinder.
Interface

Creation Method rollout

**Edge** Draws the object from edge to edge. You can change the center location by moving the mouse.

**Center** Draws the object from the center out.

Parameters rollout

- **Radius** Sets the radius of the chamfered cylinder.
- **Height** Sets the dimension along the central axis. Negative values create the chamfered cylinder below the construction plane.
- **Fillet** Chamfers the top and bottom cap edges of the chamfered cylinder. Higher numbers result in a more refined fillet along the cap edge.
- **Height Segs** Sets the number of divisions along the corresponding axis.
- **Fillet Segs**
- **Sides**
- **Cap Segs**
- **Smooth**
- **Slice From**
- **Slice To**
- **Generate Mapping Coords**
- **Real-World Map Size**

Extended Primitives | 435
**Fillet Segs** Sets the number of segments in the filleted edges of the cylinder. Adding fillet segments curves the edges, producing a filleted cylinder.

**Sides** Sets the number of sides around the chamfered cylinder. Higher numbers shade and render as true circles with Smooth on. Lower numbers create regular polygonal objects with Smooth off.

**Cap Segs** Sets the number of concentric divisions along the center of the chamfered cylinder’s top and bottom.

**Smooth** Blends the faces of the chamfered cylinder, creating a smooth appearance in rendered views.

**Slice On** Enables the Slice function. Default=off. When you create a slice and then turn off Slice On, the complete chamfered cylinder reappears. You can use this check box to switch between the two topologies.

**Slice From, Slice To** Sets the number of degrees around the local Z axis from a zero point at the local X axis. For both settings, positive values move the end of the slice counterclockwise; negative values move it clockwise. Either setting can be made first. When the ends meet, the whole chamfered cylinder reappears.

**Generate Mapping Coords** Generates coordinates for applying mapped materials to the chamfered cylinder. Default=on.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material’s Coordinates rollout on page 6201. Default=off.

**OilTank Extended Primitive**

Create panel > Geometry button > Extended Primitives > Object Type rollout > OilTank button

Create menu > Extended Primitives > Oil Tank

Use OilTank to create a cylinder with convex caps.
Examples of oil tanks

Procedures

To create an oil tank:

1. From the Create menu, choose Extended Primitives > Oil Tank.
2. Drag the mouse to define the radius of the base of the oil tank.
3. Release the mouse button, and then move the mouse vertically to define the height of the oil tank. Click to set the height.
4. Move the mouse diagonally to define the height of the convex caps (toward the upper left to increase the height; toward the lower right to decrease it).
5. Click again to finish the oil tank.
**Interface**

**Creation Method rollout**

Edge Draws the object from edge to edge. You can change the center location by moving the mouse.

Center Draws the object from the center out.

**Parameters rollout**

**Radius** Sets the radius of the oil tank.

**Height** Sets the dimension along the central axis. Negative values create the oil tank below the construction plane.

**Cap Height** Sets the height of the convex caps. The minimum value is 2.5 percent of the Radius setting. The maximum value is 99 percent the Radius setting, unless the absolute value of the Height setting is less than twice the Radius setting, in which case cap height cannot exceed 49.5 percent of the absolute value of the Height setting.
**Overall/Centers** Determines what the Height value specifies. Overall is the overall height of the object. Centers is the height of the midsection of the cylinder, not including its convex caps.

**Blend** When greater than 0, creates a bevel at the edge of the caps.

**Sides** Sets the number of sides around the oil tank. To create a smoothly rounded object, use a higher number of sides and turn Smooth on. To create an oil tank with flat sides, use a lower number of sides and turn Smooth off.

**Height Segs** Sets the number of divisions along the oil tank's major axis.

**Smooth** Blends the faces of the oil tank, creating a smooth appearance in rendered views.

**Slice On** Turns on the Slice function. Default=off. When you create a slice and then turn off Slice On, the complete oil tank reappears. You can therefore use this check box to switch between the two topologies.

**Slice From, Slice To** Sets the number of degrees around the local Z axis from a zero point at the local X axis. For both settings, positive values move the end of the slice counterclockwise; negative values move it clockwise. Either setting can be made first. When the ends meet, the whole oil tank reappears.

**Generate Mapping Coords** Generates coordinates for applying mapped materials to the oil tank. Default=on.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

### Capsule Extended Primitive

Create panel > Geometry button > Extended Primitives > Object Type rollout > Capsule button

Create menu > Extended Primitives > Capsule

Use Capsule to create a cylinder with hemispherical caps.
Examples of capsules

Procedures

To create a capsule:

1. From the Create menu, choose Extended Primitives > Capsule.
2. Drag the mouse to define the radius of the capsule.
3. Release the mouse button, and then move the mouse vertically to define the height of the capsule.
4. Click to set the height and finish the capsule.

Interface

Creation Method rollout

Edge Draws the object from edge to edge. You can change the center location by moving the mouse.

Center Draws the object from the center out.
Parameters rollout

Radius Sets the radius of the capsule.

Height Sets the height along the central axis. Negative values create the capsule below the construction plane.

Overall/Centers Determines what the Height value specifies. Overall specifies the overall height of the object. Centers specifies the height of the midsection of the cylinder, not including its domed caps.

Sides Sets the number of sides around the capsule. Higher numbers shade and render as true circles with Smooth on. Lower numbers create regular polygonal objects with Smooth off.

Height Segs Sets the number of divisions along the capsule's major axis.

Smooth Blends the faces of the capsule, creating a smooth appearance in rendered views.

Slice On Turns on the Slice function. Default=off.
When you create a slice and then turn off Slice On, the complete capsule reappears. You can use this check box to switch between the two topologies.
Slice From, Slice To Sets the number of degrees around the local Z axis from a zero point at the local X axis. For both settings, positive values move the end of the slice counterclockwise; negative values move it clockwise. Either setting can be made first. When the ends meet, the whole capsule reappears.

Generate Mapping Coords Generates coordinates for applying mapped materials to the capsule. Default=on.

Real-World Map Size Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material’s Coordinates rollout on page 6201. Default=off.

Spindle Extended Primitive

Create panel > Geometry button > Extended Primitives > Object Type rollout > Spindle button
Create menu > Extended Primitives > Spindle

Use the Spindle primitive to create a cylinder with conical caps.
Examples of spindles

Procedures

To create a spindle:

1. From the Create menu, choose Extended Primitives > Spindle.
2. Drag the mouse to define the radius of the base of the spindle.
3. Release the mouse button, and then move the mouse vertically to define the height of the spindle. Click to set the height.
4. Move the mouse diagonally to define the height of the conical caps (toward the upper left to increase the height; toward the lower right to decrease it).
5. Click again to finish the spindle.
Interface

Creation Method rollout

**Edge** Draws the object from edge to edge. You can change the center location by moving the mouse.

**Center** Draws the object from the center out.

Parameters rollout

- **Radius**: Sets the radius of the spindle.
- **Height**: Sets the dimension along the central axis. Negative values create the spindle below the construction plane.
- **Cap Height**: Sets the height of the conical caps. The minimum value is 0.1; the maximum value is ½ the absolute value of the Height setting.
Overall/Centers  Determines what the Height value specifies. Overall specifies the overall height of the object. Centers specifies the height of the midsection of the cylinder, not including its conical caps.

Blend  When greater than 0, creates a fillet where the caps meet the body of the spindle.

Sides  Sets the number of sides around the spindle. Higher numbers shade and render as true circles with Smooth on. Lower numbers create regular polygonal objects with Smooth off.

Cap Segs  Sets the number of concentric divisions along the center of the spindle's top and bottom.

Height Segs  Sets the number of divisions along the spindle's major axis.

Smooth  Blends the faces of the spindle, creating a smooth appearance in rendered views.

Slice On  Turns on the Slice function. Default=off.
When you create a slice and then turn off Slice On, the complete spindle reappears. You can therefore use this check box to switch between the two topologies.

Slice From, Slice To  Sets the number of degrees around the local Z axis from a zero point at the local X axis.
For both settings, positive values move the end of the slice counterclockwise; negative values move it clockwise. Either setting can be made first. When the ends meet, the whole spindle reappears.

Generate Mapping Coords  Sets up the required coordinates for applying mapped materials to the spindle. Default=on.

Real-World Map Size  Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

L-Ext Extended Primitive

Create panel > Geometry button > Extended Primitives > Object Type rollout > L-Ext button

Create menu > Extended Primitives > L-Extrustion

Use L-Ext to create an extruded L-shaped object.
Example of L-Ext

**Procedures**

To create an L-Ext object:

1. From the Create menu, choose Extended Primitives > L-Ext.
2. Drag the mouse to define the base. (Press Ctrl to constrain the base to a square.)
3. Release the mouse and move it vertically to define the height of the L-extrusion.
4. Click, and then move the mouse vertically to define the thickness or width of the walls of the L-extrusion.
5. Click to finish the L-extrusion.
Interface

Creation Method rollout

Corners Draws the object from corner to corner. You can change the center location by moving the mouse.

Center Draws the object from the center out.

Parameters rollout

Side/Front Length Specify the lengths of each "leg" of the L.

Side/Front Width Specify the widths of each "leg" of the L.

Height Specifies the height of the object.

Side/Front Segs Specify the number of segments for a specific "leg" of the object.

Width/Height Segs Specify the number of segments for the overall width and height.
NOTE The object's dimensions (Back, Side, Front) are labeled as though it were created in the Top or Perspective viewports, and seen from the front in world space.

**Generate Mapping Coords** Sets up the required coordinates for applying mapped materials to the object. Default=on.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

### Gengon Extended Primitive

Create panel > Geometry button > Extended Primitives > Object Type rollout > Gengon button

Create menu > Extended Primitives > Gengon

Use Gengon to create an extruded, regular-sided polygon with optionally filleted side edges.

Examples of gengons
Procedures

To create a gengon:

1. From the Create menu, choose Extended Primitives > Gengon.
2. Set the Sides spinner to specify the number of side wedges in the gengon.
3. Drag the mouse to create the radius of the gengon.
4. Release the mouse button, then move the mouse vertically to define the height of the gengon. Click to set the height.
5. Move the mouse diagonally to specify the size of the chamfer along the side angles (toward the upper left to increase the size; toward the lower right to decrease it).
6. Click to finish the gengon.

TIP In the Parameters rollout, increase the Fillet Segs spinner to round the chamfered corners into fillets.

Interface

Creation Method rollout

Edge Draws the object from edge to edge. You can change the center location by moving the mouse.

Center Draws the object from the center out.
Parameters rollout

**Parameters**

- **Sides**: Sets the number of sides around the gengon. Higher numbers shade and render as true circles with Smooth on. Lower numbers create regular polygonal objects with Smooth off.

- **Radius**: Sets the radius of the gengon.

- **Fillet**: Sets the width of the chamfered corners.

- **Height**: Sets the dimension along the central axis. Negative values create the gengon below the construction plane.

- **Side Segs**: Sets the number of divisions around the gengon.

- **Height Segs**: Sets the number of divisions along the gengon’s major axis.

- **Fillet Segs**: Sets the number of divisions for the edge filleting. Increasing this setting will produce round, filleted corners instead of chamfers.

- **Smooth**: Blends the faces of the gengon, creating a smooth appearance in rendered views.

- **Generate Mapping Coords**: Sets up the required coordinates for applying mapped materials to the gengon. Default=on.

- **Real-World Map Size**: Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by
the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

**C-Ext Extended Primitive**

Create panel > Geometry > Extended Primitives > Object Type rollout > C-Ext button

Create menu > Extended Primitives > C-Extrusion

Use C-Ext to create an extruded C-shaped object.

![Example of C-Ext](image)

**Procedures**

**To create a C-Ext object:**

1. From the Create menu, choose Extended Primitives > C-Extrusion.
2. Drag the mouse to define the base. (Press Ctrl to constrain the base to a square.)
3. Release the mouse and move it vertically to define the height of the C-extrusion.
4. Click, and then move the mouse vertically to define the thickness or width of the walls of the C-extrusion.
5. Click to finish the C-extrusion.
Interface

Creation Method rollout

**Corners** Draws the object from corner to corner. You can change the center location by moving the mouse.

**Center** Draws the object from the center out.

Parameters rollout

<table>
<thead>

</tbody>
</table>

**Generate Mapping Coords**

**Real-World Map Size**

**Back/Side/Front Length** Specify the length of each of the three sides.

**Back/Side/Front Width** Specify the width of each of the three sides.

**Height** Specifies the overall height of the object.

**Back/Side/Front Segs** Specify the number of segments for a specific side of the object.
NOTE The object’s dimensions (Back, Side, Front) are labeled as though it were created in the Top or Perspective viewports, and seen from the front in world space.

**Width/Height Segs** Set these to specify the number of segments for the overall width and height of the object.

**Generate Mapping Coords** Sets up the required coordinates for applying mapped materials to the object. Default=on.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material’s Coordinates rollout on page 6201. Default=off.

### RingWave Extended Primitive

Create panel > Geometry button > Extended Primitives > Object Type rollout > RingWave button

Create menu > Extended Primitives > RingWave

Use the RingWave object to create a ring, optionally with irregular inner and outer edges whose shapes can be animated. You can also animate the growth of the ringwave object, and you can use keyframing to animate all numeric settings. Use RingWave for various types of special-effects animation, for example, to depict the shock wave emanating from the explosion of a star or planet.
Example of ringwave

**Procedures**

**To create a basic animated ringwave:**

1. On the menu bar choose Create > Extended Primitives > RingWave.
2. Drag in a viewport to set the outer radius of the ringwave.
3. Release the mouse button, and then move the mouse back toward the center of the ring to set the inner radius.
4. Click to create the ringwave object.
5. Drag the time slider to see the basic animation. This is determined by the Inner Edge Breakup group > Crawl Time settings.
6. To animate the ring's growth, choose RingWave Timing group > Grow And Stay or Cyclic Growth.
Interface

Parameters rollout
**RingWave Size group**

Use these settings to change the ringwave's basic parameters.

**Radius** Sets the outside radius of the ringwave.

**Radial Segs** Sets the segment count between the inner and outer surfaces in the direction of the radius.

**Ring Width** Sets the mean ring width as measured inward from the outer radius.

**Sides** Sets the number of segments in the circumferential direction for both the inner, outer, and end (cap) surfaces.

**Height** Sets the height of the ringwave along its major axis.

---

**TIP** If you leave the Height at 0 for an effect like a shock wave, you will want to apply a two-sided material so that the ring can be seen from both sides.

**Height Segs** Sets the number of segments in the direction of the height.

---

**RingWave Timing group**

Use these settings for ringwave animation where the ringwave grows from nothing to its full size.

**No Growth** Sets a static ringwave, which appears at Start Time and disappears after End Time.

**Grow and Stay** Animates a single growth cycle. The ringwave begins growing at the Start Time and reaches its full size at Start Time plus Grow Time.

**Cyclic Growth** The ringwave grows repeatedly from the Start Time to Start Time plus Grow Time.

For example, if you set Start Time to 0 and Grow Time to 25, leaving End Time at the default value of 100, and choose Cyclic Growth, the ringwave grows from nothing to its full size four times over the course of the animation.

**Start Time** The frame number where the ringwave appears, and begins to grow if you choose Grow and Stay or Cyclic Growth.

**Grow Time** The number of frames after Start Time the ringwave takes to reach full size. Grow Time is available only if Grow and Stay or Cyclic Growth is chosen.

**End Time** The frame number after which the ringwave disappears.
Outer Edge Breakup group

Use these settings to change the shape of the ringwave’s outer edge.

**TIP** For effects like shock waves, the ringwave typically has little or no breakup on the outer edge but relatively massive breakup on the inner edge.

**On** Turns on breakup of the outer edge. The remaining parameters in this group are active only when this is on. Default=off.

**Major Cycles** Sets the number of major waves around the outer edge.

**Width Flux** Sets the size of the major waves, expressed as a percentage of the unmodulated width.

**Crawl Time** Sets the number of frames each major wave takes to move around the outer circumference of the RingWave.

**Minor Cycles** Sets the number of random-sized smaller waves in each major cycle.

**Width Flux** Sets the average size of the smaller waves, expressed as a percentage of the unmodulated width.

**Crawl Time** Sets the number of frames each minor wave takes to move across its respective major wave.

Inner Edge Breakup group

Use these settings to change the shape of the ringwave’s inner edge.

**On** Turns on the breakup of the inner edge. The remaining parameters in this group are active only when this is on. Default=on.

**Major Cycles** Sets the number of major waves around the inner edge.

**Width Flux** Sets the size of the major waves, expressed as a percentage of the unmodulated width.

**Crawl Time** Sets the number of frames each major wave takes to move around the inner circumference of the RingWave.

**Minor Cycles** Sets the number of random-sized smaller waves in each major cycle.

**Width Flux** Sets the average size of the smaller waves, expressed as a percentage of the unmodulated width.
Crawl Time  Sets the number of frames each minor wave takes to move across its respective major wave.

NOTE  Negative values in the Crawl Time parameters change the direction of the wave. To produce interference patterns, use Crawl Time settings of opposite sign for major and minor waves, but similar Width Flux and Cycles settings.

TIP  To produce the best "random" results, use prime numbers for major and minor cycles that differ by a multiple of two to four. For example, a major wave of 11 or 17 cycles using a width flux of 50 combined with a minor wave of 23 or 31 cycles with a width flux of 10 to 20 makes a nice random-appearing edge.

Texture Coordinates  Sets up the required coordinates for applying mapped materials to the object. Default=on.

Smooth  Applies smoothing to the object by setting all polygons to smoothing group 1. Default=on.

Prism Extended Primitive

Create panel > Geometry button > Extended Primitives > Object Type rollout > Prism button
Create menu > Extended Primitives > Prism

Use Prism to create a three-sided prism with independently segmented sides.

Example of a prism
Procedures

To create a prism with an isosceles triangle as its base:

1. Choose Isosceles on the Creation Method rollout.

2. Drag horizontally in the viewport to define the length of Side 1 (along the X axis). Drag vertically to define the length of Sides 2 and 3 (along the Y axis).
   (To constrain the base to an equilateral triangle, press Ctrl before performing this step.)

3. Release the mouse, and move it vertically to define the height of the prism.

4. Click to complete the prism.

5. On the Parameters rollout, alter the length of the sides as needed.

To create a prism with a scalene or obtuse triangle at its base:

1. Choose Base/Apex in the Creation Method rollout.

2. Drag horizontally in the viewport to define the length of Side 1 (along the X axis). Drag vertically to define the length of Sides 2 and 3 (along the Y axis).

3. Click, and then move the mouse to specify the placement of the apex of the triangle. This alters the length of sides 2 and 3, and the angles of the corners of the triangle.

4. Click, and then move the mouse vertically to define the height of the prism.

5. Click to complete the prism.

Interface

Creation Method rollout

Isosceles Draws a prism with an isosceles triangle at its base.

Base/Apex Draws a prism with a scalene or obtuse triangle at its base.
Parameters rollout

![Parameters rollout](image)

**Side (n) Length** Sets the length of triangle's corresponding side (and thus the triangle's corner angles).

**Height** Sets the dimension of the prism's central axis.

**Side (n) Segs** Specifies the number of segments for each side of the prism.

**Height Segs** Sets the number of divisions along the prism's central axis.

**Generate Mapping Coordinates** Sets up the required coordinates for applying mapped materials to the prism. Default=off.

### Hose Extended Primitive

Create panel > Geometry > Extended Primitives > Object Type rollout > Hose button

Create menu > Extended Primitives > Hose

The Hose object is a flexible object that you can connect between two objects, whereupon it reacts to their movement. It's similar to Spring on page 849, but does not have dynamics properties. You can specify the overall diameter and length of the hose, the number of turns, and the diameter and shape of its "wire."
Hose models a workable spring on a motorcycle

Procedures

To create a hose:

1. From the menu bar, choose Create > Extended Primitives > Hose.
2. Drag the mouse to define the radius of the hose.
3. Release the mouse, and then move it to define the length of the hose.
4. Click to finish the hose.

To bind a hose to two objects:

1. Add a hose and two other objects. Select the hose.
2. In the Modify panel > Hose Parameters rollout > End Point Method group, choose Bound To Object Pivots.
3. In the Binding Objects group, click Pick Top Object, and then select one of the two objects.
4. In the Binding Objects group, click Pick Bottom Object, and then select the second of the two objects.
   The two ends of the hose attach themselves to the two objects.
5. Move one of the objects.
   The hose adjusts itself to remain attached to both objects.
Interface

Hose Parameters rollout > End Point Method group

Free Hose Choose this when using the hose as a simple object that’s not bound to other objects.

Bound to Object Pivots Choose this when binding the hose to two objects, using the buttons in the Binding Objects group.

Hose Parameters rollout > Binding Objects group

Available only when Bound To Object Pivots is chosen. Use the controls to pick the objects to which the hose is bound and to set the tension between them. "Top" and "Bottom" are arbitrary descriptors; the two bound objects can have any positional relationship to each other.

Each end point of the hose is defined by the center of the overall diameter. This end point is placed at the pivot point of the object to which it is bound. You can adjust the relative position of the binding object to the hose by transforming the binding object while the Affect Object Only button is turned on in the Hierarchy panel > Adjust Pivot rollout.

Top (label) Displays the name of the "top" binding object.

Pick Top Object Click this button and then select the "top" object.
Tension Determines the tension of the hose curve near the Top object as it reaches for the Bottom object. Lower the tension to have the bend occur closer to the Top object, raise the tension to have the bend occur further away from the Top object. Default=100.

Bottom (label) Displays the name of the "bottom" binding object.

Pick Bottom Object Click this button and then select the "bottom" object.

Tension Determines the tension of the hose curve near the Bottom object as it reaches for the Top object. Lower the tension to have the bend occur closer to the Bottom object, raise the tension to have the bend occur further away from the Bottom object. Default=100.

**Hose Parameters rollout > Free Hose Parameters group**

![Free Hose Parameters](image)

**Height** Use this field to set the straight-line height or length of the hose when it is not bound. This is not necessarily the actual length of the hose. Available only when Free Hose is chosen.
Hose Parameters rollout > Common Hose Parameters group

Segments The total number of segments in the hose's length. Increase this setting for a smooth profile when the hose is curved. Default=45.

Flex Section Enable When on, lets you set the following four parameters for the central, flexible section of the hose. When off, the hose's diameter is uniform throughout its length.

Starts The percentage of the hose length from the starting extremity of the hose at which the flex section begins. By default, the starting end of the hose is the end at which the object pivot appears. Default=10%.

Ends The percentage of the hose length from the end extremity of the hose at which the flex section ends. By default, the end extremity of the hose is opposite the end at which the object pivot appears. Default=90%.

Cycles The number of corrugations in the flex section. The number of visible cycles is limited by the number of segments; if Segments isn't high enough to support the number of cycles, then not all cycles will appear. Default=5.

**TIP** To set the appropriate number of segments, first set Cycles, and then increase Segments until the number of visible cycles stops changing.
**Diameter** The relative width of the "outside" parts of the cycles. At negative settings, these are smaller than the overall hose diameter. At positive settings, these are larger than the overall hose diameter. Default=-20%. Range=-50% to 500%.

**Smoothing** Defines the geometry that gets smoothed. Default=All:
- **All** The entire hose is smoothed.
- **Sides** Smoothing is applied along the length of the hose but not around its circumference.
- **None** No smoothing is applied.
- **Segments** Smoothing is applied only on the inner section of the hose.

**Renderable** When on, the hose is rendered using the specified settings. When off, the hose is not rendered. Default=on.

**Generate Mapping Coords** Sets up required coordinates for applying mapped materials to the hose. Default=on.
Hose Parameters rollout > Hose Shape group

Sets the shape of the hose cross section. Default=Round Hose.

**Round Hose** Sets a circular cross section.

**Diameter** The maximum width of the hose at the ends.

**Sides** The number of sides of the hose. A Sides setting of 3 gives a triangular cross section; 4 gives a square cross section; and 5 gives a pentagonal cross section. Increase Sides for a circular cross section. Default=8.

**Rectangular Hose** Lets you specify different settings for width and depth.

**Width** The width of the hose.

**Depth** The height of the hose.
Fillet The amount by which the cross-section corners are rounded. For this to be visible, Fillet Segs must be set to 1 or higher. Default=0.

Fillet Segs The number of segments across each filleted corner. A Fillet Segs setting of 1 cuts the corner straight across; use higher settings for rounded corners. Default=0.

Rotation The orientation of the hose along its long axis. Default=0.

D-Section Hose Similar to Rectangular Hose, but rounds one side for a D-shaped cross-section.

Width The width of the hose.

Depth The height of the hose.

Round Sides The number of segments on the rounded side. Increase for a smoother profile. Default=4.

Fillet The amount by which the two cross-section corners opposite the rounded side are rounded. For this to be visible, Fillet Segs must be set to 1 or higher. Default=0.

Fillet Segs The number of segments across each filleted corner. A Fillet Segs setting of 1 cuts the corner straight across; use higher settings for rounded corners. Default=0.

Rotation The orientation of the hose along its long axis. Default=0.

Architectural Objects

3ds Max provides an array of architectural objects, useful as building blocks for models of homes, businesses, and similar projects. These include: AEC Extended objects (Foliage, Railing, and Wall), Stairs, Doors, and Windows.

AEC Extended Objects

Create panel > Geometry > AEC Extended

Create menu > AEC Objects
AEC Extended objects are designed for use in the architectural, engineering, and construction fields. Use Foliage to create plants, Railing to create railings and fences, and Wall to create walls.

The Object Name and Wireframe Color rollout on page 8182 in each AEC Extended object's creation panel functions identically. The remaining rollouts are covered in each object's topic.

Working with AEC Design Elements

3ds Max includes such features as Foliage, Doors, Windows, Stairs, Railing, and Wall to make exploring three-dimensional design ideas much easier.

This section provides general information about these features. For detailed explanations and procedures, see the topics listed below:

- Doors on page 525
- Windows on page 541
- Stairs on page 506
- Railing on page 482
- Wall on page 491
- Foliage on page 474

Doors and Windows

3ds Max supplies a number of parametric window and door objects that you can place into wall openings to add realism to an architectural model. These objects let you control details like trim and panel fill in your model.

TIP Use Snaps on page 2828 for added precision when adding doors and windows.

When you create a new door or window, you must select four points in the scene that define the size and orientation of the rectangle that will be the
door or window. You may find it easier to select these points in a given sequence, depending on your scene and views of the scene.

If you already have a rectangular hole you want to fill, you can still create a door or window to your specifications by using the following procedure.

To create a door or window:

1. Set up an angled User view so that you can see the bottom and one vertical edge of the opening and its full height.

2. Set the appropriate object snaps, such as Vertex or Endpoint. This helps make the model more precise.

3. After clicking Window or Door, choose one of two Creation Methods: Width/Depth/Height or Width/Height/Depth.

4. Make parameter adjustments to define details.

The width and orientation of the door/window is always defined by the first mouse click and subsequent mouse drag. Depending on the creation method you use, either the height or depth of the object is defined next.

If you have no object snaps set and are working in a Perspective or User Viewport, using the Width/Depth/Height Creation Method creates an upright Door or Window. The Width/Height/Depth Creation Method creates the object as if it were lying on its side.

Allowing Non-vertical Jambs

The Allow Non-vertical Jambs toggle is useful for creating doors or windows that do not fit in a vertical plane, such as a skylight window in a sloping roof. By default, this toggle is off, making the third point in the creation sequence either directly above (Width/Height/Depth) or on the same horizontal plane (Width/Depth/Height) with the second point.

When you turn on Allow Non-vertical Jambs, the third point in the creation sequence falls wherever you choose and the fourth point is added by 3ds Max. Its offset from the plane is determined by the first three points.

Using the Width/Height/Depth Creation Method in Perspective and User viewports with Allow Non-vertical Jambs off can be an efficient way to create doors and windows with Object Snaps. However, it can also be confusing at first. Keep in mind that the third point you define, the Height, is interpreted as a point on the home grid until you indicate a point higher or lower than the grid. If you are using an Object Snap setting, 3ds Max might not know
you mean a point off the grid unless you bring the cursor in proximity to a nonplanar point to which it can snap.

**Additional Parameters**

There are additional parameters specific to each door and window type that control overall dimension parameters, as well as detailed parameters for sub-object components such as mullions, trim, and panels within leaves. See [Doors on page 525](#) and [Windows on page 541](#) for more information on these parameters.

**Animating Doors and Windows**

Certain door and window creation parameters, including the Open parameter, can be animated. See [Doors on page 525](#) and [Windows on page 541](#) for more information.

**Creating Stairs and Railings**

3ds Max contains four types of stair objects: [spiral stairs on page 514](#), [U-type stairs on page 522](#) with an intermediate landing, [L-type stairs on page 511](#) with a landing at the bend in the stair, and [straight stairs on page 519](#) with no intermediate landing. A complementary Railing object can be used to create any number of handrail designs that follow along a spline path.

For more information, see [Stairs on page 506](#).

**The Railing Object**

Use the Railing button on the Create panel in the to produce railing objects. Railing components include rails, [AEC Extended category on page 467](#) posts, and fencing. Fencing includes pickets (balusters) or solid-filled material (such as glass or wood strips).

You can create a railing in two ways: specify the orientation and height of the railing, or pick a spline path and apply the railing to that path. The spline path with a railing is called a rail path. Later, if you edit the rail path, the Railing object automatically updates to follow the changes you make. Rail paths can occupy three-dimensional space.

When you create the lower rails, posts, and fencing components of a Railing object, you use a special version of the Spacing Tool to specify the spacing of those components. 3ds Max displays the Spacing Tool dialog for each railing component: Lower Rail, Post Spacing, or Picket Spacing. For more information on the Spacing Tool, see [Spacing Tool on page 953](#).
Creating Walls

Use the Wall button on page 491 on the Create panel, in the AEC Extended category, to produce straight-wall objects. A wall object is made up of sub-object segments that you can edit with the Modify panel.

You can:

■ Break or insert wall segments to create separate wall objects.
■ Delete wall segments.
■ Connect two wall objects.

When you create two wall segments that meet at a corner, 3ds Max removes any duplicate geometry. This “cleaning up” of the corners might involve trimming. 3ds Max cleans up only the first two wall segments of a corner, not other wall segments that might share the corner. 3ds Max does not clean up intersections. You can edit the segments of a wall using sub-object selection mode on the Modify panel. For example, you can define a wall’s height profile. 3ds Max moves the active grid to the plane of the wall you’re editing. This allows you to snap to the profile vertices in the plane of the wall.

If you move, scale, or rotate the wall object, the linked door and window moves, scales, or rotates along with the wall. If you move the linked door or window along the wall, using the door or window’s Local coordinate system and activating Restrict to XY Plane in the Axis Constraints toolbar on page 910, the opening will follow. Also, if you change a door or window's overall width and height in the Modify panel, the hole will reflect those changes.

Usage Tips

The following are a few tips for working with wall objects:

■ Use the Top viewport when creating wall objects.
■ Single walls with many windows and doors can slow down snap calculations and movement of the wall object. To speed up insertion and editing, use multiple walls instead of a single wall.
■ You can speed up performance in a scene with many walls, windows, and doors by collapsing them. First save an uncollapsed version for any future
parametric changes you might want to make. Then right-click the wall and pick Select Children from the right-click menu. Next use Collapse in the Utility rollout to collapse them all.

For complete information, see Wall on page 491.

To create a wall:

1. On the Create panel, in the AEC Extended category, click Wall.
2. Use Customize > Units Setup to establish precision, and then set the parameters for the Width, Height, and Justification of the wall.
3. In any viewport, click, release the mouse, drag the wall segment to the length you want and click again. This creates a wall segment. You can end the wall or you can continue to create another wall segment.
4. To complete the wall, right-click, or to add another wall segment, drag the next wall segment to the length you want and click again. If you create a room by ending a segment at the end of another segment of the same wall object, 3ds Max displays the Weld Point dialog. This dialog lets you convert the two end vertices into a single vertex, or keep the two end vertices separate.
5. If you want the wall segments to be welded at a corner (when you move one wall, the other wall stays at the corner), click Yes. Otherwise, click No.
6. Right-click to complete the wall, or continue to add another wall segment.

To attach separate walls:

1. Select a wall object.
2. On the Modify panel, click Attach, and then pick another wall object. The two wall objects become part of the same wall object, but are not physically connected.

Attach stays active, and you can continue clicking wall segments to attach. To stop attaching, click the Attach button or right-click in the active viewport.

To attach multiple wall objects simultaneously to the selected wall object, click Attach Multiple on the Modify panel to open the Attach Multiple dialog. This works the same as the Select From Scene dialog on page 206,
except that it shows only wall objects; choose multiple walls to attach, and then click the Attach button.

**To connect vertices in a wall:**

This method lets you connect two separate wall sections with a new segment.

TIP: It is easier to work with wall vertices in wireframe view mode.

1. Select a wall object that has more than one section. Typically you would use Attach to create such an object.
2. In the **modifier stack** on page 8187, go to the Vertex sub-object level.
3. Click Connect and point the mouse over an end vertex until the cursor changes to a cross.
4. Click once over the end vertex.
5. Move the cursor to another end vertex, and then click to connect the two segments.

**To insert a vertex in a wall:**

It is easier to work with wall vertices in wireframe view mode.

1. Select a wall segment.
2. In the **modifier stack** on page 8187, go to the Vertex sub-object level.
3. Click Insert.
   A highlighted line appears along the bottom of the wall, showing where you can insert vertices.
4. Click anywhere on the highlighted line to insert a vertex.
   The new vertex is attached to the mouse cursor.
5. Move the mouse to position the vertex, and then click to place it.
   Now the mouse is attached to one of the new segments.
6. Move the mouse along the segment and click to add vertices.
7. Right-click to finish working on this segment. You can now insert vertices in other segments, or right-click again to exit Insert mode.
Foliage

Create panel > Geometry > AEC Extended > Foliage button
Create menu > AEC Objects > Foliage

Foliage produces various types of plant objects such as tree species. 3ds Max generates mesh representations to create fast, efficient, and good-looking plants.

You control height, density, pruning, seed, canopy display, and level of detail. The seed on page 480 option controls creation of different representations of the same species. You can create millions of variations of the same species, so each object can be unique. With the viewport canopy mode on page 481 option, you can control the amount of plant detail, reducing the number of vertices and faces 3ds Max uses to display the plant.
Some of the plants that can be created from the standard library

Tips

- Use the Spacing tool on page 953 to place plants along a path.
- Use vertex or face snapping (see Snaps Settings on page 2819) to position plants on a surface.

Procedures

To add plants to a scene:

1. Click the Favorite Plants rollout > Plant Library button to display the Configure Palette dialog.
2. Double-click the row for each plant you want to add or remove from the Palette and click OK.
3. On the Favorite Plants rollout, select a plant and drag it to a location in a viewport. Alternatively, select a plant in the rollout and then click in the viewport to place the plant.
4 On the Parameters rollout, click the New button to display different seed variations of the plant.

5 Adjust the remaining parameters to show elements of the plants, such as leaves, fruit, branches, and if you want, to view the plant in canopy mode.

Interface

Object Name and Wireframe Color rollout

This rollout lets you set the foliage object’s name, color, and default material. For detailed information, see Object Name and Wireframe Color on page 8182.

When Favorite Plants rollout > Automatic Materials is on, each plant is assigned its own default material. For more information, see Favorite Plants rollout, following.

Keyboard Entry rollout

See Creating Primitives from the Keyboard on page 386.
Favorite Plants rollout

The palette displays the plants currently loaded from the Plant Library on page 478. There are three ways to add a plant to the scene:

- Use keyboard entry.
- Click the icon in the Favorite Plants list and then click a location in a viewport. Double-click the icon to place the plant at the world origin.
- Drag the plant from the palette and drop it into a viewport.

**Automatic Materials** Assigns default materials for the plant. To modify these material assignments, use the Material Editor on page 5641. Select the plant in the viewport, and click Main toolbar > Material Editor. Click the Get Material button on page 5687 to display the Material/Map Browser. Under Browse From, choose Selected. Then, from the list pane, double-click the material list item.
for the plant to display the materials in the Basic Parameters rollout of the Material Editor.

If you turn off Automatic Materials, 3ds Max assigns no materials to the object, unless the Name And Color rollout > Default Material check box is on and a default material is assigned. This way you can specify a particular default material for all foliage objects. For more information, see Object Name and Wireframe Color on page 8182.

When on, Automatic Materials overrides the Default Material settings.

---

**NOTE** Even if Automatic Materials is off, 3ds Max still assigns material IDs to the foliage objects, so that the object is ready for a multi/sub-object material.

**Plant Library** Displays the Configure Palette dialog. Using this window, you can view information on the available plants including their names, whether they’re in the palette, their scientific names, types, descriptions, and the approximate number of faces per object. You can also add and remove plants from the palette, and clear the palette, which removes all plants from the palette.

**TIP** To quickly add or remove a plant from the palette, double-click its row in the Configure Palette dialog. The Fav. (Favorite Plants) column entry switches between “no” and “yes.” Click OK to accept the changes and exit the window.
Parameters rollout

**Height** Controls the approximate height of the plant. 3ds Max applies a random noise factor to the height of all of the plants. Therefore, the actual height of a plant, as measured in the viewports, won't necessarily match the setting given in the Height parameter.

**Density** Controls the amount of leaves and flowers on the plant. A value of 1 displays a plant with all its leaves and flowers, .5 displays a plant with half its leaves and flowers, and 0 displays a plant with no leaves or flowers.
Two trees with varying foliage densities

**Pruning** Applies only to plants with branches. Removes branches that lie below an invisible plane parallel to the construction plane. A value of 0 prunes nothing, a value of 0.5 prunes the plant at a plane halfway up its height from the construction plane, and a value of 1 prunes everything possible from the plant. What 3ds Max prunes from the plant depends on the type of plant. The trunk is never pruned.

Three pairs of trees, showing different values of pruning

**New** Displays a random variation of the current plant. 3ds Max displays the seed value in the numeric field next to the button.

**TIP** Click the New button repeatedly until you find the variation you want. This is often easier than trying to adjust the tree using modifiers.

**Seed** A value between 0 and 16,777,215 representing the possible variations of branch and leaf placement and shape and angle of the trunk of the current plant.

**Generate Mapping Coords** Applies default mapping coordinates on page 8628 to the plant. Default=on.
Show group

Controls the display of leaves, fruit, flowers, trunk, branches, and roots of plants. Available options depend on the type of plant you select. For example, if a plant doesn’t have fruit, 3ds Max disables that option. Turning off options reduces the number of vertices and faces displayed.

Viewport Canopy Mode group

In 3ds Max, the canopy of a plant is a shell covering the outermost parts of the plant, such as the leaves or the tips of the branches and trunk. The term derives from "forest canopy." Use reasonable parameters when you create many plants and want to optimize display performance.

Because this setting applies only to the plant’s representation in the viewports, it has no effect on how 3ds Max renders the plant. For information on how 3ds Max renders the plant, see Level-of-Detail on page 481.

**When Not Selected** Displays the plant in canopy mode when it’s not selected.

**Always** Always displays the plant in canopy mode.

**Never** Never displays the plant in canopy mode. 3ds Max displays all the features of the plant.

Level-of-Detail group

AEC Extended Objects | 481
Controls how 3ds Max renders the plant. For information on how 3ds Max displays the plant in the viewports, see Viewport Canopy Mode on page 481.

**Low** Renders the plant canopy, providing the lowest level of detail.

**Medium** Renders a reduced-face-count version of the plant. How 3ds Max reduces the face count varies from plant to plant, but it usually involves removing smaller elements of the plant or reducing the number of faces in the branches and trunk.

**High** Renders all the faces of the plant, providing the highest level of detail.

---

**TIP** Set the parameters before creating multiple plants. This can avoid slowing down the display, and might reduce editing you have to do on the plants.

---

### Railing

Create panel > Geometry > AEC Extended > Railing button

Create menu > AEC Objects > Railing

Components of the railing object include rails, posts, and fencing. Fencing includes either pickets (balusters) or solid-filled material, such as glass or wood strip.

Railings used to create fences in a field.

You can create a railing object either by specifying the orientation and height of the railing, or by picking a spline path and applying the railing to that path. When 3ds Max applies railing to a spline path, the latter is called a *rail path*. Later, if you edit the rail path, the railing object automatically updates to follow the changes you made. You can use three-dimensional splines as rail paths.

When you create the lower rails, posts, and fencing components of a railing, you use the Spacing tool on page 953 to specify the spacing of those components.
components. 3ds Max names the Spacing tool dialog for each railing component: Lower Rail Spacing, Post Spacing, or Picket Spacing.

**TIP** Use Railing to create complete railings for stairs. See Stairs on page 506 for more information.

### Railings and Materials

By default, 3ds Max assigns five different material IDs to railings. The `aectemplates.mat` material library includes *Rail-Template*, a multi/sub-object material on page 6120 designed to be used with railings. Each component of the railing/material is listed below along with its corresponding Material ID.

<table>
<thead>
<tr>
<th>Material ID</th>
<th>Railing/Material Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Lower rails</td>
</tr>
<tr>
<td>2</td>
<td>Posts of the railing</td>
</tr>
<tr>
<td>3</td>
<td>Solid fill of the railing</td>
</tr>
<tr>
<td>4</td>
<td>Top of the railing</td>
</tr>
<tr>
<td>5</td>
<td>Pickets of the railing</td>
</tr>
</tbody>
</table>

**NOTE** 3ds Max does not automatically assign a material to the railing object. To use the included material, open the library and then assign the material to your object.

### Procedures

The following procedures describe how to create railings combining each of the components: upper rail, lower rails, posts, picket fencing, and solid filled fencing.

You can create a railing object in any viewport, but for best results, use a Perspective, Camera, or Top viewport.

**To create a railing:**

1. Click and drag the railing to the desired length.
2 Release the mouse button, and then move the mouse vertically to set the height. Click to finish.

By default, 3ds Max creates the top rail along with two posts, a lower rail at half the railing height, and two evenly spaced pickets.

3 If you need to, change any of the parameters to adjust the segments, length, profile, depth, width, and height of the rail.

To adjust lower rails:

1 To modify the lower rail, or add more, choose an option from the Lower Rail(s) group > Profile list.

2 Specify the depth and width for the lower rails and then click the Lower Rail(s) > Spacing button.

3 Specify the number of lower rails you want using the Count option. Click Close to apply your changes. For more information on spacing options in this dialog, see Spacing Tool on page 953.

To create posts:

1 If you want to modify the posts, or add more, choose an option from the Profile list under the Posts rollout.

2 Specify the depth and width of the posts and how much they should extend above the top rail. Then click the Posts rollout > Spacing button.

3 Specify the number of posts you want using the Count option. Click Close to apply your changes. For more information on spacing options in this dialog, see Spacing Tool on page 953.

To create picket fencing:

1 Choose Fencing rollout > Type list > Pickets. The Solid Fill options will be unavailable.

2 Choose an option from the Profile list, specify the depth and width of the pickets, and then click the Picket rollout > Spacing button.
3 Specify the number of pickets you want using the Count option. Click Close to apply your changes. For more information on spacing options in this dialog, Spacing Tool on page 953.

To create solid-fill fencing:

1 Choose Fencing rollout > Type list > Solid Fill. (The options under Picket are unavailable).
2 Under Solid Fill, adjust the options for Thickness and offsets.

To create railings along a spline path:

Before you can create railings along a spline path, you need to create a spline, or use an existing spline from your scene.

1 Click Create panel > Geometry > AEC Extended > Railing.
2 Click Pick Railing Path, then select a spline in your scene. Since the number of segments is 1 by default, the upper rail extends for one segment between the start and end of the spline.
3 Change the amount of segments using the Modify panel > Segment setting.
   The higher the segment value, the more closely the railing approximates the spline shape.
4 If you want the railing to contain corners where the spline does, turn on Respect Corners.
5 Complete the remainder of the railing options as described in the preceding procedures.
   Thereafter, the spline is associated with the railing; any changes you make to the spline shape are reflected in the railing.

Interface

Name and Color rollout

This rollout lets you set the selected railing's name and color. For detailed information, see Object Name and Wireframe Color on page 8182.
Railing rollout

Pick Railing Path  Click this, and then click a spline in the viewport to use as the railing path. 3ds Max uses the spline as the path along which to apply the railing object.

If you edit the spline you’ve used as a railing path, the railing adjusts to the changes you make. 3ds Max doesn’t immediately recognize 2D Shapes from a linked AutoCAD drawing. To recognize Shapes from a linked AutoCAD drawing, edit the Shape with Edit Spline on page 1424 in the Modify panel.

TIP  When you create a railing using a closed spline for the rail path, open the Post Spacing dialog on page 953, turn off Start Offset and End Offset, and lock End Offset. This will ensure that 3ds Max properly creates the railing with any fill, pickets, and posts you specify.
NOTE Railing objects that use Pick Path do not stay on the path when substituted using the Substitute modifier. Substituted externally referenced railings do not undo when railings are associated with a path.

**Segments** Sets the number of segments of the railing object. Available only when you're using a railing path.

For a close approximation to a railing path, increase the number of segments. Be aware that a high number of segments increases file size and slows down the rendering speed. You might use fewer segments when the spline path has a low curvature (or none) and fewer segments provide an adequate approximation.

**Respect Corners** Puts corners in the railing to match the corners of the railing path.

**Length** Sets the length of the Railing object. When you drag the mouse, the length displays in the edit box.

**Top Rail group**

The defaults produce a top rail component, consisting of one segment by the length you specify, a square profile, four units deep, three units wide, and the height you specify.

1. Width
2. Depth
3. Height
4. Profile for the square top rail
5. Profile for the round top rail

**Profile** Sets the cross-section shape of the top rail.

**Depth** Sets the depth of the top rail.

**Width** Sets the width of the top rail.
**Height** Sets the height of the top rail. During creation, you can drag the top rail to the height you want using the mouse in the viewport. Or you can enter the height amount from the keyboard or use the spinners.

**Lower Rail(s) group**

Controls the profile, depth, width, and spacing between the lower rails. You specify how many lower rails you want using the Lower Rail Spacing button.

![A railing with the rails defined by their profile, depth, and width as planks.](image)

**Profile** Sets the cross-section shape of the lower rails.

**Depth** Sets the depth of the lower rails.

**Width** Sets the width of the lower rails.

**Lower Rail Spacing** Sets the spacing of the lower rails. When you click this button, the Lower Rail Spacing dialog displays. Specify the number of lower rails you want using the Count option. For more information on spacing options in this dialog, see [Spacing Tool](#) on page 953.

**Generate Mapping Coords** Assigns mapping coordinates on page 8628 to the railing object.

---

**NOTE**

If a visible viewport is set to a non-wireframe or non-bounding-box display, Generate Mapping Coordinates is on for all primitives to which you apply a material containing a map with Show Map In Viewport on. If all viewports are set to wireframe or bounding box, 3ds Max turns on Generate Mapping Coordinates for primitives containing mapped materials at render time.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material’s Coordinates rollout on page 6201. Default=off.
Posts rollout

Controls the profile, depth, width, extension, and spacing between the posts. You specify how many posts you want using the Post Spacing button.

**Profile** Sets the cross-section shape of the posts: none, Square, or Round.

**Depth** Sets the depth of the posts.

**Width** Sets the width of the posts.

**Extension** Sets the amount the posts extend above the bottom of the top railing.

**Post Spacing** Sets the spacing of the posts. When you click this button, the Post Spacing dialog displays. Specify the number of posts you want using the Count option. For more information on spacing options in this dialog, see Spacing Tool on page 953.

**TIP** Setting Profile to (none) makes an "invisible" post. You might want to do this to create a railing with gaps between solid fill fencing. Or you could use it to make a railing with openings between groups of pickets. This is different from setting the post count to 0 in the Post Spacing dialog.
Fencing rollout

**Type**
Sets the type of fencing between the posts: none, Pickets, or Solid Fill.

**Picket group**
Controls the profile, depth, width, and spacing between the pickets. Specify how many pickets you want using the Picket Spacing button. Available only when you set Type to Pickets.

1. A railing with pickets using a square profile
2. A railing with pickets using a round profile
Profile Sets the cross-section shape of the pickets.

Depth Sets the depth of the pickets.

Width Sets the width of the pickets.

Extension Sets the amount the pickets extend above the bottom of the top railing.

Bottom Offset Sets the amount the pickets are offset from the bottom of the railing object.

Picket Spacing Sets the spacing of the pickets. When you click this button, the Picket Spacing dialog displays. Specify the number of pickets you want using the Count option. For more information on spacing options in this dialog, see Spacing Tool on page 953.

Solid Fill group

Controls the thickness and offsets of the solid fill between the posts. Available only when you set Type to Solid.

Thicknes Sets the thickness of the solid fill.

Top Offset Sets the offset of the solid fill from the bottom of the top rail.

Bottom Offset Sets the offset of the solid fill from the bottom of the railing object.

Left Offset Sets the offset between the solid fill and the adjacent left post.

Right Offset Sets the offset between the solid fill and the adjacent right post.

Wall

Create panel > Geometry > AEC Extended > Object Type rollout > Wall button
Create menu > AEC Objects > Wall

The Wall object is made up of three sub-object types that you can edit in the Modify panel. Similarly to the way you edit splines, you can edit the wall object on page 501, its vertices on page 502, its segments on page 503, and its profile on page 504.

When you create two wall segments that meet at a corner, 3ds Max removes any duplicate geometry. This "cleaning up" of the corners might involve
trimming. 3ds Max cleans up only the first two wall segments of a corner, not any other wall segments that might share the corner. 3ds Max does not clean up intersections.

**Inserting Doors and Windows in a Wall**

3ds Max can automatically make openings for doors and windows in a wall. At the same time, it links the door or window to the wall as it child. The most effective way of doing both is to create the doors and windows directly on a wall segment by snapping to the faces, vertices, or edges of the wall object.

If you move, scale, or rotate the wall object, the linked door or window moves, scales, or rotates along with the wall. If you move the linked door or window along the wall, using the door or window's local coordinate system and constraining motion to the XY plane on page 8039, the opening will follow. Also, if you change a door or window's overall width and height on the Modify panel, the hole will reflect those changes.

For further information, see the procedure To create and place a window or door in a wall on page 497.

**Walls and Materials**

By default, 3ds Max assigns five different material IDs to walls. The aectemplates.mat material library includes Wall-Template, a multi/sub-object material on page 6120 designed to be used with walls. Each component of the wall/material is listed below along with its corresponding Material ID.

<table>
<thead>
<tr>
<th>Material ID</th>
<th>Wall/Material Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Vertical ends of the wall</td>
</tr>
<tr>
<td>2</td>
<td>Outside of the wall</td>
</tr>
<tr>
<td>3</td>
<td>Inside of the wall</td>
</tr>
<tr>
<td>4</td>
<td>Top of the wall, including any edges cut out of the wall</td>
</tr>
<tr>
<td>5</td>
<td>Bottom of the wall</td>
</tr>
</tbody>
</table>
NOTE 3ds Max does not automatically assign a material to the wall object. To use the included material, open the library and then assign the material to your object.

NOTE The definitions of slots 2 and 3 are interchangeable; inside and outside simply depend on your point of view, and how you created the wall.

See also:
- Editing Wall Objects on page 500

Tips
- To make a passageway through a wall you can perform a Boolean operation on page 713 with the wall as Operand A, and another object, such as a box or an extruded archway shape, as Operand B. The wall will still be accessible at the Boolean sub-object level. Then, you can add a window or door in the passageway, and link on page 3630 it as a child of the wall.
- Single walls with many windows and doors can become slow to use because of the amount of boolean calculations used. To speed up movement and editing, you might consider using multiple walls instead of a single wall.
- You can speed up performance in a scene with many walls, windows and doors by collapsing them. First save an uncollapsed version for any future parametric changes you might want to make. Then double-click the wall to select it and its children. Next use Convert To from the right-click menu to convert them to an editable mesh, and so on.

Procedures

To create a wall:

You can create a wall in any viewport, but for vertical walls, use a Perspective, Camera, or Top viewport.

1. Set parameters for the Width, Height, and Justification of the wall.

2. In a viewport, click and release, move the mouse to set the desired length for the wall segment, and click again.

   This creates a wall segment. You can end the wall by right-clicking or you can continue to create another wall segment.
To add another wall segment, move the mouse to set the length of the next wall segment and click again.

If you create a room by ending a segment at the end of another segment of the same wall object, 3ds Max displays the Weld Point dialog. This dialog lets you convert the two end vertices into a single vertex, or to keep the two end vertices distinct.

If you want the wall segments to be welded at that corner so that when you move one wall, the other wall stays correct at the corner, click Yes. Otherwise, click No.

Right-click to end the wall, or continue to add other wall segments.

To attach separate walls:

1. Select a wall object.
2. On the Modify panel, click Attach, and then pick another wall object. The two wall objects become part of the same wall object, but are not physically connected.

Attachment stays active, and you can continue clicking wall segments to attach.

To stop attaching, click the Attach button or right-click in the active viewport.

To attach multiple wall objects simultaneously to the selected wall object, click Attach Multiple on the Modify panel to open the Attach Multiple dialog. This works the same as the Select From Scene dialog on page 206, except that it shows only wall objects; choose multiple walls to attach, and then click the Attach button.

To connect vertices in a wall:

This method lets you connect two separate wall sections with a new segment.

TIP It is easier to work with wall vertices in wireframe view mode.

1. Select a wall object that has more than one section. Typically you would use Attach to create such an object.
2. In the modifier stack on page 8187, go to the Vertex sub-object level.
3. Click Connect and point the mouse over an end vertex until the cursor changes to a cross.
4. Click once over the end vertex.
5 Move the cursor to another end vertex, and then click to connect the two segments.

To insert a vertex in a wall:
To insert a vertex in a wall: It is easier to work with wall vertices in wireframe view mode.

1 Select a wall segment.
2 In the modifier stack on page 8187, go to the Vertex sub-object level.
3 Click Insert.
   A highlighted line appears along the bottom of the wall, showing where you can insert vertices.
4 Click anywhere on the highlighted line to insert a vertex.
   The new vertex is attached to the mouse cursor.
5 Move the mouse to position the vertex, and then click to place it.
   Now the mouse is attached to one of the new segments.
6 Move the mouse along the segment and click to add vertices.
7 Right-click to finish working on this segment. You can now insert vertices in other segments, or right-click again to exit Insert mode.

To detach and reorient a copy of a wall segment:

TIP It is easier to work with wall vertices in wireframe view mode.

1 Select a wall.
2 In the modifier stack on page 8187, go to the Segment sub-object level.
3 Select a wall segment.
4 Turn on both Reorient and Copy, and then click Detach.
5 Enter a name for the new wall object in the Detach dialog or click OK to accept the default name.
   3ds Max copies the original wall’s Local coordinate system on page 8621 when it makes the copy of the detached segment. It places the new object so that its Local coordinate system is coincident with the World space origin on page 8768.
To add a gable point to a wall profile or adjust for uneven terrain:

**TIP** It is easier to work with wall vertices in wireframe view mode.

1. Select a wall.
2. In the modifier stack on page 8187, go to the Profile sub-object level.
3. Select a wall profile by clicking a wall segment.
   A grid appears.
4. To add a gable point procedurally, set the height and click Create Gable. If you prefer to add the profile point manually, click Insert, click a point on the highlighted top profile, drag the new point into place and then release where you want to place the new gable point. You can move profile points you create with Insert only within the plane of the wall segment, and you cannot move them below the original top edge.

   If you want to adjust the profile for uneven terrain below a wall, click Insert, pick the highlighted bottom profile and add points as necessary.

   If you want to extend multiple segments uniformly downward below floor level, do the following: At the Segment sub-object level, select the segments and, on the Edit Segment rollout, enter a negative Bottom Offset value to move the segments downward. Add the absolute value of the Bottom Offset setting back to the Height value to bring the top of the wall height back up and make it flush with the other wall segments.

To apply a texture to a wall:

Walls are created with five different material IDs on page 8633 for their various parts.
The \textit{aectemplates.mat} material library includes \textit{Wall-Template}, a Multi/Sub-Object material designed for use with walls. You can copy or copy and modify this template, or create your own material as follows:

1. Create a \textbf{Multi/Sub-Object material} on page 6120 using five textures for the following Material IDs:
   - Slot #1 is the material for the vertical ends on the wall
   - Slot #2 is the material for the outside of the wall
   - Slot #3 is the material for the inside of the wall
   - Slot #4 is the material for the top of the wall, as well as any inside edges cut out of the wall
   - Slot #5 is the material for the bottom of the wall

   \textbf{NOTE}: The definitions of slots 2 and 3 are interchangeable; inside and outside simply depend on your point of view, and how you created the wall.

2. If the top and bottom surfaces of the wall aren't visible in the rendered scene, you can use a three-sided material instead. The inside and outside of the wall are relative to the direction in which the wall was created. To swap a texture between slots in the Material Editor, drag one of the textures over the other slot in the Basic Parameters rollout of the Multi/Sub-Object material, and then choose Swap.

3. For greater control in tiling across the wall surface, apply a \textbf{Map Scaler world-space modifier} on page 1147 to the wall. Then adjust the scale of the map in the Map Scaler's Parameters rollout.

\textbf{To create and place a window or door in a wall:}

For best results, perform this procedure in a wireframe viewport.

1. Create a \textbf{window} on page 541 or \textbf{door} on page 525 (hereafter referred to as "window" for brevity) directly on an existing wall. You can define the window's exact dimensions after insertion. Use \textbf{edge snap} on page 2819 for the first snaps to place and align the window on the wall and to establish its exact depth. Snap to and then click the near top edge of the wall to start creation. Drag to another edge snap point on the near top edge of the wall and release to align the window with the wall segment and to set its width. Snap to the rear top edge of the wall to set the proper depth and click. Move the cursor downward and click to define the window.
height. This final click doesn't require a snap, as it simply defines a rough height.

2 The window should now be cut out of the wall. On the Modify panel for windows or doors, set the correct width and height. Change the depth if it's different from the snap depth you set above.

3 Use vertex snap to move the window or door from a reference point to a known point on the wall segment. Then
   Next, use relative offset values from this new position to accurately locate the window or door. As an example, following the next two steps, you could move a window from its top left corner to the top left corner of the wall segment so that you can then move it 3 feet to the right and 2 feet down.

4 With the window or door selected, set the coordinate system to Local.

5 On the Coordinate Display on page 8081, activate Offset mode and then enter the offset distances on the X axis for horizontal and the Y axis for vertical.

NOTE For best results, do not position an inserted window or door at the bottom of a wall.

Interface

Keyboard Entry rollout

![Keyboard Entry rollout](image)

- **X**: Sets the coordinate position along the X axis for the start point of a wall segment in the active construction plane.

498 | Chapter 6  Creating Geometry
Y Sets the coordinate position along the Y axis for the start point of a wall segment in the active construction plane.

Z Sets the coordinate position along the Z axis for the start point of a wall segment in the active construction plane.

Add Point Adds the point from the X, Y, and Z coordinate values you enter.

Close Ends creation of the wall object and creates a segment between the end point of the last segment and the start point of the first segment, to make a closed wall.

Finish Ends creation of the wall object, leaving it open ended.

Pick Spline Lets you use a spline as the wall path. Click this, and then click a spline in the viewport to use as the wall path. 3ds Max uses the spline as the path along which to apply the wall object. 3ds Max doesn’t immediately recognize 2D Shapes from a linked AutoCAD drawing. To recognize Shapes from a linked AutoCAD drawing, edit the Shape with Edit Spline on page 1424 from the Modify panel.

NOTE If you designate a curved spline as the path, 3ds Max creates straight wall segments that approximate the spline as closely as possible, with one wall segment per spline segment.

Parameters rollout

![Parameters rollout](image)

AEC Extended Objects | 499
The defaults produce a wall object 5 units wide, 96 units high, and justified at the center of the wall.

**Width** Sets the thickness of the wall. Range=0.01 unit to 100,000 units. Default=5.

**Height** Sets the height of the wall. Range=0.01 unit to 100,000 units. Default=96.

**Justification group**

**Left** Justifies the wall at the left edge of its baseline (the line between the wall's front and back sides, which is equal to the wall thickness). If you turn Grid Snap on, the left edge of the wall's baseline snaps to the grid line.

**Center** Justifies the wall at the center of its baseline. If you turn Grid Snap on, the center of the wall's baseline snaps to the grid line. This is the default.

**Right** Justifies the wall at the right edge of its baseline. If you turn Grid Snap on, the right edge of the wall's baseline snaps to the grid line.

**Generate Mapping Coords** Assigns mapping coordinates on page 8628 to the wall. Default=on.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

**Editing Wall Objects**

Select a wall object. > Modify panel

This topic describes the Wall options on the Modify panel.

**TIP** It’s generally easiest to edit wall objects in wireframe mode.

**See also:**

■ **Wall** on page 491
Interface

Edit Object rollout

This rollout appears when you select a wall object at the object level; other rollouts, discussed below appear at the different sub-object levels.

Attach  Attaches another wall in a viewport to the selected wall by a single pick. The object you attach must also be a wall. 3ds Max applies the material of the selected wall to the wall being attached.

Attach Multiple  Attaches other walls in a viewport to the selected wall. Click this button to open the Attach Multiple dialog, which lists all the other wall objects in the scene. Select the walls you want to attach from the list and click the Attach button. 3ds Max applies the material of the selected wall to the walls being attached.

Justification group

See Justification on page 500.

Generate Mapping Coords.  Assigns mapping coordinates on page 8628 to the wall. Default=on.

Real-World Map Size  Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.
**Edit Vertex rollout**

Appears at the Vertex sub-object level. Each wall segment has two vertices; one in each bottom corner. In wireframe views, wall vertices appear as + symbols. Connected segments in the same wall object each share a vertex. Moving a wall vertex has the effect of scaling attached segments as well as rotating them about their other vertices. You cannot rotate or scale wall vertices.

**Connect** Lets you connect any two vertices, creating a new linear segment between the vertices.
Click this button, click a vertex, and then click a second vertex on a different segment. When you move the cursor over a valid second vertex, the mouse icon changes to a Connect icon.

**Break** Lets you disconnect segments at a shared vertex.

**TIP** Select a vertex shared between wall segments, and then click the Break button. The segments become disconnected, and each has its own end vertex at the position of the previously shared vertex.

**Refine** Adds a vertex to the position along a wall segment that you click.
When you move the cursor over a valid Refine point, the mouse icon changes to a Refine icon.

**Insert** Inserts one or more vertices, creating additional segments. When you move the cursor over a valid Insert point, the mouse icon changes to an Insert icon. Right-click to stop inserting new vertices and segments.

**Delete** Deletes the currently selected vertex or vertices, including any segments in between.
Deleting vertices shared by two or more segments doesn’t create a gap, but rather results in a single segment connecting vertices adjacent to those being deleted.
Edit Segment rollout

This rollout appears when you select a wall object and then access Segment sub-object level.

Each wall segment is defined by, and effectively connects, two wall vertices. Moving a segment is the same as moving its two vertices in tandem. It has the effect of scaling adjacent wall segments as well as rotating them about their other vertices. You can scale a wall segment horizontally only (any Scale function does this). You cannot rotate a segment.

Break Specifies a break point in a wall segment.
You needn't select a segment first. When you move the cursor over the object, the mouse icon changes to a Break icon. The position you select on the segment becomes two coincident vertices, and 3ds Max breaks the segment in two.

Detach Detaches wall segments you select and creates a new wall object out of them.

Same Shape Detaches the wall segment keeping it part of the same wall object. If you also turn on Copy, 3ds Max places a detached copy of the segment in the same location.
Reorient Detaches the wall segment, copies the object’s Local coordinate system on page 8621, and places the segment so that its object Local coordinate system is coincident with the World space origin on page 8768. If you also turn on Copy, 3ds Max detaches a copy of the segment and leaves the original segments in place.

Copy Copies the detached wall segment rather than moving it.

Divide Subdivides each segment by the number of vertices specified in the Divisions spinner. Select one or more segments, set the Divisions spinner, and then click Divide.

Divisions Sets the number by which to divide the segment.

Insert Provides the same function as the Insert button on page 502 in Vertex sub-object selection. Inserts one or more vertices, creating additional segments. When you move the cursor over the a valid Insert point, the mouse icon changes to an Insert icon. Right click to stop inserting new vertices and segments.

Delete Deletes any selected wall segments in the current wall object.

Refine Provides the same function as the Refine button on page 502 at the Vertex sub-object level. Adds a vertex to the position along a wall segment you select. When you move the cursor over a valid Refine point, the mouse icon changes to a Refine icon.

Parameters group

Width Changes the width of a selected segment or segments.

Height Changes the height of a selected segment or segments.

Bottom Offset Sets the distance of the bottom of the selected segment or segments from the floor.

Edit Profile rollout

This rollout appears when you select a wall object and then access Profile sub-object level.

The term "profile" refers to the outline of a wall segment's top and bottom edges. When in Profile sub-object mode, the selected wall object's inner horizontal edges appear dark orange. Click any of these edges to select the corresponding segment, highlight it in red, and place a temporary active grid in the plane of the segment. At that point, you can insert and delete vertices.
along the horizontal edges, move an inserted vertex along the grid to change
the profile, create gables, and change the grid properties.

![Edit Profile](image)

**Insert** Inserts a vertex so that you can adjust the profile of the selected wall segment.

Use this option to adjust the profile of walls under gables or to align walls to a slope. When you move the cursor over the selected segment, the mouse icon changes to an Insert icon. Click to insert a new profile point, then drag and release to position and place it. You can add new profile points to both the top and the bottom of the wall, but you cannot position profile points below the original top edge or above the original bottom edge.

**Delete** Deletes the selected vertices on the profile of the selected wall segment.

**Create Gable** Creates a gable by moving the center point of the top profile of the selected wall segment to a height you specify.

Select the segment, set the height, and then click Create Gable.

**Height** Specifies the height of a gable.

**Grid Properties group**

The grid constricts profile point insertion and movement to the plane of the wall and allows you to snap to grid points on the plane of the wall.

**Width** Sets the width of the active grid.

**Length** Sets the length of the active grid.

**Spacing** Sets the size of the smallest square in the active grid.
Stairs

Create panel > Geometry > Stairs
Create menu > AEC Objects

You can create four different types of stairs in 3ds Max: Spiral Stair on page 514, Straight Stair on page 519, L-Type Stair on page 511, or U-Type Stair on page 522.

Railings and Materials

By default, 3ds Max assigns seven different material IDs to stairs. The aectemplates.mat material library includes Stair-Template, a multi/sub-object material on page 6120 designed to be used with stairs. Each component of the stair/material is listed below along with its corresponding Material ID.

<table>
<thead>
<tr>
<th>Material ID</th>
<th>Railing/Material Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Treads of the stairs</td>
</tr>
<tr>
<td>2</td>
<td>Front riser of the stairs</td>
</tr>
<tr>
<td>3</td>
<td>Bottom, back, and sides of the risers of the stairs</td>
</tr>
<tr>
<td>4</td>
<td>Center pole of the stairs</td>
</tr>
<tr>
<td>5</td>
<td>Handrails of the stairs</td>
</tr>
<tr>
<td>6</td>
<td>Carriage of the stairs</td>
</tr>
<tr>
<td>7</td>
<td>Stringers of the stairs</td>
</tr>
</tbody>
</table>

NOTE 3ds Max does not automatically assign a material to the stairs object. To use the included material, open the library and then assign the material to your object.
Procedures

To create railings on stairs:

1. Create the stairs. See individual stair-type topics for more information.

2. In the Generate Geometry group, turn on Rail Path > Left and Right. 3ds Max places left and right rail paths above the stairs.

3. In the Railings rollout, set Height to 0.0.

4. Click Create panel > AEC Extended > Railing on page 482 to create the first railing.

5. Click Railing rollout > Pick Railing Path and select one of the rail paths on the stairs.

6. Adjust the railing parameters. 3ds Max remembers the parameters you set. When you create the next railing, it will have the same parameters as you set for the first railing.

7. Right-click to end the creation of the first railing.

8. Click Railing again to create the second railing.

9. Click Pick Railing Path and select the other rail path on the stairs.

Interface

Object Type rollout

Stair Selection Buttons Click one of these to specify the type of stairs you want to create.

Name and Color rollout

This rollout lets you set the stairs object’s name and color. For detailed information, see Object Name and Wireframe Color on page 8182.
Parameters rollout > Type group

Open Creates an open riser stair, as shown on the left in the illustration above.

Closed Creates a closed riser stair, as shown in the center in the illustration above.

Box Creates a stair with closed risers and closed stringers on both sides, as shown on the right in the illustration above.

Rise group

3ds Max keeps one Rise option locked while you adjust the other two. To lock an option, you click a push pin. To unlock an option you click a raised push pin. 3ds Max locks the spinner value of the parameter with the depressed push pin and allows the spinner values of the parameter with the raised push pins to change.

Overall Controls the height of the flight of stairs.

Riser Ht Controls the height of the risers.

Riser Ct Controls the number of risers. There will always be one more riser than steps. This implied riser is between the top step of the stair and the upper floor.
Linear stair with five risers
1 through 4. Risers
5. The implied riser
6. The upper floor you snap to
7. The lower floor you snap to
8. The steps

**Stringers rollout**

These controls are available only when you turn on Stringers on the Parameters rollout > Generate Geometry group.

- **Depth** Controls how far down the stringers reach toward the floor.
- **Width** Controls the width of the stringers.
- **Offset** Controls the vertical distance of the stringers from the floor.
- **Spring from Floor** Controls whether the stringer starts at the floor, flush with the start of the first riser, or if the stringer extends below the floor. You control the amount the stringer extends below the floor with the Offset option.
Carriage rollout

These controls are available only when you turn on Carriage on the Parameters rollout > Generate Geometry group.

Depth Controls how far down the carriage reaches toward the floor.

Width Controls the width of the carriage.

Carriage Spacing Sets the spacing of the carriage. When you click this button, the Carriage Spacing dialog displays. Specify the number of carriages you want using the Count option. For more information on spacing options in this dialog, see Spacing Tool on page 953.

Spring from Floor Controls whether the carriage starts at the floor, flush with the start of the first riser, or if the carriage extends below the floor. You control the amount the carriage extends below the floor with the Offset option.
**Railings rollout**

These controls are available only when you turn on one or more of the Handrail or Rail Path options on the Parameters rollout > Generate Geometry group. Also, Segments and Radius aren’t available if neither of the Handrail options is on.

**Height** Controls the height of the railings from the steps.

**Offset** Controls the offset of the railings from the ends of the steps.

**Segments** Controls the number of segments in the railings. Higher values display smoother railings.

**Radius** Controls the thickness of the railings.

**L-Type Stair**

Create panel > Geometry > Stairs > L-Type Stair button
Create menu > AEC Objects > L-Type Stair

The L-Type Stair object lets you create a staircase with two flights at right angles to each other.

Types of L-type stair: open, closed, and boxed
L-type stairs have two flights at right angles, and a landing.

Procedures

To create L-Type stairs:

1. In any viewport, drag to set the length for the first flight. Release the mouse button, then move the cursor and click to set the length, width, and direction for the second flight.

2. Move the cursor up or down to define the rise of the stairs, then click to end.

3. Adjust the stairs by using the options in the Parameters rollout.

Interface

Generate Geometry group
**Stringers** Creates stringers along the ends of the treads of the stairs. To modify the stringers’ depth, width, offset and spring from the floor, see Stringers rollout on page 509.

**Carriage** Creates an inclined, notched beam under the treads which supports the steps or adds support between the stringers of the stairs. You might also know this as a *carriage piece*, a *horse*, or a *rough string*. See Carriage rollout on page 510 to modify the parameters.

**Handrail** Creates left and right handrails. See Railings rollout on page 511 to modify the handrails’ height, offset, number of segments, and radius.

**Rail Path** Creates left and right paths you can use to install railings on the stairs. See Stairs on page 506 for the instructions on how to do this.

**Layout group**

<table>
<thead>
<tr>
<th>Layout</th>
<th></th>
</tr>

**Thickness** Controls the thickness of the steps.

**Depth** Controls the depth of the steps.

---

**Generate Mapping Coords** Applies default mapping coordinates on page 8628 to the stairs.

**NOTE** If a visible viewport is set to a non-wireframe or non-bounding-box display, Generate Mapping Coordinates is on for all primitives to which you apply a material containing a map with Show Map In Viewport on. If all viewports are set to wireframe or bounding box, 3ds Max turns on Generate Mapping Coordinates for primitives containing mapped materials at render time.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material’s Coordinates rollout on page 6201. Default=off.

---

**Spiral Stair**

Create panel > Geometry > Stairs > Spiral Stair button
Create menu > AEC Objects > Spiral Stair

The Spiral Stair object lets you specify the radius and number of revolutions, add stringers and a center pole, and more.

Types of spiral stair: open, closed, and boxed

Spiral stairs wind around a center

Procedures

To create spiral stairs:

1 In any viewport, click for the start point of the stairs, and drag to specify the radius you want.
2 Release the mouse button, move the cursor up or down to specify the overall rise, and click to end.
3 Adjust the stairs with options in the Parameters rollout.

Interface

Generate Geometry group

Generate Geometry
- Stringers
- Carriage
- Center Pole
Handrail: Inside
Outside
Rail Path: Inside
Outside
Stringers Creates stringers along the ends of the treads of the stairs. To modify the stringers’ depth, width, offset and spring from the floor, see Stringers rollout on page 509.

Carriage Creates an inclined, notched beam under the treads which supports the steps or adds support between the stringers of the stairs. You might also know this as a carriage piece, a horse, or a rough string. See Carriage rollout on page 510 to modify the parameters.

Center Pole Creates a pole at the center of the spiral. See Center Pole rollout on page 518 to modify the parameters of the pole.

Handrail Creates inside and outside handrails. See Railings rollout on page 511 to modify the handrails’ height, offset, number of segments, and radius.

Rail Path Creates inside and outside paths which you can use to install railings on the stairs. See Stairs on page 506 for the instructions on how to do this.

Layout group

CCW Orient the spiral stairs to be a right-hand flight of stairs.

CW Orient the spiral stairs to be a left-hand flight of stairs.

Left: CCW (counterclockwise) right-hand spiral stairs. The arrow indicates “Up.”

Right: CW (clockwise) left-hand spiral stairs. The arrow indicates “Up.”
**Radius** Controls the size of the radius of the spiral.

**Revs** Controls the number of revolutions in the spiral.

**Width** Controls the width of the spiral stairs.

**Steps group**

**Thickness** Controls the thickness of the steps.

**Depth** Controls the depth of the steps.

**Segs** Controls the number of segments 3ds Max uses to construct the steps.

**Generate Mapping Coords** Applies default mapping coordinates on page 8628 to the stairs.
NOTE If a visible viewport is set to a non-wireframe or non-bounding-box display, Generate Mapping Coordinates is on for all primitives to which you apply a material containing a map with Show Map In Viewport on. If all viewports are set to wireframe or bounding box, 3ds Max turns on Generate Mapping Coordinates for primitives containing mapped materials at render time.

Real-World Map Size Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material’s Coordinates rollout on page 6201. Default=off.

Center Pole rollout

These controls are available only when you turn on Center Pole on the Parameters rollout > Generate Geometry group.

Radius Controls the radius size of the center pole.

Segments Controls the number of segments in the center pole. Higher values display a smoother pole.

Height The spinner controls the height of the center pole. Turning on Height lets you adjust the height of the pole independently of the stairs. Turning off Height makes the spinner unavailable and locks the top of the pole to the top of the implied last riser. Typically, this riser would attach to the fascia of a landing.
Left: The center pole locked to the top of the implied last riser. (Height turned off.)

Right: The center pole adjusted to the height you specify. (Height turned on.)

**Straight Stair**

Create panel > Geometry > Stairs > Straight Stair button

Create menu > AEC Objects > Straight Stair

The Straight Stair object lets you create a simple staircase, with optional stringers, carriage, and handrail.

Types of straight stair: open, closed, and boxed

Straight stairs have a single flight.

**Procedures**

To create straight stairs:

1. In any viewport, drag to set the length. Release the mouse button, then move the cursor and click to set the width you want.

2. Move the cursor up or down to define the rise of the stairs, and click to end.
3 Adjust the stairs with the options in the Parameters rollout.

**Interface**

**Generate Geometry group**

![Generate Geometry panel]

**Stringers** Creates stringers along the ends of the treads of the stairs. To modify the stringers’ depth, width, offset and spring from the floor, see Stringers rollout on page 509.

**Carriage** Creates an inclined, notched beam under the treads which supports the steps or adds support between the stringers of the stairs. You might also know this as a carriage piece, a horse, or a rough string. See Carriage rollout on page 510 to modify the parameters.

**Handrail** Creates left and right handrails. See Railings rollout on page 511 to modify the handrails’ height, offset, number of segments, and radius.

**Rail Path** Creates left and right paths you can use to install railings on the stairs. See Stairs on page 506 for the instructions on how to do this.

**Layout group**

![Layout panel]

**Length** Controls the length of the stairs.

**Width** Controls the width of the stairs.
Steps group

**Thickness** Controls the thickness of the steps.

**Depth** Controls the depth of the steps.

**Generate Mapping Coords** Applies default mapping coordinates on page 8628 to the stairs.

**NOTE** If a visible viewport is set to a non-wireframe or non-bounding-box display, Generate Mapping Coordinates is on for all primitives to which you apply a material containing a map with Show Map In Viewport on. If all viewports are set to wireframe or bounding box, 3ds Max turns on Generate Mapping Coordinates for primitives containing mapped materials at render time.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by
the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

**U-Type Stair**

Create panel > Geometry > Stairs > U-Type Stair button
Create menu > AEC Objects > U-Type Stair

The U-Type Stair object lets you create a two-flight staircase, with the two flights parallel to each other and a landing between them.

Types of U-type stair: open, closed, and boxed

U-type stairs have two flights in opposite directions, and a landing.

**Procedures**

To create U-Type stairs:

1. In any viewport, drag to set the length for the first flight. Release the mouse button, then move the cursor and click to set the width of the landing, or the distance separating the two flights.
2. Click and move the cursor up or down to define the rise of the stairs, then click to end.
3. Adjust the stairs by using the options in the Parameters rollout.
Interface

Generate Geometry group

Stringers Creates stringers along the ends of the treads of the stairs. To modify the stringers’ depth, width, offset and spring from the floor, see Stringers rollout on page 509.

Carriage Creates an inclined, notched beam under the treads which supports the steps or adds support between the stringers of the stairs. You might also know this as a carriage piece, a horse, or a roughstring. See Carriage rollout on page 510 to modify the parameters.

Handrail Creates left and right handrails. See Railings rollout on page 511 to modify the handrails’ height, offset, number of segments, and radius.

Rail Path Creates left and right paths you can use to install railings on the stairs. See Stairs on page 506 for the instructions on how to do this.

Layout group

Left/Right Controls the position of the two flights (Length 1 and Length 2) relative to each other. If you select left, then the second flight is on the left
from the landing. If you select right, then the second flight is the right from the landing.

**Length 1** Controls the length of the first flight of stairs.

**Length 2** Controls the length of the second flight of stairs.

**Width** Controls the width of the stairs, including the steps and the landing.

**Offset** Controls the distance separating the two flights and thus the length of the landing.

**Steps group**

![Steps](image)

**Thickness** Controls the thickness of the steps.

![Step thickness variance between two stairs](image)

**Depth** Controls the depth of the steps.

![Step depth variance between two stairs](image)
Generate Mapping Coords  Applies default mapping coordinates on page 8628 to the stairs.

NOTE  If a visible viewport is set to a non-wireframe or non-bounding-box display, Generate Mapping Coordinates is on for all primitives to which you apply a material containing a map with Show Map In Viewport on. If all viewports are set to wireframe or bounding box, 3ds Max turns on Generate Mapping Coordinates for primitives containing mapped materials at render time.

Real-World Map Size  Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

Doors

Create panel > Geometry > Doors
Create menu > AEC Objects

The door models provided let you control details of a door's appearance. You can also set the door to be open, partially open, or closed, and you can animate the opening.
Different door types in a model of a house

There are three kinds of doors. The **Pivot door** on page 535 is the familiar door that is hinged on one side only. The **Bifold door** on page 539 is hinged in the middle as well as the side, like many closet doors. You can also make these kinds of doors a set of double doors. The **Sliding door** on page 537 has a fixed half and a sliding half.

The topic for each kind of door describes its unique controls and behavior. Most door parameters are common to all kinds of doors, and are described here.

**Doors and Materials**

By default, 3ds Max assigns five different material IDs to doors. The `aectemplates.mat` material library includes **Door-Template**, a multi/sub-object material designed to be used with doors. Each component of the door/material is listed below along with its corresponding Material ID.
<table>
<thead>
<tr>
<th>Material ID</th>
<th>Door/Material Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Front</td>
</tr>
<tr>
<td>2</td>
<td>Back</td>
</tr>
<tr>
<td>3</td>
<td>Inner Bevel (used for glazing when Panels set to Glass or Beveled).</td>
</tr>
<tr>
<td>4</td>
<td>Frame</td>
</tr>
<tr>
<td>5</td>
<td>Inner Door</td>
</tr>
</tbody>
</table>
NOTE 3ds Max does not automatically assign a material to the door object. To use the included material, open the library and then assign the material to your object.

Making an Opening for a Door

To make an opening in a wall, you can perform a Boolean operation on page 713 with the wall as Operand A, and another object, such as a box, as Operand B. Then, you can create and add a door in the opening, and link on page 3630 it, if you choose, as a child of the wall.

NOTE Using snaps, you can insert a door in a wall object, automatically linking the two and creating a cutout for the door. See the procedure To create and place a window or door in a wall: on page 497.

Procedures

To create a door:

1. On the Object Type rollout, click the button for the type of door you want to create.

2. Choose options as needed, such as changing the default creation method. Turn off Create Frame to eliminate the door frame. Turn on Allow Non-vertical Jambs if you want an inclined door.

3. Drag the mouse in the viewport to create the first two points, defining the width and angle of the base of the door.

4. Release the mouse and move to adjust the depth of the door (default creation method), and then click to set. By default, the depth is perpendicular to the line between the first two points and parallel to the active grid.

5. Move the mouse to adjust the height, and then click to finish. The height is perpendicular to the plane defined by the first three points and perpendicular to the active grid.

You can adjust the Height, Width, and Depth values on the Parameters rollout.

On the Creation Method rollout, you can change the creation order to width-height-depth instead of width-depth-height.
To create a door material:

1. Create a door or select an existing door.
2. Open the Material Editor, and select a slot for the material.
3. Click the Type button below the Material Editor toolbar. The Material/Map Browser dialog opens.
4. In the Material list, double-click the Multi/Sub-Object item, and then on the Replace Material dialog that appears, choose either option and click OK.
5. On the Multi/Sub-Object Basic Parameters rollout, click Set Number and change Number Of Materials to 5. Click OK.
6. Optionally, change the sub-material names to those specified in the above table on page 527.
7. Edit the material as you would any Multi/Sub-Object material.

To animate a door:

You can animate a door opening and closing by keyframing the Open setting.

1. Create a door or select an existing door.
   If using an existing door, also access the Modify panel.
2. Set the Parameters rollout > Open parameter to the amount you want the door to be open at the start of the animation. If you want it to be closed, set it to 0.
3. Click the Auto Key button and advance to the first keyframe.
4. Change the Open setting.
5. Continue moving to any additional keyframes and changing the Open setting as necessary.
6. Play the animation.

Interface

The topic for each kind of door describes its unique controls and behavior. Most door parameters are common to all kinds of doors, and are described here.
Object Type rollout

There are three kinds of doors in 3ds Max:

**Pivot** The familiar door type that is hinged on one side only. See Pivot Door on page 535.

**Sliding** Has a fixed half and a sliding half. See Sliding Door on page 537.

**BiFold** Hinged in the middle as well as the side, like many closet doors. You can also use this type of door to make a set of double doors. See BiFold Door on page 539.

Name and Color rollout

See Object Name and Wireframe Color on page 8182.

Creation Method rollout

You define each type of door with four points: Drag the first two, followed by two move-click sequences. The Creation Method setting determines the order in which these actions define the door's dimensions.

**Width/Depth/Height** The first two points define the width and angle of the base of the door. You set these points by dragging in a viewport, as the first step in creating a door. The first point, where you click and hold before dragging, defines a point on the jamb at the hinge for single-pivot and bifold doors (both jambs have hinges on double doors, and sliding doors have no hinge). The second point, where you release the button after dragging, specifies the width of the door, as well as the direction from one jamb to the other.
This lets you align the door with a wall or opening when you place it. The third point, where you click after moving the mouse, specifies the depth of the door, and the fourth click, where you click after moving the mouse again, specifies the height.

**Width/Height/Depth** Works like the Width/Depth/Height option, except that the last two points create first the height and then the depth.

**NOTE** With this method, the depth is perpendicular to the plane set by the first three points. Thus, if you draw the door in the Top or Perspective viewport, the door lies flat on the active grid.

**Allow Non-vertical Jambs** Lets you create tilted doors. Set snaps on page 2807 to define points off the construction plane. Default=off.
Parameters rollout

Height Sets the overall height of the door unit.

Width Sets the overall width of the door unit.

Depth Sets the depth of the door unit.

Open With Pivot doors, specifies in degrees the extent to which the door is open. With Sliding and BiFold doors, Open specifies the percent that the door is open.
Frame group

This rollout has controls for the door-jamb frame. Though part of the door object, the frame behaves as if it were part of the wall. It doesn't move when you open or close the door.

Create Frame This is turned on as a default to display the frame. Turn this off to disable display of the frame.

Width Sets the width of the frame parallel to the wall. Available only when Create Frame is on.

Depth Sets the depth of the frame as it projects from the wall. Available only when Create Frame is on.

Door Offset Sets the location of the door relative to the frame. At 0.0, the door is flush with one edge of the trim. Note that this can be a positive or negative value. Available only when Create Frame is on.

Generate Mapping Coords Assigns mapping coordinates to the door.

Real-World Map Size Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.
Leaf Parameters rollout

Provides controls that affect the door itself (as opposed to the door unit, which includes the frame). You can adjust the dimensions of the door, add panels, and adjust the dimensions and placement of those panels. The total number of panels for each door element is the number of horizontal divisions times the number of vertical divisions. Pivot doors have a single door element unless they are double doors. BiFold doors have two door elements, or four if they are double doors. Sliding doors have two door elements.

**Thickness** Sets the thickness of the door.

**Stiles/Top Rail** Sets the width of the panel framing on the top and sides. This setting is apparent only if the door is paneled.

**Bottom Rail** Sets the width of the panel framing at the base of the door. This setting is apparent only if the door is paneled.
# Panels Horiz. Sets the number of panel divisions along the horizontal axis.
# Panels Vert. Sets the number of panel divisions along the vertical axis.
Muntin Sets the width of the separations between the panels.

**Panels group**

Determines how panels are created in the door.

None The door has no paneling.
Glass Creates glass panels with no beveling.
Thickness Sets the thickness of the glass panels.
Beveled Choose this to have beveled panels.
The remaining spinners affect the beveling of the panels.
Bevel Angle Specifies the angle of the bevel between the outer surface of the door and the surface of the panel.
Thickness 1 Sets the outer thickness of the panel.
Thickness 2 Sets the thickness where the bevel begins.
Middle Thick. Sets the thickness of the inner part of the panel.
Width 1 Sets the width where the bevel begins.
Width 2 Sets the width of the inner part of the panel.

**Pivot Door**

Create panel > Geometry > Doors > Pivot button
Create menu > AEC Objects > Pivot Door
The Pivot door is hinged on one side only. You can also make the door a double door, with two door elements, each hinged on its outer edge.
Single and double pivot doors

This topic describes only controls and behavior unique to the Pivot door. Most door parameters are common to all kinds of doors; see Doors on page 525.
Interface

Parameters rollout

The Parameters rollout contains three check boxes specific to Pivot doors.

**Double Doors** Makes a double door.

**Flip Swing** Changes the direction the door swings.

**Flip Hinge** Places the door hinges on the opposite side of the door. This option is unavailable for double doors.

**Sliding Door**

Create panel > Geometry > Doors > Sliding button
Create menu > AEC Objects > Sliding Door

The Sliding door slides as if on a track or railing. It has two door elements: one remains stationary while the other moves.
Sliding doors with different numbers of panels

This topic describes only controls and behavior unique to the Sliding door. Most door parameters are common to all kinds of doors; see Doors on page 525.
Interface

Parameters rollout

Flip Front Back Changes which element is in front, compared to the default.

Flip Side Changes the current sliding element to the stationary element, and vice versa.

BiFold Door

Create panel > Geometry > Doors > BiFold button
Create menu > AEC Objects > BiFold Door

The BiFold door is hinged in the middle as well as on the side. It has two door elements. You can also make the door a double door, with four door elements.
Single and double bifold doors

This topic describes only controls and behavior unique to the BiFold door. Most door parameters are common to all kinds of doors; see Doors on page 525.
Interface

Parameters rollout

The Parameters rollout contains three check boxes specific to BiFold doors.

**Double Doors** Makes the door a double door, with four door elements, meeting in the center.

**Flip Swing** Makes the door swing in the opposite direction from the default.

**Flip Hinge** Makes the door hinged on the opposite side from the default. Flip Hinge is unavailable when Double Doors is on.

Windows

Create panel > Geometry > Windows
Create menu > AEC Objects

The window object lets you control details of a window's appearance. You can also set the window to be open, partially open, or closed, and you can animate the opening over time.
Different types of windows in a model of a house

3ds Max offers six kinds of windows:

- The **Casement window** on page 552 has one or two door-like sashes that swing inward or outward.
- The **Pivoted window** on page 556 pivots at the center of its sash, either vertically or horizontally.
- The **Projected window** on page 558 has three sashes, two of which open like awnings in opposite directions.
- The **Sliding window** on page 560 has two sashes, one of which slides either vertically or horizontally.
- The **Fixed window** on page 554 doesn't open.
- The **Awning window** on page 549 has a sash that is hinged at the top.

**Windows and Materials**

By default, 3ds Max assigns five different material IDs to windows. The *aeetemplates.mat* material library includes *Window-Template*, a multi/sub-object
material designed to be used with windows. Each component of the window/material is listed below along with its corresponding Material ID.

<table>
<thead>
<tr>
<th>Material ID</th>
<th>Window/Material Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Front Rails</td>
</tr>
<tr>
<td>2</td>
<td>Back Rails</td>
</tr>
<tr>
<td>3</td>
<td>Panels (glazing), with 50% opacity</td>
</tr>
<tr>
<td>4</td>
<td>Front Frame</td>
</tr>
<tr>
<td>5</td>
<td>Back Frame</td>
</tr>
</tbody>
</table>
NOTE 3ds Max does not automatically assign a material to the window object. To use the included material, open the library and then assign the material to your object.

Making an Opening for a Window

To make an opening in a wall, you can perform a **Boolean operation** on page 713 with the wall as Operand A, and another object, such as a box, as Operand B. Then, you can create and add a window in the opening, and **link** on page 3630 it, if you choose, as a child of the wall.

NOTE Using snaps, you can insert a window in a wall object, automatically linking the two and creating a cutout for the window. See the procedure **To create and place a window or door in a wall**: on page 497.

Procedures

To create a window:

1. On the Object Type rollout, click the button for the type of window you want to create.

2. Choose options as needed, such as changing the default creation method. Turn on **Allow Non-vertical Jambs** if you want an inclined window.

3. Drag the mouse in the viewport to create the first two points, defining the width and angle of the base of the window.

4. Release the mouse and move to adjust the depth of the window (default creation method), and then click to set.
   
   By default, the depth is perpendicular to the line between the first two points and parallel to the active grid.

5. Move the mouse to adjust the height, and then click to finish.
   
   The height is perpendicular to the plane defined by the first three points and perpendicular to the active grid.

   You can adjust the height, width, and depth values on the **Parameters rollout**.

   In the Creation Method rollout, you can change the creation order to **width-height-depth** instead of **width-depth-height**.
To create a window material:

1. Create a window or select an existing window.
2. Open the Material Editor, and select a slot for the material.
3. Click the Type button below the Material Editor toolbar. The Material/Map Browser dialog opens.
4. In the Material list, double-click the Multi/Sub-Object item, and then on the Replace Material dialog that appears, choose either option and click OK.
5. On the Multi/Sub-Object Basic Parameters rollout, click Set Number and change Number Of Materials to 5. Click OK.
6. Optionally, change the sub-material names to those specified in the above table on page 543.
7. Edit the material as you would any Multi/Sub-Object material.

To animate a window:

You can animate a window opening and closing by keyframing the Open setting.

1. Create a window or select an existing window.
2. If using an existing window, also access the Modify panel.
3. Set the Parameters rollout > Open parameter to the amount you want the window to be open at the start of the animation. If you want it to be closed, set it to 0.
4. Click the Auto Key button on page 8090 to turn it on, and advance to the first keyframe.
5. Change the Open setting.
6. Continue moving to any additional keyframes and changing the Open setting as necessary.
7. Play the animation.
**Interface**

Most window parameters are common to all kinds of windows, and are described here. The topic for each window type describes its unique controls and behavior.

**Object Type rollout**

Six types of window are available in 3ds Max:

- **Awning** Has a sash that is hinged at the top. See Awning on page 549.
- **Casement** Has one or two door-like sashes that swing inward or outward. See Casement on page 552.
- **Fixed** Doesn't open. See Fixed on page 554.
- **Pivoted** Pivots at the center of its sash, either vertically or horizontally. See Pivoted on page 556.
- **Projected** Has three sashes, two of which open like awnings in opposite directions. See Projected on page 558.
- **Sliding** Has two sashes, one of which slides vertically or horizontally. See Sliding on page 560.

**Name and Color rollout**

See Object Name and Wireframe Color on page 8182.
**Creation Method rollout**

You define each type of window with four points: Drag the first two, followed by two move-click sequences. The Creation Method setting determines the order in which these actions define the window's dimensions.

**Width/Depth/Height** The first two points define the width and angle of the base of the window. You set these points by dragging in a viewport, as the first step in creating a window. This lets you align the window with a wall or opening when you place it. The third point, where you click after moving the mouse, specifies the depth of the window, and the fourth click, where you click after moving the mouse again, specifies the height.

**Width/Height/Depth** Works like the Width/Depth/Height option, except that the last two points create first the height and then the depth.

**NOTE** With this method, the depth is perpendicular to the plane set by the first three points. Thus, if you draw the window in the Top or Perspective viewport, the door lies flat on the active grid.

**Allow Non-vertical Jambs** Select to create tilted windows. Set snaps on page 2807 to define points off the construction plane. Default=off.
Parameters rollout

Height/Width/Depth Specifies the overall dimensions of the window.
Frame group

**Horiz. Width** Sets the width of the horizontal part of the window frame (at the top and bottom). This setting also affects the glazed portion of the window's width.

**Vert. Width** Sets the width of the vertical part of the window frame (at the sides). This setting also affects the glazed portion of the window's height.

**Thickness** Sets the thickness of the frame. This also controls the thickness of casements or railings on the window's sashes.

Glazing group

**Thickness** Specifies the thickness of the glass.

**Generate Mapping Coordinates** Creates the object with the appropriate mapping coordinates on page 8628 already applied.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

Awning Window

Create panel > Geometry > Windows > Awning button
Create menu > AEC Objects > Awning Window

The Awning window has one or more sashes that are hinged at the top.
Awning window
Interface

Parameters rollout

The topic for each kind of window describes its unique controls and behavior. Some window parameters are common to all kinds of windows; see Windows on page 541.

Rails and Panels group

**Width** Sets the width (depth) of the rails in the sashes.

**Panel Count** Sets the number of sashes in the window. If you use more than one sash, each is hinged at its top edge. Range=1 to 10.

Open Window group

**Open** Specifies the percent the window is open. This control is animatable.
Casement Window

Create panel > Geometry > Windows > Casement button
Create menu > AEC Objects > Casement Window
The Casement window has one or two sashes that are hinged on the side, like a door.

Casement window
The topic for each kind of window describes its unique controls and behavior. Some window parameters are common to all kinds of windows; see Windows on page 541.

Casements group

Panel Width Changes the size of the glazed panel within each sash.

One/Two Specifies the number of window panels: one or two. Using two panels creates a window like a double door; each panel is hinged on its outside side edge.
**Open Window group**

*Open* Specifies the percent that the window is open. This control is animatable.

*Flip Swing* Turn this on to have the sashes open in the opposite direction.

**Fixed Window**

Create panel > Geometry > Windows > Fixed button
Create menu > AEC Objects > Fixed Window

Fixed windows do not open, thus have no Open Window control. In addition to the standard window object parameters, the Fixed window provides the Rails And Panels group of settings for subdividing the window.

![Fixed windows](image.png)
Interface

Parameters rollout

The topic for each kind of window describes its unique controls and behavior. Some window parameters are common to all kinds of windows; see Windows on page 541.

Rails and Panels group

**Width** Sets the width (depth) of the rails in the sashes.

**# Panels Horiz** Sets the number of horizontal divisions in the window.

**# Panels Vert** Sets the number of vertical divisions in the window.

**Chamfered Profile** Chamfers the rails between the glazed panels, as in a conventional wooden window. When Chamfered Profile is off, the rails have a rectangular profile.
Pivoted Window

Create panel > Geometry > Windows > Pivoted button
Create menu > AEC Objects > Pivoted Window

A pivoted window has one sash only, hinged midway through the side of the sash. It can swing open either vertically or horizontally.
Interface

Parameters rollout

The topic for each kind of Window describes its unique controls and behavior. Most Window parameters are common to all kinds of Windows; see Windows on page 541.

Rails group

Width Sets the width of the rails in the sash.

Pivots group

Vertical Rotation Switches the pivot axis from horizontal to vertical.
Open Window group

Open Specifies the percent that the window is open. This control is animatable.

Projected Window

Create panel > Geometry > Windows > Projected button
Create menu > AEC Objects > Projected Window

Projected windows have three sashes: The top sash doesn’t move, while the bottom two sashes swing open like awning windows, but in opposite directions.
Interface

Parameters rollout

The topic for each kind of window describes its unique controls and behavior. Some window parameters are common to all kinds of windows; see Windows on page 541.

Rails and Panels group

**Width** Sets the width (depth) of the rails in the sashes.

**Middle Height** Sets the height of the middle sash, relative to the window's frame.

**Bottom Height** Sets the height of the bottom sash, relative to the window’s frame.
**Open Window group**

*Open* Specifies the percent that the two movable sashes are open. This control is animatable.

**Sliding Window**

Create panel > Geometry > Windows > Sliding button
Create menu > AEC Objects > Sliding Window

Sliding windows have two sashes: one fixed, one movable. The sliding part can move either vertically or horizontally.
The topic for each kind of Window describes its unique controls and behavior. Most Window parameters are common to all kinds of Windows; see Windows on page 541.

**Rails and Panels group**

**Rail Width** Sets the width of the rails in the sash.

# **Panels Horiz** Sets the number of horizontal divisions in each sash.

# **Panels Vert** Sets the number of vertical divisions in each sash.
Chamfered Profile  Chamfers the rails between the glazed panels, as in a conventional wooden window. When Chamfered Profile is off, the rails have a rectangular profile.

Open Window group

Hung  When on, the window slides vertically. When off, the window slides horizontally.

Open  Specifies the percent that the window is open. This control is animatable.

mental ray Object

The mental ray object category contains one object type: the mr Proxy object. Use this object to lighten the rendering load with geometry-heavy scenes.

mr Proxy Object

Set mental ray as the current renderer. > Create panel > Geometry button > mental ray > Object Type rollout > mr Proxy button

The mr Proxy object is intended for use in large scenes to be rendered with mental ray. This object type is useful when scenes contain many instances of an object, such as an auditorium with hundreds or thousands of instances of a seat model. It is also particularly useful for objects with extremely high polygon counts, in that it obviates both the conversion to mental ray format and the presence of the source object at render time, thus saving time and freeing up a great deal of memory for rendering. The only drawbacks are the reduced fidelity of the proxy object in the viewports and the inability to edit proxies directly.

The basic usage of the mr Proxy object is that you create and optionally animate the “source” object, apply a material, and then save a copy to disk for possible future modification. Next, you convert the object to mr Proxy format and write the proxy to a disk file or series of files, after which it appears in the viewports as a point cloud (a set of vertices showing the object size and approximate shape). Finally, you delete the source object, as its presence in the scene is no longer necessary. You can then use the mr Proxy object like any object in the scene, instancing it, transforming it, and so on. When you
render, mental ray loads the disk files and uses the geometry defined therein. However, if you need to modify it (such as changing a modifier parameter, or editing a sub-object), you need to load the source object, modify it, reconnect it to the proxy object, and rewrite the files.

**NOTE** Using Select Similar on page 228 with an mr Proxy object selects all mr Proxy objects, even if they use different source objects.

### Procedures

**To use the mr Proxy object:**

1. Make sure mental ray is the active renderer.
2. Create or load the object that is to serve as the source object. Apply any necessary modifiers and material. Be sure to save a copy for future reference.
3. Add an mr Proxy object. Until you define the source object, the mr Proxy object appears in the scene as a wireframe cube.
4. Go to the Modify panel. The mr Proxy object requires that you specify the source object from the Modify panel.
5. Click the source object button, which currently reads “None,” and then select the source object. The name of the source object appears on the button.

**TIP** If you plan to modify the source object, do so before converting it to mr Proxy format. Because the mr Proxy geometry is loaded by mental ray at render time, the renderer ignores any modifiers that change the geometry. The one exception is the Skew modifier on page 1664, which affects the object’s transformation matrix rather than its sub-object geometry, and thus can modify a proxy.

6. Click the Write Object To File button, enter a file name, and click Save. This opens the mr Proxy Creation dialog, which lets you set parameters for the proxy object file, including animation frames and preview settings. Change settings as necessary and then click OK to continue. The file is saved in the MIB format and its path and file name are placed in the Proxy File field. After you save the file, the Display group shows...
the proxy geometry and the viewport shows the object, by default, as a **point cloud**: a group of vertices that roughly defines the object’s shape. You can change the number of points in the cloud and use a bounding box to represent the object, with or without the point cloud. (When the point cloud is on, you can toggle the bounding box, but when you turn off the point cloud, the bounding box always displays.)

If you like, you can now delete the original object.

**TIP** To select an mr Proxy object when represented as a point cloud, click one of the vertices.

If the object is difficult to visualize in the viewports, increase the Display group > Viewport Verts value.

You can now use this object as any other object in 3ds Max, applying materials, copying it, animating with it, and so on.
To use materials with the mr Proxy object:

When you convert an object to mr Proxy format, the proxy does not inherit the object’s material. An efficient way to handle this is with the XRef material.

1. Create or load the object that is to serve as the source object. Apply any necessary modifiers and material, and then save a copy.

2. Create the mr Proxy object and then convert the source object, as described in the preceding procedure. Delete the source object.

3. Apply an XRef material on page 6783 to the proxy object.

4. Set the material to use the material from the source object file you saved in step 1.

Then, to modify the material on the proxy, load the source object, edit its material, and save the file. Because the material on the proxy object is externally referenced, it updates automatically.

Example: To use an animated source object:

The mr Proxy object supports vertex-level animation as well as topological changes in the source object. For example, you could create a fluid simulation with a particle system to which BlobMesh on page 701 is applied, and then bake it out to a series of mr Proxy files. This procedure gives an example of how to use this feature.

1. Create a source object and add vertex-level animation. For example, you could apply the Bend modifier and then set keys for different values of the Angle parameter.

2. Add an mr Proxy object.

3. Go to the Modify panel, click the source object (“None”) button and then select the object from step 1.

4. Click the Write Object To File button, enter a file name, and click Save. On the mr Proxy Creation dialog, choose either animation option (Active Time Segment or Custom Range) and, if you like, toggle the Preview Generation switches. Click OK to continue.

3ds Max writes a pair of files (geometry and thumbnail) for each animation frame.

5. You control animation playback in the Proxy object with the Animation Support group settings. When you save or load an animated Proxy, 3ds Max automatically enables the On check box in this group and sets Frames
to the number of frames in the animation. You can change the value to the number of frames you want to use from the animation. Also, you can adjust the rate at which the animation appears in the proxy object by adjusting the Replay Speed value, and change the frame at which the playback begins with the Frame Offset parameter. Last, to have the animation play back and forth, turn on Ping-Pong Replay.

Interface

NOTE Before using the mr Proxy object, make sure mental ray is the active renderer.
Parameters rollout

Source Object group

[source object button] Shows the name of the source object, or, if you haven’t assigned one, the text “None.” To assign an object, click the button and then
select the source object. The name of the source object then appears on the
button, unless you delete the source object subsequently. In that case, the
button label returns to “None,” although the mr Proxy object still functions
normally, assuming you’ve saved the object to an MIB file.

**Clear source object slot** Restores the source object button label to
“None,” but doesn’t otherwise affect the proxy object.

**Write Object to File** Lets you save the object as an MIB file, which you can
then load into another mr Proxy object using the Proxy File controls.
Clicking the button opens a File Name dialog, where you can navigate to the
desired folder and enter a file name. Then, when you click Save, 3ds Max
opens the **mr Proxy Creation dialog** on page 570. Set parameters as desired and
then click OK.

This saves a file named `[file name].mib`, containing the geometry data, and
another named `[file name].mib.bmp`, which contains the thumbnail image that
appears on the Parameters rollout.

**NOTE** The MIB file contains only geometry, not materials. You can apply different
materials to each instance or copy of an mr Proxy object.

If Animation Support is on, 3ds Max writes a sequence of both types of file,
with a four-digit frame number appended to the base file name for each file.
For example, if you use the file name `Test` and set Animation Support group
> Frames to 10, then the first pair of files are named `Test0000.mib` and
`Test0000.mib.bmp`, the second pair are named `Test0001.mib` and
`Test0001.mib.bmp`, and so on.

**Proxy File group**

**Proxy File** This editable field shows the location and name of the base MIB
file stored with the Write Object To File command. To use a different file you
can edit the field manually or click the [...] button and use the File Name
dialog to choose a new file.

... [browse] Click this button to choose an MIB file to load into the proxy
object. You can use this button to load an existing MIB file into a new proxy
object, allowing you to easily transfer objects between different scenes.
NOTE If you load an MIB file that’s part of an animated sequence, you’re given the opportunity to load the entire sequence. Confirming automatically turns on animation support and sets the animation parameters to appropriate values. For details, see Animation Support group on page 569.

Scale Adjusts the size of the proxy object. Alternatively, you can use the Scale tool to resize the object.

Display group

Viewport Verts The number of vertices displayed in the point cloud for the proxy object. For best performance, display only enough vertices to make the object recognizable.

Show Point Cloud When on, the proxy object appears as a point cloud (group of vertices) in the viewports. When on, you can combine this with Show Bounding Box (see following).

NOTE When the object is selected, the point cloud always displays.

Show Bounding Box When on, the proxy object appears as a bounding box in the viewports. Available only when Show Point Cloud is on. When Show Point Cloud is off, the bounding box always displays.

[preview window] Shows the thumbnail image stored for the current frame of the MIB file. The thumbnail is generated when you click Write Object To File. The image includes the current scene background. Also, if you turn off Exclude Other Objects on the Preview Generation Options rollout, it includes other objects in the scene.

Animation Support group

These settings control animation playback; animation recording is controlled by the mr Proxy Creation settings (see following) when you save the Proxy object.
On

When enabled, plays animation in the proxy object if the current MIB file is part of an animation sequence. When off, the proxy object remains in the state of the last animation frame.

Saving or loading an animated Proxy object automatically enables animation playback.

The remaining Animation Support settings are available only when animation is enabled.

Frames

The number of frames to use from the animation, starting at the first frame of the animation + the Frame Offset value.

After the last frame plays, the animation repeats, either from the first frame forward again, or, if Ping-Pong Replay is on, back and forth.

Saving or loading an animated Proxy object automatically sets Frames to the correct value.

Replay Speed

Lets you adjust the playback speed as a multiplier. For example, if you load a 100-frame animation and then set Replay Speed to 0.5 (half speed), 3ds Max plays back each frame twice, so the animation takes 200 frames to play back fully. Default=1.0 (full speed).

Frame Offset

Lets you start the animation playback at a frame other than the first. Add this value to the start frame (see Geometry to Write on page 571) to determine at which frame the animation starts playing back.

Ping-Pong Replay

When on, the animation plays forward, then in reverse, then forward again and so on. When off, it plays forward only.

mr Proxy Creation dialog

This dialog opens when you click Write Object To File on page 568 and then enter a file name and click Save. They determine whether and how animation is saved to the proxy file, and how to display the preview.
Geometry to Write Choose the option that specifies how to save deformation animation, such as that produced by modifiers, in the proxy file. Transform animation, such as rotation of the entire object, is not saved.

- **Current Frame** Saves no animation; only the state of the object in the current frame.

- **Active Time Segment** Saves all animation in the active time segment on page 8496.

- **Custom Range** Saves animation only in the frame range you specify with the Start and End values.

Preview Generation group

These settings determine how to display the object preview on page 569, and are saved with the proxy file.

**Include only Source Object in Preview** When on, the preview image contains only the geometry in the proxy object. When off, the preview shows any additional geometry in the scene within the extent of the image zoom (see Automatic Zoom Extents, following). Default=on.
**Automatic Zoom Extents** When on, zooms the preview image to the bounding box of the proxy object before rendering the image. Default=on.

---

**Shapes**

Create panel > Shapes
Create menu > Shapes

A shape is an object made from one or more curved or straight lines. 3ds Max includes the following shape types: *Splines and Extended Splines* on page 577 and *NURBS Curves* on page 2464.

**Using Shapes**

Shapes are 2D and 3D lines and groups of lines that you typically use as components of other objects. Most of the default shapes are made from splines. You use these spline shapes to do the following:

- Generate planar and thin 3D surfaces
- Define loft components such as paths, shapes, and fit curves
- Generate surfaces of revolution
- Generate extrusions
- Define motion paths

3ds Max supplies 11 basic spline shape objects, two types of NURBS curves, and five extended splines. You can quickly create these shapes using mouse or keyboard entry and combine them to form compound shapes. For information about the methods and parameters used to create these shapes, see *Splines and Extended Splines* on page 577.

**Creating Shapes**

To access the shape-creation tools, go to the Create panel and click the Shapes button. You'll find the standard shapes under Splines in the category list, Point Curve and CV Curve under NURBS curves, and WRectangle, Channel, Angle, Tee, and Wide Flange under Extended Splines.

As you add plug-ins, other shape categories might appear in this list.

---

572 | Chapter 6  Creating Geometry
The Object Type rollout contains the spline creation buttons. You can combine one or more of these spline types into a single shape.

**Create Shape from Edges**

You can create shapes from edge selections in mesh objects. In Edit/Editable Mesh objects, at the Edge selection level, in the Edit Geometry rollout, is a button called Create Shape from Edges that creates a spline shape based on selected edges. See [Editable Mesh (Edge)] on page 2209. Similarly, with Editable Poly objects, you can use the Create Shape button at the Edge selection level. See [Editable Poly (Edge)] on page 2269.

**Editable Splines**

You can convert a basic spline to an editable spline object on page 620. The editable spline has a variety of controls that let you directly manipulate it and its sub-objects. For example, at the Vertex sub-object level you can move vertices or adjust their Bezier handles. Editable splines let you create shapes that are less regular, more free-form than the basic spline options.

When you convert a spline to an editable spline, you lose the ability to adjust or animate its creation parameters.

**Renderable Shapes**

When you use a shape to create a 3D object by lofting, extruding, or other means, the shape becomes a renderable 3D object. However, you can make a shape render without making it into a 3D object. There are three basic steps to rendering a shape:

1. On the Rendering rollout of the shape's creation parameters, turn on Enable In Renderer.
2. Specify the thickness for the spline using the Thickness spinner in the Rendering rollout.
3 If you plan to assign a mapped material to the spline, turn on Generate Mapping Coords.

When Enable In Renderer is on, the shape is rendered using a circle as a cross section. Mapping coordinates are generated with U mapped once around the perimeter, and V mapped once along the length.

3ds Max provides control over renderable shapes; viewports, including wireframe viewports, can display the geometry of renderable shapes. The rendering parameters for shapes appear in their own rollout.

The Steps settings affect the number of cross sections in the renderable shape.

Please observe the following:

- When you apply a modifier that converts a shape into a mesh (such as Extrude on page 1425 or Lathe on page 1474), the object automatically becomes renderable, regardless of the state of the Enable in Renderer check box.
You need to turn on the Enable in Renderer check box only when you want to render an unmodified spline shape in the scene.

- As with all objects, a shape's layer must be on for the shape to render. See Layer Properties on page 7956.
- The Object Properties dialog on page 283 also has a Renderable check box, which is turned on by default. Both this check box and the General rollout > Renderable check box must be turned on in order to render a shape.

### Shapes as Planar Objects

A straightforward usage for shapes is 2D cutouts or planar objects. Examples include ground planes, text for signs, and cutout billboards. You create a planar object by applying an Edit Mesh modifier on page 1321 to a closed shape, or by converting it to an editable mesh object on page 2192.

![2D objects](image)

2D objects

You can also apply an Edit Mesh modifier to a 3D shape (for example, a shape whose vertices have been moved vertically away from the construction plane by different amounts) to create a curved surface. The resulting 3D surface often requires manual editing of faces and edges to smooth surface ridges.

### Extruded and Lathed Shapes

You can apply modifiers to a shape to create a 3D object. Two of these modifiers are Extrude and Lathe. Extrude on page 1425 creates a 3D object by adding height to a shape. Lathe on page 1474 creates a 3D object by rotating a shape about an axis.
Lofting Shapes

You create Lofts on page 742 by combining two or more splines in special ways. Shapes form the lofting path, loft cross-sections, and loft fit curves.

Shapes as Animation Paths

You can use shapes to define the position of an animated object. You create a shape and use it to define a path that some other object follows.

Some possible ways for a shape to control animated position are:

- You can use a Path constraint on page 3596 to use a shape to control object motion.
You can convert a shape into position keys using the Motion panel > Trajectories > Convert From function (see Trajectories on page 3411).

See also:
- Edit Modifiers and Editable Objects on page 1052
- Modifying at the Sub-Object Level on page 1054
- Modifier Stack Controls on page 8187

Splines and Extended Splines

Create panel > Shapes > Splines
Create menu > Shapes
Create panel > Shapes > Extended Splines

Splines include the following object types: Line on page 584, Rectangle on page 588, Circle on page 590, Ellipse on page 591, Arc on page 592, Donut on page 596, NGon on page 597, Star on page 599, Text on page 600, Helix on page 605, and Section on page 607. Extended Splines include the following object types: WRectangle on page 611, Channel on page 613, Angle on page 615, Tee on page 617, and Wide on page 618. This topic covers aspects of spline and extended spline creation that are common to all spline object types, including the parameters available in the General rollout.

For parameters unique to a particular spline or extended spline type, see its section.

Procedures

To control starting a new shape manually:

1. On the Create panel, turn off the check box next to the Start New Shape button.
2. Click the Start New Shape button.
   
   Each spline is added to the compound shape. You can tell you are creating a compound shape because all the splines remain selected.
4. Click Start New Shape to complete the current shape and prepare to start another.

Issues to remember about creating shapes:

■ You can go back and change the parameters of a shape containing a single spline after the shape is created.

■ You can create a compound shape by adding splines to a shape: Select the shape, turn off Start New Shape, and then create more splines.

■ You cannot change the parameters of a compound shape. For example, create a compound shape by creating a circle and then adding an arc. Once you create the arc, you cannot change the circle parameters.

To create a spline using keyboard entry:

1. Click a spline creation button.

2. Expand the Keyboard Entry rollout.

3. Enter X, Y, and Z values for the first point.

4. Enter values in any remaining parameter fields.

5. Click Create.

Interface

Object Type rollout (Splines and Extended Splines)
**AutoGrid** Lets you automatically create objects on the surface of other objects by generating and activating a temporary construction plane based on normals of the face that you click.

For more information, see *AutoGrid* on page 2792.

**Start New Shape** A shape can contain a single spline or it can be a compound shape containing multiple splines. You control how many splines are in a shape using the Start New Shape button and check box on the Object Type rollout. The check box next to the Start New Shape button determines when new shapes are created. When the box is on, 3ds Max creates a new shape object for every spline you create. When the box is off, splines are added to the current shape until you click the Start New Shape button.

**Shape Selection buttons** Lets you specify the type of shape to create.

**Name and Color rollout**

Lets you name an object and assign it a viewport color. For details, see *Object Name and Wireframe Color* on page 8182.
Rendering rollout

Lets you turn on and off the renderability of a spline or NURBS curve, specify its thickness in the rendered scene, and apply mapping coordinates.

You can animate render parameters, such as the number of sides, but you cannot animate the Viewport settings.

You can convert the displayed mesh into a mesh object by applying an Edit Mesh or Edit Poly modifier or converting to an editable mesh or editable poly object. If Enable In Viewport is off when converting, closed shapes will be “filled in” and open shapes will contain only vertices; no edges or faces. If Enable In Viewport is on when converting, the system will use the Viewport settings for this mesh conversion. This gives maximum flexibility, and will always give the conversion of the mesh displayed in the viewports.

**Enable In Renderer** When on, the shape is rendered as a 3D mesh using the Radial or Rectangular parameters set for Renderer.
Enable In Viewport  When on, the shape is displayed in the viewport as a 3D mesh using the Radial or Rectangular parameters set for Renderer.

Use Viewport settings  Lets you set different rendering parameters, and displays the mesh generated by the Viewport settings. Available only when Enable in Viewport is turned on.

Generate Mapping Coords  Turn this on to apply mapping coordinates. Default=off.

3ds Max generates the mapping coordinates in the U and V dimensions. The U coordinate wraps once around the spline; the V coordinate is mapped once along its length. Tiling is achieved using the Tiling parameters in the applied material. For more information, see Mapping Coordinates on page 5636.

Real-World Map Size  Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.

Viewport  Choose this to specify Radial or Rectangular parameters for the shape as it will display in the viewports when Enable In Viewport is on.

Renderer  Choose this to specify Radial or Rectangular parameters for the shape as it will display when rendered or when viewed in the viewport when Enable In Viewport is turned on.

Radial  Displays the 3D mesh as a cylindrical object.

Thickness  Specifies the diameter of the viewport or rendered spline mesh. Default=1.0. Range=0.0 to 100,000,000.0.

Splines rendered at thickness of 1.0 and 5.0, respectively

Sides  Sets the number of sides (or facets) for the spline mesh in the viewport or renderer. For example, a value of 4 results in a square cross section.
**Angle** Adjusts the rotational position of the cross-section in the viewport or renderer. For example, if the spline mesh has a square cross section you can use Angle to position a "flat" side down.

**Rectangular** Displays the spline's mesh shape as a rectangle.

**Length** Specifies the size of the cross-section along the local Y axis.

**Width** Specifies the size of the cross-section along the local X axis.

**Angle** Adjusts the rotational position of the cross-section in the viewport or renderer. For example, if you have a square cross-section you can use Angle to position a "flat" side down.

**Aspect** Sets the aspect ratio for rectangular cross-sections. The Lock check box lets you lock the aspect ratio. When Lock is turned on, Width is locked to Length that results in a constant ratio of Width to Length.

**Auto Smooth** If Auto Smooth is turned on, the spline is auto-smoothed using the threshold specified by the Threshold setting below it. Auto Smooth sets the smoothing based on the angle between spline segments. Any two adjacent segments are put in the same smoothing group if the angle between them is less than the threshold angle.

**NOTE** Turning Auto Smooth on for every situation does not always give you the best smoothing quality. Altering the Threshold angle may be necessary or turning Auto Smooth off may produce the best results.

**Threshold** Specifies the threshold angle in degrees. Any two adjacent spline segments are put in the same smoothing group if the angle between them is less than the threshold angle.

**Interpolation rollout**

These settings control how a spline is generated. All spline curves are divided into small straight lines that approximate the true curve. The number of divisions between each vertex on the spline are called steps. The more steps used, the smoother the curve appears.
**Steps** Spline steps can be either adaptive (that is, set automatically by turning on Adaptive) or specified manually.

When Adaptive is off, use the Steps field/spinner to set the number of divisions between each vertex. Splines with tight curves require many steps to look smooth while gentle curves require fewer steps. Range=0 to 100.

**Optimize** When on, removes unneeded steps from straight segments in the spline. Optimize is not available when Adaptive is on. Default=on.

**Adaptive** When off, enables manual interpolation control using Optimize and Steps. Default=off.

When on, Adaptive sets the number of steps for each spline to produce a smooth curve. Straight segments always receive 0 steps.

Optimized spline left and adaptive spline right. Resulting wireframe view of each, respectively, on the right.

The main use for manual interpolation of splines is in morphing or other operations where you must have exact control over the number of vertices created.

**Creation Method rollout**

Many spline tools use the Creation Methods rollout. On this rollout you choose to define splines by either their center point or their diagonal.

**Edge** Your first click defines a point on the side or at a corner of the shape and you drag a diameter or the diagonal corner.
Center Your first click defines the center of the shape and you drag a radius or corner point.

Text on page 600 and Star on page 599 do not have a Creation Methods rollout.

Line on page 584 and Arc on page 592 have unique Creation Methods rollouts that are discussed in their respective topics.

**Keyboard Entry rollout**

You can create most splines using keyboard entry. The process is generally the same for all splines and the parameters are found under the Keyboard Entry rollout. Keyboard entry varies primarily in the number of optional parameters. The image above shows a sample Keyboard Entry rollout for the Circle shape.

The Keyboard Entry rollout contains three fields for the X, Y, and Z coordinates of the initial creation point, plus a variable number of parameters to complete the spline. Enter values in each field and click the Create button to create the spline.

**Line Spline**

Create panel > Shapes > Splines > Object Type rollout > Line

Create menu > Shapes > Line

Use Line to create a free-form spline made of multiple segments.
Procedures

To create a line:

1. Go to the Create panel and choose Shapes.
2. On the Object Type rollout, click the Line button.
3. Choose a creation method.
4. Click or drag the start point. Clicking creates a corner vertex; dragging creates a Bezier vertex.
5. Click or drag additional points. Clicking creates a corner vertex; dragging creates a Bezier vertex.
6. Do one of the following:
   - Right-click to create an open spline.
   - Click the first vertex and click Yes in the "Close spline?" dialog to create a closed spline.

To create a line using rectilinear and angle-snap options:

These two options aid in creating regular shapes:

- While creating a spline with the mouse, press and hold Shift to constrain new points to 90-degree-angle increments from previous points. Use the
default Initial type setting of Corner and click all subsequent points to create fully rectilinear shapes.

- While creating a spline with the mouse, press and hold Ctrl to constrain new points to angle increments determined by the current Angle Snap setting on page 2816. To set this angle, go to Tools menu > Grids And Snaps > Grid And Snap Settings, click the Options tab on page 2828 in the Grid And Snap Settings dialog, and change the value in the Angle (deg) field.

The angle for each new segment relates to the previous segment, so the angle snap works only after you've placed the first two spline vertices (that is, the first segment). Angle Snap need not be enabled for this feature to work.

To create a line from the keyboard:

1. Enter values in the X, Y, and Z fields to specify a vertex coordinate.
2. Click Add Point to add a vertex to the current line at the specified coordinate.
3. Repeat steps 1 and 2 for each additional vertex.
4. Do one of the following:
   - Click Finish to create an open spline.
   - Click Close to connect the current vertex to the first vertex and create a closed spline.

Interface

Automatic Conversion to an Editable Spline

Because the Line object has no dimension parameters to be carried over to the Modify panel, it converts to an editable spline on page 620 when you move from the Create panel to the Modify panel. While you are creating the line, the Create panel displays the original controls, such as Interpolation, Rendering, Creation Method, and Keyboard Entry. After creating the line, when you go to the Modify panel you have immediate access to the Selection and Geometry rollouts to edit the vertices or any part of the shape.

Rendering and Interpolation rollouts

All spline-based shapes share these parameters. See Splines on page 577 for an explanation of these parameters.
Creation Method rollout

Creation method options for lines are different from other spline tools. You choose options to control the type of vertex created when you click or drag vertices.

You can preset the default types of spline vertices during line creation with these settings:

**Initial Type group**

Sets the type of vertex you create when you click a vertex location.

- **Corner**: Produces a sharp point. The spline is linear to either side of the vertex.
- **Smooth**: Produces a smooth, nonadjustable curve through the vertex. The amount of curvature is set by the spacing of the vertices.

**Drag Type group**

Sets the type of vertex you create when you drag a vertex location. The vertex is located at the cursor position where you first press the mouse button. The direction and distance that you drag are used only when creating Bezier vertices.

- **Corner**: Produces a sharp point. The spline is linear to either side of the vertex.
- **Smooth**: Produces a smooth, nonadjustable curve through the vertex. The amount of curvature are set by the spacing of the vertices.
- **Bezier**: Produces a smooth, adjustable curve through the vertex. The amount of curvature and direction of the curve are set by dragging the mouse at each vertex.
Keyboard Entry rollout

Keyboard entry for lines is different from keyboard entry for other splines. Entering keyboard values continues to add vertices to the existing line until you click Close or Finish.

Add Point Adds a new point to the line at the current X/Y/Z coordinates.

Close Closes the shape, adding a final spline segment between the most recent vertex and the first.

Finish Finishes the spline without closing it.

Rectangle Spline

Create panel > Shapes > Splines > Object Type rollout > Rectangle
Create menu > Shapes > Rectangle
Use Rectangle to create square and rectangular splines.

Examples of rectangles
Procedures

To create a rectangle:

1. Go to the Create panel and choose Shapes.
2. Click Rectangle.
3. Choose a creation method.
4. Drag in a viewport to create a rectangle.
   Optionally, press Ctrl while dragging to constrain the spline to a square.

Interface

Rendering and Interpolation rollouts

All spline-based shapes share these parameters. See Splines on page 577 for an explanation of these parameters.

Creation Method rollout

The Rectangle shape uses the standard creation methods of Center or Edge. Most spline-based shapes share the same Creation Method parameters. See Splines on page 577 for an explanation of these parameters.

Parameters rollout

Once you have created a rectangle, you can make changes using the following parameters:

Length Specifies the size of the rectangle along the local Y axis.

Width Specifies the size of the rectangle along the local X axis.

Corner Radius Creates rounded corners. When set to 0, the rectangle contains 90-degree corners.
Circle Spline

Create panel > Shapes > Splines > Object Type rollout > Circle
Create menu > Shapes > Circle
Use Circle to create closed circular splines made of four vertices.

Example of circle

Procedures

To create a circle:

1. Go to the Create panel and choose Shapes.
2. Click Circle.
3. Choose a creation method.
4. Drag in a viewport to draw the circle.

Interface

Rendering and Interpolation rollouts

All spline-based shapes share these parameters. See Splines on page 577 for explanations of these parameters.
Creation Method rollout

The Circle shape uses the standard creation methods of Center or Edge. Most spline-based shapes share the same Creation Method parameters. See Splines on page 577 for an explanation of these parameters.

Parameters rollout

Once you have created a circle, you can make changes using the following parameter:

Radius  Specifies the radius of the circle.

Ellipse Spline

Create panel > Shapes > Splines > Object Type rollout > Ellipse
Create menu > Shapes > Ellipse

Use Ellipse to create elliptical and circular splines.

Examples of ellipses

Procedures

To create an ellipse:

1  Go to the Create panel and choose Shapes.
2  Click Ellipse.
3  Choose a creation method.
4 Drag in a viewport to draw the ellipse. Optionally, press Ctrl while dragging to constrain the spline to a circle.

Interface

Rendering and Interpolation rollouts

All spline-based shapes share these parameters. See Splines on page 577 for explanations of these parameters.

Creation Method rollout

The Ellipse shape uses the standard creation methods of Center or Edge. Most spline-based shapes share the same Creation Method parameters. See Splines on page 577 for an explanation of these parameters.

Parameters rollout

Once you have created an Ellipse, you can make changes using the following parameters:

- **Length** Specifies the size of the Ellipse along the local Y axis.
- **Width** Specifies the size of the Ellipse local X axis.

**Arc Spline**

Create panel > Shapes > Splines > Object Type rollout > Arc
Create menu > Shapes > Arc
Use Arc to create open and closed circular arcs made of four vertices.
Procedures

To create an arc using the end-end-middle method:

1. Go to the Create panel and choose Shapes.
2. Click Arc.
3. Choose the End-End-Middle creation method.
4. Drag in a viewport to set the two ends of the arc.
5. Release the mouse button, then move the mouse and click to specify a third point on an arc between the two endpoints.

Creating an arc using the End-End-Middle creation method

To create an arc using the center-end-end method:

1. Go to the Create panel and choose Shapes.
2. Click Arc.
3. Choose the Center-End-End creation method.
4. Press the mouse button to define the center of the arc.
5. Drag and release the mouse button to specify the start point of the arc.
Move the mouse and click to specify the other end of the arc.

Creating an arc using the Center-End-End creation method

**Interface**

**Rendering and Interpolation rollouts**

All spline-based shapes share these parameters. See Splines on page 577 for an explanation of these parameters.

**Creation Method rollout**

These options determine the sequence of mouse clicks involved in the creation of the arc.

**End-End-Middle** Drag and release to set the two endpoints of the arc, and then click to specify the third point between the two endpoints.

**Center-End-End** Press the mouse button to specify the center point of the arc, drag and release to specify one endpoint of the arc, and click to specify the other endpoint of the arc.
Parameters rollout

Once you have created an arc, you can make changes using the following parameters:

**Radius** Specifies the arc radius.

**From** Specifies the location of the start point as an angle measured from the local positive X axis.

**To** Specifies the location of the end point as an angle measured from the local positive X axis.

**Pie Slice** When on, creates a closed spline in the form of a pie. The start point and end point are connected to the center with straight segments.

Closed pie slice arcs

**Reverse** When on, the direction of the arc spline is reversed, and the first vertex is placed at the opposite end of an open arc. As long as the shape remains an original shape (and not an editable spline), you can switch its direction by toggling Reverse. Once the arc is converted to an editable spline, you can use Reverse at the Spline sub-object level to reverse direction.
Donut Spline

Create panel > Shapes > Splines > Object Type rollout > Donut
Create menu > Shapes > Donut
Use Donut to create closed shapes from two concentric circles. Each circle is made of four vertices.

Example of donut

Procedures

To create a donut:

1. Go to the Create panel and choose Shapes.
2. Click Donut.
3. Choose a creation method.
4. Drag and release the mouse button to define the first donut circle.
5. Move the mouse and then click to define the radius of the second concentric donut circle.
   The second circle can be larger or smaller than the first.
Interface

Rendering and Interpolation rollouts

All spline-based shapes share these parameters. See Splines on page 577 for explanations of these parameters.

Creation Method rollout

The Donut shape uses the standard creation methods of Center or Edge. Most spline-based shapes share the same Creation Method parameters. See Splines on page 577 for an explanation of these parameters.

Parameters rollout

Once you have created a donut, you can make changes using the following parameters:

- **Radius 1** Sets the radius of the first circle.
- **Radius 2** Sets the radius of the second circle.

NGon Spline

Create panel > Shapes > Splines > Object Type rollout > NGon
Create menu > Shapes > NGon

Use NGon to create closed flat-sided or circular splines with any number (N) of sides or vertices.

Examples of NGons
Procedures

To create an NGon:

1. Go to the Create panel and choose Shapes.
2. Click NGon.
3. Choose a creation method.
4. Drag and release the mouse button in a viewport to draw the NGon.

Interface

Rendering and Interpolation rollouts

All spline-based shapes share these parameters. See Splines on page 577 for an explanation of these parameters.

Creation Method rollout

The NGon shape uses the standard creation methods of Center or Edge. Most spline-based shapes share the same Creation Method parameters. See Splines on page 577 for an explanation of these parameters.

Parameters rollout

Once you have created an NGon, you can make changes using the following parameters:

- **Radius**: Specifies the NGon radius. You can use either of two methods to specify the radius:
  - **Inscribed**: The radius from the center to the corners of the NGon
- **Circumscribed**  The radius from the center to the sides of the NGon.

**Sides**  Specifies the number of sides and vertices used by the NGon. Range=3 to 100.

**Corner Radius**  Specifies the degree of rounding to apply to the corners of the NGon. A setting of 0 specifies a standard unrounded corner.

**Circular**  When on, specifies a circular NGon.

### Star Spline

Create panel > Shapes > Splines > Object Type rollout > Star

Create menu > Shapes > Star

Use Star to create closed star-shaped splines with any number of points. Star splines use two radiiuses to set the distance between the outer points and inner valleys.

![Examples of stars](image)

**Procedures**

**To create a star:**

1. Go to the Create panel and choose Shapes.
2. Click Star.
3. Drag and release the mouse button to define the first star radius.
4. Move the mouse and then click to define the second star radius.
Interface

Rendering and Interpolation rollouts

All spline-based shapes share these parameters. See Splines on page 577 for explanations of these parameters.

Parameters rollout

Once you have created a star, you can make changes using the following parameters:

**Radius 1** Specifies the radius of the inner vertices (the valley) of the star.

**Radius 2** Specifies the radius of the outer vertices (the points) of the star.

**Points** Specifies the number of points on the star. Range=3 to 100.

A star has twice as many vertices as the specified number of points. Half the vertices lie on one radius, forming points, and the remaining vertices lie on the other radius, forming valleys.

**Distortion** Rotates the outer vertices (the points) about the center of the star. This produces a sawtooth affect.

**Fillet Radius 1** Rounds the inner vertices (the valleys) of the star.

**Fillet Radius 2** Rounds the outer vertices (the points) of the star.

Text Spline

Create panel > Shapes > Splines > Object Type rollout > Text

Create menu > Shapes > Text
Use Text to create splines in the shape of text.

The text can use any Windows font installed on your system, or a Type 1 PostScript font installed in the directory pointed to by the Fonts path on the Configure System Paths dialog on page 8293. Because fonts are loaded only at first use, changing the font path later has no immediate effect: once you have used the font manager, you must restart 3ds Max before you can use a new font path.

Examples of text

You can edit the text in the Create panel, or later in the Modify panel.

**Using Text Shapes**

Text shapes maintain the text as an editable parameter. You can change the text at any time. If the font used by your text is deleted from the system, 3ds Max still properly displays the text shape. However, to edit the text string in the edit box you must choose an available font.

The text in your scene is just a shape where each letter and, in some cases, pieces of each letter are individual splines. You can apply modifiers like Edit Spline on page 1424, Bend on page 1165, and Extrude on page 1425 to edit Text shapes just like any other shape.

**Procedures**

**To create text:**

1. Go to the Create panel and choose Shapes.
2. Click Text.
Enter text in the Text box.

Do either of the following to define an insertion point:
- Click in a viewport to place the text in the scene.
- Drag the text into position and release the mouse button.

**To enter a special Windows character:**

1. Hold down the Alt key.
2. Enter the character’s numeric value on the numeric keypad.
   - You must use the numeric keypad, not the row of numbers above the alphabetic keys.
   - For some characters, you must enter a leading zero. For example, 0233 to enter an e with an acute accent.
3. Release the Alt key.

**Interface**

Settings available for text include kerning, leading, justification, multiple lines, and a manual update option.

**Rendering and Interpolation rollouts**

All spline-based shapes share these parameters. See Splines on page 577 for an explanation of these parameters.
Once you have created text, you can make changes using the following parameters:

**Font list** Choose from a list of all available fonts. Available fonts include:
- Fonts installed in Windows.
- Type 1 PostScript fonts located in the directory pointed to by the Fonts path on the Configure System Paths dialog on page 8293.

**Italic style button** Toggles italicized text.

**Underline style button** Toggles underlined text.

**Align Left** Aligns text to the left side of its bounding box.
**Center** Aligns text to the center of its bounding box.

**Align Right** Aligns text to the right side of its bounding box.

**Justify** Spaces all lines of text to fill the extents of the bounding box.

**NOTE** The four text-alignment buttons require multiple lines of text for effect because they act on the text in relation to its bounding box. If there's only one line of text, it's the same size as its bounding box.

**Size** Sets the text height where the height measuring method is defined by the active font. The first time you enter text, the default size is 100 units.

**Kerning** Adjusts the kerning (the distance between letters).

**Leading** Adjusts the leading (the distance between lines). This has an effect only when multiple lines of text are included in the shape.

**Text edit box** Allows for multiple lines of text. Press Enter after each line of text to start the next line.

- The initial session default is "VIZ Text."
- The initial session default is "MAX Text."
- The edit box does not support word wrap.
- You can cut and paste single- and multi-line text from the Clipboard.

**Update group**

These options let you select a manual update option for situations where the complexity of the text shape is too high for automatic updates.

**Update** Updates the text in the viewport to match the current settings in the edit box. This button is available only when Manual Update is on.

**Manual Update** When on, the text that you type into the edit box is not shown in the viewport until you click the Update button.
**Helix Spline**

Create panel > Shapes > Splines > Object Type rollout > Helix
Create menu > Shapes > Helix
Use Helix to create open flat or 3D helices or spirals.

![Example of helixes](image)

**Examples of helixes**

**Procedures**

**To create a helix:**

1. Go to the Create panel and choose Shapes.
2. Click Helix.
3. Choose a creation method.
4. Press the mouse button to define the first point of the Helix start circle.
5. Drag and release the mouse button to define the second point of the Helix start circle.
6. Move the mouse and then click to define the height of the Helix.
7. Move the mouse and then click to define the radius of the Helix end.

**Interface**

**Rendering rollout**

All spline-based shapes share these parameters. See Splines on page 577 for explanations of these parameters.
Interpolation

The helix differs from other spline-based shapes in that it always uses *adaptive interpolation*: the number of vertices in a helix is determined by the number of turns.

Creation Method rollout

The Helix shape uses the standard creation methods of Center or Edge. Most spline-based shapes share the same Creation Method parameters. See Splines on page 577 for an explanation of these parameters.

Parameters rollout

Once you have created a helix, you can make changes using the following parameters:

**Radius 1** Specifies the radius for the Helix start.

**Radius 2** Specifies the radius for the Helix end.

**Height** Specifies the height of the Helix.

**Turns** Specifies the number of turns the Helix makes between its start and end points.

**Bias** Forces the turns to accumulate at one end of the helix. Bias has no visible affect when the height is 0.0.
Helical spline varied only by bias settings

- A bias of –1.0 forces the turns toward the start of the helix.
- A bias of 0.0 evenly distributes the turns between the ends.
- A bias of 1.0 forces the turns toward the end of the helix.

CW/CCW The direction buttons set whether the Helix turns clockwise (CW) or counterclockwise (CCW).

Section Spline

Create panel > Shapes > Splines > Object Type rollout > Section
Create menu > Shapes > Section
Section is a special type of spline that generates shapes based on a cross-sectional slice through mesh objects.

The Section object appears as a bisected rectangle. You simply move and rotate it to slice through one or more mesh objects, and then click the Create Shape button to generate a shape based on the 2D intersection.
Red line shows the section shape based on the structure.

Procedures

To create and use a section shape:

1. Go to the Create panel and choose Shapes.
2. Click Section.
3. Drag a rectangle in the viewport in which you want to orient the plane. (For example, create it in the Top viewport to place the Section object parallel with the XY home grid.)
   The Section object appears as a simple rectangle with crossed lines indicating its center. With the default settings, the rectangle is for display purposes only, because the effect of the Section object extends along its plane to the full extents of the scene.
4. Move and rotate the section so that its plane intersects mesh objects in the scene.
   Yellow lines are displayed where the sectional plane intersects objects.
On the Create panel, click Create Shape, enter a name in the resulting dialog, and click OK. An editable spline on page 620 is created, based on the displayed cross sections.

**Interface**

**Rendering and Interpolation rollouts**

All spline-based shapes share these parameters. See Splines on page 577 for an explanation of these parameters.

**Section Parameters rollout**

Create Shape Creates a shape based on the currently displayed intersection lines. A dialog is displayed in which you can name the new object. The resulting shape is an editable spline consisting of curve segments and corner vertices, based on all intersected meshes in the scene.

**Update group**

Provides options for specifying when the intersection line is updated.
When Section Moves Updates the intersection line when you move or resize the Section shape.

When Section Selected Updates the intersection line when you select the section shape, but not while you move it. Click the Update Section button to update the intersection.

Manually Updates the intersection line only when you click the Update Section button.

Update Section Updates the intersection to match the current placement of the Section object when using When Section Selected or Manually option.

NOTE When using When Section Selected or Manually, you can offset the generated cross section from the position of the intersected geometry. As you move the section object, the yellow cross-section lines move with it, leaving the geometry behind. When you click Create Shape, the new shape is generated at the displayed cross-section lines in the offset position.

Section Extents group

Choose one of these options to specify the extents of the cross-section generated by the section object.

Infinite The section plane is infinite in all directions, resulting in a cross section at any mesh geometry in its plane.

Section Boundary The cross-section is generated only in objects that are within or touched by the boundary of the section shape.

Off No cross section is displayed or generated. The Create Shape button is disabled.

Color swatch Click this to set the display color of the intersection.

Section Size rollout

![Section Size rollout](image)
Provides spinners that let you adjust the length and width of the displayed section rectangle.

**Length/Width** Adjust the length and width of the displayed section rectangle.

**NOTE** If you convert the section grid to an editable spline, it's converted to a shape based on the current cross section.

---

**Extended Splines**

Extended splines are enhancements to the original spline set.

**WRectangle Spline**

Create panel > Shapes > Extended Splines > Object Type rollout > WRectangle
Create menu > Shapes > WRectangle

Use WRectangle to create closed shapes from two concentric rectangles. Each rectangle is made of four vertices. The WRectangle is similar to the Donut tool except it uses rectangles instead of circles.

WRectangle stands for “walled rectangle”.

**Example of WRectangle**

**Procedures**

**To create a wrectangle:**

1. Go to the Create panel and choose Shapes.
2. Open the Shapes List and choose Extended Splines.
3  Click WRectangle.
4  Drag and release the mouse button to define the outer rectangle.
5  Move the mouse and then click to define the inner rectangle.

Interface

Rendering and Interpolation rollouts

All spline-based shapes share these parameters. For explanations, see Splines and Extended Splines on page 577.

Creation Method rollout

The WRectangle shape uses the standard creation methods of Center or Edge. Most spline-based shapes share the same Creation Method parameters. For explanations, see Splines and Extended Splines on page 577.

Parameters rollout

Length  Controls the height of the wrectangle section.
Width  Controls the width of the wrectangle section.
Thickness  Controls the thickness of the walls of the wrectangle.
Sync Corner Fillets  When turned on, Corner Radius 1 controls the radius of both the interior and exterior corners of the wrectangle. It also maintains the thickness of the section. Default=on.
Corner Radius 1 Controls the radius of all four interior and exterior corners of the section.
If Sync Corner Fillets is turned off, Corner Radius 1 controls the radius of the four exterior corners of the rectangle.

Corner Radius 2 Controls the radius of the four interior corners of the rectangle.
Corner Radius 2 is only available when Sync Corner Fillets is turned off.

NOTE Take care when adjusting these settings. There are no constraining relationships between them. Therefore, it’s possible to set an inside radius (Corner Radius 2) that is greater than the length and width of the sides.

Channel Spline

Create panel > Shapes > Extended Splines > Object Type rollout > Channel
Create menu > Shapes > Channel

Use Channel to create a closed “C” shaped spline. You have the option to specify the interior and exterior corners between the vertical web and horizontal legs of the section.

Example of Channel

Procedures

To create a channel:

1. Go to the Create panel and choose Shapes.
2. Open the Shapes List and select Extended Splines.
3. Click Channel.
4 Drag and release the mouse button to define the outer perimeter of the channel.

5 Move the mouse and then click to define the thickness of the walls of the channel.

Interface

Rendering and Interpolation rollouts

All spline-based shapes share these parameters. For explanations, see Splines and Extended Splines on page 577.

Creation Method rollout

The Channel shape uses the standard creation methods of Center or Edge. Most spline-based shapes share the same Creation Method parameters. For explanations, see Splines and Extended Splines on page 577.

Parameters rollout

![Parameters rollout image]

**Length** Controls the height of the vertical web of the channel.

**Width** Controls the width of the top and bottom horizontal legs of the channel.

**Thickness** Controls the thickness of both legs of the angle.

**Sync Corner Fillets** When turned on, Corner Radius 1 controls the radius of both the interior and exterior corners between the vertical web and horizontal legs. It also maintains the thickness of the channel. Default=on.
Corner Radius 1 Controls the exterior radius between the vertical web and horizontal legs of the channel.

Corner Radius 2 Controls the interior radius between the vertical web and horizontal legs of the channel.

**NOTE** Take care when adjusting these settings. There are no constraining relationships between them. Therefore, it's possible to set an inside radius (Corner Radius 2) that is greater than the length of the web or width of the legs.

**Angle Spline**

Create panel > Shapes > Extended Splines > Object Type rollout > Angle
Create menu > Shapes > Angle

Use Angle to create a closed “L” shaped spline. You have the option to specify the radii of the corners between the vertical and horizontal legs of the section.

![Example of Angle](image)

**Procedures**

**To create an Angle spline:**

1. Go to the Create panel and choose Shapes.
2. Open the Shapes List and select Extended Splines.
3. Click Angle.
4. Drag and release the mouse button to define the initial size of the angle.
5. Move the mouse and then click to define the thickness of the walls of the angle.
Interface

Rendering and Interpolation rollouts

All spline-based shapes share these parameters. For explanations, see Splines and Extended Splines on page 577.

Creation Method rollout

The Angle shape uses the standard creation methods of Center or Edge. Most spline-based shapes share the same Creation Method parameters. For explanations, see Splines and Extended Splines on page 577.

Parameters rollout

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Length</th>
<th>Width</th>
<th>Thickness</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
</tr>
</tbody>
</table>

- **Sync Corner Fillets** When turned on, Corner Radius 1 controls the radius of both the interior and exterior corners between the vertical and horizontal legs. It also maintains the thickness of the section. Default=on.

- **Corner Radius 1** Controls the exterior radius between the vertical and horizontal legs of the angle.

- **Corner Radius 2** Controls the interior radius between the vertical and horizontal legs of the angle.
**Edge Radii** Controls the interior radius at the outermost edges of the vertical and horizontal legs.

**NOTE** Take care when adjusting these settings. There are no constraining relationships between them. Therefore, it's possible to set an inside radius (Corner Radius 2) that is greater than the length or width of the legs of the angle.

---

**Tee Spline**

Create panel > Shapes > Extended Splines > Object Type rollout > Tee

Create menu > Shapes > Tee

Use Tee to create a closed T-shaped spline. You can specify the radius of the two interior corners between the vertical web and horizontal flange of the section.

---

![Example of Tee](image)

**Example of Tee**

**Procedures**

**To create a Tee spline:**

1. Go to the Create panel and choose Shapes.
2. Open the Shapes List and select Extended Splines.
3. Click Tee.
4. Drag and release the mouse button to define the initial size of the tee.
5. Move the mouse and then click to define the thickness of the walls of the tee.
Interface

Rendering and Interpolation rollouts

All spline-based shapes share these parameters. For explanations, see Splines and Extended Splines on page 577.

Creation Method rollout

The Tee shape uses the standard creation methods of Center or Edge. Most spline-based shapes share the same Creation Method parameters. For explanations, see Splines and Extended Splines on page 577.

Parameters rollout

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Length: 0.0</td>
</tr>
<tr>
<td>Width: 0.0</td>
</tr>
<tr>
<td>Thickness: 0.0</td>
</tr>
<tr>
<td>Corner Radius: 0.0</td>
</tr>
</tbody>
</table>

Length Controls the height of the vertical web of the tee.

Width Controls the width of the flange crossing the tee.

Thickness Controls the thickness of the web and flange.

Corner Radius Controls the radius of the two interior corners between the vertical web and horizontal flange of the section.

NOTE Take care when adjusting these settings. There are no constraining relationships between them. Therefore, it's possible to set a radius (Corner Radius) that is greater than the length of the web or width of the flange.

Wide Flange Spline

Create panel > Shapes > Extended Splines > Object Type rollout > Wide Flange
Create menu > Shapes > Wide Flange
Use Wide Flange to create a closed spline shaped like a capital letter I. You can specify the interior corners between the vertical web and horizontal flanges of the section.

Example of Wide Flange

**Procedures**

To create a Wide Flange spline:

1. Go to the Create panel and choose Shapes.
2. Open the Shapes List and select Extended Splines.
3. Click Wide Flange.
4. Drag and release the mouse button to define the initial size of the wide flange.
5. Move the mouse and then click to define the thickness of the walls of the wide flange.

**Interface**

**Rendering and Interpolation rollouts**

All spline-based shapes share these parameters. For explanations, see Splines and Extended Splines on page 577.

**Creation Method rollout**

The Wide Flange shape uses the standard creation methods of Center or Edge. Most spline-based shapes share the same Creation Method parameters. For explanations, see Splines and Extended Splines on page 577.
Parameters rollout

![Parameters Rollout](image)

**Length** Controls the height of the vertical web of the wide flange.

**Width** Controls the width of the horizontal flanges crossing the wide flange.

**Thickness** Controls the thickness of the web and flanges.

**Corner Radius** Controls the radius of the four interior corners between the vertical web and horizontal flanges.

**NOTE** Take care when adjusting these settings. There are no constraining relationships between them. Therefore, it's possible to set a radius (Corner Radius) that is greater than the length of the web or width of the flanges.

---

**Editable Spline**

Create or select a spline > Modify panel > Right-click spline entry in the stack display > Convert To: Editable Spline

Create a line > Modify panel

Create or select a spline > Right-click the spline > Transform (lower-right) quadrant of the quad menu > Convert To: > Convert to Editable Spline

Editable Spline provides controls for manipulating an object as a spline object and at three sub-object levels: vertex, segment, and spline.

The functions in Editable Spline are the same as those in the Edit Spline modifier on page 1424. The exception is that when you convert an existing spline shape to an editable spline, the creation parameters are no longer accessible or animatable. However, the spline's interpolation settings (step settings) remain available in the editable spline.

When a spline-editing operation (typically, moving a segment or vertex) causes end vertices to overlap, you can use the Weld on page 640 command to weld...
the overlapping vertices together or the **Fuse** on page 641 command if you want the two overlapping vertices to occupy the same point in space but remain separate vertices.

---

**NOTE** Welding coincident vertices is controlled by the **End Point Auto-Welding feature** on page 7.

---

### Show End Result

If you have several modifiers higher in the modifier stack, and want to see the results of edits in an Edit Spline modifier or Editable Spline object, then turn on **Show End Result** on the Modify panel. As you edit the spline network, you’ll be able to see the result of modifiers above the Editable Spline object. This is useful for Surface Tools work where you add a Surface modifier above an Editable Spline object in the modifier stack.

**See also:**
- [Edit Modifiers and Editable Objects](#) on page 1052
- [Modifying at the Sub-Object Level](#) on page 1054
- [Modifier Stack Controls](#) on page 8187

### Procedures

To **produce an editable spline object**, first select the shape, and then do one of the following:

1. Right-click the shape entry in the stack display and choose **Convert To: Editable Spline**.

2. In a viewport, right-click the object and choose Convert To: > **Convert to Editable Spline** from the Transform (lower-right) quadrant of the quad menu.

3. Create a shape with two or more splines by first turning off **Start New Shape** (on the Create panel). Any shape made up of two or more splines is automatically an editable spline.

4. Apply an Edit Spline modifier to a shape, and then collapse the stack. If you use the **Collapse utility** on page 2022 to collapse the stack, be sure to choose Output Type > **Modifier Stack Result**.
5 Import a .shp file.
6 Merge a shape from a 3ds Max file.

To select shape sub-objects:
1 Expand the object’s hierarchy in the stack display and choose a sub-object level, or click one of the sub-object buttons at the top of the Selection rollout.

You can also right-click the object in the viewports and choose a sub-object level from the quad menu: Tools 1 (upper-left) quadrant > Sub-objects > Choose the sub-object level.

2 Click a selection or transform tool, and then select sub-objects using standard click or region-selection techniques.

Because sub-object selections can be complex, you might consider using one of the following techniques to prevent clearing the sub-object selection by accident:
■ Use Lock Selection on page 8079.
■ Name the sub-object selection (see Named Selection Sets List on page 185).

To clone sub-object selections:
■ Hold down the Shift key while transforming the sub-objects.

You can clone segment and spline sub-objects, but not vertices.

To draw a spline cage:
1 Select a segment sub-object on a spline.
2 On the Geometry rollout in the Connect Copy group, turn on Connect.
3 Hold down the Shift key and transform the selected segment. You can move, rotate or scale using the transform gizmo to control the direction. Notice that with Connect Copy on, new splines are drawn between the locations of the segment and its clone.

Tip Use Area Selection or Fuse before selecting and moving these vertices. They will not move together as they do with the Cross-Section modifier. Or use Fuse to keep the vertices together.
Interface

The following controls are available at the object (top) level and at all sub-object levels.

Rendering and Interpolation rollouts

These creation parameters appear in these rollouts for editable splines. For splines to which the Edit Spline modifier has been applied, creation parameters are available by selecting the object type entry (for example, Circle or NGon) at the bottom of the modifier stack on page 8187.

Rendering rollout

Controls here let you turn on and off the renderability of the shape, specify its thickness in the rendered scene, and apply mapping coordinates. The spline mesh can be viewed in the viewports. You can animate the render parameters, such as the number of sides. Viewport settings cannot be animated.
You can also convert the displayed mesh into a mesh object by applying an Edit Mesh modifier or converting to an Editable Mesh. The system will use the Viewport settings for this mesh conversion if Use Viewport Settings is turned on; otherwise it will use the Renderer settings. This gives maximum flexibility, and will always give the conversion of the mesh displayed in the viewports.

**Enable In Renderer** When on, the shape is rendered as a 3D mesh using the Radial or Rectangular parameters set for Renderer.

**Enable In Viewport** When on, the shape is displayed in the viewport as a 3D mesh using the Radial or Rectangular parameters set for Renderer.

**Use Viewport settings** Lets you set different rendering parameters, and displays the mesh generated by the Viewport settings. Available only when Enable in Viewport is turned on.

**Generate Mapping Coords** Turn this on to apply mapping coordinates. Default=off.

The U coordinate wraps once around the thickness of the spline; the V coordinate is mapped once along the length of the spline. Tiling is achieved using the Tiling parameters in the material itself.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material’s Coordinates rollout on page 6201. Default=off.

**Viewport** Choose this to specify Radial or Rectangular parameters for the shape as it will display in the viewport when Enable In Viewport is turned on.

**Renderer** Choose this to specify Radial or Rectangular parameters for the shape as it will display when rendered or when viewed in the viewport when Enable In Viewport is turned on.

**Radial** Displays the 3D mesh as a cylindrical object.

- **Thickness** Specifies the diameter of the viewport or rendered spline mesh. Default=1.0. Range=0.0 to 100,000,000.0.
Splines rendered at thickness of 1.0 and 5.0, respectively

- **Sides** Sets the number of sides (or facets) for the spline mesh in the viewport or renderer. For example, a value of 4 results in a square cross section.

- **Angle** Adjusts the rotational position of the cross-section in the viewport or renderer. For example, if the spline mesh has a square cross section you can use Angle to position a "flat" side down.

**Rectangular** Displays the spline's mesh shape as rectangular.

- **Aspect** Sets the aspect ratio for rectangular cross-sections. The Lock check box lets you lock the aspect ratio. When Lock is turned on, Width is locked to Depth that results in a constant ratio of Width to Depth.

- **Length** Specifies the size of the cross-section along the local Y axis.

- **Width** Specifies the size of the cross-section along the local X axis.

- **Angle** Adjusts the rotational position of the cross-section in the viewport or renderer. For example, if you have a square cross-section you can use Angle to position a "flat" side down.

- **Aspect** The ratio of length to width. This control is linked to the Length setting: when Aspect is unlocked, changing Length changes Aspect and vice-versa. When Aspect is locked, the control is unavailable, and changing Length or Width automatically changes the Width or Length (respectively) to maintain the current aspect ratio.

**Auto Smooth** When on, the spline is auto-smoothed using the threshold specified by the Threshold setting. Auto Smooth sets the smoothing based on the angle between spline segments. Any two adjacent segments are put in the
same smoothing group if the angle between them is less than the threshold angle.

**Threshold** Specifies the threshold angle in degrees. Any two adjacent spline segments are put in the same smoothing group if the angle between them is less than the threshold angle.

**Interpolation rollout**

The Interpolation controls set how 3ds Max generates a spline. All spline curves are divided into small straight lines that approximate the true curve. The number of divisions between each vertex on the spline is called *steps*. The more steps used, the smoother the curve appears.

![Interpolation rollout](image)

Splines used in above lathed objects contained two steps (left) and 20 steps (right)

**Steps** Use the Steps field to set the number of divisions, or steps, 3ds Max uses between each vertex. Splines with tight curves require many steps to look smooth while gentle curves require fewer steps. Range=0 to 100.

Spline steps can be either adaptive or manually specified. The method used is set by the state of the Adaptive check box. The main use for manual interpolation is to create splines for morphing or other operations where you must have exact control over the number of vertices created.

**Optimize** When on, removes unneeded steps from straight segments in the spline. Default=on.
NOTE Optimize is not available when Adaptive is on.

Optimize was used to create spline in this lathed object.

Adaptive When on, automatically sets the number of steps for each spline to produce a smooth curve. Straight segments always receive 0 steps. When off, enables manual interpolation control using Optimize and Steps. Default=off.

Selection rollout
Provides controls for turning different sub-object modes on and off, working with named selections and handles, display settings, and information about selected entities.

When you first access the Modify panel with an editable spline selected, you're at the Object level, with access to several functions available as described in *Editable Spline (Object)* on page 630. You can toggle the sub-object modes and access relevant functions by clicking sub-object buttons at the top of the Selection rollout.

You can work with parts of shapes and splines using shape sub-object selection of the Editable Spline object. Clicking a button here is the same as selecting a sub-object type in the Modifier List. Click the button again to turn it off and return to object selection level.

- **Vertices** Define points and curve tangents.
- **Segments** Connect vertices.
- **Splines** Are a combination of one or more connected segments.

**Named Selections group**

- **Copy** Places a named selection into the copy buffer.
- **Paste** Pastes a named selection from the copy buffer.
- **Lock Handles** Normally you can transform the tangent handles of only one vertex at a time, even when multiple vertices are selected. Use the Lock Handles controls to transform multiple Bezier and Bezier Corner handles simultaneously.
- **Alike** As you drag the handle of an incoming vector, all incoming vectors of the selected vertices move simultaneously. Likewise, moving the outgoing tangent handle on one vertex moves the outgoing tangent handle for all selected vertices.
- **All** Any handle you move affects all handles in the selection, regardless of whether they're broken. This option is also useful when working with a single Bezier Corner vertex when you want to move both handles.
Shift+click a handle to "break" the tangent and move each handle independently. The Alike option must be chosen to break the tangent.

**Area Selection** Lets you select automatically all vertices within a specific radius of the vertex you click. At the Vertex sub-object level, turn on Area Selection, and then set the radius with the spinner to the right of the Area Selection check box. This is useful when moving vertices that have been created using Connect Copy or Cross Section button.

**Segment End** Select a vertex by clicking a segment. In Vertex sub-object, turn on and select a segment close to the vertex that you want selected. Use this when there are a number of coincident vertices and you want to select a vertex on a specific segment. The cursor changes to a cross when it is over a segment. By holding down the Ctrl key you can add to the selection.

**Select By** Selects vertices on the selected spline or segment. First select a spline or segment in sub-object spline or segment, then turn on vertex sub-object and click Select By and choose Spline or Segment. All the vertices on the selected spline or segment are selected. You can then edit the vertices.

**Display group**

**Show Vertex Numbers** When on, 3ds Max displays vertex numbers next to the selected spline's vertices at any sub-object level.

**Selected Only** When on, the vertex number or numbers appear only next to selected vertices.

**Soft Selection**

For information on the Soft Selection rollout settings, see **Soft Selection Rollout** on page 2014.

**Selection Info**

At the bottom of the Selection rollout is a text display giving information about the current selection. If 0 or more than one sub-object is selected, the text gives the number selected.

At the Vertex and Segment sub-object levels, if one sub-object is selected, the text gives the identification numbers of the current spline (with respect to the current object) and of the current selected sub-object. Each spline object contains a spline number 1; if it contains more than one spline, the subsequent splines are numbered consecutively higher.
When a single spline is selected at the Spline sub-object level, the first line displays the identification number of the selected spline and whether it’s open or closed, and the second line displays the number of vertices it contains. When more than one spline is selected, the number of splines selected is displayed on the first line, and the total number of vertices they contain is displayed on the second line.

**Geometry rollout**

The Geometry rollout provides functions for editing a spline object and sub-objects. The functions available at the spline object level (when no sub-object level is active; see Editable Spline (Object) on page 630) are also available at all sub-object levels, and work exactly the same at each level. Other functions are also available, depending on which sub-object level is active. Those that apply to other sub-object levels are unavailable.

**Editable Spline (Object)**

Select an editable spline > Modify panel > Editable spline (not a sub-object level) selected in the modifier stack

Select an editable spline > Right-click the spline > Tools 1 (upper-left) quadrant of the quad menu > Sub-objects > Top-level

The functions available at the editable spline object level (that is, when no sub-object level is active) are also available at all sub-object levels, and work exactly the same at each level.

**Interface**

**Rendering, Interpolation, and Selection rollouts**

See the Editable Spline topic for information on the Rendering and Interpolation rollouts on page 623, and Selection rollout on page 627 settings.
**New Vertex Type group** The radio buttons in this group let you determine the tangency of the new vertices created when you Shift+Clone segments or splines. If you later use Connect Copy, vertices on the splines that connect the original segment or spline to the new one will have the type specified in this group.

This setting has no effect on the tangency of vertices created using tools such as the Create Line button, Refine, and so on.

- **Linear** New vertices will have linear tangency.
- **Smooth** New vertices will have smooth tangency. When this option is chosen, new vertices that overlap are automatically welded.
- **Bezier** New vertices will have bezier tangency.
- **Bezier Corner** New vertices will have bezier corner tangency.
Create Line Adds more splines to the selected spline. These lines are separate spline sub-objects; create them in the same way as the line spline on page 584. To exit line creation, right-click or click to turn off Create Line.

Break Splits a spline at the selected vertex or vertices. Select one or more vertices and then click Break to create the split. There are now two superimposed non-connected vertices for every previous one, allowing the once-joined segment ends to be moved away from each other.

Attach Lets you attach another spline in the scene to the selected spline. Click the object you want to attach to the currently selected spline object. The object you're attaching to must also be a spline.

Unattached splines (left) and attached splines (right)

When you attach an object, the materials of the two objects are combined in the following way:

- If the object being attached does not have a material assigned, it inherits the material of the object it is being attached to.
- Likewise if the object you're attaching to doesn't have a material, it inherits the material of the object being attached.
- If both objects have materials, the resulting new material is a multi/sub-object material on page 6120 that encompasses the input materials. A dialog appears offering three methods of combining the objects' materials and material IDs. For more information, see Attach Options Dialog on page 2233.

Attached shapes lose their identity as individual shapes, with the following results:
The attached shape loses all access to its creation parameters. For example, once you attach a circle to a square you cannot go back and change the radius parameter of the circle.

The modifier stack of the attached shape is collapsed. Any edits, modifiers, and animation applied to the attached shape are frozen at the current frame.

**Reorient** When on, rotates the attached spline so that its creation local coordinate system is aligned with the creation local coordinate system of the selected spline.

**Attach Mult.** Click this button to display the Attach Multiple dialog, which contains a list of all other shapes in the scene. Select the shapes you want to attach to the current editable spline, then click OK.

**Cross Section** Creates a spline cage out of cross-sectional shapes. Click Cross Section, select one shape then a second shape, splines are created joining the first shape with the second. Continue clicking shapes to add them to the cage. This functionality is similar to the Cross Section modifier, but here you can determine the order of the cross sections. Spline cage tangency can be defined by choosing Linear, Bezier, Bezier Corner or Smooth in New Vertex Type group.

**End Point Auto-Welding group**

- **Automatic Welding** When Automatic Welding is turned on, an end point vertex that is placed or moved within the threshold distance of another end point of the same spline is automatically welded. This feature is available at the object and all sub-object levels.

- **Threshold** A proximity setting that controls how close vertices can be to one another before they are automatically welded. Default=6.0.

**Insert** Inserts one or more vertices, creating additional segments. Click anywhere in a segment to insert a vertex and attach the vertex to the mouse. Optionally move the mouse and then click to place the new vertex. Continue moving the mouse and clicking to add vertices. A single click inserts a corner vertex, while a drag creates a Bezier (smooth) vertex.

Right-click to complete the operation and release the mouse. At this point, you're still in Insert mode, and can begin inserting vertices in a different segment. Otherwise, right-click again or click Insert to exit Insert mode.
Editable Spline (Vertex)

Select an editable spline > Modify panel > Expand the editable spline in the stack display > Vertex sub-object level

Select an editable spline > Modify panel > Selection rollout > Vertex button

Select an editable spline > Right-click the spline > Tools 1 (upper-left) quadrant of the quad menu > Sub-objects > Vertex

While at the Editable Spline (Vertex) level, you can select single and multiple vertices and move them using standard methods.

If the vertex is of the Bezier or Bezier Corner type, you can also move and rotate handles, thus affecting the shapes of any segments joined at the vertex. You can copy and paste the handles between vertices using tangent copy/paste. You can reset them or switch between types using the quad menu. The tangent types are always available on the quad menu when a vertex is selected; your cursor doesn't have to be directly over them in the viewport.

Procedures

To set a vertex type:

1. Right-click any vertex in a selection.
2. Choose a type from the shortcut menu. Each vertex in a shape can be one of four types:
   - **Smooth**: Nonadjustable vertices that create smooth continuous curves. The curvature at a smooth vertex is determined by the spacing of adjacent vertices.
   - **Corner**: Nonadjustable vertices that create sharp corners.
   - **Bezier**: Adjustable vertex with locked continuous tangent handles that create a smooth curve. The curvature at the vertex is set by the direction and magnitude of the tangent handles.
   - **Bezier Corner**: Adjustable vertex with discontinuous tangent handles that create a sharp corner. The curvature of the segment as it leaves the corner is set by the direction and magnitude of the tangent handles.
To copy and paste vertex tangent handles:

1. Turn on Vertex Selection, then Select the vertex you want to copy from.

2. On the Geometry rollout scroll down to the Tangent group and click Copy.

3. Move your cursor over the vertices in the viewport. The cursor changes to a copy cursor. Click the handle you wish to copy.

4. On the Geometry rollout scroll down to the Tangent group and click Paste.

5. Move your cursor over the vertices in the viewport. The cursor changes to a paste cursor. Click the handle you wish to paste to.
The vertex tangency changes in the viewport.

To reset vertex handle tangency:
It is easy to make the handles very small and coincident with the vertex, which makes them hard to select and edit. Reset the vertex handle tangency to redraw your handles

1. Select the vertex that is problematic.
2. Right-click and choose Reset Tangents.

Any vertex handle editing you have done is discarded and the handles are reset.

Interface

Soft Selection rollout
For information on the Soft Selection rollout settings, see Soft Selection Rollout on page 2014.

Geometry rollout

New Vertex Type group

The radio buttons in this group let you determine the tangency of the new vertices created when you Shift+Clone segments or splines. If you later use Connect Copy, vertices on the splines that connect the original segment or spline to the new one will have the type specified in this group.

This setting has no effect on the tangency of vertices created using tools such as the Create Line button, Refine, and so on.

- **Linear**  New vertices will have linear tangency.
- **Smooth**  New vertices will have smooth tangency.
  When this option is chosen, new vertices that overlap are automatically welded.
- **Bezier**  New vertices will have bezier tangency.
■ **Bezier Corner**  New vertices will have bezier corner tangency.

---

**Create Line** Adds more splines to the selected object. These lines are separate spline sub-objects; create them in the same way as the line spline on page 584. To exit line creation, right-click or click to turn off Create Line.

**Break** Splits a spline at the selected vertex or vertices. Select one or more vertices and then click Break to create the split. There are now two superimposed non-connected vertices for every previous one, allowing the once-joined segment ends to be moved away from each other.

**Attach** Attaches another spline in the scene to the selected spline. Click the object you want to attach to the currently selected spline object. The object you're attaching must also be a spline.

For further details, see **Attach** on page 632.

**Attach Mult.** Click this button to display the Attach Multiple dialog, which contains a list of all other shapes in the scene. Select the shapes you want to attach to the current editable spline, then click OK.

■ **Reorient**  When on, reorients attached splines so that each spline's creation local coordinate system is aligned with the creation local coordinate system of the selected spline.

**Cross Section** Creates a spline cage out of cross-sectional shapes. Click Cross Section, select one shape then a second shape, splines are created joining the first shape with the second. Continue clicking shapes to add them to the cage. This functionality is similar to the Cross Section modifier, but here you can determine the order of the cross sections. Spline cage tangency can be defined by choosing Linear, Bezier, Bezier Corner or Smooth in New Vertex Type group.

**TIP** When you edit the spline cage, use Area Selection before selecting your vertices. This will keep their positions together as you transform them.

---

Editable Spline | 637
Refine group

The Refine group includes a number of functions useful for building spline networks for use with the Surface modifier on page 1763.

**Refine** Lets you add vertices without altering the curvature values of the spline. Click Refine, and then select any number of spline segments to add a vertex each time you click (the mouse cursor changes to a "connect" symbol when over an eligible segment). To finish adding vertices, click Refine again, or right-click in the viewport.

You can also click existing vertices during a refine operation, in which case 3ds Max displays a dialog asking if you want to **Refine** or **Connect Only** to the vertex. If you choose Connect Only, 3ds Max will not create a vertex: it simply connects to the existing vertex.

The Refine operation creates a different type of vertex depending on the types of vertices on the endpoints of the segment being refined.

- If the bordering vertices are both Smooth types, the Refine operation creates a Smooth type vertex.
- If the bordering vertices are both Corner types, the Refine operation creates a Corner type vertex.
- If either of the bordering vertices is a Corner or Bezier Corner, the Refine operation creates a Bezier Corner type.
- Otherwise, the operation creates a Bezier type vertex.

**Connect** When on, creates a new spline sub-object by connecting the new vertices. When you finish adding vertices with Refine, Connect makes a separate copy of each new vertex and then connects all of the copies with a new spline.

**NOTE** For Connect to work, you must turn it on before you click Refine.
After turning on Connect and before beginning the refinement process, turn on any combination of these options:

- **Linear**  When on, makes all segments in the new spline straight lines by using Corner vertices. When Linear is off, the vertices used to create the new spline are of the Smooth type.

- **Bind First**  Causes the first vertex created in a refinement operation to be bound to the center of the selected segment. See Bound Vertex on page 8528.

- **Closed**  When on, connects the first and last vertices in the new spline to create a closed spline. When Closed is off, Connect always creates an open spline.

- **Bind Last**  Causes the last vertex created in a refinement operation to be bound to the center of the selected segment. See Bound Vertex on page 8528.

**End Point Auto-Welding group**

![End Point Auto-Welding](image)

**Automatic Welding**  When Automatic Welding is turned on, an end point vertex that is placed or moved within the threshold distance of another end point of the same spline is automatically welded. This feature is available at the object and all sub-object levels.

**Threshold**  The threshold distance spinner is a proximity setting that controls how close vertices can be to one another before they are automatically welded. Default=6.0.
Weld Converts two end vertices, or two adjacent vertices within the same spline, into a single vertex. Move either two end vertices or two adjacent vertices near each other, select both vertices, and then click Weld. If the vertices are within the unit distance set by the Weld Threshold spinner (to the right of the button), they’re converted into a single vertex. You can weld a selection set of vertices, as long as each pair of vertices is within the threshold.

Connect Connects any two end vertices, resulting in a linear segment, regardless of the tangent values of the end vertices. Click the Connect button, point the mouse over an end vertex until the cursor changes to a cross, and then drag from one end vertex to another end vertex.

Insert Inserts one or more vertices, creating additional segments. Click anywhere in a segment to insert a vertex and attach the mouse to the spline. Then optionally move the mouse and click to place the new vertex. Continue moving the mouse and clicking to add vertices. A single click inserts a corner vertex, while a drag creates a Bezier (smooth) vertex. Right-click to complete the operation and release the mouse. At this point, you’re still in Insert mode, and can begin inserting vertices in a different segment. Otherwise, right-click again or click Insert to exit Insert mode.

Make First Specifies which vertex in the selected shape is the first vertex. The first vertex of a spline is indicated as a vertex with a small box around it. Select one vertex on each spline within the currently edited shape that you want to change and click the Make First button. On open splines, the first vertex must be the endpoint that is not already the first vertex. On closed splines, it can be any point that isn’t already the first vertex. Click the Make First button, and the first vertices will be set.
The first vertex on a spline has special significance. The following table defines how the first vertex is used.

<table>
<thead>
<tr>
<th>Shape Use</th>
<th>First Vertex Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Loft Path</td>
<td>Start of the path. Level 0.</td>
</tr>
<tr>
<td>Loft Shape</td>
<td>Initial skin alignment.</td>
</tr>
<tr>
<td>Path Constraint</td>
<td>Start of the motion path. 0% location</td>
</tr>
<tr>
<td></td>
<td>on the path.</td>
</tr>
<tr>
<td>Trajectory</td>
<td>First position key.</td>
</tr>
</tbody>
</table>

**Fuse** Moves all selected vertices to their averaged center. Fuse is useful for making vertices coincide when building a spline network for use with the Surface modifier on page 1763.

**NOTE** Fuse doesn't join the vertices; it simply moves them to the same location.

![Three selected vertices (left); fused vertices (right)](image)

**Cycle** Selects successive coincident vertices. Select one of two or more vertices that share the exact same location in 3D space, and then click Cycle repeatedly until the vertex you want is selected.
Cycle is useful for selecting a specific vertex from a group of coincident vertices at a spline intersection when building a spline network for use with the Surface modifier on page 1763.

**TIP** Watch the info display at the bottom of the Selection rollout to see which vertex is selected.

**CrossInsert** Adds vertices at the intersection of two splines belonging to the same spline object. Click CrossInsert, and then click the point of intersection between the two splines. If the distance between the splines is within the unit distance set by the CrossInsert Threshold spinner (to the right of the button), the vertices are added to both splines. You can continue using CrossInsert by clicking different spline intersections. To finish, right-click in the active viewport or click the CrossInsert button again. CrossInsert is useful for creating vertices at spline intersections when building a spline network for use with the Surface modifier on page 1763.

**NOTE** CrossInsert doesn’t join the two splines, but simply adds vertices where they cross.

**Fillet** Lets you round corners where segments meet, adding new control vertices. You can apply this effect interactively (by dragging vertices) or numerically (using the Fillet spinner). Click the Fillet button, and then drag vertices in the active object. The Fillet spinner updates to indicate the fillet amount as you drag.
If you drag one or more selected vertices, all selected vertices are filleted identically. If you drag an unselected vertex, any selected vertices are first deselected.

You can continue using Fillet by dragging on different vertices. To finish, right-click in an active viewport or click the Fillet button again.

A fillet creates a new segment connecting new points on both segments leading to the original vertex. These new points are exactly <fillet amount> distance from the original vertex along both segments. New fillet segments are created with the material ID of one of the neighboring segments (picked at random).

For example, if you fillet one corner of a rectangle, the single corner vertex is replaced by two vertices moving along the two segments that lead to the corner, and a new rounded segment is created at the corner.
**NOTE** Unlike the Fillet/Chamfer modifier, you can apply the Fillet function to any type of vertex, not just Corner and Bezier Corner vertices. Similarly, adjoining segments need not be linear.

- **Fillet Amount** Adjust this spinner (to the right of the Fillet button) to apply a fillet effect to selected vertices.

**Chamfer** Lets you bevel shape corners using a chamfer function. You can apply this effect interactively (by dragging vertices) or numerically (using the Chamfer spinner). Click the Chamfer button, and then drag vertices in the active object. The Chamfer spinner updates to indicate the chamfer amount as you drag.

If you drag one or more selected vertices, all selected vertices are chamfered identically. If you drag an unselected vertex, any selected vertices are first deselected.

You can continue using Chamfer by dragging on different vertices. To finish, right-click in an active viewport or click the Chamfer button again.

A chamfer "chops off" the selected vertices, creating a new segment connecting new points on both segments leading to the original vertex. These new points are exactly <chamfer amount> distance from the original vertex along both segments. New chamfer segments are created with the material ID of one of the neighboring segments (picked at random).

For example, if you chamfer one corner of a rectangle, the single corner vertex is replaced by two vertices moving along the two segments that lead to the corner, and a new segment is created at the corner.

**NOTE** Unlike the Fillet/Chamfer modifier, you can apply the Chamfer function to any type of vertex, not just Corner and Bezier Corner vertices. Similarly, adjoining segments need not be linear.

- **Chamfer Amount** Adjust this spinner (to the right of the Chamfer button) to apply a chamfer effect to selected vertices.

**Tangent group**

![Tangent group interface](image)
Tools in this group let you copy and paste vertex handles from one vertex to another.

**Copy**  Turn this on, then choose a handle. This action copies the selected handle tangent into a buffer.

**Paste**  Turn this on, then click a handle. This pastes the handle tangent onto the selected vertex.

**Paste Length**  When this is on, the handle length is also copied. When this is off, only the handle angle is considered, the handle length is unchanged.

**Hide and Bind group**

- **Hide**  Hides selected vertices and any connected segments. Select one or more vertices, and then click Hide.
- **Unhide All**  Displays any hidden sub-objects.
- **Bind**  Lets you create bound vertices on page 8528. Click Bind, and then drag from any end vertex in the current selection to any segment in the current selection except the one connected to the vertex. Before dragging, when the cursor is over an eligible vertex, it changes to a + cursor. While dragging, a dashed line connects the vertex and the current mouse position, and when the mouse cursor is over an eligible segment, it changes to a "connect" symbol. When you release over an eligible segment, the vertex jumps to the center of the segment and is bound to it.
  
  Bind is useful for connecting splines when building a spline network for use with the **Surface modifier** on page 1763.

- **Unbind**  Lets you disconnect bound vertices on page 8528 from the segments to which they're attached. Select one or more bound vertices, and the click the Unbind button.

- **Delete**  Deletes the selected vertex or vertices, along with one attached segment per deleted vertex.
Display group

Show selected segs When on, any selected segments are highlighted in red at the Vertex sub-object level. When off (the default), selected segments are highlighted only at the Segment sub-object level.
This feature is useful for comparing complex curves against each other.

Editable Spline (Segment)

Select an editable spline > Modify panel > Expand the editable spline in the stack display > Segment sub-object level
Select an editable spline > Modify panel > Selection rollout > Segment button
Select an editable spline > Right-click the spline > Tools 1 (upper-left) quadrant of the quad menu > Sub-objects > Segment

A segment is the portion of a spline curve between two of its vertices. While at the Editable Spline (Segment) level, you can select single and multiple segments and move, rotate, scale or clone them using standard methods.

Procedures

To change segment properties:

1. Select an editable spline segment, and then right-click.

2. On the Tools 1 (upper-left) quadrant of the quad menu, choose Line or Curve.
The effect of changing segment properties varies according to the type of vertices at the segment end.

- Corner vertices always result in line segments regardless of the segment property.
- Smooth vertices can support both line or curve segment properties.
- Bezier and Bezier Corner vertices apply their tangent handles only to curve segments. Tangent handles are ignored by line segments.
- A tangent handle associated with a line segment displays an X at the end of the handle. You can still transform the handle, but it has no effect until the segment is converted to a curve segment.

**TIP** If you have problems transforming the handles, display the axis constraints toolbar and change the transform axis there.

### Interface

#### Rendering, Interpolation, and Selection rollouts

For information on the Rendering, Interpolation on page 623 and Selection rollout on page 627 settings, see Editable Spline on page 620.

#### Soft Selection rollout

For information on the Soft Selection rollout settings, see Soft Selection Rollout on page 2014.

#### Geometry rollout

##### New Vertex Type group

The radio buttons in this group let you determine the tangency of the new vertices created when you Shift+Clone segments or splines. If you later use Connect Copy, vertices on the splines that connect the original segment or spline to the new one will have the type specified in this group.
This setting has no effect on the tangency of vertices created using tools such as the Create Line button, Refine, and so on.

- **Linear**  New vertices will have linear tangency.
- **Smooth**  New vertices will have smooth tangency. When this option is chosen, new vertices that overlap are automatically welded.
- **Bezier**  New vertices will have bezier tangency.
- **Bezier Corner**  New vertices will have bezier corner tangency.

---

**Create Line** Adds more splines to the selected spline. These lines are separate spline sub-objects; create them in the same way as the line spline on page 584. To exit line creation, right-click or click to turn off Create Line.

**Break** Lets you specify a break point at any segment in the shape (you do not have to first select a segment). When on, the mouse icon changes to a Break icon. You can now click any spot on a segment. The clicked spot becomes two coincident vertices, and the segment is split into two parts.

**Attach** Attaches another spline in the scene to the selected spline. Click the object you want to attach to the currently selected spline object. The object you're attaching to must also be a spline.

For further details, see Attach on page 632.

**Reorient** Reorients the attached spline so that its creation local coordinate system is aligned with the creation local coordinate system of the selected spline.

**Attach Mult.** Click this button to display the Attach Multiple dialog, which contains a list of all other shapes in the scene. Select the shapes you want to attach to the current editable spline, then click OK.

**Cross Section** Creates a spline cage out of cross-sectional shapes. Click Cross Section, select one segment then another sub-object segment, splines are
created joining the first shape with the second. Continue clicking segments
to add them to the cage. All segments must be part of the same object to build
cross sections. This functionality is similar to the Cross Section modifier, but
here you can determine the order of the cross sections. Spline cage tangency
can be defined by choosing Linear, Bezier, Bezier Corner or Smooth in New
Vertex Type group.

TIP When you want to move these vertices, turn on Area Selection before you
select them. When you transform them, the vertices will stay together.

**Refine group**

The Refine group includes a number of functions useful for building spline
networks for use with the Surface modifier on page 1763.

**Refine** Lets you add vertices without altering the curvature values of the spline.
Click Refine, and then select any number of spline segments to add a vertex
each time you click (the mouse cursor changes to a "connect" symbol when
over an eligible segment). To finish adding vertices, click Refine again, or
right-click in the viewport.

You can also click existing vertices during a refine operation, in which case
3ds Max displays a dialog asking if you want to **Refine** or **Connect** to the
vertex. If you choose Connect, 3ds Max will not create a vertex: it simply
connects to the existing vertex.

The Refine operation creates a different type of vertex depending on the types
of vertices on the endpoints of the segment being refined.

- If the bordering vertices are both Smooth types, the Refine operation creates
  a Smooth type vertex.

- If the bordering vertices are both Corner types, the Refine operation creates
  a Corner type vertex.

- If either of the bordering vertices is a Corner or Bezier Corner, the Refine
  operation creates a Bezier Corner type.

- Otherwise, the operation creates a Bezier type vertex.
Connect When on, creates a new spline sub-object by connecting the new vertices. When you finish adding vertices with Refine, Connect makes a separate copy of each new vertex and then connects all of the copies with a new spline.

**NOTE** For Connect to work, you must turn it on before you click Refine.

After turning on Connect and before beginning the refinement process, turn on any combination of these options:

- **Linear** When on, makes all segments in the new spline linear by using Corner vertices. When Linear is off, the vertices used to create the new spline are of the Smooth type.

- **Bind First** Causes the first vertex created in a refinement operation to be bound to the center of the selected segment.
  For more information, see Bound Vertex on page 8528.

- **Closed** When on, connects the first and last vertices in the new spline to create a closed spline. When Closed is off, Connect always creates an open spline.

- **Bind Last** Causes the last vertex created in a refinement operation to be bound to the center of the selected segment.
  For more information, see Bound Vertex on page 8528.

**Connect Copy group**

**Connect Copy** When on, Shift+cloning a segment creates a new spline sub-object with additional splines that connect the new segment’s vertices to the vertices of the original segment. It is analogous to Shift+cloning edges in Editable Mesh and Editable Poly objects.

**NOTE** For Connect Copy to work, you must turn it on before you Shift+Clone.

**Threshold** Determines the distance soft selection will use when Connect Copy is on. A higher threshold results in more splines being created; a lower threshold results in fewer splines.
End Point Auto-Welding group

Automatic Welding When Automatic Welding is turned on, an end point vertex that is placed or moved within the threshold distance of another end point of the same spline is automatically welded. This feature is available at the object and all sub-object levels.

Threshold The threshold distance spinner is a proximity setting that controls how close vertices can be to one another before they are automatically welded. Default=6.0.

Insert Inserts one or more vertices, creating additional segments. Click anywhere in a segment to insert a vertex and attach the mouse to the spline. Then optionally move the mouse and click to place the new vertex. Continue moving the mouse and clicking to add vertices. A single click inserts a corner vertex, while a drag creates a Bezier (smooth) vertex.

Right-click to complete the operation and release the mouse. At this point, you're still in Insert mode, and can begin inserting vertices in a different segment. Otherwise, right-click again or click Insert to exit Insert mode.
**Hide** Hides selected segments. Select one or more segments, and then click Hide.

**Unhide All** Displays any hidden sub-objects.

**Delete** Deletes any selected segments in the current shape.

**Selected and deleted segment**

**Divide** Subdivides the selected segment or segments by adding the number of vertices specified by the spinner. Select one or more segments, set the Divisions spinner (to the button's right), and then click Divide. Each selected segment is divided by the number of vertices specified in the Divisions spinner. The distance between the vertices depends on the segment's relative curvature, with areas of greater curvature receiving more vertices.
Detach  Lets you select several segments in various splines and then detach them (or copy them) to form a new shape. Three options are available:

- **Same Shp**  (Same Shape) When on, Reorient is disabled, and a Detach operation keeps the detached segment as part of the shape (rather than producing a new shape). If Copy is also on, you end up with a detached copy of the segment in the same location.

- **Reorient**  The detached segment copies the position and orientation of the source object's creation Local coordinate system. The new detached object is moved and rotated so that its Local coordinate system is positioned and aligned with the origin of the current active grid.

- **Copy**  Copies the detached segment rather than moving it.
Original and detached splines

Display group

Show selected segs When on, any selected segments are highlighted in red at the Vertex sub-object level. When off (the default), selected segments are highlighted only at the Segment sub-object level. This feature is useful for comparing complex curves against each other.

Surface Properties rollout
Material group

You can apply different material IDs to spline segments (see Material ID on page 8633). You can then assign a multi/sub-object material on page 6120 to such splines, which appears when the spline is renderable, or when used for lathing or extrusion. Be sure to turn on Generate Material IDs and Use Shape IDs when lofting, lathing or extruding.

Set ID Lets you assign a particular material ID number to selected segments for use with multi/sub-object materials and other applications. Use the spinner or enter the number from the keyboard. The total number of available IDs is 65,535.

Select ID Selects the segments or splines corresponding to the Material ID specified in the adjacent ID field. Type or use the spinner to specify an ID, then click the Select ID button.

Select By Name This drop-down list shows the names of sub-materials if an object has a Multi/Sub-object material assigned to it. Click the drop arrow and select a material from the list. The segments or splines that are assigned that material are selected. If a shape does not have a Multi/Sub-Object material assigned to it, the name list will be unavailable. Likewise, if multiple shapes are selected that have an Edit Spline modifier applied to them, the name list is inactive.

Clear Selection When turned on, selecting a new ID or material name forces a deselection of any previously selected segments or splines. When turned off, selections are cumulative so new ID or material name selections add to a previous selection set of segments or splines. Default=on.

Editable Spline (Spline)

Select an editable spline > Modify panel > Expand the editable spline in the stack display > Spline sub-object level
Select an editable spline > Modify panel > Selection rollout > Spline button
Select an editable spline > Right-click the spline > Tools 1 (upper-left) quadrant of the quad menu > Sub-objects > Spline

While at the Editable Spline (Spline) level, you can select single and multiple splines within a single spline object and move, rotate, and scale them using standard methods.
Procedures

To change spline properties:

- You change the properties of a spline from Line to Curve by right-clicking and choosing Line or Curve from the Tools 1 (upper-left) quadrant of the quad menu.
  Changing the spline property also changes the property of all vertices in the spline:
  - Choosing Line converts vertices to Corners.
  - Choosing Curve converts vertices to Beziers.

Interface

Rendering, Interpolation and Selection rollouts

For information on the Rendering, Interpolation on page 623 and Selection rollout on page 627 settings, see Editable Spline on page 620.

New Vertex Type group

The radio buttons in this group let you determine the tangency of the new vertices created when you Shift+Clone segments or splines. If you later use Connect Copy, vertices on the splines that connect the original segment or spline to the new one will have the type specified in this group.

This setting has no effect on the tangency of vertices created using tools such as the Create Line button, Refine, and so on.

- **Linear**  New vertices will have linear tangency.
- **Smooth**  New vertices will have smooth tangency. When this option is chosen, new vertices that overlap are automatically welded.
- **Bezier**  New vertices will have bezier tangency.
- **Bezier Corner**  New vertices will have bezier corner tangency.

---

**Create Line** Adds more splines to the selected spline. These lines are separate spline sub-objects; create them in the same way as the line spline on page 584. To exit line creation, right-click or click to turn off Create Line.

**Attach** Attaches another spline in the scene to the selected spline. Click the object you want to attach to the currently selected spline object. The object you're attaching to must also be a spline.

For further details, see Attach on page 632.

**Reorient** Reorients the attached spline so that its creation local coordinate system is aligned with the creation local coordinate system of the selected spline.

**Attach Mult.** Click this button to display the Attach Multiple dialog, which contains a list of all other shapes in the scene. Select the shapes you want to attach to the current editable spline, then click OK.

**Cross Section** Creates a spline cage out of cross-sectional shapes. Click Cross Section, select one shape then a second shape, splines are created joining the first shape with the second. Continue clicking shapes to add them to the cage. This functionality is similar to the Cross Section modifier, but here you can determine the order of the cross sections. Spline cage tangency can be defined in the New Vertex Type group.
**TIP** When you edit the spline cage, use Area Selection before selecting your vertices. This will keep their positions together as you transform them.

**Connect Copy group**

Connect Copy When on, Shift+Cloning a spline creates a new spline sub-object with additional splines that connect the new spline's vertices to the vertices of the original segment. It is analogous to Shift+Cloning edges in Editable Mesh and Editable Poly objects.

**NOTE** For Connect Copy to work, you must turn it on before you Shift+Clone.

Threshold Determines the distance soft selection uses when Connect Copy is on. A higher value results in more splines being created, a lower value results in fewer splines.

**End Point Auto-Welding group**

Automatic Welding When Automatic Welding is turned on, an endpoint vertex that is placed or moved within the threshold distance of another endpoint of the same spline is automatically welded. This feature is available at the object and all sub-object levels.

Threshold A proximity setting that controls how close vertices can be to one another before they are automatically welded. Default=6.0.

**Insert** Inserts one or more vertices, creating additional segments. Click anywhere in a segment to insert a vertex and attach the mouse to the spline. Then optionally move the mouse and click to place the new vertex. Continue moving the mouse and clicking to add vertices. A single click inserts a corner vertex, while a drag creates a Bezier (smooth) vertex.

Right-click to complete the operation and release the mouse. At this point, you're still in Insert mode, and can begin inserting vertices in a different segment. Otherwise, right-click again or click Insert to exit Insert mode.

**Reverse** Reverses the direction of the selected spline. If the spline is open, the first vertex will be switched to the opposite end of the spline. Reversing the direction of a spline is usually done in order to reverse the effect of using the Insert tool at vertex selection level.
Outline makes a copy of the spline, offset on all sides to the distance specified by the Outline Width spinner (to the right of the Outline button). Select one or more splines and then adjust the outline position dynamically with the spinner, or click Outline and then drag a spline. If the spline is open, the resulting spline and its outline will make a single closed spline.

**NOTE** Normally, if using the spinner, you must first select a spline before using Outline. If, however, the spline object contains only one spline, it is automatically selected for the outlining process.
**Center** When off (default), the original spline remains stationary and the outline is offset on one side only to the distance specified by Outline Width. When Center is on, the original spline and the outline move away from an invisible center line to the distance specified by Outline Width.

**Boolean** Combines two closed polygons by performing a 2D Boolean operation that alters the first spline you select, and deletes the second one. Select the first spline, then click the Boolean button and the desired operation, and then select the second spline.

**NOTE** 2D Booleans only work on 2D splines that are in the same plane.
There are three Boolean operations:

- **Union**  Combines two overlapping splines into a single spline, in which the overlapping portion is removed, leaving non-overlapping portions of the two splines as a single spline.

- **Subtraction**  Subtracts the overlapping portion of the second spline from the first spline, and deletes the remainder of the second spline.

- **Intersection**  Leaves only the overlapping portions of the two splines, deleting the non-overlapping portion of both.

---

**Mirror**  Mirrors splines along the length, width, or diagonally. Click the direction you want to mirror first so it is active, then click Mirror.

- **Copy**  When selected, copies rather than moves the spline as it is mirrored.

- **About Pivot**  When on, mirrors the spline about the spline object’s pivot point (see Pivot on page 3762). When off, mirrors the spline about its geometric center.
Mirrored splines

**Trim** Use Trim to clean up overlapping segments in a shape so that ends meet at a single point.

To trim, you need intersecting splines. Click the portion of the spline you want to remove. The spline is searched in both directions along its length until it hits an intersecting spline, and deleted up to the intersection. If the section intersects at two points, the entire section is deleted up to the two intersections. If the section is open on one end and intersects at the other, the entire section is deleted up to the intersection and the open end. If the section is not intersected, or if the spline is closed and only one intersection is found, nothing happens.

**Extend** Use Extend to clean up open segments in a shape so that ends meet at a single point.

To extend, you need an open spline. The end of the spline nearest the picked point is extended until it reaches an intersecting spline. If there is no intersecting spline, nothing happens. Curved splines extend in a direction tangent to the end of the spline. If the end of a spline lies directly on a boundary (an intersecting spline), then it looks for an intersection further along.

**Infinite Bounds** For the purposes of calculating intersections, turn this on to treat open splines as infinite in length. For example, this lets you trim one linear spline against the extended length of another line that it doesn't actually intersect.
Hide  Hides selected splines. Select one or more splines, and then click Hide.

Unhide All  Displays any hidden sub-objects.

Delete  Deletes the selected spline.

Close  Closes the selected spline by joining its end vertices with a new segment.

Detach  Copies selected splines to a new spline object, and deletes them from the currently selected spline if Copy is clear.

-  Reorient  The spline being detached is moved and rotated so that its creation local coordinate system is aligned with the creation local coordinate system of the selected spline.

-  Copy  When selected, copies rather than moves the spline as it is detached.

Explode  Breaks up any selected splines by converting each segment to a separate spline or object. This is a time-saving equivalent of using Detach on each segment in the spline in succession.

You can choose to explode to splines or objects. If you choose Object, you're prompted for a name; each successive new spline object uses that name appended with an incremented two-digit number.

**Surface Properties rollout**

![Surface Properties rollout](image)

**Material group**

You can apply different material IDs (see material ID on page 8633) to splines in shapes containing multiple splines. You can then assign a multi/sub-object material on page 6120 to such shapes, which appears when the spline is renderable, or when used for lathing or extrusion.
Set ID Lets you assign a particular material ID number to selected segments for use with multi/sub-object materials and other applications. Use the spinner or enter the number from the keyboard. The total number of available IDs is 65,535.

Select ID Selects the segments or splines corresponding to the Material ID specified in the adjacent ID field. Type or use the spinner to specify an ID, then click the Select ID button.

Select By Name This drop-down list shows the names of sub-materials if an object has a Multi/Sub-object material assigned to it. Click the drop arrow and select a material from the list. The segments or splines that are assigned that material are selected. If a shape does not have a Multi/Sub-Object material assigned to it, the name list will be unavailable. Likewise, if multiple shapes are selected that have an Edit Spline modifier applied to them, the name list is inactive.

Clear Selection When turned on, selecting a new ID or material name, forces a deselection of any previously selected segments or splines. If turned off, selections are cumulative so new ID or material name selections add to a previous selection set of segments or splines. Default=on.

Shape Check Utility

Utilities panel > Utilities rollout > More button > Utilities dialog > Shape Check

The Shape Check utility tests spline and NURBS-based shapes and curves for self-intersection and graphically displays any instances of intersecting segments. Self-intersecting shapes used to produce lathed, extruded, lofted, or other 3D objects can result in rendering errors.

The utility is "sticky" in that once you've picked a shape object for it to check, you can pan/zoom viewports and it will continually display the locations of intersecting curves in the shape you pick.

If a shape is animated, moving the time slider will recheck the shape on each frame of the animation, allowing for easy checking of these changing shapes.
Intersection points highlighted by Shape Check

Interface

**Pick Object** Click this button, and then click the shape for the utility to check. You can pick only spline- and NURBS-based shapes and curves. Points of intersection discovered by the utility are highlighted with red boxes. The text below the button indicates whether any points of intersection occur.

**Close** Closes the utility.
**Compound Objects**

Create panel > Geometry > Compound Objects
Create menu > Compound

Compound objects typically combine two or more existing objects into a single object.

![Compound Objects](image)

**Morph Compound Object**

Select an object. > Create panel > Geometry > Compound Objects > Object Type rollout > Morph
Select an object. > Create menu > Compound > Morph

Morphing is an animation technique similar to tweening in 2D animation. A Morph object combines two or more objects by interpolating the vertices of the first object to match the vertex positions of another object. When this interpolation occurs over time, a morphing animation results.
Seed or base object, and the target objects at specific frames
The resulting animation

The original object is known as the seed or base object. The object into which the seed object morphs is known as the target object.

You can morph one seed into multiple targets; the seed object's form changes successively to match the forms of the target objects as the animation plays.

Before you can create a morph, the seed and target objects must meet these conditions:

- Both objects must be mesh, patch, or poly objects.
- Both objects must have an equal number of vertices.

If these conditions don't apply, the Morph button is unavailable.

You can use any kind of object as a morph target, including an animated object or another morph object, as long as the target is a mesh that has the same number of vertices as the seed object.

Creating a morph involves the following steps:

- Model the base object and target objects.
Select the base object.

Click Create panel > Geometry > Compound Objects > Morph.

Add the target objects.

Animate.

**Setting Up the Morph Geometry**

Make sure that the objects you want to use as the seed and targets have the same number of vertices.

**TIP** When you create Loft objects that you want to use as morph seeds and targets, make sure that Morph Capping is on and Adaptive Path Steps and Optimize are turned off. All shapes in the Loft object must have the same number of vertices.

You should also turn off Adaptive and Optimize for other shape-based objects that you want to use with Morph, such as those with Extrude or Lathe modifiers.

**WARNING** The selected object is permanently converted to a morph object as soon as you click Morph, whether or not you proceed to select a target object. The only way to restore the original object is to undo the Morph click.

**Morph Object and Morpher Modifier**

There are two ways to set up morphing animations: the Morph compound object and the Morpher modifier.

The Morpher modifier on page 1518 is more flexible because you can add it multiple times at any place in an object's modifier stack display. This flexibility lets you animate the base object or the morph targets before reaching the Morpher modifier, for example with a noise modifier. The Morpher modifier works hand in hand with the Morpher material. The Morpher modifier is the ideal way to morph characters.

The Barycentric Morph controller can be simpler to use in Track View. The Track View display for Compound Morph has only one animation track regardless of the number of targets. Each key on the track represents a morph result based on a percentage of all the targets. For basic morphing needs, Compound Morph may be preferable to the Morpher modifier.

Lastly, you can add the Morpher modifier to the stack of a Compound Morph object.
Procedures

Example: To create a basic morph:

1. On the Create panel > Geometry > Patch Grids > Object Type rollout, click Quad Patch.
2. In the Top viewport, click and drag to create a patch on the left side of the viewport.
3. Right-click the modifier stack display in the Modify panel and select Convert To Editable Patch from the pop-up menu.
4. Right-click the patch, and then click Move in the Transform quadrant of the quad menu.
5. In the Top viewport, hold Shift and drag with the patch to create a copy on the right side of the viewport.
6. On the Modify panel > Selection rollout, go to the Vertex sub-object level.
7. In the Front viewport, select and move vertices on the selected patch to alter its shape.
8. On the Modify panel, in the stack display, click Editable Patch again to return to the top level.
9. Select the original patch in the viewports.
10. On the Create panel > Geometry > Compound Objects > Objects Type rollout, click Morph.
11. On the Pick Targets rollout, click Pick Target.
12. In the viewports, click the second patch object. Both patch objects are listed in the Morph Targets list.
13. Click Modify panel.
   Morph displays above the Editable Patch in the modifier stack.
14. Move the time slider to frame 10.
15. In the Morph Targets list, click M_QuadPatch01.
16. On the Current Targets rollout, click Create Morph Key.
    On the track bar, a key is displayed at frame 10.
17. On the track bar, right-click the key at frame 10 and click QuadPatch01:Morph in the menu.
A Key Info dialog displays.

18 On the Key Info dialog, select M_QuadPatch01 from the list.

19 On the Key Info dialog, drag the percentage spinner.
   The base object changes shape.

20 Close the Key Info dialog and drag the time slider back and forth. The
   patch morphs its shape.

To select the targets for a morph:

1 Select the seed object.

2 On the Create panel > Geometry > Compound Objects, click Morph.
   The name of the seed object is displayed at the top of the Morph Targets
   list on the Current Targets rollout.

3 On the Pick Targets rollout, choose the method for creating targets:
   Reference, Move, Copy, or Instance.

4 Click Pick Target.

5 Select one or more target objects in the viewports.
   As you select each target, its name is added to the Morph Targets list. If
   an object can't be a target (for example, if it has a different number of
   vertices than the morph seed), you can't select it.
   If you select a target object while you are not at frame 0, creating the
   target also creates a morph key. You can create additional morph keys
   from targets you've already selected, as described in the following
   procedure.

To create morph keys from existing targets:

1 Drag the time slider to the frame where you want to place the morph
   key.

   NOTE The Auto Key button does not need to be on to set morph keys.

2 Highlight the name of a target object on the Morph Targets list.
   The Create Morph Key button is available only when a target object name
   is selected.

3 Click Create Morph Key.
3ds Max places a morph key at the active frame.

4 To preview the effect of the morph, drag the time slider back and forth. You can view and edit the morph keys in Track View, which also lets you view the morph’s target object parameters.

Interface

Pick Targets rollout

![Pick Targets](image)

When you pick target objects, you designate each target as a Reference, Move (the object itself), Copy, or Instance. Base your selection on how you want to use the scene geometry after you create the morph.

**Pick Target** Use this button to designate the target object or objects.

**Reference/Copy/Move/Instance** Lets you specify how the target is transferred to the compound object. It can be transferred either as a reference on page 8699, a copy, an instance on page 8611, or it can be moved, in which case the original shape is not left behind.

- Use Copy when you want to reuse the target geometry for other purposes in the scene.

- Use Instance to synchronize morphing with animated changes to the original target object.

- Use Move if you've created the target geometry to be only a morph target, and have no other use for it.

You can use an animated object or another morph as the target of a morph.
Current Targets rollout

Morph Targets Displays a list of the current morph targets.

Morph Target Name Use this field to change the name of the selected morph target in the Morph Targets list.

Create Morph Key Adds a morph key for the selected target at the current frame.

Delete Morph Target Deletes the currently highlighted morph target. If morph keys reference the deleted target, then those keys are deleted as well.

Scatter Compound Object

Select an object. > Create panel > Geometry > Compound Objects > Object Type rollout > Scatter

Select an object. > Create menu > Compound > Scatter

Scatter is a form of compound object that randomly scatters the selected source object either as an array, or over the surface of a distribution object.
The plane of the hill is used to scatter the trees and two different sets of rocks.

Procedures

To create a Scatter object:

1. Create an object to be used as a source object.
2. Optionally, create an object to be used as a distribution object.
3. Select the source object, and then click Scatter in the Compound Objects panel.

**NOTE** The source object must be either a mesh object or an object that can be converted to a mesh object. If the currently selected object is invalid, the Scatter button is unavailable.
Results of scattering source object with distribution object visible (above) and hidden (below)

You now have two choices. You can either scatter the source object as an array without using a distribution object, or use a distribution object to scatter the object. See the following procedures.

To scatter the source object without a distribution object:

1. Choose Use Transforms Only in the Scatter Objects rollout > Distribution group.
2. Set the Duplicates spinner to specify the desired total number of duplicates of the source object.
3. Adjust the spinners on the Transforms rollout to set random transformation offsets of the source object.

To scatter the source object using a distribution object:

1. Make sure the source object is selected.
2 Choose the method by which you want to clone the distribution object (Reference, Copy, Move, or Instance.)

3 Click Pick Distribution Object, and then select the object you want to use as a distribution object.

4 Make sure that Use Distribution Object on the Scatter Object rollout is chosen.

5 Use the Duplicates spinner to specify the number of duplicates. (This is not necessary if you're using the All Vertices, All Edge Midpoints or All Face Centers distribution methods.)

6 Choose a distribution method in the Scatter Object rollout > Distribute Object Parameters group under Distribute Using.

7 Optionally, adjust the Transform spinners to randomly transform the duplicates.

8 If the display is too slow, or the meshes too complicated, consider choosing Proxy on the Display rollout or decreasing the percentage of displayed duplicates by reducing the Display percentage.

Most of the spinner values are animatable, so you can animate things like the number of duplicates, their transformations, and so on.
Scatter objects (the grass) with a high number of duplicates

Interface

Pick Distribution Object rollout

Contains the options for selecting a distribution object.

**Object** Displays the name of the distribution object selected with the Pick button.

**Pick Distribution Object** Click this button, then click an object in the scene to specify it as a distribution object.
Reference/Copy/Move/Instance Lets you specify how the distribution object is transferred to the scatter object. It can be transferred either as a reference on page 8699, a copy, an instance on page 8611, or moved, in which case the original shape is not left behind.

Scatter Objects rollout

The options on this rollout let you specify how the source object is scattered, and let you access the objects that make up the compound Scatter object.

Distribution group

These two options let you choose the basic method of scattering the source object.

Use Distribution Object Scatters the source object based on the geometry of the distribution object.

Use Transforms Only This options doesn't need a distribution object. Instead, duplicates of the source object are positioned using the offset values on the Transforms rollout. If all of the Transform offsets remain at 0, you won't see the array because the duplicates occupy the same space.
Objects group

Contains a list window showing the objects that make up the Scatter object.

List Window Click to select an object in the window so that you can access it in the Stack. For example, if your distribution object is a sphere, you can click Distribution: D_Sphere01, open the Stack list, and select Sphere to access the sphere’s parameters.

Source Name Lets you rename the source object within the compound Scatter object.

Distribution Name Lets you rename the distribution object.

Extract Operand Extract a copy or an instance of the selected operand. Choose an operand in the list window to enable this button.

NOTE This button is available only on the Modify panel. You can’t extract an operand while the Create panel is active.

Instance/Copy This option lets you specify how the operand is extracted: as either an instance or a copy.

Source Object Parameters group

These options affect the source object locally.

Duplicates Specifies the number of scattered duplicates of the source object. This number is set to 1 by default, but you can set it to 0 if you want to animate the number of duplicates, beginning with none. Note that the Duplicates number is ignored if you’re distributing the duplicates using either Face Centers or Vertices. In these cases, one duplicate is placed at each vertex or face center, depending on your choice.
**Base Scale** Alters the scale of the source object, affecting each duplicate identically. This scale occurs before any other transforms.

**Vertex Chaos** Applies a random perturbation to the vertices of the source object.

**Animation Offset** Lets you specify the number of frames by which each source object duplicate’s animation is offset from the previous duplicate. You can use this feature to produce wave-type animation. At the default setting of 0, all duplicates move identically.

**Distribution Object Parameters group**

These options affect how the duplicates of the source object are arranged, relative to the distribution object. These options have an effect only when a distribution object is used.

**Perpendicular** When on, orients each duplicate object perpendicular to its associate face, vertex, or edge in the distribution object. When off, the duplicates maintain the same orientation as the original source object.

**Use Selected Faces Only** When on, limits distribution to the selected faces passed up the Stack. Perhaps the easiest way to do this is to use the Instance option when picking the distribution object. You can then apply a Mesh Select modifier to the original object and select only those faces you want to use for the distribution of the duplicates.
Distribute Using

The following options let you specify how the geometry of the distribution object determines the distribution of the source object. These options are ignored if you're not using a distribution object.

**Area** Distributes duplicate objects evenly over the total surface area of the distribution object.

**Even** Divides the number of faces in the distribution object by the number of duplicates, and skips the appropriate number of faces in the distribution object when placing duplicates.

**Skip N** Skips N number of faces when placing duplicates. The editable field specifies how many faces to skip before placing the next duplicate. When set to 0, no faces are skipped. When set to 1, every other face is skipped, and so on.

**Random Faces** Applies duplicates randomly over the surface of the distribution object.

**Along Edges** Assigns duplicates randomly to the edges of the distribution object.
All Vertices Places a duplicate object at each vertex in the distribution object. The Duplicates value is ignored.

All Edge Midpoints Places a duplicate at the midpoint of each segment edge.

All Face Centers Places a duplicate object at the center of each triangular face on the distribution object. The Duplicates value is ignored.

Volume Scatters objects throughout the distribution object’s volume. All other options restrict distribution to the surface. Consider turning on Display rollout > Hide Distribution Object with this option.

Objects fill a spherical volume with Volume turned on

Display group

<table>
<thead>
<tr>
<th>Display:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>✔ Result</td>
<td></td>
</tr>
<tr>
<td>□ Operands</td>
<td></td>
</tr>
</tbody>
</table>

Result/Operands Choose whether to display the results of the scatter operation or the operands before the scattering.
The settings in the Transforms rollout let you apply random transform offsets to each duplicate object. The values in the transform fields specify a maximum offset value that’s applied randomly with a positive or negative value to each duplicate. Thus, if you set a rotation angle of 15 degrees, duplicates are rotated randomly from -15 to +15 degrees. For example, one duplicate might be rotated 8 degrees, another -13, another 5, and so on. You can use the Transform...
settings with or without a distribution object. When there is no distribution object, you must adjust the Transform settings in order to see the duplicates.

**Rotation group**

Specifies random rotation offsets.

**X, Y, Z deg** Enter the maximum random rotational offset you want about the local X, Y, or Z axis of each duplicate.

**Use Maximum Range** When on, forces all three settings to match the maximum value. The other two settings become disabled, and the setting containing the maximum value remains enabled.

**Local Translation group**

Specifies translation of the duplicates along their local axes.

**X, Y, Z** Enter the maximum random movement you want along the X, Y, or Z axis of each duplicate.

**Use Maximum Range** When on, forces all three settings to match the maximum value. The other two settings become disabled, and the setting containing the maximum value remains enabled.

**Translation on Face group**

Lets you specify the translation of duplicates along barycentric on page 8517 face coordinates of the associate face in the distribution object. These settings have no effect if you're not using a distribution object.

**A, B, N** The first two settings specify the barycentric coordinates on the surface of the face, while the N setting sets the offset along the normal of the face.

**Use Maximum Range** When on, forces all three settings to match the maximum value. The other two settings become disabled, and the setting containing the maximum value remains enabled.

**Scaling group**

Lets you specify the scaling of duplicates along their local axes.

**X, Y, Z %** Specifies the percent of random scaling along the X, Y, or Z axis of each duplicate.
Use **Maximum Range** When on, forces all three settings to match the maximum value. The other two settings become disabled, and the one containing the maximum value remains enabled.

Lock **Aspect Ratio** When on, maintains the original aspect ratio of the source object. Typically, this provides uniform scaling of duplicates. When Lock Aspect Ratio is off, and any of the X, Y, and Z settings contain values greater than 0, the result is non-uniform scaling of duplicates because the values represent random scaling offsets in both positive and negative directions.

**Display rollout**

Provides options that affect the display of the Scatter object.

**Display Options group**

These options affect the display of the source and destination objects.

**Proxy** Displays the source duplicates as simple wedges and speeds up viewport redraws when manipulating a complex Scatter object. This has no effect on the rendered image, which always displays the mesh duplicates.

**Mesh** Displays the full geometry of the duplicates.

**Display %** Specifies the percentage of the total duplicate objects that appear in the viewports. This has no effect on the rendered scene.

**Hide Distribution Object** Hides the distribution object. The hidden object does not appear in the viewport or in the rendered scene.
**Uniqueness group**

Lets you set a seed number upon which the random values are based. Thus, altering this value changes the overall effect of the scattering.

**New** Generates a new, random seed number.

**Seed** Use this spinner to set the seed number.

**Load/Save Presets rollout**

Let you store preset values to use in other Scatter objects. For example, after setting all of your parameters for a specific Scatter object and saving the settings under a specific name, you can then select another Scatter object and load the preset values into the new object.

**Preset Name** Lets you define a name for your settings. Click the Save button to save the current settings under the preset name.

**Saved Presets group**

A list window containing saved preset names.

**LOAD** Loads the preset currently highlighted in the Saved Presets list.
SAVE Saves the current name in the Preset Name field and places it in the Saved Presets window.

DELETE Deletes the selected items in the Save Presets window.

NOTE Animated parameter values subsequent to frame 0 are not stored.

Conform Compound Object

Select an object. > Create panel> Geometry > Compound Objects > Object Type rollout > Conform

Select an object. > Create menu > Compound > Conform

Conform is a compound object created by projecting the vertices of one object, called the Wrapper, onto the surface of another object, called the Wrap-To. There is also a space-warp version of this function; see Conform space warp on page 2987.

Conform fits the road to the surface of the hills.
Because the space-warp version is somewhat easier to use, it's a good idea to read that topic first, try the example, and then return here. This topic provides additional methods of projecting the wrapper vertices.

**NOTE** This tool gives you the ability to morph between any two objects, regardless of the number of vertices in each object. See **Vertex Projection Direction group** on page 692 for more information.

### Procedures

**Example: To create a Conform object:**

1. Position two objects, one of which will be the Wrapper, and the other the Wrap-To. (For this example, create a box as the Wrap-To object, and then create a larger sphere that completely surrounds it. The sphere will be the Wrapper.)

2. Select the Wrapper object (the sphere), and click Create panel > Geometry > Compound Objects > Object Type rollout > Conform button.

   **NOTE** Both objects used in Conform must be either mesh objects or objects that can be converted to mesh objects. If the selected Wrapper object is invalid, the Conform button is unavailable.

3. Specify the method of vertex projection in the Vertex Projection Direction group. (Use Along Vertex Normals for this example.)

   **NOTE** If you were to choose Use Active Viewport, you would next activate whichever viewport looks in the direction that you want to project the vertices. For example, if the Wrapper hovered over a Wrap-To terrain on the home plane, you’d activate the Top viewport.

4. Choose Reference, Copy, Move, or Instance to specify the type of cloning to perform on the Wrap-To object. (Choose Instance for this example.)

5. Click Pick Wrap-To Object, and then click the object onto which to project the vertices. (You can press the H key and use the Pick Object dialog on page 206 to select the box.)

   The list windows display the two objects, and the compound object is created with the Wrapper object conforming to the Wrap-To object. (In the example, the sphere is wrapped into the shape of the box.)

6. Use the various parameters and settings to alter the vertex projection direction, or adjust the vertices that are being projected.
To project a road onto terrain:

1. Create the road and terrain objects.

   **TIP** You can quickly make a terrain by creating a patch grid on page 2408 and applying the Noise modifier on page 1544 to it. For the road, you can use a Loft compound object on page 742 by lofting a rectangle along a curved line. Both objects must have a sufficient level of detail to conform smoothly.

2. Orient both the road and the terrain so you are looking straight down at them in the Top viewport. Position the road so it's completely above the terrain (higher on the world Z axis).

   **NOTE** For the conform projection to work correctly, the road should not extend beyond the boundaries of the terrain when viewed in the Top viewport.

3. Select the road object.

4. Click Conform.

5. In the Pick Wrap-To Object rollout, make sure the Instance option is selected.

6. Click Pick Wrap-To Object, and click the terrain.

   An instance of the terrain object is created, with the same object color as the road.

7. Activate the Top viewport. In the Parameters rollout > Vertex Projection Direction group, choose Use Active Viewport, and click Recalculate Projection.

8. In the Update group, turn on Hide Wrap-To Object.

   This hides the instance of the terrain so you can clearly see the road projected onto it.

   The Parameters rollout > Wrapper Parameters group > Standoff Distance value sets the number of units by which the road sits above the terrain along the world Z axis.

9. If necessary, adjust the Standoff Distance to raise or lower the road.
Interface

Pick Wrap-To Object rollout

Object Displays the name of the selected Wrap-To object.

Pick Wrap-To Object Click this button, and then select the object to which you want the current object to wrap.

Reference/Copy/Move/Instance This option lets you specify how the Wrap-To object is transferred to the Conform object. It can be transferred either as a reference on page 8699, a copy, an instance on page 8611, or it can be moved, in which case the original is not left behind.

Parameters rollout

Contains all parameters for the Conform object.

Objects group

Provides a list window and two edit fields that let you navigate the compound object and rename its components.
**List Window** Lists the Wrapper and the Wrap-To objects. Click to select an object in the window so that you can access it in the Modifier stack.

**Wrapper Name** Lets you rename the wrapper object within the compound Conform object.

**Wrap-To Object Name** Lets you rename the Wrap-To object.

**Vertex Projection Direction group**

Choose one of these seven options to determine the projection of the vertices.

- **Use Active Viewport** The vertices are projected away (inward) from the active viewport.

- **Recalculate Projection** Recalculates the projection direction for the currently active viewport. Because the direction is initially assigned when you pick the Wrap-To object, if you want to change viewports after assignment, click this button to recalculate the direction based on the new active viewport.

- **Use Any Object's Z Axis** Lets you use the local Z axis of any object in the scene as a direction. Once an object is assigned, you can alter the direction of vertex projection by rotating the direction object.

- **Pick Z-Axis Object** Click this button, and then click the object you want to use to indicate the direction of the projection source.
Object Displays the name of the direction object.

- **Along Vertex Normals** Projects the vertices of the Wrapper object inward along the reverse direction of its vertex normals. A vertex normal is a vector produced by averaging the normals of all faces attached to that vertex. If the Wrapper object encloses the Wrap-To object, the Wrapper takes on the form of the Wrap-To object.

- **Towards Wrapper Center** Projects the vertices toward the bounding center of the Wrapper object.

- **Towards Wrapper Pivot** Projects the vertices toward the original pivot center of the Wrapper object.

- **Towards Wrap-To Center** Projects the vertices toward the bounding center of the Wrap-To object.

- **Towards the Wrap-To Pivot** Projects the vertices toward the pivot center of the Wrap-To object.

**NOTE** Towards Wrapper Pivot and Towards the Wrap-To Pivot operate on the position of the original pivot point of the object before the Conform object is created. Once you create the Conform object, it's a new compound object with a single pivot point.

**TIP** You can animate the conforming effect by morphing between the compound object and a previously made copy of the original wrapper object. To do this, however, you must turn on Hide Wrap-To Object in the Update group so that the original object and the compound object have the same number of vertices. Using this technique, you can effectively morph between two objects with a different number of vertices.

**Wrapper Parameters group**

![Wrapper Parameters](image-url)
Provides controls that determine how far the vertices are projected.

**Default Projection Distance** The distance a vertex in the Wrapper object will move from its original location if it does not intersect the Wrap-To object.

**Standoff Distance** The distance maintained between the vertex of the Wrapper object and the surface of the Wrap-To object. For example, if you set Standoff Distance to 5, the vertices can be pushed no closer than 5 units from the surface of the Wrap-To object.

**Use Selected Vertices** When turned on, only the selected vertex sub-objects of the Wrapper object are pushed. When turned off, all vertices in the object are pushed, regardless of the Modifier stack selection. To access the Modifier stack of the Wrapper object, select the Wrapper object in the list window, open the Modifier stack, and select the base object name. At this point you can apply a Mesh Select modifier, for example, and select the vertices you want to affect.

**Update group**

The items in this group determine when the projection for the compound object is recalculated. Because complex compound objects can slow performance, you can use these options to avoid constant calculation.

- **Always** The object is updated constantly.
- **When Rendering** The object is recalculated only when the scene is rendered.
- **Manually** Activates the Update button for manual recalculation.

**Update** Recalculates the projection.

**Hide Wrap-To Object** When on, hides the Wrap-To object.
Display group

Determines whether the shape operands are displayed.

- **Result**  Displays the result of the operation.
- **Operands**  Displays the operands.

**Connect Compound Object**

Select an object. > Create panel > Geometry > Compound Objects > Object
Type rollout > Connect

Select an object. > Create menu > Compound > Connect

The Connect compound object lets you connect two or more objects between "holes" in their surfaces. To do this, you delete faces in each object to create one or more holes in their surfaces, position them so that the holes face one another, and then apply Connect.
**NOTE** Connect is not suited to NURBS objects, because they convert into many separate meshes instead of one big mesh. The workaround is simple: apply a Weld modifier to the NURBS object (thus converting it to a mesh and zipping up its seams) before using it as part of a connect.

Connect generates the best mapping coordinates it can for the bridges between the various holes in the meshes. While some ideal cases, such as a cylinder above another cylinder, can generate good UVW map interpolations, most cases cannot. You’ll need to apply mapping to the bridge faces with a UVW Map modifier on page 1932.

Vertex colors, on the other hand, interpolate smoothly.

**Notes:**

- You can use Connect on objects that have multiple sets of holes. Connect will do its best to match up the holes between the two objects.

- The mapping coordinates assigned to the original two objects are maintained to the extent possible. You might find irregularities in the
bridged area, depending on the complexity and difference between the two original sets of mapping coordinates and the types of geometry.

**Procedures**

To create a Connect object:

1. Create two mesh objects.
2. Delete faces on each to create holes where you want to bridge the objects. Position the objects so that the normals of the deleted faces of one object point toward the normals of the deleted faces of the other object (assuming that deleted faces could have normals).
3. Select one of the objects. On the Create panel > Geometry > Compound Object Type rollout, click Connect.
4. Click the Pick Operand button, and then select the other object.
5. Faces are generated connecting the holes in the two objects.
6. Adjust the connection with the various options.

**Example: To connect two cylinders:**

1. Create a cylinder with a radius of 15 and a height of 30. Use the default settings for the remaining parameters.
2. Create a second cylinder centered on the first with a radius of 30, a height of 30, and 13 sides. (The fewer sides are to demonstrate the mesh interpolation in the connection.)
3. Move the first, narrower cylinder straight up along Z so its bottom cap is about 15 units above the top cap of the larger cylinder.
4. Convert both cylinders to editable meshes.
5. Delete the lower cap of the upper cylinder, and the upper cap of the bottom cylinder. (Hint: Go to Editable Mesh (Polygon) mode, select each end in turn, and then press the Delete key.)
6. Exit sub-object mode, select the lower cylinder, and click Connect.
7. Click the Pick Operand button, and then click the upper cylinder. New faces are created that span the openings in the two cylinders.
Example continued: To try out some options and create animation:

1. Go to the Modify panel and increase the Segments spinner to 5 or more. As the segments increase, the connection becomes curved.
2. Set the Tension spinner to 0 to straighten the connecting surface, increase it to 1, and then return it to 0.5.
3. Try different combinations of the Bridge and Ends options.
4. Select the upper cylinder, turn on the Auto Key button, and apply various transforms at different frames.
5. Play the animation.

Interface

Pick Operand rollout

Pick Operand Click this button to connect an additional operand to the original object.
For example, you might begin with a single object with two holes, and arrange two additional objects, each with one hole, outside of those holes. Click the Pick Operand button and select one of the objects, which is connected, and then click Pick Operand again and select the other object, which is connected. Both connected objects are added to the Operands list.

Reference/Copy/Move/Instance Lets you specify how the operand is transferred to the compound object. It can be transferred either as a reference on page 8699, a copy, an instance on page 8611, or moved, in which case the original is not left behind.

NOTE Connect works only with objects that are capable of being converted into editable surfaces, such as editable meshes on page 2192.
Parameters rollout

Operands group

Operands list Displays the current operands. Select an operand to rename, delete or extract by clicking it in this list.

Name Renames a selected operand. Type in a new name, and then press Tab or Enter.

Delete Operand Deletes a selected operand from the list.

Extract Operand Extracts a copy or an instance of the selected operand. Choose an operand in the list to enable this button.

NOTE This button is available only in the Modify panel. You can't extract an operand while in the Create panel.

Instance/Copy Lets you specify how the operand is extracted: as either an instance or a copy.

Connect Compound Object | 699
Interpolation group

**Segments** Sets the number of segments in the connecting bridge.

**Tension** Controls the curvature in the connecting bridge. A value of 0 provides no curvature, while higher values create curves that attempt to more smoothly match the surface normals on either end of the connecting bridge. This spinner has no apparent effect when Segments is set to 0.

Smoothing group

**Bridge** Applies smoothing between the faces in the connecting bridge.

**Ends** Applies smoothing between the faces that border the old and new surfaces of the connecting bridge and the original objects. When turned off, 3ds Max assigns a new material ID number to the bridge. The new number is one higher than the highest ID number assigned to either of the original objects. When on, the ID number is taken from one of the original objects.

**NOTE** If both Bridge and Ends are on, but the original objects contain no smoothing groups, then smoothing is assigned to the bridge and to the faces bordering the bridge.

Display/Update rollout

Display group

Determines whether the shape operands are displayed.

- **Result** Displays the result of the operation.
Operands
Displays the operands.

Update group
These options determine when the projection for the compound object is recalculated. Because complex compound objects can slow performance, you can use these options to avoid constant calculation.

- **Always**  The object is updated constantly.
- **When Rendering**  The object is recalculated only when the scene is rendered.
- **Manually**  Activates the Update button for manual recalculation.

Update  Recalculates the projection.

BlobMesh Compound Object

Create panel > Geometry > Compound Objects > Object Type rollout > BlobMesh
Create menu > Compound > BlobMesh

The BlobMesh compound object creates a set of spheres from geometry or particles, and connects the spheres together as if they were made of a soft, liquid substance. When the spheres move within a certain distance of one another, they connect together. When they move apart, they take on a spherical form again.
In the 3D industry, the general term for spheres that operate in this way is metaballs on page 8638. The BlobMesh compound object generates metaballs based on specified objects in the scene, and the metaballs, in turn, form a mesh result called a blobmesh. A blobmesh is ideal for simulating thick liquids and soft substances that move and flow when animated.

When you associate an object or particle system with the BlobMesh compound object, the metaballs are placed and sized differently depending on the object used to generate them:

- For geometry and shapes, a metaball is placed at each vertex, and the size of each metaball is determined by the size of the original BlobMesh object. Soft selection can be used to vary the sizes of the metaballs.
- For particles, a metaball is placed at each particle, and the size of each metaball is determined by the size of the particle on which it's based.
For helpers, a metaball is placed at the pivot point, and the size of the metaball is determined by the original BlobMesh object.

**NOTE** You can apply motion blur on page 8644 to a BlobMesh object to enhance the effects of motion in renderings. For particle systems other than Particle Flow, use Image motion blur. For Particle Flow particle systems and all other types of objects including geometry, shapes, and helpers, use Object motion blur.

### Procedures

**To create a blobmesh from geometry or helpers:**

1. Create one or more geometry or helper objects. If the scene requires animation, animate the objects as desired.

2. Click BlobMesh, and click anywhere on the screen to create the initial metaball.

3. Go to the Modify panel.

4. In the Blob Objects group, click Add. Select the objects you wish to use to create metaballs. A metaball appears at each vertex of each selected object, or at the centers of helper objects.

5. In the Parameters rollout, set the Size parameter as necessary to cause the metaballs to connect.

**To create a blobmesh with soft selection on geometry:**

1. Create a geometry object, and convert it to an Editable Mesh or Editable Poly.

2. Apply a Mesh Select modifier to the object, and select some of the vertices on the object.

3. In the Soft Selection rollout, turn on Use Soft Selection. Set the Falloff value as desired.

4. Apply a Turn to Mesh or Turn to Poly modifier to the object. This will retain the soft selection and pass it up the stack regardless of whether you exit the sub-object mode.

5. Click Create panel > Compound Objects > BlobMesh, and click anywhere on the screen to create the initial metaball.

6. Go to the Modify panel.
In the Blob Objects group, click Add. Select the Editable Mesh or Editable Poly object. A metaball appears at each vertex of the selected object.

In the Parameters rollout, turn on Use Soft Selection. Metaballs are limited to those vertices that are affected by the soft selection.

Set the Size and Min. Size parameters to set the sizes of the metaballs.

To create a blobmesh with soft selection on a spline:

1. Create the spline, and convert it to an Editable Spline.
2. In the Rendering rollout, turn on both Enable In Renderer and Enable In Viewport.
3. Apply a Mesh Select modifier, and select the appropriate vertices for soft selection.
4. In the Soft Selection rollout, turn on Use Soft Selection. Set the Falloff value as desired.
5. Apply a Turn to Mesh or Turn to Poly modifier to the object.
   This will retain the soft selection and pass it up the stack regardless of whether you exit the sub-object mode.
6. Click Create panel > Compound Objects > BlobMesh, and click anywhere on the screen to create the initial metaball.
7. Go to the Modify panel.
8. In the Blob Objects group, click Add. Select the Editable Spline. A metaball appears at each vertex of the selected object.
9. In the Parameters rollout, turn on Use Soft Selection. Metaballs are limited to those vertices that are affected by the soft selection.
10. Set the Size and Min. Size parameters to set the sizes of the metaballs.
To create a blobmesh from a particle system:

When you use BlobMesh with a particle system, a metaball is created at each particle's location. The size of the metaball is determined by the size of the particle.

1. Create a particle system on page 2997, and set up its parameters to animate the particles.

2. Click Create panel > Compound Objects > BlobMesh, and click anywhere on the screen to create the initial metaball.

3. Go to the Modify panel.

4. In the Blob Objects group, click Add. Select the particle system. A metaball appears at each particle in the system.

5. If you have added a Particle Flow system on page 2997 to the blobmesh and you want to create metaballs only for particles in specific events, click Add on the Particle Flow Parameters rollout to choose the events from a list.

**TIP** If you need to prevent the particles from rendering, do not hide them as this can prevent the blobmesh from generating correctly. Instead, turn off the particle system's Renderable option on the Object Properties dialog on page 283.
Interface

Parameters rollout

Size The radius of each metaball for objects other than particles. For particles, the size of each metaball is determined by the size of the particle, which is set by parameters in the particle system. Default=20.
NOTE The apparent size of the metaballs is affected by the Tension value. When Tension is set to its lowest possible value, the radius of each metaball accurately reflects the Size setting. Higher Tension values will tighten the surface, and make the metaballs smaller.

**Tension** Determines how relaxed or tight the surface will be. A smaller value makes a looser surface. This value can range from 0.01 to 1.0. Default=1.0.

**Evaluation Coarseness** Sets the coarseness, or density, of the resulting blobmesh. When Relative Coarseness (see following) is off, the Render and Viewport values set the absolute height and width of blobmesh faces, and lower values create a smoother, denser mesh. When Relative Coarseness is on, the height and width of blobmesh faces is determined by the ratio of metaball size to this value. In this case, higher values create a denser mesh. Range (both)=0.001 to 1000.0. Render default=3.0, Viewport default =6.0.

The lower end of the range for both Coarseness settings is 0.001, which allows for high-resolution metaball geometry when Relative Coarseness is off. Using such low values can also cause lengthy calculation delays; if this happens and you wish to halt calculation, press Esc.

**Relative Coarseness** Determines how the coarseness values will be used. If this option is turned off, the Render Coarseness and View Coarseness values are absolute, where the height and width of each face on the blobmesh is always equal to the coarseness value. This means the faces on the blobmesh will retain a fixed size even if the metaballs change size. If this option is turned on, the size of each blobmesh face is based on the ratio of the metaball size to the coarseness, which will cause the blobmesh face size to change as the metaballs become larger or smaller. Default=Off.

**Large Data Optimization** This option provides an alternate method for calculating and displaying the blobmesh. This method is more efficient than the default method only when a large number of metaballs are present, such as 2,000 or more. Turn on this option only when using a particle system or other object that produces a large number of metaballs. Default=Off.

**Off in Viewport** Turns off the display of the blobmesh in viewports. The blobmesh will still appearing in renderings. Default=Off.

**Use Soft Selection** If soft selection has been used on geometry you add to the blobmesh, turning on this option causes the soft selection to be used for the size and placement of metaballs. Metaballs are placed at selected vertices with the size set by the Size parameter. For vertices that lie within the falloff set on the geometry’s Soft Selection rollout, smaller metaballs are placed. For vertices outside the falloff, no metaballs are placed. This option has an effect only if the Vertex sub-object level for the geometry is still enabled, and Use Soft
Selection on the geometry’s Soft Selection rollout is turned on. If Use Soft Selection is turned off either for the blobmesh for the geometry, metaballs are placed at all vertices on the geometry. Default=Off.

**Min Size** Sets the minimum size for metaballs within the falloff when Use Soft Selection is turned on. Default=10.0.

**Pick** Allows you to pick objects or particle systems from the screen to add to the blobmesh.

**Add** Displays a selection dialog where you can select objects or particle systems to add to the blobmesh.

**Remove** Removes objects or particles from the blobmesh.

**Particle Flow Parameters rollout**

Use this rollout if you have added a Particle Flow system to the blobmesh, and want particles to generate metaballs only during specific events. Before you can specify events on this rollout, you must add the Particle Flow system to the blobmesh on the Parameters rollout.

**All Particle Flow Events** When turned on, all Particle Flow Events will generate metaballs. When turned off, only Particle Flow Events specified in the PFlow Events list will generate metaballs.
**Add** Displays a list of PFlow events in the scene so you can pick events to add to the PFlow Events list.

**Remove** Removes the selected event from the PFlow Events list.

---

**ShapeMerge Compound Object**

Select an object. > Create panel > Geometry > Compound Objects > Object Type rollout > ShapeMerge

Select an object. > Create menu > Compound > ShapeMerge

ShapeMerge creates a compound object consisting of a mesh object and one or more shapes. The shapes are either embedded in the mesh, altering the edge and face patterns, or subtracted from the mesh.

ShapeMerge combines the lettering, a text shape, with the mesh that models the tire.
Procedures

To create a ShapeMerge object:

1. Create a mesh object and one or more shapes
2. Align the shapes in the viewport so they can be projected toward the surface of the mesh object.
3. Select the mesh object, and click the ShapeMerge button.
4. Click Pick Shape, and then select the shape.

The geometry of the surface of the mesh object is altered to embed a pattern matching that of the selected shape.

Interface

Pick Operand rollout

Pick Shape Click this button, and then click the shape you want to embed in the mesh object. The shape is projected onto the mesh object in the direction of the shape's local negative Z axis. For example, if you create a box, and then create a shape in the Top viewport, the shape is projected onto the top of the box. You can repeat this process to add shapes, and the shapes can be projected in different directions. Simply click Pick Shape again, and then pick another shape.

Reference/Copy/Move/Instance Lets you specify how the shape is transferred to the compound object. It can be transferred either as a reference on page 8699, a copy, an instance on page 8611, or moved, in which case the original shape is not left behind.
Parameters rollout

Operands group

**Operands list** Lists all operands in the compound object. The first operand is the mesh object, and any number of shape-based operands can follow.

**Delete Shape** Remove selected shapes from the compound object.

**Extract Operand** Extracts a copy or an instance of the selected operand. Choose an operand in the list window to enable this button.

**Instance/Copy** Lets you specify how the operand is extracted. It can be extracted either as an instance on page 8611 or a copy.

Operation group

These options determine how the shape is applied to the mesh.
Cookie Cutter Cuts the shape out of the mesh object's surface.

Merge Merges the shape with the surface of the mesh object.

Invert Reverses the effect of Cookie Cutter or Merge. With the Cookie Cutter option, the effect is obvious. When Invert is off, the shape is a hole in the mesh object. When Invert is on, the shape is solid and the mesh is missing. When you're using Merge, Invert reverses the sub-object mesh selection. As an example, if you merge a circle shape and apply a Face Extrude, the circular area is extruded when Invert is off, and all but the circular area is extruded when Invert is on.

Output Sub-Mesh Selection group

Provides options that let you specify what selection level is passed up the Stack. The ShapeMerge object stores all selection levels; that is, it stores the vertices, faces, and edges of the merged shape with the object. (If you apply a Mesh Select modifier and go to the various sub-object levels, you'll see that the merged shape is selected.) Thus, if you follow the ShapeMerge with a modifier that acts on a specific level, such as Face Extrude, that modifier will work properly.

If you apply a modifier that can work on any selection level, such as Volume Select or XForm, the options will specify which selection level is passed to that modifier. Although you can use a Mesh Select modifier on page 1500 to specify a selection level, the Mesh Select modifier considers the selection only at frame 0. If you've animated the shape operand, that animation will be passed up the Stack for all frames only by using the Output Sub-Mesh Selection options.

- None Outputs the full object.
- Face Outputs the faces within the merged shape.
- Edge Outputs the edge of the merged shape.
- Vertex Outputs the vertices defined by the spline of the shape.
Display/Update rollout

Display group

Determines whether the shape operands are displayed.

- **Result**  Displays the result of the operation.
- **Operands**  Displays the operands.

Update group

These options specify when the display is updated. Typically, you use them when you've animated the merged shape operands and the viewport display is slow.

- **Always**  Updates the display at all times.
- **When Rendering**  Updates the display only when the scene is rendered.
- **Manually**  Updates the display only when you click the Update button.

**Update** Updates the display when any option except Always is chosen.

Boolean Compound Object

Select an object. > Create panel > Geometry > Compound Objects > Object Type rollout > Boolean
Select an object. > Create menu > Compound > Boolean
A Boolean object combines two other objects by performing a Boolean operation on them.

**TIP**  ProBoolean on page 799 is an improved, up-to-date, and more-complete implementation of the Boolean compound object. In general, it is recommended that you use ProBoolean rather than Boolean for combining 3D objects.

These are the Boolean operations for geometry:

**Union**  The Boolean object contains the volumes of both original objects. The intersecting or overlapping portion of the geometry is removed.

**Intersection**  The Boolean object contains only the volume common to both original objects (in other words, where they overlapped).

**Subtraction (or difference)**  The Boolean object contains the volume of one original object with the intersecting volume removed.

The two original objects are designated operands A and B.

You can layer Booleans in the stack display, so that a single object can incorporate many Booleans. By navigating through the stack display, it's possible to revisit the components of each Boolean and make changes to them.
Subtraction: A-B (above); B-A (below)
Booleans with Objects That Have Materials Assigned to Them

Most primitives use several material IDs on page 8633 on their surfaces. For example, a box uses material IDs 1–6 on its sides. If you assign a Multi/Sub-Object material on page 6120 with six sub-materials, 3ds Max automatically assigns one to each side. If you assign a Multi/Sub-Object material with two sub-materials, 3ds Max assigns the first material to sides 1, 3, and 5, and the second to sides 2, 4, and 6.

When you create a Boolean from objects that have materials assigned to them, 3ds Max combines the materials in the following way:

- If operand A doesn't have a material, it inherits operand B's material.
- If operand B doesn't have a material, it inherits operand A's material.
- If both operands have materials, the resulting material is a Multi/Sub-Object material that combines the materials from both operands.

For more information, see Material Attach Options Dialog on page 728.

Solutions When Working with Booleans

The Boolean algorithm caused unpredictable behavior in earlier releases. The solutions are discussed here.
Surface Topology

Boolean requires that operands' surface topology be intact: This means no missing or overlapping faces and no unwelded vertices. The surface should be one continuous closed surface.

The Boolean corrects operands that fail to meet this requirement. However, the automatic correction may not be exactly what you want, so in some cases it might be safer to correct the surfaces manually.

To check for holes in the geometry, use the STL-Check modifier on page 1746 or the Measure utility on page 2882.

To fill holes, use the Cap Holes modifier on page 1185.

Face Normals

Booleans require that the face normals of the surface be consistent. Flipped normals can produce unexpected results. Surfaces where some faces are facing one way and adjacent faces are flipped are also problematic, and are commonly found in geometry imported from CAD programs. The Boolean fixes these faces as best it can. Again, it might make more sense to correct these manually.

Use shaded viewports to look for normal problems, watching for objects that appear inside-out or look otherwise incorrect. You can also turn on Show in the Editable Mesh (Face) on page 2216 > Surface Properties rollout > Normals group. Fix normals here, or with a Normal modifier on page 1551.

Overlapping Elements

Because Boolean operations depend on a clear understanding of what is inside and what is outside a mesh, meshes that overlap themselves can produce invalid results. For instance, if you use the Collapse utility on page 2022 with two overlapping objects without turning on the Boolean feature, the resulting object will not make a good Boolean operand. This is also a problem for the Teapot primitive on page 416 (with all parts turned on), which overlaps itself.

If you need to use such an object as a Boolean operand, you might reconstruct it as a single non-overlapping mesh by separating the components and combining them with Boolean.

Working with Inverted Meshes

Boolean doesn't always produce the ideal result on "inverted meshes" (meshes that have been turned inside-out by having their normals flipped). The problem is that the area inside the flipped mesh is correctly seen as "outside," but the
area outside it may also be seen as “outside.” To remedy this, instead of inverting the mesh, make a very large box or other primitive centered on (but not touching) the mesh and subtract the mesh from it using Boolean. Then convert it to an editable mesh, and delete the box faces. This produces a correctly inverted mesh that works correctly with Boolean.

Alignment

If two Boolean operands are perfectly aligned without actually intersecting, the Boolean operation might produce the wrong result. Although this is rare, if it does occur, you can eliminate it by making the operands overlap slightly.

Relative Complexity Between Operands

Boolean works best when the two operands are of similar complexity. If you wish to subtract text (a complex object made of many faces and vertices) from a box without any segments, the result is many long, skinny faces that are prone to rendering errors. Increasing the number of box segments produces better results. Try to maintain a similar complexity between operands.

Coplanar Faces/Colinear Edges

Previously, Boolean required that objects overlap. If two objects did not overlap but merely touched an edge to an edge, or a face to a face, the Boolean would fail.

Boolean allows for non-overlapping objects. Coincident faces/edges and vertices are no longer a problem. You can use objects completely encased within another object, where no edges intersect, to create Booleans.

See also Collapse Utility on page 2022 to create Booleans with multiple objects.

See also:

- Fixing Boolean Problems on page 8463

Procedures

To create a Boolean object:

1. Select an object. This object becomes operand A.
2. Click Boolean. The name of operand A appears in the Operands list on the Parameters rollout.
3 On the Pick Boolean rollout, choose the copy method for operand B: Reference, Move, Copy, or Instance. (These methods are described in the Pick Boolean rollout section, later in this topic.)

4 On the Parameters rollout, choose the Boolean operation to perform: Union, Intersection, Subtraction (A-B), or Subtraction (B-A). You can also choose one of the Cut operations, described later in the Operation group section.

5 On the Pick Boolean rollout, click Pick Operand B.

6 Click in a viewport to select operand B. 3ds Max performs the Boolean operation.

The operand objects remain as sub-objects of the Boolean object. By modifying the creation parameters of the Boolean's operand sub-objects, you can later change operand geometry in order to change or animate the Boolean result.

Example: To create and modify a single object that contains multiple Boolean:

Suppose you want to create a box with two holes in it. One hole is to be cut by a sphere, and the second by a cylinder. If you want to make changes to the sphere or the cylinder later, you can do so by following these steps:

1 Create a Boolean following the steps in the previous sections. The original object (the box) is converted to a Boolean, and is designated operand A. The second object (the sphere) is converted to operand B.

2 Deselect the Boolean object. Build the cylinder if it does not already exist.

3 Select the Boolean object; and under Compound Objects, click Boolean again.

4 Click Pick Operand B and click the cylinder in the viewport. It is converted to operand B.

5 On the Modify panel, choose Operand B from the Parameters rollout > Operands list. If you want to see operand B, choose Display/Update rollout > Display group > Operands or Result + Hidden Ops.

If you want to animate the Cylinder or the Cylinder's parameters you can now access them in the modifier stack display.

6 If you want to modify the sphere’s parameters, choose the box in the Operands list.

7 Now there are two entries labeled Boolean in the stack display. Choose the lower entry. The Sphere is displayed in the Operands list.
Choose the Sphere from the Operands list. The sphere’s parameters are available by clicking the sphere’s name in the modifier stack display.

Use this technique to change parameters or animate any of the operands within the multiple Boolean.

You can also navigate multiple Booleans through Track View. Clicking the operand in Track View gives you direct access to its entry in the modifier stack display. In complex objects with many Booleans, this is an easier method than the one outlined above.

Interface

Pick Boolean rollout

When you select operand B, you designate it as a Reference, Move (the object itself), Copy, or Instance, according to your choice in the Pick Boolean rollout for Boolean objects. Base your selection on how you want to use the scene geometry after you create the Boolean.

Because you usually create Boolean objects from overlapping objects, if the B object isn’t removed (if you don’t use the default Move option), it often obstructs your view of the completed Boolean. You can move the Boolean or the B object to better see the result.

Pick Operand B Use this button to select the second object to use to complete the Boolean operation.

Reference/Copy/Move/Instance Lets you specify how operand B is transferred to the Boolean object. It can be transferred either as a reference on page 8699, a copy, an instance on page 8611, or moved.

Use Reference to synchronize modifier-induced changes to the original object with operand B, but not vice-versa.

Use Copy when you want to reuse the operand B geometry for other purposes in the scene.
- Use Instance to synchronize animation of the Boolean object with animated changes to the original B object, and vice-versa.

- Use Move (the default) if you've created the operand B geometry only to create a Boolean, and have no other use for it. Object B geometry becomes part of the Boolean object regardless of which copy method you use.

**Parameters rollout**

**Operands group**

**Operands list field** Displays the current operands.

**Name** Edit this field to change the name of the operands. Choose an operand in the Operands list and it will also appear in the Name box.

**Extract Operand** Extracts a copy or an instance of the selected operand. Choose one of the operands in the list window to enable this button.
NOTE  This button is available only in the Modify panel. You can't extract an operand while the Create panel is active.

Instance/Copy  Lets you specify how the operand is extracted: as either an instance on page 8611 or a copy.

Operation group

Union  The Boolean object contains the volume of both original objects. The intersecting or overlapping portion of the geometry is removed.

Intersection  The Boolean object contains only the volume that was common to both original objects (in other words, where they overlapped).

Subtraction (A-B)  Subtracts the intersection volume of operand B from operand A. The Boolean object contains the volume of operand A with the intersection volume subtracted from it.

Subtraction (B-A)  Subtracts the intersection volume of operand A from operand B. The Boolean object contains the volume of operand B with the intersection volume subtracted from it.

Cut  Cuts operand A with operand B, but doesn't add anything to the mesh from operand B. This works like the Slice modifier on page 1727, but instead of using a planar gizmo, Cut uses the shape of operand B as the cutting plane. Cut treats the geometry of the Boolean object as volumes rather than closed solids. Cut does not add geometry from operand B to operand A. Operand B intersections define cut areas for altering geometry in operand A.

There are four types of Cut:

■  **Refine**  Adds new vertices and edges to operand A where operand B intersects the faces of operand A. 3ds Max refines the resulting geometry of operand A with additional faces inside the intersected area of operand B. Faces cut by the intersection are subdivided into new faces. You might use this option to refine a box with text so that you can assign a separate material ID to the object.

■  **Split**  Works like Refine but also adds a second or double set of vertices and edges along the boundary where operand B cuts operand A. Split produces two elements belonging to the same mesh. Use Split to break an object into two parts along the bounds of another object.

■  **Remove Inside**  Deletes all operand A faces inside operand B. This option modifies and deletes faces of operand A inside the area intersected by operand B. It works like the subtraction options, except that 3ds Max adds...
no faces from operand B. Use Remove Inside to delete specific areas from your geometry.

- **Remove Outside**  Deletes all operand A faces outside operand B. This option modifies and deletes faces of operand A outside the area intersected by operand B. It works like the Intersection option, except that 3ds Max adds no faces from operand B. Use Remove to delete specific areas from your geometry.

### Display/Update rollout

![Display/Update rollout](image)

**Display group**

Visualizing the result of a Boolean can be tricky, especially if you want to modify or animate it. The Display options on the Boolean Parameters rollout help you visualize how the Boolean is constructed.

The display controls have no effect until you've created the Boolean.

- **Result**  Displays the result of the Boolean operation; that is, the Boolean object itself.

- **Operands**  Displays the operands instead of the Boolean result.

  **TIP** When operands are difficult to see in a viewport, you can use the Operand list to select one or the other. Click the name of the A or B operand to select it.

- **Results + Hidden Ops**  Displays the "hidden" operands as wireframe.
Operand geometry remains part of the compound Boolean object, although it isn't visible or renderable. The operand geometry is displayed as wireframes in all viewports.
Displaying the result (A-B)
Displaying the hidden operand after A-B
Displaying the hidden operand after B-A

Update group

By default, Booleans are updated whenever you change the operands. A scene that contains one or more complicated, animated Booleans can impede performance. The update options provide alternate methods to improve performance.

■ **Always**  Updates Booleans immediately when you change an operand, including the original object of an instanced or referenced B operand. This is the default behavior.

■ **When Rendering**  Updates Booleans only when you render the scene or click Update. With this option, viewports don’t always show current geometry, but you can force an update when necessary.

■ **Manually**  Updates Booleans only when you click Update. With this option, the viewports and the render output don’t always show current geometry, but you can force an update when necessary.

**Update** Updates the Boolean. The Update button is not available when Always is selected.
Material Attach Options Dialog

Use objects with different materials assigned to them. > Create panel > Geometry > Compound Objects > Object Type rollout > Boolean > Pick Boolean rollout > Pick Operand B button > Select object in the viewport that is operand B.

When you use Boolean operations with objects that have been assigned different materials, 3ds Max displays the Material Attach Options dialog. This dialog offers five methods for handling the materials and the material IDs on page 8633 in the resultant Boolean object.

**NOTE** If operand A has no material, and operand B has a material assigned, the Boolean dialog lets you choose to inherit the material from operand B.

If operand A has a material assigned and operand B has no material assigned, the Boolean object automatically inherits materials from operand A.

**Procedures**

To create a Boolean from objects that match material IDs to material:

1. Create a Boolean on page 718 using at least one object that has a multi/sub-object material on page 6120 assigned to it.
2. On the Pick Boolean rollout, click Pick Operand B.
3. Click in a viewport and select the B operand. 3ds Max displays the Match Attach Options dialog.
4. Choose Match Material IDs to Material to complete the Boolean operation.
Match Material IDs to Material 3ds Max modifies the number of material IDs in the combined object to be no greater than the number of sub-materials assigned to the operands. For example, if you combine two boxes that have standard materials and each box is assigned six material IDs (the default), the resulting combined object has two operands with one material ID each, rather than the 12 that would result from using the Match Material to Material ID option. After you complete the operation, 3ds Max creates a new multi/sub-object material with two slots. 3ds Max assigns the sub-materials to the operands as they appeared before the operation. The number of resulting material IDs matches the number of materials between the original objects. You might use this option to reduce the number of material IDs.

Match Material to Material IDs Maintains the original material ID assignment in the operands by adjusting the number of sub-materials in the resultant multi/sub-object material. For example, if you combine two boxes, both assigned single materials, but with their default assignment of six material IDs, the result would be a multi/sub-object material with 12 slots (six containing instances of one box's material, and six containing instances of the other box's material). Use this option when it's important to maintain the original material ID assignments in your geometry. Also use this option when material IDs have been assigned, but materials have not been assigned.

NOTE To make the instanced sub-materials unique, select them in Track View, and click the Make Unique button on the Track View toolbar. You can also make them unique one at a time with the Make Unique button on page 5692 in the Material Editor.

Do Not Modify Mat IDs or Material If the number of material IDs in an object is greater than the number of sub-materials in its multi/sub-object material, then the resultant face-material assignment might be different after the Boolean operation.
Discard New Operand Material Discards the material assignment of operand B. 3ds Max assigns operand A's material to the Boolean object.

Discard Original Material Discards the material assignment of operand A. 3ds Max assigns operand B's material to the Boolean object.

NOTE A UVW Map modifier on page 1932 must be used with compound objects to apply mapping coordinates.

Terrain Compound Object

Select spline contours. > Create panel > Geometry > Compound Objects > Object Type rollout > Terrain
Select spline contours. > Create menu > Compound > Terrain

The Terrain button lets you produce terrain objects. 3ds Max generates these objects from contour line data.

To create Terrain, you select editable splines representing elevation contours and create a mesh surface over the contours. You can also create a "terraced" representation of the terrain object so that each level of contour data is a step, resembling traditional study models of land forms.
Using contours to build a terrain

Upper left: The contours
Upper right: The terrain object
Lower left: Terrain object used as the basis of a landscape

If you import an AutoCAD drawing file to use as contour data, 3ds Max names each object based on the AutoCAD object’s layer, color, or object type. A number is appended to each name. For example, an AutoCAD object on the layer BASE becomes an object named BASE.01. See Importing DWG Files on page 7666 for more information.

After you import or create the contour data, select the objects, and click the Terrain button, 3ds Max creates a new triangulated mesh object based on the contour data. The name of the first selected spline becomes the name of the terrain object. Other splines in the selection are treated according to the previously set Reference, Move, Copy, or Instance selection in the Pick Operand rollout, described below.

Keep in mind that the Terrain object can use any spline objects as operands, whether they are horizontal splines or not. Though the most common scenario is when sets of elevational contours are used to create terrain forms, it is possible to append or refine Terrain objects by using non-horizontal splines.
NOTE To ensure that 3ds Max imports polylines as splines, when you import an AutoCAD drawing file, turn off Import AutoCAD DWG File dialog > Geometry Options group > Cap Closed Entities.

Following are examples of uses of the Terrain feature:

- Visualizing the effects of grading plans in 3D.
- Maximizing views or sunlight by studying topographical undulation of land forms.
- Analyzing elevation changes by using color on the data.
- Adding buildings, landscaping, and roads to a terrain model to create virtual cities or communities.
- Viewing corridors and completing ridge analyses from particular locations on a site by adding cameras to the scene.

Procedures

To analyze elevation changes:

1. Import or create contour data.
2. Select the contour data, and click the Terrain button.
3. On the Color By Elevation rollout, enter elevation zone values between the maximum and minimum elevations in the Base Elev box. Click Add Zone after entering the value. 3ds Max displays the zones in the list under the Create Defaults button.
4. Click the Base Color swatch to change the color of each elevation zone. For example, you could use a deep blue for low elevations, a light blue for intermediate elevations, and perhaps greens for higher elevations.
5. Click Solid To Top of Zone to see the elevation changes in a striped effect.
6. Click Blend To Color Above to see the elevation changes blended.

Interface

Name and Color rollout

Displays the name of the terrain object. 3ds Max uses the name of one of the selected objects to name the terrain object.
**Pick Operand rollout**

- **Pick Operand** Adds splines to the terrain object. You might do this if you didn't select all the objects before generating the terrain object, or if some objects in the imported data weren't included in the terrain object. You can also use this option to add existing splines in the current scene to the terrain object.

- **Reference/Copy/Move/Instance** When you click Pick Operand, the copy method you designate determines how the operands are used. When Move is the method, the original contour data is moved from the scene and into the operands of the new terrain object. Copy, Reference, and Instance retain the original contour data in the scene and create copies, references or instances of the contour data as operands in the terrain object. This is similar to the copy method for **Boolean** on page 713.

- **Override** Allows you to select closed curves that override any other operand data within their interior. Within the area an Override operand encloses (as seen in plan), other curves and points of the mesh are disregarded and the elevation of the Override operand supersedes them. An Override operand is indicated in the operands list by a # after its name. Override is only effective on closed curves. If multiple override operands overlap, later overrides (higher operand numbers) take preference.
Parameters rollout

Operand list Displays the current operands. Each operand is listed as "Op" followed by a number and the name of the object that is being used as the operand. The operand name comprises layer, color, or object type name plus a numeric suffix.

Delete Operand Deletes a selected operand from the Operands list.

Operand list Displays the current operands. Each operand is listed as "Op" followed by a number and the name of the object that is being used as the operand. The operand name comprises layer, color, or object type name plus a numeric suffix.

Delete Operand Deletes a selected operand from the Operands list.
Form group

- **Graded Surface**  Creates a graded surface of the mesh over the contours.

Terrain created as a graded surface

- **Graded Solid**  Creates a graded surface with skirts around the sides and a bottom surface. This represents a solid that is visible from every direction.

- **Layered Solid**  Creates a "wedding cake" or laminated solid similar to cardboard architectural models.
Terrain created as a "layered solid" surface, with levels

Stitch Border When on, suppresses the creation of new triangles around the edges of terrain objects when edge conditions are defined by splines that are not closed. Most terrain forms display more reasonably when this is turned off.

Retriangulate The basic Terrain algorithm tends to flatten or notch contours when they turn sharply upon themselves. A typical situation in which this may happen is when a narrow creek bed is described with contours; the resulting form may look more like a series of cascades at each elevational contour, rather than a smoothly descending ravine. When Retriangulate is checked, a somewhat slower algorithm is used that follows contour lines more closely. This may be particularly evident in the Layered Solid display mode. For additional precision, try using Retriangulate in conjunction with horizontal interpolation.

Display group

- Terrain Displays only the triangulated mesh over the contour line data.
- **Contours** Displays only the contour line data of the terrain object.
- **Both** Displays both the triangulated mesh and the contour line data of the terrain object. You can select the terrain object by clicking its surface, but not by clicking a contour line. When Both is selected, contour lines may not be apparent in Wireframe display modes or when Edged Faces are displayed.

**Update group**

The items in this group box determine when 3ds Max recalculates the projection for the terrain object. Because complex terrain objects can slow performance, you can use these options to avoid constant calculation.

- **Always** Updates the terrain object immediately when you change an operand, including the original object of an instanced or referenced operand.
- **When Rendering** Updates the terrain object when you render the scene or when you click Update. With this option, viewports won’t show current geometry unless you click Update.
- **Manually** Updates the terrain object when you click Update.

**Update** Updates the terrain object. This button is not enabled only when Always is the active option.
Simplification rollout

Horizontal group

- **No Simplification**  Uses all the operands' vertices to create a complex mesh. This results in greater detail and a larger file size than the two fractional options.

- **Use 1/2 of Points**  Uses half the set of vertices in the operands to create a less complex mesh. This results in less detail and a smaller file size than using No Simplification.

- **Use 1/4 of Points**  Uses a quarter of the vertices in the operands to create a less complex mesh. This results in the least detail and smallest file size of these options.

- **Interpolate Points * 2**  Doubles the set of vertices in the operands to create a more refined but more complex mesh. This is most effective in terrain forms that use constructive curves such as circles and ellipses. This results in more detail and a larger file size than using No Simplification.

- **Interpolate Points * 4**  Quadruples the set of vertices in the operands to create a more refined but more complex mesh. This is most effective in terrain forms that use constructive curves such as circles and ellipses. This results in more detail and a larger file size than using No Simplification.
Vertical group

- **No Simplification**  Uses all the spline operands vertices of the terrain object to create a complex mesh. This results in greater detail and a larger file size than the other two options.

- **Use 1/2 of Lines**  Uses half the set of spline operands of the terrain object to create a less complex mesh. This results in less detail and a smaller file size than using No Simplification.

- **Use 1/4 of Lines**  Uses a quarter of the spline operands of the terrain object to create a less complex mesh. This results in the least detail and smallest file size of the three options.
Color by Elevation rollout

Maximum Elev. Displays the maximum elevation in the Z axis of the terrain object. 3ds Max derives this data from the contour data.

Minimum Elev. Displays the minimum elevation in the Z axis of the terrain object. 3ds Max derives this data from the contour data.

Reference Elev. This is the reference elevation, or datum, that 3ds Max uses as a guide for assigning colors to zones of elevation. After entering a reference elevation, click the Create Defaults button. 3ds Max treats elevations above the reference elevation as solid land and those below the reference elevation as water.
If you enter a value no greater than the minimum elevation in the object, 3ds Max divides the range between the reference and minimum elevations into five color zones: dark green, light green, yellow, purple, and light gray. If you enter a value between the minimum and maximum elevations, 3ds Max creates six color zones. Two zones (dark blue and light blue) are used for elevations below the reference elevation. These are considered to be under water. One zone (dark yellow) is used for a narrow range around the reference elevation. Three zones (dark green, light green, light yellow) are used for elevations above the reference elevation. If you enter a value at or above the maximum elevation, 3ds Max divides the range between the minimum and reference elevations into three zones (dark blue, medium blue, light blue).

**Zones by Base Elevation group**

Create Defaults Creates elevation zones. 3ds Max lists the elevation at the bottom of each zone, referenced to the datum (the reference elevation). 3ds Max applies the color of the zone at the base elevation. Whether the colors blend between zones depends on your choice of the Blend to Color Above or Solid to Top of Zone option.

**Color Zone group**

The items in this group box assign colors to elevation zones. For example, you might want to change levels of blue to indicate the depth for water. Your changes in the Color Zone area don't affect the terrain object until you click the Modify Zone or Add Zone button.

- **Base Elev** This is the base elevation of a zone to which you assign color. After entering a value, click Add Zone to display the elevation in the list under Create Defaults.
- **Base Color** Click the color swatch to change the color of the zone.
- **Blend to Color Above** Blends the color of the current zone to the color of the zone above it.
- **Solid to Top of Zone** Makes a solid color at the top of the zone without blending to the color of the zone above it.

Modify Zone Modifies selected options of a zone.
Add Zone Adds values and selected options for a new zone.
Delete Zone Deletes a selected zone.
Loft Compound Object

Select a path or shape. > Create panel > Geometry > Compound Objects >
Object Type rollout > Loft

Select a path or shape. > Create menu > Compound Objects > Loft

Loft objects are two-dimensional shapes extruded along a third axis. You create
loft objects from two or more existing spline objects. One of these splines
serves the path. The remaining splines serve as cross-sections, or shapes, of
the loft object. As you arrange shapes along the path, 3ds Max generates a
surface between the shapes.

Roadway created as a lofted shape

You create shape objects to serve as a path for any number of cross-section
shapes. The path becomes the framework that holds the cross sections forming
your object. If you designate only one shape on the path, 3ds Max assumes
an identical shape is located at each end of the path. The surface is then
generated between the shapes.

3ds Max places few restrictions on how you create a loft object. You can create
curved, three-dimensional paths and even three-dimensional cross sections.
When using Get Shape, as you move the cursor over an invalid shape, the reason the shape is invalid is displayed in the prompt line.

Unlike other compound objects, which are created from the selected object as soon as you click the compound-object button, a Loft object is not created until you click Get Shape or Get Path, and then select a shape or path.

Loft is enabled when the scene has one or more shapes. To create a loft object, first create one or more shapes and then click Loft. Click either Get Shape or Get Path and select a shape in the viewports.

Once you create a loft object, you can add and replace cross-section shapes or replace the path. You can also change or animate the parameters of the path and shapes. Another method is to use the Modify panel's Deformations rollout to add complexity. See Deformations on page 770 for further information.

Once you've created a loft object, you can also use the Modify panel's Deformations rollout to add complexity. See Deformations on page 770 for further information.

You can't animate the path location of a shape.

You can convert loft objects to NURBS surfaces on page 2483.

**Procedures**

**To create a loft object:**

Creating loft objects is detailed and offers many choices, but the basic process is quite simple.

1. Create a shape to be the loft path.

2. Create one or more shapes to be loft cross sections.

3. Do one of the following:
   - Select the path shape and use Get Shape to add the cross sections to the loft.
   - Select a shape and use Get Path to assign a path to the loft. Use Get Shape to add additional shapes.

You can use the loft display settings to view the skin generated by your loft in both wireframe and shaded views.
NOTE 3ds Max builds the loft at the location of the first object you select: if you
select a path and use Get Shape, it appears at the location of the path, and if you
select a shape and use Get Path, it appears at the location of the shape.

To create a loft with Get Path:
1. Select a shape as the first cross-section shape.
2. Click Create panel > Geometry > Compound Objects > Loft.
3. On the Creation Method rollout, click Get Path.
4. Choose Move, Copy, or Instance.
5. Click a shape for the path.
   The cursor changes to the Get Path cursor as you move it over valid path
   shapes. If the cursor does not change over a shape, that shape is not a
   valid path shape and cannot be selected. The first vertex of the selected
   path is placed at the first shape's pivot and the path tangent is aligned
   with the shape's local Z axis.
   When you click the path, 3ds Max builds the loft at the location of the
   shape. The location of the path doesn’t matter.

To create a loft with Get Shape:
1. Select a valid path shape as the path.
2. If the selected shape is not a valid path, the Get Shape button is
   unavailable.
3. Click Create panel > Geometry > Compound Objects > Loft.
4. On the Creation Method rollout, click Get Shape.
5. Choose Move, Copy, or Instance.
6. Click a shape.
   The cursor changes to the Get Shape cursor as you move it over potential
   shapes. The selected shape is placed at the first vertex of the path.
   When you click the shape, 3ds Max builds the loft at the location of the
   path. The location of the shape doesn’t matter.

TIP You can flip the shape along the path by holding down Ctrl when using
Get Shape. For example, if you select the lowercase letter “b” with a Ctrl+click,
the loft will look like the letter “d”.

744 | Chapter 6   Creating Geometry
Creation Method Rollout

Select a path or shape. > Create panel > Geometry > Compound Objects > Object Type rollout > Loft > Creation Method rollout

Select a path or shape. > Create menu > Compounds > Loft > Creation Method rollout

You can choose between a shape or a path for creating the loft object using the Creation Method rollout, as well as the type of action for the loft object.

Interface

On the Creation Method rollout, you determine whether to use a shape or path for creating the loft object, and the type of action you want for the resulting loft object.

NOTE 3ds Max builds the loft at the location of the first object you select: if you select a path and use Get Shape, it appears at the location of the path, and if you select a shape and use Get Path, it appears at the location of the shape.

Get Path Assigns a path to the selected shape or changes the current assigned path.

Get Shape Assigns a shape to the selected path or changes the current assigned shape.

TIP Hold down Ctrl while getting the shape to flip the direction of the shape’s Z axis.

Move/Copy/Instance Lets you specify how the path or shape is transferred to the loft object. It can be moved, in which case no copy is left behind, or transferred as a copy or an instance on page 8611.

TIP Use the Instance option if you expect to edit or modify the path after the loft is created.
Surface Parameters Rollout

Select a path or shape. > Create panel > Geometry > Compound Objects > Object Type rollout > Loft > Surface Parameters rollout

Select a path or shape. > Create menu > Compounds > Loft > Surface Parameters rollout

On the Surface Parameters rollout, you control smoothing of the surface of the loft as well as designate if texture mapping is applied along the loft object.

Interface
Smoothing group

Left: Smoothing the length
Right: Smoothing the width
Rear: Smoothing both length and width

**Smooth Length** Provides a smooth surface along the length of the path. This type of smoothing is useful when your path curves or when shapes on the path change size. Default=on.

**Smooth Width** Provides a smooth surface around the perimeter of the cross-section shapes. This type of smoothing is useful when your shapes change the number of vertices or change form. Default=on.
Mapping group

Bitmap used to create the lines on the road

Mapped roadway showing U and V dimensions for the loft

**Apply Mapping** Turns lofted mapping coordinates on and off. Apply Mapping must be on in order to access the remaining items.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=off.
Length Repeat Sets the number of times a map repeats along the length of the path. The bottom of the map is placed at the first vertex of the path.

Width Repeat Sets the number of times a map repeats around the perimeter of cross-section shapes. The left edge of a map is aligned with the first vertex of each shape.

Normalize Determines how path vertex spacing affects a map along both the path length and shape width. When on, vertices are ignored. Map coordinates and Repeat values are applied evenly along the length of the path and around the shapes. When off, major path divisions and shape vertex spacing affects map coordinate spacing. Map coordinates and Repeat values are applied proportionally according to the path division spacing or shape vertex spacing.

Before and after applying Normalize to loft

Materials group

Generate Material IDs Creates Material IDs during the loft process.

Use Shape IDs Offers the choice of using the spline material IDs to define the material IDs.

NOTE Prior to version 3 of 3ds Max, splines could not hold material IDs.
**NOTE**  Shape IDs are inherited from shape cross sections, not from the path spline.

Shape material IDs used to give the roadway two materials: concrete for supports and railings, asphalt with white lines for the traffic lanes

---

**Output Group**

**Patch**  The lofting process produces a patch object.

**Mesh**  The lofting process produces a mesh object. This is the default, and was the only output type available with Loft in versions prior to version 3 of 3ds Max.

You can also create NURBS objects from lofting by choosing Convert To: NURBS from the **modifier stack right-click menu** on page 8200.

**Path Parameters Rollout**

Select a path or shape. > Create panel > Geometry > Compound Objects > Object Type rollout > Loft > Path Parameters rollout
Select a path or shape. > Create menu > Compounds > Loft > Path Parameters rollout

The Path Parameters rollout lets you control the position of shapes at various intervals along the path of the loft object.

**Interface**

On the Path Parameters rollout, you control the position of multiple shapes at different intervals along the path of the loft object.

**Path** Lets you set a path level by entering a value or dragging the spinner. If Snap is on, the value will jump to the previous snap increment. The Path value depends on the selected measuring method. Changing the measuring method causes the Path value to change.

**Inserting different shapes at different positions on the path**

**Snap** Lets you set a consistent distance between shapes along the path. The Snap value depends on the selected measuring method. Changing the measuring method also changes the Snap value to keep snap spacing constant.

**On** When On is turned on, Snap is active. Default=off.

**Percentage** Expresses the path level as a percentage of the total path length.

**Distance** Expresses the path level as an absolute distance from the first vertex of the path.
**Path Steps** Places shapes on path steps and vertices, rather than as a percentage or a distance along the path.

When Path Steps is on, the following take place:

- The Path spinner specifies the step along the path. The first step, at 0, is the first vertex.
- The total number of steps, including vertices, appears in parentheses beside the Path spinner.
- The current path level is indicated by the standard yellow X when it's a step, and by a small boxed X when it's a vertex.
- Get Shape places a selected shape on the specified step or a vertex of the path.
- Adaptive Path Steps on the Skin Parameters rollout is unavailable. (If it were available, the path steps and shapes would change positions along the path, depending on the result of the adaptive algorithm.)

Please note the following when using the Path Steps option:

- When you switch to Path Steps with a loft object that already contains one or more shapes, an alert message tells you that this action may relocate shapes. This is because there are a limited number of path steps, and only one shape can be on a single step or vertex. The Percentage and Distance options, on the other hand, provide an almost unlimited number of levels on which to place shapes. Thus, if you change from Percentage or Distance to Path Steps, the shapes must be moved to existing steps. If there are more shapes than can be moved to nearby steps, you could end up with more than one shape on a step. Switching from Path Steps to either Percentage or Distance, however, can always be done without loss of data.
- If you alter the Path Steps spinner while in Path Steps mode, the location of your shapes might change. An alert message warns you of this.
- If you animate the topology of the path while in Path Steps mode (such as animating the number of sides of an NGon), your shapes might jump around trying to find a legitimate position, and you could end up with more than one shape on the same path level.

**Pick Shape** Sets the current level at any shape on the path. When you pick a shape on the path, Snap is turned off and Path is set to the level of the picked shape, where a yellow X appears. Pick Shape is available only from the Modify panel.
**Previous Shape** Jumps the path level from its current location to the previous shape along the path. A yellow X appears at the current level. Clicking this button turns Snap off.

**Next Shape** Jumps the path level from its current location to the next shape along the path. A yellow X appears at the current level. Clicking this button turns Snap off.

**Skin Parameters Rollout**

Select a path or shape. > Create panel > Geometry > Compound Objects > Object Type rollout > Loft > Skin Parameters rollout

Select a path or shape. > Create menu > Compounds > Loft > Skin Parameters rollout

On the Skin Parameters rollout, you adjust the complexity of the mesh of the loft object. You can also optimize the mesh by controlling the face count.

**Procedures**

**Example: To use a constant cross-section:**

1. Enlarge the Front viewport to full screen, and then draw a Rectangle object on page 588 with Ctrl held down to create a square about 20 x 20 units.

2. Create another rectangle beside it about 200 x 100 units.

3. Apply a Skew modifier to the large rectangle, but don't alter the Skew parameters.

4. Create a loft object in which the larger rectangle is the path and the square is the shape.

5. On the Modify panel, open the Skin Parameters rollout, and make sure Skin is on in the Display group.

   You can now see the wireframe structure of the lofted rectangle, with cross-sectional sides parallel to its corners.

   Make sure the color assigned the loft object is easily visible. Change it if necessary.

6. Turn off Constant Cross-Section, and observe the corners.

   When Constant Cross-Section is off, the corners become pinched.
7 Turn on Constant Cross-Section to restore the corners. Acute angles can cause problems when the cross sections formed by the path steps intersect at the corners. You can mitigate this by avoiding acute angles or by reducing the path steps.

8 Press H on the keyboard to open the Select From Scene dialog on page 206, and select Rectangle02 (the second larger rectangle).

9 On the Modify panel, change the Skew Axis to Y, and then set the Amount spinner to 95.

10 Use Zoom Region to zoom in on the upper-right corner of the rectangle so you can see the mesh in detail. At a skew of less than 100, the acute angle still works because the path cross-sections haven't intersected.

11 Set the Skew Amount to 300, and examine the same corner. At this angle, the path cross sections intersect, causing problems in the mesh.

12 Select the loft object, and set Path Steps to 1. The cross sections no longer intersect, and the corner is clean. When creating straight-edge molding for architectural modeling, you can avoid mangled corners simply by reducing the path steps to 0.
Interface

Capping group

**Cap Start** When on, the end of a loft at the first vertex of the path is covered, or capped. When off, the end is open, or uncapped. Default=on.

**Cap End** When on, the end of a loft at the last vertex of the path is covered, or capped. When off, the end is open, or uncapped. Default=on.

**Morph** Arranges cap faces in a predictable, repeatable pattern necessary for creating morph targets. Morph capping can generate long, thin faces that do not render or deform as well as those created with grid capping.

**Grid** Arranges cap faces in a rectangular grid trimmed at the shape boundaries. This method produces a surface of evenly sized faces that can be deformed easily by other modifiers.
Roadway lofted with capping turned off
Roadway lofted with capping turned on

**Options group**

**Shape Steps** Sets the number of steps between each vertex of the cross-section shapes. This value affects the number of sides around the perimeter of the loft.
Left: Shape Steps=0.
Right: Shape Steps=4.

Path Steps Sets the number of steps between each main division of the path. This value affects the number of segments along the length of the loft.
Frame lofted with Path Steps=1
Frame lofted with Path Steps=5

**Optimize Shapes** When on, the Shape Steps setting is ignored for straight segments of cross-section shapes. If multiple shapes are on the path, only straight segments that have a match on all shapes are optimized. Default=off.
Optimize Shapes turned on

Optimize Path When on, the Path Steps setting is ignored for straight segments of the path. Curved sections respect the Path steps setting. Available only with Path Steps mode. Default=off.
When Optimize Path is off, the lofted roadway uses more steps.
When Optimize Path is on, straight sections of the lofted roadway don't require additional steps.

Adaptive Path Steps When on, analyzes the loft and adapts the number of path divisions to generate the best skin. Main divisions along the path occur at path vertices, shape locations, and deformation curve vertices. When off, main divisions along the path occur only at path vertices. Default=on.

Contour When on, each shape follows the curvature of the path. The positive Z axis of each shape is aligned with the tangent to the path at the shape's level. When off, shapes remain parallel and have the same orientation as a shape placed at level 0. Default=on.
Lofting the roadway with Contour off causes it to twist.
Banking When on, shapes rotate about the path whenever the path bends and changes height in the path’s local Z axis. The bank amount is controlled by 3ds Max. Banking is ignored if the path is 2D. When off, shapes do not rotate about their Z axis as they traverse a 3D path. Default=on.
Constant Cross Section When on, the cross sections are scaled at angles in the path to maintain uniform path width. When off, the cross sections maintain their original local dimensions, causing pinching at path angles.
Frame lofted with Constant Cross Section turned off
Frame lofted with Constant Cross Section turned on

**Linear Interpolation** When on, generates a loft skin with straight edges between each shape. When off, generates a loft skin with smooth curves between each shape. Default=off.
Flip Normals When on, reverses the normals 180 degrees. Use this option to correct objects that are inside-out. Default=off.

Quad sides When on, and when two sections of a loft object have the same number of sides, the faces that stitch the sections together are displayed as quads. Sides between sections with different numbers of sides are not affected, and are still connected with triangles. Default=off.

Transform Degrade Causes the loft skin to disappear during sub-object shape/path transformations. For example, moving a vertex on the path causes the loft to disappear. When off, you can see the skin during these Sub-Object transformations. Default=off.

Display group

Skin When on, displays a loft's skin in all views using any shading level and ignores the Skin In Shaded setting. When off, displays only the loft sub-objects. Default=on.
Skin in Shaded When on, displays a loft’s skin in shaded views regardless of the Skin setting. When off, skin display is controlled by the Skin setting. Default=on.
The loft object now retains the Skin and Skin In Shaded settings from one loft object to the next one created.

Deformations

Select a Loft object. > Modify panel > Deformations rollout

Deformation controls let you scale, twist, teeter, bevel or fit shapes along the path. The interface for all deformations is a graph. Lines with control points on the graph represent the deformations along the path. Control points on the graphs can be moved or animated for modeling purposes or for various special effects.

Manually creating and placing shapes along the path to produce these models would be a difficult task. Lofts solve this problem through the use of deformation curves. The deformation curves define changes in scale, twisting, teetering, and beveling along the path.

You gain access to loft deformation curves through the Modify panel's Deformations rollout. Deformations are not available in the Create panel. You must open the Modify panel after you've lofted to access the Deformations rollout, which offers the following features:

- Each deformation button displays its own deformation dialog.
- You can display any or all of the deformation dialogs simultaneously.
- The button to the right of each deformation button is a toggle to enable or disable the deformation's effect.

See also:
- Deformation Dialog on page 781

Procedures

To apply deformations to a loft:

1. Select a loft object.
2  Go to the Modify panel and choose Loft from the modifier stack display if it's not already displayed.

3  Expand the Deformations rollout.

4  Click the deformation that you want to use.
   The window for the selected deformation appears.

**To toggle the deformation effect:**

- Click Enable/Disable to the right of the deformation buttons.

**Interface**

![Deformations rollout]

- **Deform Scale** on page 771
- **Deform Twist** on page 773
- **Deform Teeter** on page 774
- **Deform Bevel** on page 777
- **Deform Fit** on page 779

**Deform Scale**

Select a Loft object. > Modify panel > Deformations rollout > Scale

You can loft objects such as columns and bugles from a single shape that changes only its scale as it travels along a path. Use Scale deformation when you want to make these types of objects.
TIP By animating scale, a loft object can appear to travel along a path. Using this technique, you can create animations in which letters or lines write themselves onto the screen.

These are the properties of Scale deformation curves:

- The two curves are red for X-axis scaling and green for Y-axis scaling.
- Default curve values are at 100%.
- Values greater than 100% make the shape larger.
- Values between 100% and 0% make the shape smaller.
- Negative values scale and mirror the shape.

See Deformation Dialog on page 781 for specific information on the dialog controls.

Scale deformation curve dialog

Procedures

To use Scale deformation:

1. Select a loft object.
2. Click Loft in the modifier stack display.
3. Click Scale on the Deformations rollout.

4. Edit the deformation curves for the X axis and Y axis.

**Deform Twist**

Select a Loft object. > Modify panel > Deformations rollout > Twist

Twist deformation lets you create objects that spiral or twist along their length. Twist specifies the amount of rotation about the path.

![Twist deformation curve dialog](image1)

Twist deformation curve dialog

![Using twist to deform the lofted roadway](image2)

Using twist to deform the lofted roadway
These are the properties of Twist deformation curves:

■ A single red curve determines shape rotation about the path.
■ The default curve value is 0 degrees of rotation.
■ Positive values produce counterclockwise rotation, when viewed from the start of the path.
■ Negative values produce clockwise rotation.
■ Both twist deformation and banking produce rotation about the path. Twist rotation is added to a shape after the banking angle is applied. You can use Twist deformation to exaggerate or reduce the amount of banking.

See Deformation Dialog on page 781 for specific information on the dialog controls.

**Procedures**

**To use Twist deformation:**

1. Select a loft object.
2. Click Loft in the modifier stack display.
3. Click Twist on the Deformations rollout.
4. Edit the single deformation curve to specify rotation about the path.

**Deform Teeter**

Select a Loft object. > Modify panel > Deformations rollout > Teeter

Teeter deformation rotates shapes about their local X axis and Y axis. Teetering is what 3ds Max does automatically when you select Contour on the Skin Parameters rollout. Use Teeter deformation when you want to manually control contour effects.
Teeter deformation curve dialog

Roadway lofted with no teeter
These are the properties of Teeter deformation curves:

■ The two curves are red for X-axis rotation and green for Y-axis rotation.
■ Default curve values are at 0 degrees rotation.
■ Positive values rotate the shape counterclockwise about the shape's positive axis.
■ Negative values rotate the shape clockwise about the shape's positive axis.

See Deformation Dialog on page 781 for specific information on the dialog controls.

**Procedures**

**To use Teeter deformation:**

1. Select a loft object.
2. Click Loft in the modifier stack display.
3. Click Teeter on the Deformations rollout.
4. Edit the deformation curves for X axis and Y axis rotation.

**Deform Bevel**

Select a Loft object. > Modify panel > Deformations rollout > Bevel

Nearly every object that you encounter in the real world is beveled. Because it is difficult and expensive to manufacture a perfectly sharp edge, most objects are created with chamfered, filleted, or eased edges. Use Bevel deformation to simulate these effects.

![Roadway with beveled edges](image)

**NOTE** Bevel is not available when loft output is set to Patch.

These are the properties of Bevel deformation curves:

- The single red curve is for bevel amount.
- Bevel values are specified in current units.
• The default curve value is 0 units.
• Positive values reduce the shape, bringing it closer to the path.
• Negative values add to the shape, moving it away from the path.

When shapes are nested, the bevel direction is reversed for interior shapes. See Deformation Dialog on page 781 for specific information on the dialog controls.

**Normal and Adaptive Beveling**

The Bevel Deformation dialog provides three types of beveling: Normal, Adaptive Linear, and Adaptive Cubic. These are available from a flyout at the right end of the dialog toolbar.

With normal beveling, the beveled shape remains parallel to the original, regardless of the crotch angle of the shape. Steep crotch angles combined with excessive bevel amounts result in overshooting at the crotch.

Adaptive beveling alters the length of the bevel shape based on the crotch angle. Adaptive Linear alters the length-to-angle in a linear fashion. Adaptive Cubic alters it more on steep angles than on shallow angles, producing a subtly different effect. Both forms of adaptive beveling result in nonparallel beveled edges, and both are less likely to produce invalid bevels due to overshoots at the crotch.

To see the differences in the three types of beveling, loft a star shape along a straight path and apply a bevel. When you switch among the three types of beveling, you'll see the difference in the bevel outline. Alter one radius of the star to examine the beveling with shallow and with sharp crotch angles.

**Procedures**

**To use Bevel deformation:**

1. Select a loft object.
2. Click Loft in the modifier stack display.
3. Click Bevel on the Deformations rollout.
4. Adjust the deformation curve.
**Deform Fit**

Select a Loft object. > Modify panel > Deformations rollout > Fit

Fit deformation lets you use two Fit curves to define the top and side profiles of your object. Use Fit deformation when you want to generate loft objects by drawing their profiles.

Fit curves define a lofted shape.

Fit shapes are really scale boundaries. As your cross-section shape travels along the path, its X axis is scaled to fit the boundaries of the X-axis fit shape and its Y axis is scaled to fit the boundaries of the Y-axis fit shape.

**NOTE** Fit is not available when loft output is set to Patch.

**Procedures**

**To use Fit deformation:**

1. Select a loft object.
2. Click Loft in the modifier stack display.
3 Click Fit on the Deformations rollout.
4 Select shapes in the viewport to use as fit curves.

Interface

Fit Deformation dialog

The Fit Deformation dialog contains different buttons than the other deformations. For descriptions of the first eight buttons on the toolbar, see Deformation Dialog on page 781. The following descriptions apply to the tools specific to Fit deformation, and are listed from left to right in the order they appear on the toolbar.

Fit Deformation toolbar

Mirror Horizontally Mirrors the shape across the horizontal axis.

Mirror Vertically Mirrors the shape across the vertical axis.
Rotate 90 CCW Rotates the shape 90 degrees counterclockwise.

Rotate 90 CW Rotates the shape 90 degrees clockwise.

Delete Control Point Deletes the selected control point.

Reset Curve Replaces the displayed Fit curve with a rectangle 100 units wide and centered on the path. If Make Symmetrical is on, both Fit curves are reset even though only one might be displayed.

Delete Curve Deletes the displayed Fit curve. If Make Symmetrical is on, both Fit curves are deleted even though only one might be displayed.

Get Shape Lets you select the shape to use for Fit deformation. Click Get Shape, and then click the shape to use in a viewport.

Generate Path Replaces the original path with a new straight-line path.

Deformation Dialog

Select a Loft object. > Modify panel > Deformations rollout > Scale, Twist, Teeter, Bevel, or Fit

The Deformation dialogs for Scale, Twist, Teeter, Bevel, and Fit use the same basic layout.
The buttons in the window's toolbar and prompt area perform the following functions:

- Change deformation curve display.
- Edit control points (these can be animated).
- Navigate the Deformation dialog.

**Editing Deformation Curves**

A deformation curve starts as a straight line using a constant value. To produce more elaborate curves, you insert control points and change their properties.

Use the buttons in the center of the Deformation dialog toolbar to insert and change deformation curve control points (see Interface, later in this topic).

**Control Point Types**

Control points on a deformation curve can produce curves or sharp corners, depending on the control point type. To change a control point type, right-click the control point and choose one of these from the shortcut menu:

- **Corner** Non-adjustable linear control point producing a sharp corner.
- **Bezier Corner** Adjustable Bezier control point with discontinuous tangent handles set to produce a sharp corner. This type produces a curve that looks like the corner type but has control handles like the Bezier Smooth type.
- **Bezier Smooth** Adjustable Bezier control point with locked continuous tangent handles set to produce a smooth curve.

**Selecting Control Points**

Use the Move Control Point and Scale Control Point buttons with standard selection techniques to select control points.

**Procedures**

**To drag Bezier tangent handles:**

1. Select one or more Bezier Smooth or Bezier Corner control points to display their tangent handles.
2. Click one of the Move Control Point buttons.
3 Drag any tangent handle.

- Only the tangent handle you drag is affected. Tangent handles on other selected control points do not change.

- If the tangent handle you drag is part of a Bezier Smooth control point, both handles move to maintain the Bezier Smooth type.

- If the tangent handle you drag is part of a Bezier Corner control point, only that handle moves.

**To move a control point using the Position and Amount fields:**

1 Select a single control point.

2 Do one of the following:

- Move the control point horizontally by entering a value in the Position field.

- Move the control point vertically by entering a value in the Amount field.

**To change the control point type:**

You can change control point types at any time by right-clicking a selection of one or more control points.

1 Select one or more control points.

2 Right-click any selected control point.

3 Choose a control point type from the shortcut menu.

The following conditions apply to changing control point types:

- The first and last control points must use the Corner or Bezier Corner type.

- Converting a Bezier Smooth point to a Bezier Corner point unlocks the tangent handles but does not change their position. The curve appears smooth until you drag one of the tangent handles.

- Converting a Bezier Corner point or inserted Bezier point to Bezier Smooth locks the tangent handles and changes their position and magnitude. The handles are rotated to the average between their two angles. The handle magnitudes are averaged and set equal.
Interface

Buttons for working with a second curve are disabled for the Twist and Bevel deformations, which use only one curve. The disabled buttons are Make Symmetrical, Display X Axis, Display Y Axis, Display XY Axes, and Swap Deform Curves.

Make Symmetrical  You can apply the same deformation to both axes of a shape using Make Symmetrical, which is both an action button and a curve editing mode. Turning on Make Symmetrical has the following effect:

- When a single curve is displayed, it copies the displayed deformation curve to the curve for the hidden axis.
- When both axes are displayed, the Apply Symmetry dialog is also displayed. Click the button for the curve you want to apply to both axes.
- Changes you make to the selected curve are duplicated on the other curve.

When Make Symmetrical is not active, curve editing is applied only to the selected curve.

Display X Axis / Y Axis / XY Axes  You can display one or both deformation curves using the curve display buttons near the upper-left corner of the Deformation dialog.
Turn on the following buttons to display deformation curves:

- **Display X Axis** Displays only the X axis deformation curve in red.

- **Display Y Axis** Displays only the Y axis deformation curve in green.

- **Display XY Axes** Displays X axis and Y axis deformation curves together, each using its own color.

**Swap Deform Curves** Copies curves between the X axis and Y axis. This button is disabled when Make Symmetrical is on.

Click Swap Deform Curves to copy the X axis curve to the Y axis, and the Y axis curve to the X axis. It doesn’t matter which curve is currently displayed or selected.

**Move Control Points** This flyout contains three buttons for moving control points and Bezier handles:

- **Move Control Point** Changes the amount of deformation (vertical movement) and the location of the deformation (horizontal movement).

- **Move Vertical** Changes the amount of deformation without changing the location.

- **Move Horizontal** Changes the location of the deformation without changing the amount.

If one control point is selected, you can move it by entering values in the control point Position and Amount fields at the bottom of the Deformation dialog.
You cannot move end points horizontally. Intermediate control points are constrained horizontally to stay between the points on either side. The amount of horizontal constraint is determined by the control point type.

- You can move corner control points very close together, until one is directly above the other.
- You can move Bezier control points no closer than the length of their tangent handles.

**Moving Bezier Tangent Handles** You can use the Move Control Point buttons to drag a tangent handle's angle and magnitude on Bezier Smooth and Bezier Corner vertices.

Dragging a tangent handle has the following constraints:

- You cannot move tangent angles beyond vertical. This prevents deformation curves from doubling back on themselves.
- You cannot move tangent magnitudes beyond the preceding or next control point on the path.

Pressing Shift while moving a Bezier Smooth tangent handle converts the control point to a Bezier Corner type.

**Scale Control Point** Scales the value of one or more selected control points with respect to 0. Use this function when you want to change only the deformation amounts of selected control points while maintaining their relative ratio of values.

- Drag downward to reduce values.
- Drag upward to increase values.

**Insert Control Point** This flyout contains buttons for inserting two control point types.

**Insert Corner Point** Click anywhere on a deformation curve to insert a corner control point at that location.
Insert Bezier Point  Click anywhere on a deformation curve to insert a modified Bezier control point at that location. The tangent handles of the Bezier control point are set to maintain the shape of the curve before the point was inserted.

If you are not sure which type of control point you need, or if you change your mind, you can convert the point to another type by right-clicking the point and selecting the type from the shortcut menu.

Both Insert Control Point buttons put you in insertion mode. Right-click or choose another button to exit the mode.

Delete Control Point  Deletes selected control points. You can also delete selected points by pressing the Delete key.

Reset Curve  Deletes all but the end control points and sets the curves back to their default values.

Bevel Type  This flyout, available only in the Bevel Deformation dialog, lets you choose Normal, Adaptive Linear or Adaptive Cubic as the bevel type. For more information, see Deform Bevel on page 777.

Deformation grid

The area in the Deformation dialog that displays the deformation curves is called the deformation grid. This grid charts the value of the deformation along the length of the path.

These are the main grid components:

Active area  The light-colored area of the grid defines the first and last vertex boundaries of the path. The ends of the deformation curve lie on each boundary and cannot be moved off the boundary.

Horizontal lines  Mark deformation values on the vertical scale. The following table lists each deformation curve type and the meaning of the deformation values.

<table>
<thead>
<tr>
<th>Deformation Type</th>
<th>Deformation Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scale</td>
<td>Percentage</td>
</tr>
</tbody>
</table>
### Deformation Type

<table>
<thead>
<tr>
<th>Deformation Type</th>
<th>Deformation Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Twist</td>
<td>Rotation Angle</td>
</tr>
<tr>
<td>Teeter</td>
<td>Rotation Angle</td>
</tr>
<tr>
<td>Bevel</td>
<td>Current Units</td>
</tr>
</tbody>
</table>

The thick horizontal line at 0 represents the deformation value at the loft path.

**Vertical lines** Mark levels of the path. The levels displayed vary with the Adaptive Path Steps setting on the Skin Parameters rollout on page 753. If Adaptive Path Steps is on, levels are displayed at all path vertices and shape locations. If Adaptive Path Steps is off, levels are displayed only at path vertices.

**Path ruler** Measures the length of the path. The values on the ruler measure percentage along the path. You can drag the path ruler vertically in the Deformation dialog.

**Deformation curves** You can see one or two curves in the Deformation dialog, based on the deformation type and the curve display setting. The curves are color-coded by axis.

A red curve displays deformation along the shape's local X axis. A green curve displays deformation along the shape's local Y axis.

**Control Point fields** At the bottom of the Deformation dialog are two edit fields. When a single control point is selected these fields display the path location and deformation amount of the control point.

**Control Point Position** The left field displays the location of the control point on the loft path as a percentage of the total path length.

**Control Point Amount** The right field displays the deformation value of the control point.

**Deformation Dialog status bar**

The Deformation dialogs have their own view navigation buttons in the lower-right corner. These give you controls for zooming and panning the view of the deformation grid as you edit the curve values. The status bar also displays information about the current tool and the selected control point.
Numeric fields These two fields are accessible only if a single control point is selected. The first gives the point's horizontal position, and the second gives its vertical position, or value. You can edit these fields with the keyboard.

Lock Aspect This button is present only in the Fit Deformation dialog. When active, it restricts zooming to vertical and horizontal at the same time.

Zoom Extents Changes the view magnification so the entire deformation curve is visible.

Zoom Horizontal Extents Changes the view magnification along the path length so the entire path area is visible in the dialog.

Zoom Vertical Extents Changes the view magnification along the deformation values so the entire deformation curve is displayed in the dialog.

Zoom Horizontally Changes magnification along the path length.

- Drag to the right to increase magnification.
- Drag to the left to decrease magnification.

Zoom Vertically Changes magnification along the deformation value.

- Drag upward to increase magnification.
- Drag downward to decrease magnification.

Zoom Changes magnification along both the path length and the deformation value, preserving the curve aspect ratio.

- Drag upward to increase magnification.
- Drag downward to decrease magnification.
**Zoom Region** Drag a region on the deformation grid. The region is then magnified to fill the deformation dialog.

**Pan** Drag in the view to move in any direction.

**Scroll bars** Drag the horizontal and vertical scroll bars to pan the view in a single direction.

**Path Commands**

Select a Loft object. > Modify panel > Modifier stack display > Sub-object level > Path > Path Commands

The Path Commands rollout appears only when you are modifying an existing loft object and have selected Path from the Sub-Object list. The Put command allows you to make a copy or instance of the loft path.

**Interface**

The Path Commands rollout contains the following button:

- **Put** Places the path into the scene as a separate object (as a Copy or Instance).

**Shape Commands**

Select a Loft object. > Modify panel > Modifier stack display > Sub-object level > Shape > Shape Commands rollout

Shape Commands let you align and compare shapes along the loft path.
Interface

Path Level Adjusts the shape's position on the path.

Compare Displays the Compare dialog on page 792 in which you can compare any number of cross-section shapes.

Reset Undoes rotation and scale of the shape performed with the Select and Rotate or Select and Scale.

Delete Deletes the shape from the loft object.

Align group

The six buttons in this group let you align the selected shape in relation to the path. Looking down at a shape from the viewport in which it's created, the orientation is left to right along the X axis, and top to bottom along the Y axis.

You can use a combination of these buttons for placements such as corner alignment. The operations are additive. In other words, you can use both Bottom and Left to place the shape in the lower-left quadrant.

Center Centers the shape on the path, based on the bounding box of the shape.

Default Returns the shape to its position when first placed on the loft path. When you use Get Shape, the shape is placed so that the path goes through its pivot point. This is not always the same as the center of the shape. Therefore, clicking Center is different than clicking Default.
**Left** Aligns the left edge of the shape to the path.

**Right** Aligns the right edge of the shape to the path.

**Top** Aligns the top edge of the shape to the path.

**Bottom** Aligns the bottom edge of the shape to the path.

**Put group**

**Put** Puts the shape into the scene as a separate object.

**Compare Dialog**

Select a Loft object. > Modify panel > Modifier stack display > Sub-object level > Shape > Shape Commands rollout > Compare button

The Compare dialog lets you compare any number of cross-section shapes in a loft object for purposes of making sure their first vertices are properly aligned. If shapes' first vertices aren't aligned, unexpected lofting results can occur.
**Interface**

**Pick Shape** Lets you select shapes to display from the selected loft object. Click the Pick Shape button in the upper-left corner of the dialog. Then, in the viewport, select the shapes to display. Select a shape a second time to remove it from the display.

When you position the mouse cursor over a shape in the loft object, the cursor image changes to show whether the shape appears in the dialog window: a + sign appears if the shape isn't selected (indicating that if you select the shape, it will be added to the dialog window), and a - sign appears if the shape is already selected.
With each shape, the Compare dialog displays the first vertex as a small square. For correct lofting, the first vertices of all shapes on the path need to be in the same position.

**Reset** Removes all shapes from the display.

**Dialog controls**

You can scroll the Compare dialog with the scroll bars at the bottom and right sides. You can also use the buttons in the lower-right corner to perform View Extents, Pan, Zoom, and Zoom Region functions.

**Align group**

While the Compare dialog is open, you can affect the shapes' positions in the dialog window with the Shape Commands rollout > Align group buttons. Turn off Pick Shape, select a shape in the viewport, and then click the Align group buttons. See *Shape Commands* on page 790 for further information.

**Mesher Compound Object**

Create panel > Geometry > Compound Objects > Object Type rollout > Mesher

Create menu > Compound > Mesher

The Mesher compound object converts procedural objects to mesh objects on a per-frame basis so that you can apply modifiers such as Bend or UVW Map. It can be used with any type of object, but is designed primarily to work with *particle systems* on page 3292. Mesher is also useful for low-overhead instancing of objects with complex modifier stacks.

**Procedures**

**To use a Mesher object:**

1. Add and set up a particle system.
2. Click the Create panel > Geometry > Compound Objects > Object Type rollout > Mesher button.
3. Drag in a viewport to add the Mesher object. The size doesn’t matter, but the orientation should be the same as that of the particle system.
Go to the Modify panel, click the Pick Object button, and then select the particle system. The Mesher object becomes a clone of the particle system, and shows the particles as mesh objects in the viewports no matter what the particle system's Viewport Display setting is.

Apply a modifier to the Mesher object, and set its parameters. For example, you might apply a Bend modifier and set its Angle parameter to 180.

Play the animation. Depending on the original particle system and its settings, as well as any modifiers applied to the Mesher object, you might be getting unexpected results. This typically occurs because the bounding box for the modifier, as applied to the particle system, is recalculated at each frame. For example, with a bent Super Spray particle system set to spread out over time, as the particles stream away and separate, the bounding box becomes longer and thicker, potentially causing unexpected results. To resolve this, you can use another object to specify a static bounding box.

To use another object's bounding box to limit the modified Mesher object, first add and set up the object. Its position, orientation, and size are all used in calculating the bounding box.

Select the Mesher object, and go to the Mesher stack level.

In the Parameters rollout, turn on Custom Bounding Box, click the Pick Bounding box button, and then select the bounding box object. The particle stream uses the new, static bounding box.

**TIP** You can use any object as a bounding box, so it is often fastest to use the particle system itself. Move to the frame where the particle system is the size you want and pick it.

In the following illustration, you can see a Super Spray particle system (left) and a Mesher object derived from the Super Spray (right). A Bend modifier is applied to the Mesher. In the center is a box object being used as a custom bounding box. The bounding box applied to the Bend modifier is visible as an orange wireframe when the modifier is highlighted in the stack.
Using a custom bounding box with a bent particle system

To modify the particles aspect of the Mesher, edit the original particle system.

To modify the custom bounding box, move, rotate, or scale the bounding box object, and then reapply it using the Mesher object.

At this point, both particle systems will render. The original particle system must exist in order to be able to be used by the Mesher object, so if you want only the Mesher replica to render, hide the original system before rendering.
Interface

Parameters rollout

Pick Object
Click this button and then select the object to be instanced by the Mesher object. After doing so, the name of the instanced object appears on the button.
**Time Offset** The number of frames ahead of or behind the original particle system that the Mesher's particle system will run. Default=0.

**Build Only At Render Time** When on, the Mesher results do not appear in the viewports, but only when you render the scene. Default=off.

Use this option to reduce the amount of computation required for the viewport display.

**Update** After editing the original particle system settings or changing the Mesher Time Offset setting, click this button to see the changes in the Mesher system.

**Custom Bounding Box** When on, Mesher replaces the dynamic bounding box derived from the particle system and modifier with a static bounding box of the user's choice.

**Pick Bounding Box** To specify a custom bounding box object, click this button and then select the object.

The custom bounding box appears as an orange wireframe when the modifier is highlighted in the stack.

---

**TIP** You can use any object as a bounding box, so it is often fastest to use the particle system itself. Move to the frame where the particle system is the size you want and pick it.

---

**coordinate values** Displays the coordinates of the opposite corners of the custom bounding box.

**Use All PFlow Events** When on, and you've applied Mesher to a Particle Flow system, Mesher automatically creates mesh objects for every event in the system.

To use only certain events, turn this off and specify the events to use with the PFlow Events group controls (see following).

---

**PFlow Events group**

When the Mesher object is applied to a Particle Flow system, use these controls to create meshes for specific events in the system. Mesher does not create meshes for the remaining events.

**list box** Displays all Particle Flow events currently affected by Mesher.

**Add** Lets you specify Particle Flow events to be affected by Mesher.
If the Mesher object is applied to a Particle Flow system, when you click Add, an Add PF Events dialog opens listing all events in the system. Highlight the events to add, and then click OK. The events now appear in the list.

Remove Deletes highlighted events from the list.

ProBoolean/ProCutter Compound Objects

The ProBoolean and ProCutter compound objects provide you with modeling tools for combining 2D and 3D shapes in ways that would be difficult or impossible otherwise.

The ProBoolean compound object on page 801 takes a 3ds Max mesh and adds extra intelligence to it prior to performing Boolean operations. First it combines the topologies, then it determines coplanar triangles and removes incident edges. The Booleans are then performed not on triangles but N-sided polygons. Once the Boolean operations are completed, the result is retriangulated and sent back into 3ds Max with coplanar edges hidden. The result of this extra work is twofold: The reliability of the Boolean object is extremely high, and the resulting output is much cleaner in terms of having fewer small edges and triangles.
Objects combined by using ProBoolean

Advantages of ProBoolean over the legacy 3ds Max Boolean compound object include:

- **Better quality mesh**: fewer small edges, fewer narrow triangles.
- **Smaller mesh**: fewer vertices and faces.
- **Easier and faster to use**: unlimited objects per Boolean operation.
- **Cleaner-looking mesh**: coplanar edges remain hidden.
- **Integrated decimation and quad meshing**

In addition, ProCutter on page 823 is an excellent tool for exploding, breaking apart, assembling, sectioning, or fitting together objects such as a 3D puzzle. See the following illustration for an example of a goblet shattering.
ProBoolean Compound Object

Select an object. > Create panel > Geometry > Compound Objects > Object
Type rollout > ProBoolean

A Boolean object combines two or more other objects by performing a Boolean
operation or operations on them. ProBoolean adds a range of functionality
to the traditional 3ds Max Boolean object, such as the ability to combine
multiple objects at once, each using a different Boolean operation.

ProBoolean can also automatically subdivide the Boolean result into
quadrilateral faces, which lends itself well to smoothing edges with
MeshSmooth on page 1505 and TurboSmooth on page 1818.

Materials, Textures, Vertex Colors

ProBoolean and ProCutter transfer texture coordinates, vertex colors, optionally
materials, and maps from the operands to the final results. You can choose
to apply the operand material to the resulting faces, or you can retain the
original material. If one of the original operands had material maps or vertex
colors, the resulting faces derived from that operand maintain those graphical
attributes. However, when texture coordinates or vertex colors are present, it
is impossible to remove coplanar faces, so the resulting mesh quality will be
lower. We suggest that you apply textures after the ProBoolean operations.
ProBoolean provides two options for applying materials, available in the Apply Material group on the Parameters rollout (see above illustration). The default method is Apply Operand Material, which applies the operand material to the resulting faces. The alternative, Retain Original Material, causes the resulting faces to use the material of the first selected object in the Boolean operation.

The following illustration shows the difference between the two methods. The Boolean operation starts with a red box and a blue sphere, on the left. The box is used as the base object and the sphere is the subtracted operand. Using the default Apply Operand Material option gives the result shown in the center of the illustration. Choosing Retain Original Material yields the result shown on the right side of the illustration.

**Left:** Original operands  
**Middle:** Apply Operand Material active  
**Right:** Retain Original material active

**Supported Boolean Operations**

ProBoolean supports Union, Intersection, Subtraction, Merge, Attach, and Insert. The first three operations work similarly to their counterparts in the standard Boolean compound object. The Merge operation intersects and
combines two meshes without removing any of the original polygons. This can be useful for cases in which you need to selectively remove parts of the mesh.

The Attach operation combines multiple objects into one without affecting their topology; they remain essentially separate elements on page 8559 of the compound object. And the Insert operation subtracts the bounding shape of operand A from operand B, and then replaces the cut-out part with operand A.

Also supported are two variants of the Boolean operations: Imprint and Cookie Cutter. The Imprint option inserts (imprints) the intersection edges between the operands and the original mesh without removing or adding faces. Imprint only splits faces and adds new edges to the mesh of the base object (original selected object). Cookie Cutter performs the specified Boolean operation but does not add the faces from the operands into the original mesh. It can be used to cut a hole in a mesh or to get the portion of a mesh inside of another object.

Editing the Boolean Object

When you access a ProBoolean or ProCutter object from the Modify panel, you can add operands to the existing set. You can also remove and transform (move, rotate, etc.) operands.

Polygon Reduction

ProBoolean and ProCutter have a built-in decimation function. Typically, decimation is of better quality if it is integrated with the Boolean operations. The reason for this is that the Boolean object contains meta-information about which edges are intersection edges. The decimation function takes this information into account and uses it to properly maintain intersection edges.

Text, Lofts and NURBS

When performing Boolean operations with text objects on page 600, make sure characters don’t intersect each other and that each letter is closed. Also, it’s easy to inadvertently create loft objects on page 742 and NURBS objects on page 2416 in such a way as to have self-intersections. With loft objects, check the ends and points where the loft curve bends.

See also:

■ ProCutter Compound Object on page 823
Procedures

To create a ProBoolean compound object:

1. Set up objects for the Boolean operation. For example, to subtract spherical shapes from a box, create the box and spheres and arrange the spheres so that their volumes intersect the box where the subtractions should take place.

2. Select the base object. In the example in step 1, you would select the box.

3. On the Create panel > Geometry section, choose Compound Objects from the drop-down list, and then click ProBoolean.

4. On the Parameters rollout, choose the type of Boolean operation you want to use: Union, Intersection, Subtraction, etc. Also choose how 3ds Max will transfer the next operand you pick into the Boolean object: Reference, Copy, Move, or Instance. You can also choose to retain the original material, or keep the default Apply Material choice: Apply Operand Material.

5. Click the Start Picking button.

6. Pick one or more objects to participate in the Boolean operation.

7. As you pick objects, you can also change, for each newly picked object, the Boolean operation (Merge, etc.) and options (Cookie or Imprint), as well as how the next operand is transferred to the Boolean (Reference, Copy, etc.) and the Apply Material choice. You can continue picking operands as long as the Start Picking button stays pressed in. Each of the objects you pick is added to the Boolean operation.

When the Modify panel is active, you can add objects to a selected ProBoolean object by clicking the Start Picking button and then picking the objects to add.

Example: To change an existing Boolean with sub-object operations:

ProBoolean offers a great deal of flexibility in combining various Boolean operations simultaneously, plus the ability to change the way operands combine both as you build the Boolean object and after the fact.

1. Start by adding a box, a sphere, a smaller box, and a cylinder, as shown in the following illustration.
Top: Front viewport

Bottom: Perspective viewport

2 Select the box.
3 On the Create panel > Geometry section, choose Compound Objects from the drop-down list, and then click ProBoolean.

4 On the Parameters rollout, in the Operation group, choose Intersection.

5 On the Pick Boolean rollout, click Start Picking, and then click the sphere. The result is the intersection of the sphere and the box; that is, a single object that represents the common volume both objects occupy. In this case, it's the overlap of the sphere and the box. Although neither has a material at this point, the result uses the default color originally assigned by 3ds Max, at random, to the box when it was created.

6 Set Operation to Union, and then click the small box. The result is the union (adding) of the small box with the intersection of the sphere and larger box. Again, the original object's color is assigned to the result.

806 | Chapter 6  Creating Geometry
7 Set Operation to Subtraction, and then click the cylinder.
The cylinder's intersecting volume is subtracted from the previous Boolean result.

Note that the entire history of operands and operations used to build the Boolean object is listed in the hierarchy view list at the bottom of the Parameters rollout. Box01 starts the Boolean with Union, Sphere01 is
then incorporated with Intersection, Box02 is incorporated with Union, and finally Cylinder01 is incorporated with Subtraction.

**NOTE** The operation for the first object in the list has no effect on the Boolean object, but if you move it to another position in the list it does. You’ll see an example of this at the end of this exercise.

You can use the list and the other controls in the Sub-object Operations group to change the results.

8. In the list, highlight the Subtr - Cylinder01 entry, and then set Operation to Union.

9. In the Sub-object Operations group, click the Change Operation button. As a result of the change of operation, the cylinder appears in the Boolean object as an additive volume instead of a subtractive one. Also, its entry in the list changes to “Union - Cylinder01”, showing that the Boolean operation for the cylinder is now Union.

You can also change the order of the operations, which can affect the results.
10 In the list, click the Union - Cylinder01 entry to remove the highlighting, and then highlight the entry 1: Inter - Sphere01. Note that its position in the list, 1, appears in the editable field next to the Reorder Ops button.

![Image of list with operations]

11 Change the value in the field from 1 to 3, and then click the Reorder Ops button. The Inter - Sphere01 item jumps to the end of the list.

![Image of list with operations after reorder]

The Boolean object changes significantly. The new order in the list tells you how this shape was achieved: The two boxes and the cylinder were all combined with Union, adding their volumes together, and then the sphere was incorporated into that result with Intersection, leaving only the volume shared by all four objects.
Interface

Modifier stack

With an unmodified ProBoolean object selected, the modifier stack shows a single, expandable entry: ProBoolean.

Expanding this entry (by clicking the + icon) reveals a single subsidiary branch: Operands.
To transform operands in the ProBoolean object independent of the entire object, click the Operands branch to highlight it.

You can then select one or more operands, either by using standard selection methods in the viewport, or by highlighting their names in the hierarchy view on page 820 list at the bottom of the Parameters rollout.

When one, and only one, operand is selected, the object type (not its name) appears as a separate stack entry below the ProBoolean entry. Clicking this entry provides direct access to the operand's parameters on the Modify panel.
If Parameters rollout > Display is set to Result, selecting an operand displays the operand's axis tripod or transform gizmo in the viewport, although the operand itself is not visible by default.
To view the operand, set Parameters rollout > Display to Operands.

Whether or not the operands are visible, you can transform and animate them at the Operands sub-object level, as with any other object in 3ds Max.

Changing a ProBoolean object by animating the position of the subtracted operand

You can also transform and animate the base object; that is, the first object in the hierarchy view list.

**Pick Boolean rollout**

**Start Picking** Click this and then click each operand to transfer to the Boolean object in turn. Before picking each operand, you can change the Reference/Copy/Move/Instance choice, the Operation options, and the Apply Material choice.
**TIP** When you’re adding many operands to a Boolean object using the default settings, calculating the result each time you pick an object can slow down the process. To maintain optimum feedback, set Parameters rollout > Display to Operands. Then, when you’re finished, set it back to Result. Alternatively, on the Advanced Options rollout set Update to Manually, and then click the Update button to view the results after performing the Boolean operations.

Choose a radio button to specify how the next operand you pick is transferred to the Boolean object:

- **Reference** The Boolean operation uses a reference on page 8699 to the picked operand, so the object remains after being incorporated into the Boolean object. Future modifications to the originally picked object will also modify the Boolean operation. Use Reference to synchronize modifier-induced changes to the original operand with the new operand, but not vice-versa.

- **Copy** The Boolean operation uses a copy of the picked operand. The selected object is unaffected by the Boolean operation, but a copy of it participates in the Boolean operation.

- **Move** The picked operand becomes part of the Boolean operation and is no longer available as a separate object in the scene. This is the default choice.

- **Instance** The Boolean operation makes an instance on page 8611 of the selected object. Future modifications of the selected object will also modify the instanced object participating in the Boolean operation and vice-versa.
Parameters rollout

Operation group

These settings determine how the Boolean operands interact physically.

Union Combines two or more separate entities into a single Boolean object.

Intersection Creates a "new" object from the physical intersection between the original objects; the non-intersecting volumes are removed.

Subtraction Removes the volume of a selected object from the original object.
**Merge** Combines objects into a single object without removing any geometry. New edges are created where the objects intersect.

**NOTE** In the following illustration, the display property Backface Cull was turned off so that all edges are visible.

![Illustration of Merge and Union operations](image)

Left: Original object (box) and operand (small box)  
Center: Union operation; part of the smaller box is removed.  
Right: Merge operation, showing new edges at intersection

**Attach** Combines two or more separate entities into a single Boolean object without changing their topology. In essence, the operands remain separate elements within the whole.

![Illustration of Attach and Union operations](image)

Box and sphere primitives combined with Attach (left) and Union (right)
**Insert** First subtracts the second operand's bounding volume from the first, and then groups the two objects.

In effect, Insert treats the first operand as a liquid volume, so that if there's a hole in the inserted operand or some other way for the "liquid" to enter its volume, it does. The following illustration shows examples of this effect, with shaded geometry on the left and wireframe equivalents on the right.

A bowl inserted in liquid; if the bowl has a hole in it or is tilted, the liquid enters its cavity.

**NOTE** Insert does not simulate the displacement of liquid; the overall dimensions of the first operand remain constant.

**Cookie** Cuts the faces of the original mesh shape, affecting only those faces. The faces of the selected operand are not added to the Boolean result.
1. Original object (box) and operand (sphere)
2. Standard Subtraction operation
3. Subtraction with Cookie on
4. Standard Intersection operation
5. Intersection with Cookie on

**Imprint** Prints the outline of the shape (or intersection edges) onto the original mesh object.

**NOTE** The result of the Imprint operation is always the same; the main Operation choice has no effect on it.

---

**Display** Choose one of the following display modes:

- **Result** Displays only the result of the Boolean operations, not the individual operands.
  Choosing Result also activates the ProBoolean level in the modifier stack on page 810.

- **Operands** Displays the operands that define the Boolean result. Use this mode to edit the operands and modify the result.
Choosing Operands also activates the Operands level in the modifier stack on page 810.

Also, when picking many operands, use this mode to avoid having to recalculate the result each time, and then set Display back to Result at the end.

**Apply Material** Choose one of the following material application modes:

- **Apply Operand Material** New faces created by the Boolean operation acquire the material of the operand.

- **Retain Original Material** New faces created by the Boolean operation retain the material of the original object.

**Sub-object Operations group**

These functions operate on operands highlighted in the hierarchy view list (see following).

**NOTE** For these operations, you need not be at the Operands sub-object level in the modifier stack.

**Extract Selected** Based on the chosen radio button (Remove, Copy, or Inst; see following), Extract Selected applies the operation to the highlighted operand in the hierarchy view list. Three modes of extraction are available:

- **Remove** Removes the operand or operands highlighted in the hierarchy view list from the Boolean result. It essentially undoes the addition of the highlighted operand(s) to the Boolean object. Each extracted operand becomes a top-level object again.

- **Copy** Extracts a copy of the operand or operands highlighted in the hierarchy view list. The original operand remains part of the Boolean result.

- **Inst** Extracts an instance of the operand or operands highlighted in the hierarchy view list. Subsequent modifications to this extracted operand also modify the original operand, thus affecting the Boolean object.

**Reorder Ops** Changes the ordering of the highlighted operand in the hierarchy view list. The reordered operand is moved to the position listed in the text field next to the Reorder Ops button.

**Change Operation** Changes the type of operation (see Operation group on page 815) for the highlighted operand. To change the operation type, highlight...
the operand in the hierarchy view, then choose the operation type radio option, and then click Change Operation.

**Hierarchy View**

The hierarchy view, found at the bottom of the Parameters rollout, displays a list of all of the Boolean operations that define the selected mesh. Each time you perform a new Boolean operation, 3ds Max adds an entry to the list.

You can highlight operands for modification by clicking them in the hierarchy view list. To highlight multiple contiguous items in the list, click the first, and then Shift+click the last. To highlight multiple non-contiguous entries, use Ctrl+click. To remove highlighting from a list entry, Alt+click the highlighted item.

At the ProBoolean level in the modifier stack, you can perform only sub-object operations on highlighted items. At the Operands sub-object level, you can transform highlighted operands as well as perform sub-object operations; see Modifier stack on page 810 for details.
Advanced Options rollout

These options determine when updates are performed on the Boolean object after you make changes. Choose one of the following:

- **Always** Updates occur as soon as you make changes to the Boolean object.
- **Manually** Updates occur only when you click the Update button.
- **When Selected** Updates occur whenever the Boolean object is selected.
- **When Rendering** Updates are applied to the Boolean object only at render time, or when you click Update.

**Update** Applies changes to the Boolean object. Available with all options except Always.

**NOTE** When you first create a ProBoolean object with Manually or When Rendering active, no operands, including the base object, are visible until you update at least once. Thereafter, the base object is visible, but no subsequently picked operands are until you update again.
Decimation % The percentage of edges to remove from the polygons in the Boolean object, thus reducing the number of polygons. For example, a Decimation % setting of 20.0 removes 20 percent of the polygon edges.

1. Decimation % = 0.0
2. Decimation % = 30.0
3. Decimation % = 60.0
4. Decimation % = 80.0

Quadrilateral Tessellation group

These options enable quadrilateral tessellation of the Boolean object. This makes the object suitable for editing subdivision surfaces on page 2013 and for smoothing meshes. It also makes the object suitable for conversion to Editable Poly format.

For further discussion of this option, see the topic Quad Meshing and Smoothing on page 831.

Make Quadrilaterals When on, changes the tessellation of the Boolean object from triangles to quadrilaterals.

NOTE When Make Quadrilaterals is on, the Decimation setting has no effect.

Quad Size % Determines the size of the quadrilaterals as a percentage of the overall Boolean object length.

Planar Edge Removal group

This option determines how the polygons on planar faces are handled. Choose one of the following:

- Remove All Removes all extra coplanar edges on a face such that the face itself will define the polygon.
- **Remove Only Invisible**  Removes invisible edges on each face.
- **No Edge Removal**  No edges are removed.

**ProCutter Compound Object**

Select an object. > Create panel > Geometry > Compound Objects > Object Type rollout > ProCutter

The ProCutter Compound object lets you perform specialized Boolean operations, primarily for the purpose of breaking apart or subdividing volumes.

The results of ProCutter operations are particularly suitable for use in dynamics simulations where an object explodes or is shattered by impact with a force or another object.

![ProCutter used as a cookie cutter](image)

Following is a list of ProCutter features:

- Break apart a stock object into elements of an editable mesh or into separate objects using cutters that are either solids or surfaces.
Use one or more cutters on one or more stock objects at the same time.

- Perform a volume decomposition of a set of cutter objects.
- Use a single cutter many times without maintaining the history.

See also:
- ProBoolean Compound Object on page 801

Procedures

To use ProCutter:

1. Select an object to use as a cutter.
2. Activate the ProCutter compound object.
3. On the Cutter Picking Parameters rollout, click Pick Cutter Objects, and then select additional cutters.
4. On the Cutter Picking Parameters rollout, click Pick Stock Objects, and then select objects to be cut by the cutter objects.
5. In the Cutter Parameters rollout > Cutter Options group, choose the parts of the originals you wish to keep: Stock Outside Cutters, Stock Inside Cutters, Cutters Outside Stock.
6. To get separate objects to manipulate or animate, collapse the result to an Editable Mesh on page 2192 object and use the Explode tool set to 180.0. Alternatively, use Auto Extract Mesh and Explode By Elements, described below.
Interface

Cutter Picking Parameters rollout

Pick Cutter Objects When on, objects you select are designated as cutters, used to subdivide stock objects.

Pick Stock Objects When on, objects you select are designated as stock objects; that is, objects that are subdivided by cutters.

Choose a radio button to specify how the next object you pick is transferred to the ProCutter object:

- **Reference**  The Boolean operation uses a reference on page 8699 to the picked operand, so the object remains after being incorporated into the Boolean object. Future modifications to the originally picked object will also modify the Boolean operation. Use Reference to synchronize modifier-induced changes to the original operand with the new operand, but not vice-versa.

- **Copy**  The Boolean operation uses a copy of the picked operand. The selected object is unaffected by the Boolean operation, but a copy of it participates in the Boolean operation.

- **Move**  The picked operand becomes part of the Boolean operation and is no longer available as a separate object in the scene. This is the default choice.

- **Instance**  The Boolean operation makes an instance on page 8611 of the selected object. Future modifications of the selected object will also modify the instanced object participating in the Boolean operation and vice-versa.
**Cutter Tool Mode group**

These options let you use the cutter as a sculpting tool, cutting the same object repeatedly in different places. You can also get separate objects without having to go through Editable Mesh conversion.

**Auto Extract Mode** Automatically extracts the result when you select a stock object. It does not maintain the stock as a sub-object, but edits it and replaces the object with the result of the cut. This lets you quickly cut, move the cutter, and cut again.

**Explode By Elements** When Auto Extract is on, detaches each element into a separate object automatically. Has no effect when Auto Extract is off.

This convenient option makes it unnecessary to convert the ProCutter object to Editable Mesh format and then use Explode, as mentioned in this procedure on page 824. This is useful when cutting up an object. For example, you could use it to slice a loaf of bread. You use the cutter to cut a piece off, move the cutter, and then cut again.

**Parameters rollout**

You can choose any combination of the three cutting options to get the desired result. If you have non-closed meshes, the orientation of the mesh might determine which part of the stock is considered to be inside or outside the cutter.
Stock Outside Cutter The result contains the parts of the stock outside of all of the cutters. This option gives you a similar result to a Boolean subtraction of the cutters from the stock objects. The gold part of the object in the following illustration results from this option.

Stock Inside Cutter The result contains the parts of the stock inside one or more cutters. This option gives you similar results to a Boolean intersection of the cutters and the stock objects. There is some difference because each cutter is treated individually. The green, blue and red parts of the object on the left side of the following illustration are the results of this option.

Cutters Outside Stock The result contains the parts of the cutters that are not inside the stock objects. Note that the cutters will cut each other if they intersect also. You can see in the following illustration. The parts on the right side of the following illustration that are not present on the left side are results of this option.
Cylinder and sphere as cutters and box as stock
Left: Keeping stock inside and outside cutters
Right: Keeping stock inside/outside cutters and cutters outside stock

Display
Choose one of the following display modes:
■ Show Result Displays the result of the Boolean operations.
■ Show Ops Displays the operands that define the Boolean result. Use this mode to edit the operands and modify the result.

Apply Material
Choose one of the following material application modes:
■ Apply Operand Material New faces created by the Boolean operation acquire the material of the operand.
■ Retain Original Material New faces created by the Boolean operation retain the material of the original object.

Sub-object Operations group
These functions operate on operands highlighted in the hierarchy view list (see following).

Extract Selected Based on the chosen radio button (Remove, Copy, or Inst; see following), Extract Selected applies the operation to the highlighted operand in the hierarchy view list. Three modes of extraction are available:
■ Remove Removes the operand or operands highlighted in the hierarchy view list from the Boolean result. It essentially undoes the addition of the
highlighted operand(s) to the Boolean object. Each extracted operand becomes a top-level object again.

- **Copy**  
  Extracts a copy of the operand highlighted in the hierarchy view list. The original operand remains part of the Boolean.

- **Inst**  
  Extracts an instance of the operand highlighted in the hierarchy view list. Subsequent modifications to this extracted operand also modify the original operand, thus the Boolean object.

**Hierarchy View**

The hierarchy view displays a list of all operands: cutters and stock objects. You can select and edit objects using the hierarchy view, as with ProBoolean.

**Advanced Options rollout**

- **Update:**
  - Always
  - Manually
  - When Selected
  - When Rendering
  
- **Decimation %:** 0.0

- **Quadrilateral Tessellation**
  - Make Quadrilaterals
  - Quad Size %: 3.0

- **Planar Edge Removal**
  - Remove All
  - Remove Only Invisible
  - No Edge Removal
Update group

These options determine when updates are performed on the Boolean object after you make changes. Choose one of the following:

- **Always** Updates occur as soon as you make changes to the Boolean object.
- **Manually** Updates occur only when you click the Update button.
- **When Selected** Updates occur whenever the Boolean object is selected.
- **When Rendering** Updates are applied to the Boolean object only at render time, or when you click Update.

**Update** Applies changes to the Boolean object. Available with all options except Always.

**NOTE** When you first create a ProCutter object with Manually or When Rendering active, no operands, including the base object, are visible until you update at least once. Thereafter, the base object is visible, but no subsequently picked operands are until you update again.

---

**Decimation %** The percentage of edges to remove from the polygons in the Boolean object, thus reducing the number of polygons. For example, a Decimation % setting of 20.0 removes 20 percent of the polygon edges.

**Quadrilateral Tessellation group**

**Make Quadrilaterals** When on, changes the tessellation of the Boolean object from triangles to quadrilaterals. This makes the object suitable for editing subdivision surfaces on page 2013 and for smoothing meshes. It also makes the object suitable for conversion to Editable Poly format.

**Quad Size %** Determines the size of the quadrilaterals as a percentage of the overall Boolean object length.

**Planar Edge Removal group**

This option determines how the polygons on planar faces are handled. Choose one of the following:

- **Remove All** Removes all extra coplanar edges on a face such that the face itself will define the polygon.
- **Remove Only Invisible**  Removes invisible edges on each face.
- **No Edge Removal**  No edges are removed.

**Quad Meshing and Smoothing**

ProBoolean, ProCutter, and the *Quadify Mesh modifier* on page 1641 can re-mesh planar surfaces using a quadrilateral meshing algorithm. This capability, in combination with the subdivision surface tools in MeshSmooth, TurboSmooth, and Editable Poly, can produce dramatic results.

It does require some level of expertise to understand what is possible and how to achieve the best results using the quadrilateral tessellation. This topic shows the basics of how to use quad meshing and also contains tips and tricks about what works and how it works.

**TIP** To apply quadrilateral tessellation to a mesh object without performing a Boolean operation on it, simply apply the *Quadify Mesh modifier* on page 1641.

**Quad Meshing Basics**

![ProBoolean of an object containing several primitives](image-url)
To make a quadrilateral mesh, apply the Quadify Mesh modifier, or select a ProBoolean or ProCutter object, go to the Modify panel, and expand the Advanced Options panel as shown following.

To get a result similar to the following illustration, turn on Make Quadrilaterals check box:
Result of a quad mesh with Quad Size % = 3.0

To change the size of the individual quadrilaterals, adjust the Quad Size % parameter. Typically a value between 1 and 4 percent achieves the desired results. The smaller the quad size, the smaller the resulting fillets or blends between the surfaces when the mesh is smoothed. The default Quad Size value is 3.0 percent. A Quad Size value of 2.0 percent produces the following result:
Quad meshing with Quad Size % = 2.0

If you know that you have the desired result and don't plan to go back and change the quad size or the original primitives, you can convert the object to Editable Poly format and apply smoothing with the Subdivision Surface settings. If this is not the case, however, and you plan to make further adjustments, use the MeshSmooth on page 1505 or TurboSmooth on page 1818 modifier to retain the history of the ProBoolean object. The following illustration shows the result of a MeshSmooth modifier with Subdivision Amount > Iterations=1 applied to a ProBoolean object with Quad Size % set to 3.0.
MeshSmooth modifier with NURMS and Iterations=1
Quad Meshing Tips and Tricks

Sometimes the results of quad meshing can produce undesirable results in the smoothed model.

**Problem #1**: Stripes along cylinders or bumpiness on other surface

**Solution**: Increase the number of subdivisions around cylinders or along other surfaces.
To fix the problem depicted above, the number of sides on the two cylinders was changed from 18 to 30 and the number of segments on the torus was changed from 24 to 36. The following illustration shows the improved result:

**Problem #2**: Triangles along boundaries caused by conflicts with visible edges from original mesh
**Solution:** Make sure Advanced Options rollout > Planar Edge Removal is set to Remove All or create the original primitives without subdivisions on coplanar faces.

Coplanar edges not removed from original box

When rendered, misshapen geometry results from the presence of coplanar edges.
Problem #3: Poor alignment of original primitive meshes causes undesirable results.

Solution: Rotate or move original primitives into position to maximize mesh quality.

The following illustration shows the result of subtracting three spheres of the same size from a box. The left-hand sphere is aligned properly so that there are good quads along both boundaries. This should produce a good result when smoothed. The middle sphere was lifted so that there is a strip of very thin quads near the boundary. This produces very little smoothing along that edge, as you can see in the rendered image. The right-hand sphere was rotated, producing poor alignment and many triangles on the sphere as well as small quads on the plane of the box. You can see the undesirable results in the rendered image.
Quads produced by three spheres with different rotations and translations
Dynamics Objects

Create panel > Geometry > Dynamics Objects
Create menu > Dynamics

Dynamics objects are similar to other mesh objects, except that they can be made to react to the motion of objects to which they are bound, or they can provide dynamic forces when included in a dynamics simulation on page 4190.
**Damper Dynamics Object**

Create panel > Geometry > Dynamics Objects > Object Type rollout > Damper button

Create menu > Dynamics > Damper

The Damper object provides a dynamic object that can behave as either a shock-absorber or an actuator. It consists of a base, a main housing, and a piston, with an optional boot. The piston slides within the main housing, providing different heights. The overall height can be affected by binding objects, in the same way as the Spring dynamic object.

*NOTE* Damper is similar to Spring in many respects. See Spring object on page 849 for more detailed descriptions of similar parameters and procedures.

**Procedures**

To create a damper:

1. Drag and release to specify the diameter.
2. Move the mouse and click to specify the overall height of the damper.

To use a damper in a dynamics simulation:

The following must be in place to use the damper forces in a dynamics simulation:

1. Bind two objects to the ends of the damper, and choose Bound to Object Pivots in the End Point Method group box at the top of the command panel.
2. In the dynamics simulation, add the damper to the Object List. (The damper itself is not adjusted in the dynamics simulation, so all of the dynamics parameters will be disabled for the damper object.)
3. Include at least one of the bound objects or a parent of one of the bound objects in the simulation. For example, you can bind two dummy objects to the ends of a damper, and one of the dummies can be the child of an object that’s included in the simulation. In this case, the dummy itself does not need to be in the simulation.
NOTE Damper is an "ideal" object with no mass. While it can be used in dynamics simulations, it cannot participate directly in collisions or effects. As a result, when you assign a damper object to a dynamics simulation, and then view it in the Edit Object dialog, all of the parameter settings are disabled.

Interface

End Point Method group

Free Damper/Actuator Choose this when using the damper as a simple object that's not bound to others or used in a dynamics simulation.

Bound to Object Pivots Choose this option when binding the damper to two objects, using the buttons described next.
Binding Objects group

Use these controls to pick the objects to which the damper is bound. To complete the binding, you must select two binding objects, and then click Bound to Object Pivots.

Piston (label) Displays the name of the object bound to the piston of the damper.

Pick Piston Object Click this button and then select the object to be bound to the piston of the damper.

Base (label) Displays the name of the object bound to the base of the damper.

Pick Base Object Click this button and then select the object to be bound to the base of the damper.

Free Damper Parameters group

Pin-to-Pin Height Use this field/spinner to specify the distance between the bottom center of the base and the top center of the piston when the damper is not bound.

Common Damper Parameters group

Renderable When on, the object appears in the rendering; when off, the object does not appear.

Material IDs are assigned to the damper object as follows:
1: Base
2: Main housing
3: Piston
4: Boot Stop (appears only if you enable Boot Parameters)
5: Boot (appears only if you enable Boot Parameters)

Generate Mapping Coords Sets up the required coordinates for applying mapped materials to the object. Default=on.
Cylinder Parameters group

Provides parameters for the base and main cylinder of the damper.

**Base Dia** The diameter of the base, or "mount" of the damper.

**Height** The height of the base.

**Main Dia** The diameter of the main housing of the damper.

**Height** The height of the main housing.

**Sides** The number of sides of both the base and the main housing.

**Fillet 1** The size of the fillet on the lower edge of the main housing.

**Fillet Segs** The number of segments for Fillet 1. The higher this setting, the rounder the fillet profile appears.

**Fillet 2** The size of the fillet on the upper edge of the main housing.

**Fillet Segs** The number of segments for Fillet 2. The higher this setting, the rounder the fillet profile appears.

**Inside Dia** Specifies the inside diameter of the main housing, which is actually a tube rather than a cylinder.
Smooth Cylinder When on, smoothing is applied to both the base and the main housing.

**Piston Parameters group**

Provides parameters for the piston of the damper.

- **Diameter** The diameter of the piston.
- **Height** The height of the piston.
- **Sides** The number of sides in the piston.
- **Smooth Piston** When on, smoothing is applied to the piston.
The boot is an optional component of the damper that’s similar to the rubber "accordion" boot found on various types of dampers, such as shock absorbers. The boot acts like a bound dynamic object, in that one of its ends is bound to the main housing, while the other is bound to the piston. Thus, as the piston moves within the housing, the boot expands and contracts to follow.

**Enable** Turn this on to add the boot to the damper.

**Min Dia** The minimum diameter of the boot. This and the next parameter affect the depth of the accordion folds in the boot.

**Max Dia** The maximum diameter of the boot.

**Sides** The number of sides making up the boot.

**Folds** The number of accordion folds (bulges) along the height of the boot.

**Resolution** The number of segments in each fold.

**Stop Dia** The diameter of the stop, which is the ring at the top of the boot.

**Stop Thick** The thickness (height) of the stop ring.

**Setback** The distance of the stop ring from the top of the piston.
Stop Fillet  The size of the fillet on the upper edge of the stop ring.

Fillet Segs  The number of segments the stop fillet. The higher this setting, the round the fillet profile appears.

Smooth Boot  When on, smoothing is applied to the boot.

Dynamics Parameters group

Unlike the Spring object, the damper can also be used as an actuator. Basically, a damper absorbs force (like a shock absorber) while an actuator applies force.

The parameters in this group box, available only when End Point Method is set to Bound to Object Pivots, specify how forces are applied by the damper object in a dynamics simulation.

Damper Parameters  Provides parameters for a damper type of object. Specifically, this simulates a viscous linear damper, which provides linear...
resistance to motion (between the two binding objects) proportional to the rate at which the damper experiences displacement. The faster it gets hit, the harder it fights back. Push it slowly, and there’s almost no resistance.

- **Object is Damper**  Select this option to use the damper object as a damper rather than an actuator.

**Drag** Specifies the force per unit linear speed, measured in one of the methods specified below.

- **Drag is measured in**  Lets you specify the measurement of drag to use:
  - Pounds per in(ch)/sec or Newtons per m(eter)/sec.

- **Damper works in**  Provides directional options for the damper.

**Compression Only** The damper reacts only to compression forces.

**Extension Only** The damper reacts only to expansion forces.

**Both** The damper reacts to both compression and expansion forces.

**Actuator Parameters** Provides parameters for an actuator. When used as an actuator, the damper object exerts force between the two binding objects. A real-world example might be the thrusting piston in a log splitter. When used in a simulation, the force is applied by adjusting the value in the Force spinner. You can see the result only after solving the dynamics simulation.

- **Object is Actuator**  Choose this when using the damper object as an Actuator.

**Force** Specifies the amount of force exerted between the two bound objects. Positive values push the objects apart, while negative values pull them together.

- **Force is measured in**  Lets you specify the measurement of force to use:
  - Pounds per inch or Newtons per meter.

---

**Spring Dynamics Object**

Create panel > Geometry > Dynamics Objects > Object Type rollout > Spring button

Create menu > Dynamics > Spring

The Spring object is a dynamics object in the shape of a coiled spring that lets you simulate a flexible spring in dynamics simulations. You can specify the overall diameter and length of the spring, the number of turns, and the
diameter and shape of its “wire.” When used in a dynamics simulation, the compression and extension pressure of the spring are calculated as well.

**Procedures**

**To create a spring:**

1. Drag and release to specify the outside diameter.
2. Move the mouse and click to specify the overall length of the spring.

**To use a spring in a dynamics simulation:**

The following must be in place to use the spring forces in a dynamics simulation:

1. Bind two objects to the ends of the spring, and choose Bound to Object Pivots in the End Point Method group box at the top of the command panel.
2. In the dynamics simulation, add the spring to the Object List. (The spring itself is not adjustable in the dynamics Edit Object dialog, so all of the dynamics parameters will be disabled for the spring object.)
3. Include at least one of the bound objects or a parent of one of the bound objects in the simulation. For example, you can bind the ends of a spring to two dummy objects, and one of the dummies can be the child of an object that’s included in the simulation. The dummy without a parent will be stationary and the spring will pass its force through the other dummy to its parent.

**NOTE** Spring is an “ideal” object with no mass. While it can be used in dynamics simulations, it cannot participate directly in collisions or effects. A spring can only exert force on other objects in simulations. As a result, when you assign a spring object to a dynamics simulation, and then view it in the Edit Object dialog, all of the parameter settings are disabled.
Interface

Spring Parameters rollout

End Point Method group

Free Spring Choose this when using the spring as a simple object that’s not bound to other objects or used in a dynamics simulation.

Bound to Object Pivots Choose this when binding the spring to two objects, using the buttons described next.

Binding Objects group

Use these controls to pick the objects to which the spring is bound. "Top" and "Bottom" are arbitrary descriptors; the two bound objects can have any positional relationship to each other. To complete the binding, select two binding objects, and then click Bound to Object Pivots.

Each end point of the spring is defined by the center of the overall diameter and the center of the wire. This end point is placed at the pivot point of the object to which it is bound. You can adjust the relative position of the binding object to the spring by transforming the binding object while the Affect Object Only button is turned on in the Hierarchy > Pivot panel.
Top (label) Displays the name of the "top" binding object.
Pick Top Object Click this button and then select the "top" object.

Bottom (label) Displays the name of the "bottom" binding object.
Pick Bottom Object Click this button and then select the "bottom" object.

Free Spring Parameters group

Height Use this field/spinner to set the straight-line height or length of the spring when it is not bound. This is not the actual length of the spring's wire.

Common Spring Parameters group

Diameter The overall diameter of the spring, as measured at the center of the wire. (The diameter of the wire itself has no effect on this setting.)

Turns The number of full 360-degree turns in the spring.

CCW/CW Specifies whether the coils of the spring are counterclockwise (CCW) or clockwise (CW).

Automatic Segments Choose this option to force each turn of the spring to contains the same number of segments, as specified in the Segs/Turn spinner.
Thus, if you increase the number of turns, the number of segments also increases.

**Segs/Turn** This spinner lets you specify the number of segments in each 360-degree turn of the spring.

**Manual Segments** When this option is chosen, the length of the spring contains a fixed number of segments, no matter how many turns in the spring. Thus, as you increase the number of turns, you must manually increase the number of segments to maintain a smooth curve.

**Segments** This spinner lets you specify the total number of manual segments in the spring.

**Smoothing** Provides various methods of smoothing the object. The options here work the same as those in the Torus primitive on page 409.

- **All** All surfaces are smoothed.
- **Sides** Smoothing runs along the length of the wire, but not around its perimeter.
- **Segments** Smoothing runs around the perimeter of the wire, but not along its length.
- **None** No smoothing is applied.

**Renderable** When on, the object appears in the rendering; when off, the object does not appear.

**Generate Mapping Coords** Assigns mapping coordinates to the object. Default=on.
Wire Shape group

Provides three different types of wire cross-sections for the spring: round, rectangular, or D-shaped. Each type has its own set of parameters.

**Round Wire** Specifies a round wire for the spring.
- **Diameter** The diameter of the wire.
- **Sides** The number of sides that make up the cross section.

**Rectangular Wire** Specifies a rectangular wire.
- **Width** Determines the width of the cross section.
- **Depth** Determines the depth of the cross section.
- **Fillet** When combined with Fillet Segs (below), this lets you fillet (round) the corners of the cross section.
- **Fillet Segs**: Specifies the number of segments in the fillet.
- **Rotation**: Rotates the angle of the cross section along the entire length of the spring.

**D-Section Wire** Specifies a D-shaped wire.
- **Width**: Determines the width of the cross section.
- **Depth**: Determines the depth of the cross section.
- **Round Sides**: Specifies the number of segments that make up the rounded side of the D-shape.
- **Fillet**: When combined with Fillet Segs (below), this lets you fillet (round) the corners of the cross section.
- **Fillet Segs**: Specifies the number of segments in the fillet.
- **Rotation**: Rotates the angle of the cross section along the entire length of the spring.

**Dynamics Parameters group**

These parameters specify the forces that the spring contributes to a dynamic simulation.

Relaxed Hgt: 258.1
Constant k: 226.0
Spring constant is in:
- Pounds per inch
- Newtons per meter

Spring works in:
- Compression Only
- Extension Only
- Both
- Enable Nonlinearity

These parameters specify the forces that the spring contributes to a dynamic simulation.
Relaxed Hgt Specifies the height (or length) at which the spring is "relaxed" and therefore contributes no force--either compression or extension. For example, if the placement of the binding objects stretches the spring to a length of 50 units but the Relaxed Len is set to 30, then an extension force is in effect because the spring is stretched further than its relaxed length.

Constant k The amount of force exerted per unit change in length with respect to the Relaxed Hgt value. This could also be described as the measure of force-per-units-change in length as compared to the Relaxed Length. For example, if your spring is set to a Spring Constant of \( k = 10 \) lb per in, and you stretch it to be ten inches longer than the Relaxed Hgt value, it will try to close with a force of 100 pounds. If you compress it two inches shorter than the Relaxed Hgt value, it will push back with 20 pounds of force.

Spring constant is in Lets you specify the measurement of force to use: Pounds per inch or Newtons per meter.

Spring works in Lets you specify the type of force you want the spring to exert. While most springs actually provide both compression and extension force, if your simulation requires only one, you can save calculation time by using one instead of both.

- **Compression Only** This type of spring provides only expansive force when its length is shorter than the specified Free Length.

- **Extension Only** Provides contractive force when its length is greater than the specified Free Length.

- **Both** Provides both expansive and contractive force, depending on the variation from Relaxed Hgt.

Enable Nonlinearity When on, the compression and extension of the spring are non-linear, based on the assumption that a spring has physical limits to the amount it can stretch or contract. Thus, the further the spring gets from the Relaxed Hgt setting, the less linear the feedback. The non-linear compression is calculated using the relationship between the coil dimensions, wire diameter, and length. Extension compares the relationship between the wire diameter and overall spring diameter.
A system combines objects, linkages, and controllers to produce an object set that has behavior as well as geometry. Systems help you create animations that would be much more difficult or time-consuming to produce using features independently. Systems can range from simple object generators to full-scale subsystem programs.

Systems are primarily intended for plug-in on page 8687 component software. Additional systems might be available if your configuration includes plug-in systems.

You can externally reference system objects in your scene. For more information, see XRef Objects on page 7450.

**Procedures**

**To create a system:**

1. On the Create panel, click Systems. The Systems panel is displayed.
2. On the Object Type rollout, choose a system to create.
3. Drag in a viewport to create the system.

**See also:**

- Sunlight on page 5491
- Daylight on page 5491
- Biped on page 4487

**Bones System**

Create panel > Systems > Bones button

Bones System | 857
Animation menu > Bone Tools > Create Bones

A Bones system is a jointed, hierarchical linkage of bone objects that can be used to animate other objects or hierarchies.

Bones are especially useful for animating character models that have a continuous skin mesh. You can animate bones with forward or inverse kinematics. For inverse kinematics, bones can use any of the available IK solvers on page 3669, or through Interactive on page 3747 or applied IK on page 3750.

Dinosaur character modeled using bones

Bones are renderable objects. They have several parameters, such as taper and fins, that can be used to define the shape the bone represents. The fins make it easier to see how the bone is rotating.

For animation, it is very important that you understand the structure of a bone object. The bone's geometry is distinct from its link. Each link has a pivot point at its base. The bone can rotate about this pivot point. When you move a child bone, you are really rotating its parent bone.

It might be useful to think of bones as joints, because it is their pivot placements that matter, more than the actual bone geometry. Think of the
geometry as a visual aid that is drawn lengthwise from the pivot point to the bone's child object. The child object is usually another bone.

Bones system seen alone and inside a wireframe model

Any hierarchy can display itself as a bone structure (see Using Objects as Bones on page 870), by simply turning on Bone On in the Bone Editing Tools rollout on page 872.

See also:
- Bone Tools on page 871

Creating Bones

You start creating bones by clicking the Create Bones button on the Bone Editing Tools rollout on page 872, or by clicking the Bones button in the Systems category on the Create panel.

To create bones, do the following.

1. Your first click in a viewport defines the start joint of the first bone.

2. The second click in a viewport defines the start joint of the next bone. Visually only one bone is drawn at this point because bones are visual aids drawn between two pivot points. It is the actual pivot point's placement that is important.

3. Each subsequent click defines a new bone as a child of the previous bone. The result of multiple clicks is a single chain of bones.
4 Right-click to exit bone creation.
This creates a small “nub” bone at the end of the hierarchy, which is used when assigning an IK chain. If you are not going to assign an IK chain to the hierarchy, you can delete the small nub bone.

Creating a simple chain of three bones

3ds Max lets you create a branching hierarchy of bones. To create a branching hierarchy, such as legs branching from a pelvis, do the following:

1 Create a chain of bones, and then right-click to exit bone creation.

2 Click Bones (or Create Bones) again, and then click the bone where you want to begin branching. The new chain of bones branches from the bone you click.

**WARNING** The behavior of a branching bone hierarchy is not always intuitive.

**NOTE** You can also use Select And Link on page 3631 to connect one bone hierarchy to its branches. However, except for this one special case, using Select And Link with bones is not recommended. To edit an existing bone structure, whether branching or not, use the Bone Tools on page 871 instead.

**Assigning IK Controllers to Bones**

By default, bones are not assigned inverse kinematics (IK). Assigning an IK solver can be done in one of two ways. Typically, you create a bone hierarchy,
then manually assign an IK solver. This allows for very precise control over where IK chains are defined.

The other way to assign an IK solver is more automatic. When you create bones, choose IK solver from the list in the IK Chain Assignment rollout, and then turn on Assign To Children. When you exit bone creation, the chosen IK solver is automatically applied to the hierarchy. The solver extends from the first bone in the hierarchy to the last.

For more information about IK, see Introduction to Inverse Kinematics on page 3661.

Setting the Initial Position of Bones

When you first create a bones system, the position of the bones is the initial state. Before you assign an IK solver or method, you can change the initial state of the bones by moving, rotating, or stretching the bones individually.

Bone Color

By default, bones are assigned the color specified for Bones in the Colors panel on page 8272 of the Customize User Interface dialog on page 8249. Choose Object as the Element and then choose Bones in the list. You can change the color of individual bones by selecting the bone, clicking the active color swatch next to the bone’s name in the Create panel or Modify panel, and then selecting a color in the Object Color dialog on page 368.

You can also use the Bone Tools on page 871 to assign bone colors, or to assign a color gradient to a bone hierarchy.

Bone Fins

Fins are visual aids that help you clearly see a bone’s orientation. Fins can also be used to approximate a character’s shape. Bones have three sets of fins: side, front, and back. By default, fins are turned off.
Bones can have fins.
Bones with various fin configurations

**Renderable Bones**

Bones can be renderable, though by default, they are not. To make a bone renderable, turn on the Renderable check box in the bone's Object Properties dialog on page 283.
Bones can be renderable.

Object Properties for Bones

In addition to visual properties, bones have behavioral properties. The controls for these are located on the Bone Tools floater on page 871.

You can use these controls to turn other kinds of objects into bones.

Using Constraints with Bones

You can apply constraints on page 3574 to bones as long as an IK solver or method is not controlling the bones. If the bones have an assigned IK controller, you can constrain only the root of the hierarchy or chain. However, applying position controllers or constraints to a linked bone can cause undesirable effects, such as breaking of the bone chain.
The “nub” bone at the end of the chain has a Spring controller applied to it. The Spring controller is connected to an animated sphere.

Right: The sphere’s movement breaks the bone chain.

To avoid this problem, don’t apply position controllers directly to child bones. Instead, create an IK chain and apply the controller to the IK chain’s end effector.
A IK chain has been applied, connecting the end nub to its parent bone. The IK chain's end effector is connected to the ball by a Spring controller.

Right: Now when the sphere moves, the IK chain prevents the bones from breaking.

Constraints and controllers that affect orientation only, such as Orientation or Look At, do not present this problem when applied to child bones.

**Procedures**

**To create a bones system:**

1. On the Create panel, click Systems, and then click Bones. You can also access Create Bones through the Bone Tools rollout.
2. Click in a viewport. This creates a joint that is the base of the bone's hierarchy.
3. Drag to define the length of the second bone.
4. Click to set the length of the second bone, and then drag to create the third bone. Drag and click to continue creating new bones.
5. Right-click to end creation.
3ds Max creates a small “nub” bone at the end of the hierarchy. This bone is used when assigning an IK chain.

The first bone you create is at the top of the hierarchy. The last bone you create is at the bottom. For more about linked objects, see the Hierarchy Panel on page 8213.

To create a bones hierarchy with an IK solver automatically applied:

1. In the Create panel, click Systems, and then click Bones.
2. In the IK Chain Assignment rollout, select an IK solver from the list.
3. Turn on Assign To Children.
4. In a viewport, click and drag to create the bones. Right-click to end bone creation.

After the bones are created, the chosen IK solver is applied to them.

To edit the appearance of a bone:

1. Select a bone.
2. Click the Modify tab on the command panel.

To change the length of bones after they’ve been created:

**IMPORTANT** Repositioning a bone affects its length visually. More important, it affects the bone’s pivot position. The length of the bone is only a visual aid drawn between each bone’s pivot point. A bone has only one pivot. The bone you see visually is connecting its pivot point to the next bone’s pivot point.

1. Choose Animation menu > Bone Tools.
2. On the Bone Tools dialog, click Bone Edit Mode.
3. Move the child of the bone you want to change. The length of its immediate parent changes to reach the child bone.
4. Turn off Bone Edit Mode when you are finished editing the bones.
To add fins to bones:

1. Select the bone.
2. Choose Animation menu > Bone Tools.
3. Select the bones to which you want to add fins.
4. In the Fin Adjustment Tools rollout, turn on Side Fins, Front Fin or Back Fin.
5. Adjust the size and appearance of the fins with the appropriate spinners.

**NOTE** You can also add fins to an individual bone on the Modify panel.

**Interface**

**IK Chain Assignment rollout (creation time only)**

- **IK Solver drop-down list** Specifies the type of IK solver to be automatically applied if Assign To Children is turned on.
- **Assign To Children** When on, assigns the IK solver named in the IK solver list to all the newly created bones except the first (root) bone. When off, assigns a standard PRS Transform controller on page 3526 to the bones. Default=off.

**NOTE** Choosing the SplineIKSolver and turning on Assign To Children causes the **Spline IK Solver dialog** on page 3740 to appear after bones have been created.

- **Assign To Root** When on, assigns an IK solver to all the newly created bones including the first (root) bone. Turning on Assign To Children also automatically turns on Assign To Root.
Bone Parameters rollout (creation and modification time)

These controls change the appearance of the bones.

**Bone Object group**

**Width** Sets the width of the bone to be made.

**Height** Sets the height of the bone to be made.

**Taper** Adjusts the taper of the bone shape. A Taper of 0 produces a box-shaped bone.
**Bone Fins group**

**Side Fins** Lets you add a set of fins to the sides of the bones you create.
- **Size** Controls the size of the fin.
- **Start Taper** Controls the start taper of the fin.
- **End Taper** Controls the end taper of the fin.

**Front Fin** Lets you add a fin to the front of the bone you create.
- **Size** Controls the size of the fin.
- **Start Taper** Controls the start taper of the fin.
- **End Taper** Controls the end taper of the fin.

**Back Fin** Lets you add a fin to the back of the bone you create.
- **Size** Controls the size of the fin.
- **Start Taper** Controls the start taper of the fin.
- **End Taper** Controls the end taper of the fin.

**Generate Mapping Coords** Creates mapping coordinates on the bones. Since the bones are renderable, they can also have materials applied, which can use these mapping coordinates.

**Using Objects as Bones**

Select a linked object or multiple objects linked to each other. > Animation menu > Bone Tools > Object Properties rollout > Bone On toggle

You can use arbitrary objects such as cylinders or boxes as bones, controlling their animation as if they were bones in a bones system on page 857. You can apply an IK solver on page 3669 to the boned objects.

To use objects as bones, select them and then turn on the Bone On toggle on the Object Properties rollout of the Bone Tools dialog on page 871.

---

**WARNING** Turning on Freeze Length has no visible effect unless you transform the child of the object to which Freeze Length is applied.
Once you've set objects to function as bones, applying an IK solution behaves as it does for standard bone objects. The geometry of the boned objects can stretch or squash during animation.

**Procedures**

To use objects as bones:

1. Link the objects you want to display as bones.
2. Select all of these objects.
   
   **NOTE** You can set a single object to work as a bone, but this doesn't have much use.
3. Choose Animation menu > Bone Tools. The floating Bone Tools dialog is displayed.
4. On the Object Properties rollout, turn on Bone On. 3ds Max now treats the selected objects as bones.
5. Select the object to use as the start of the IK chain.
6. Choose Animation > IK Solvers > HI Solver. You can choose a different IK solver, but the HI Solver is the preferred choice.
7. Click to select the end of the IK chain. Now when you transform the boned objects, their movement is governed by the IK solver.

**Bone Tools**

Animation menu > Bone Tools

This command opens the Bone Tools floater, which provides functions for working with bones. The floater contains three rollouts, described in the following topics.
Bone Editing Tools Rollout

Animation menu > Bone Tools > Bone Tools floater > Bone Editing Tools rollout

Controls on the Bone Editing Tools rollout let you create and modify bone geometry and structure, and set bone color for one or more bones.

See also:
- Bones System on page 857

Interface

Bone Pivot Position group

Bone Edit Mode Lets you change the lengths of bones and their positions relative to one another.
When this button is on, you can change the length of a bone by moving its child bone. In effect, you can scale or stretch a bone by moving its child bone while in this mode. You can use this tool both before and after assigning an IK chain to the bone structure.

When Bone Edit Mode is on, you cannot animate, and when Auto Key or Set Key is on, Bone Edit Mode is unavailable. Turn off Auto/Set Key to edit bones.

**NOTE** Moving a bone in Bone Edit mode affects the length of both the child and its parent. If the bones aren't spatially aligned in the usual way (for example, if you are using other objects as bones), this might have unexpected results.

**Bone Tools group**

**Create Bones** Begins the bone-creation process. Clicking this button is the same as clicking Create panel > Systems > Bones on page 857.

**Create End** Creates a nub bone at the end of the currently selected bone. If the selected bone is not at the end of a chain, the nub is linked in sequence between the currently selected bone and the next bone in the chain.

**Remove Bone** Removes the currently selected bone. The bone's parent bone is stretched to reach the removed bone's pivot point, and any children of the removed bone are linked to its parent. Any IK chains that included the removed bone will remain intact.

**Connect Bones** Creates a connecting bone between the currently selected bone and another bone. When you click this button, a dotted line appears in the active viewport from the first selected bone. Move the cursor to another bone to create a new connecting bone. The first selected bone will become a parent to the connecting bone, which is in turn a parent to the second selected bone.

**Delete Bone** Deletes the currently selected bone, removing all its parent/child associations. A nub is placed at the end of the deleted bone's parent. Any IK chains that included this bone become invalid.

**Reassign Root** Makes the currently selected bone the root (parent) of the bone structure.

If the current bone is the root, clicking this has no effect. If the current bone is the end of the chain, the chain is completely reversed. If the current bone is in the middle of the chain, the chain becomes a branching hierarchy.

**Refine** Splits a bone in two. Click Refine, and then click a bone where you want it to split.
Mirror Opens the Bone Mirror dialog (see following), which lets you create mirror copies of selected bones without changing the sign of the bones' scale. Instead, Mirror flips one of the bone axes: Y or Z. You can specify the mirroring axis and the flip axis with the dialog controls.

**Bone Mirror Dialog**

![Bone Mirror Dialog](image)

Opens when you click the Mirror button. Use it to specify the mirroring axis, the flip axis, and an offset value.

While the dialog is open, you can see a preview of the mirrored bone(s) in the viewports. Click OK to create the bones, or Cancel to prevent creation.

**Mirror Axis** Choose an axis or plane about which the bones will be mirrored: X/Y/Z or XY/YZ/ZX.

**Bone Axis to Flip** To avoid creating a negative scale, choose the bone axis to flip: Y or Z.

**Offset** The distance between the original bones and the mirrored bones. Use this to move the mirrored bones to the other side of the character.

**Bone Coloring group**

**Selected Bone Color** Sets the color for selected bones.

**Apply Gradient** Applies a gradient color across several bones based on the Start Color and End Color values. This option is available only when two or more bones are selected. The Start Color is applied to the highest parent bone in the selected chain, while the End Color is applied to the last child object in the selected chain. Intermediate colors in the gradient are applied to bones in between.
Start Color Sets the starting color for the gradient.

End Color Sets the ending color for the gradient.

**Fin Adjustment Tools Rollout**

Animation menu > Bone Tools > Bone Tools floater > Fin Adjustment Tools rollout

Controls on the Fin Adjustment Tools rollout are for adjusting some aspects of bone geometry, including fins.
**Interface**

**Absolute** Sets the fin parameters as absolute values. Use this option to set the same fin values for all selected bones.

**Relative** Sets the fin parameters relative to their current values. Use this option to retain size relationships between bones with different-sized fins.

**Copy**Copies the bone and fin settings for the currently selected bone, in preparation for pasting to another bone.
Paste Pastes the copied bone and fin settings to the currently selected bone.

**Bone Objects group**

**Width** Sets the width of the bone.

**Height** Sets the height of the bone.

**Taper** Adjusts the taper of the bone shape. A Taper with a 0 value produces a box-shaped bone. Higher values pinch the bone where it joins its child bone, while lower values expand that end of the bone.

**Fins group**

**Side Fins** Adds side fins to selected bones.
- **Size** Controls the size of the fin.
- **Start Taper** Controls the start taper of the fin.
- **End Taper** Controls the end taper of the fin.

**Front Fin** Adds front fins to selected bones.
- **Size** Controls the size of the fin.
- **Start Taper** Controls the start taper of the fin.
- **End Taper** Controls the end taper of the fin.

**Back Fin** Adds fins to the backs of selected bones.
- **Size** Controls the size of the fin.
- **Start Taper** Controls the start taper of the fin.
- **End Taper** Controls the end taper of the fin.

**Object Properties Rollout (Bone Tools)**

Animation menu > Bone Tools > Bone Tools floater > Object Properties rollout

Controls on the Object Properties rollout for bones let you turn other objects into bones. They also control bone rigidity and alignment.

**NOTE** You can reset the scale of bones with the Reset Scale option.
Interface

**Bone On/Off** When turned on, the selected bone or object behaves as a bone. Turning this option off causes the object to stop behaving like a bone: there is no auto alignment or stretching. Default=on for bone objects, off for other kinds of objects.

**NOTE** Turning this option on doesn’t immediately cause objects to align or stretch. However, future transforms of children can cause rotation and stretching.

**Freeze Length** When turned on, the bone maintains its length. When turned off, the bone’s length is based on the translation of its child bone. This option is available only if Bone On is on. Default=on.

**WARNING** When you turn on Freeze Length, this has no visible effect unless you transform the child of the object to which Freeze Length is applied.

**Auto-Align** When turned off, the bone’s pivot point doesn’t align to its child object. The translation of a child bone will not be converted into rotation of the parent. Instead, the child is allowed to move away from the parent’s X axis. This option is available only if Bone On is on. Default=on.

**NOTE** Changing the Auto-Align state does not have an immediate visual effect on the skeleton. It affects future behavior when bones are moved.
Correct Negative Stretch  When turned on, any stretching of the bone that results in a negative scale factor will be corrected to a positive number. This option is available only if Bone On is on. Default=on.

Realign  Causes the bone's X axis to realign and point at the child bone (or the average pivot of multiple children). Normally this alignment is maintained, and there is no need to use this option. However, it is possible for the bones to come out of alignment by turning off Auto-Align and moving a child bone. Use Realign to align the bone back to its child. This option is available only if Bone On is on.

Reset Stretch  Stretches the bone to reach its child object if the child has been moved away from the bone. This option is available only if Bone On is on.

Reset Scale  Resets a stretched bone's internally calculated scale to 100% on each axis. Using this option avoids unexpected behavior due to objects which are both linked and scaled. This option has no visual effect on the bone. This option is available only if Bone On is on.

Stretch Factor Information

Under the Correct Negative Stretch options is a text display giving information about the number of bones selected and the respective stretch factor for all three axes. If more than one bone is selected, the Stretch Factor text displays undefined.

NOTE  The Stretch Factor text only updates when you are in Bone Edit Mode on page 872.

Stretch and Axis Options

Stretch  Determines what kind of stretch takes place when the child bone is transformed and Freeze Length is off. Default=Scale.

■  None  No stretch takes place.

■  Scale  Lets the bone scale. The stretch happens along one axis.

■  Squash  Lets the bone squash. The bone gets fatter as it gets shorter, and thinner as it gets longer.

Axis  Determines the axis used for the stretch.

■  X/Y/Z  Choose the axis for scaling or squashing.

■  Flip  Flips the stretch along the selected axis.
Ring Array System

Create panel > Systems > Ring Array button

The Ring Array object consists of a dummy object on page 2840 surrounded by a ring of boxes. You can arrange the boxes in the ring along a sine curve, vary their number, and animate the ring array’s parameters. You can also replace the boxes with other objects using Track View, as described in the Procedures section, below.

![Example of ring array]

Procedures

To create the ring array system:

1. On the Create panel, click Systems, and then click Ring Array.
2. Drag in a viewport to set the center and radius of the array.
   A dummy object appears at the center. By default, four boxes are evenly spaced in a circle around it.

To animate the ring array:

1. Turn on Auto Key.
2. Move to a nonzero frame.
3. Adjust the ring array parameters.
   You can't animate the number of boxes in the ring.
4. Repeat steps 2 and 3 for additional keyframes.
NOTE To animate the ring array after creation, use the Motion panel, not the Modify panel.

To put other kinds of objects in the ring:
You can use either version of Track View: Curve Editor or Dope Sheet.

1 In the Track View Controller window, click the name of object container of the object to put in the ring.
The name highlights.

2 Still in the Controller window, right-click and choose Copy from the menu.

3 Highlight the object container of one of the ring array boxes.
4 Right-click and choose Paste.

5 In the Paste dialog, choose Copy or Instance. Optionally, to replace all the boxes with the copied object, turn on Replace All Instances. Click OK.

The box or boxes are replaced with the copied object.

**TIP** To see the replacement objects, you might need to refresh the viewports.
Top: Object substituted for boxes in array
Bottom: The result
Interface

These parameters control ring arrays. To adjust and animate the ring array after creation, select one of the array objects (not the dummy), and then go to the Motion panel, not the Modify panel.

**Radius** Sets the radius of the ring. You set the initial Radius value when you drag to create the ring array.

**Amplitude** Sets the amplitude of the ring's sine curve, in active units. Amplitude is a height offset from the local origin of the center dummy object.

**Cycles** Sets the number of cycles in the ring's sine curve. When Cycles is 0.0, the ring is flat. When Cycles is 1.0, the ring is tilted. Greater values increase the number of peaks in the curve.

**Phase** Offsets the phase of the wave. That is, it has the effect of moving the wave along the circumference of the ring. Whole values have no effect; only fractional values do.

**Number** Sets the number of boxes in the ring.
Moving, Rotating, and Scaling Objects

To change an object’s position, orientation, or scale, click one of the three transform buttons on the main toolbar or choose a transform from a shortcut menu. Apply the transform to a selected object using the mouse, the status bar Coordinate Display fields, a type-in dialog, or any combination of the above.

The column can be moved, rotated, and scaled.
Scaling and Dimensions

If you scale an object and later check its base parameters in the Modify panel, you see the dimensions of the object before it was scaled. The base object exists independently of the scaled object that is visible in your scene.

You can use the Measure utility on page 2882 to measure the current dimensions of an object that has been scaled or changed by a modifier.

See also:
- Creating Copies and Arrays on page 981
- Using Shift+Clone on page 996

Using Transforms

A transform is an adjustment of an object’s position, orientation, or scale, relative to the 3D world (or world space) in which you’re working.

Changing a model by changing its position, rotation, or scale

You can apply three types of transform to an object:

- Position on page 914
- Rotation on page 915
This section presents these brief topics designed to help you quickly start learning how to transform objects, and how to animate your transforms:

- Using Transform Gizmos on page 889
- Animating Transforms on page 902
- Transform Managers on page 904
- Specifying a Reference Coordinate System on page 906
- Choosing a Transform Center on page 907
- Using the Axis Constraints on page 910

**Failure to Move or Rotate**

In some cases, an object might fail to move or rotate, even when the proper button is on and the object is selected. This could be due to one of the following reasons:

- The object is frozen on page 191.
- A transform controller has been assigned to the object. See Animation Controllers on page 3424.
- Inverse Kinematics mode is on and the preference called Always Transform Children of the World is off. See Introduction to Inverse Kinematics (IK) on page 3661.

**Procedures**

To transform an object using the main toolbar:

1. On the main toolbar, click one of the three transform buttons: Select And Move on page 914, Select And Rotate on page 915, or Select And Scale on page 917. These buttons are usually referred to as Move, Rotate, and Scale.
2 Position the mouse over the object you want to transform.
   ■ If the object is already selected, the cursor changes to indicate the transform.
   ■ If the object is not selected, the cursor changes to a crosshairs to show that the object can be selected.

3 Drag the mouse to apply the transform.
   If you drag the mouse over an unselected object, it becomes selected and is also transformed.
   You can restrict transforms to one or two axes easily with the transform gizmo on page 889.

To cancel a transform:
   ■ Right-click while you’re dragging the mouse.

To transform an object from the quad menu:
   1 Right-click a selected object. The quad menu on page 8052 lists the three transforms.
   2 Choose one of the transforms. The equivalent transform button is selected on the main toolbar.
   3 Drag the object to apply the transform.

To use transform type-in:
   1 Choose Tools menu > Transform Type-In to display the dialog.
   2 Apply a transform to a selected object.
   3 You can do any of the following, switching from one to the other as required.
      ■ Type a value in an axis field and press Enter to apply the transform change to the selection.
      ■ Drag a spinner in an axis field to update the selection.
      ■ Drag the object to apply the transform and read the resulting change in the dialog.
For example, if Move is active, the dialog fields read out both the absolute and offset positions of the selected object in world space. If no object is selected, the fields turn gray.

**To use transform type-in on the status bar:**

1. Select an object or a group of objects.
2. On the main toolbar, choose a transform (Move, Rotate, or Scale) to perform on the objects.
3. On the status bar, you can do any of the following, switching from one to another as required:
   - Type a value in an axis field and press Enter to apply the transform change to the selection. The Absolute/Offset toggle, to the right of the X, Y, and Z fields, lets you switch between entering values that are absolute (in world space) or offset (relative to the selection’s present position, orientation, and dimensions).
   - Drag a spinner in an axis field to update the selection.
   - Drag the object to apply the transform and read the resulting change in the X, Y, and Z fields.

**TIP** To see the Z field, drag the transform type-in portion of the toolbar while a pan hand is visible.

**Using Transform Gizmos**

Select an object. > main toolbar > Click any transform button to display the object’s Transform Gizmo icon.

The Transform gizmos are viewport icons that let you quickly choose one or two axes when transforming a selection with the mouse.

You choose an axis by placing the mouse over any axis of the icon, and then drag the mouse to transform the selection along that axis. In addition, when moving or scaling an object, you can use other areas of the gizmo to perform transforms along any two axes simultaneously. Using a gizmo avoids the need to first specify a transform axis or axes on the **Axis Constraints toolbar** on page 8039, and also lets you switch quickly and easily between different transform axes and planes.
Chapter 7   Moving, Rotating, and Scaling Objects
A Transform gizmo appears when one or more objects are selected and one of the transform buttons (Select And Move on page 914, Select And Rotate on page 915, or Select And Scale on page 917) is active on the main toolbar. Each transform type uses a different gizmo. By default, each axis is assigned one of three colors: X is red, Y is green, and Z is blue. The corners of the Move gizmo are assigned the two colors of the related axes; for example, the corner for the XZ plane is red and blue.

When you position the mouse over any axis, it turns yellow to indicate that it’s active. Similarly, position the mouse over one of the plane handles, and both associated axes turn yellow. You can now drag the selection along the indicated axis or axes. Doing so changes the Axis Constraints toolbar "Restrict to ..." setting on page 910.
NOTE When no transform tool is active and you select one or more objects, axis tripods appear in the viewport.

The axis tripod appears when the transform gizmo is inactive.

Each axis tripod consists of three lines, labeled X, Y, and Z, and shows you three things:

- The orientation of the tripod reveals the orientation of the current reference coordinate system.
- The location of the junction of the three axis lines shows where the current transform center is.
- The highlighted red axis lines show the current axis constraints on page 910.

Move Gizmo

The Move gizmo includes plane handles, and the option to use a center box handle.
You can select any of the axis handles to constrain movement to that axis. In addition, the plane handles allow you to constrain movement to the XY, YZ, or XZ planes. The selection hotspot is within the square formed by the plane handles. You can change the size and offset of the handles and other settings on the Gizmos panel on page 8354 of the Preferences dialog on page 8298.

The Move gizmo with the YZ axes selected.

You can constrain translation to the viewport plane by dragging the center box. To use this optional control, turn on Move In Screen Space on page 8356.

Rotate Gizmo

The Rotate gizmo is built around the concept of a virtual trackball. You can rotate an object freely, about the X, Y, or Z axis, or about an axis perpendicular to the viewport.
The axis handles are circles around the trackball. Drag anywhere on one of them to rotate the object about that axis. As you rotate about the X, Y, or Z axis a transparent slice provides a visual representation of the direction and amount of rotation. If you rotate more than 360°, the slice overlaps and the shading becomes increasingly opaque. 3ds Max also displays numerical data to indicate a precise rotational measurement.
In addition to XYZ rotation, you can also use free rotation or the viewport handle to rotate objects.

Drag inside the Rotate gizmo (or the outer edge of the gizmo) to perform free rotation. Rotation should behave as if you were actually spinning the trackball.

The outermost circle around the Rotate gizmo is the Screen handle, which lets you rotate the object on a plane parallel to the viewport.

You can adjust settings for the Rotate gizmo on the Gizmos panel on page 8354 of the Preferences dialog on page 8298.

**Scale Gizmo**

The Scale gizmo includes plane handles and scaling feedback through the stretching of the gizmo itself.

The plane handles let you perform uniform and non-uniform scaling without changing your selection on the main toolbar:

- To perform Uniform scaling, drag in the center of the gizmo.
The Transform gizmo with Uniform scaling selected.

- To perform non-uniform scaling, drag on a single axis or a plane handle.
To perform a Squash operation, you must choose Select and Squash on page 920 on the main toolbar.

The Scale gizmo provides feedback by changing its size and shape; in the case of a uniform scale operation, it will grow or shrink as the mouse moves, and during non-uniform scaling, the gizmo will stretch and deform while dragging. However, once the mouse button is released, the gizmo returns to its original size and shape.

You can adjust settings for the Scale gizmo on the Gizmos panel on page 8354 of the Preferences dialog on page 8298.

**Notes**

Using a Transform gizmo sets the default axis constraint to the last axis or plane you used.
If Lock Selection Set is on, you can drag anywhere in the viewport to transform the object. Dragging an axis, however, still applies the constraint along that axis.

See also:

- Gizmos Preferences on page 8354

Procedures

Example: To explore use of the transform gizmo:

1. Reset 3ds Max, then create a sphere, and then click the Select and Move button.
   The Transform gizmo appears at the center of the sphere. Because the default axis constraint on the Axis Constraints toolbar is XY Plane, the X and Y shafts of the Transform gizmo are yellow (active), while the Z shaft is blue.

2. Use Orbit on page 8152 to adjust the Perspective view for a better view of the Transform gizmo. When you’re done, right-click to return to Select And Move.

3. Point to any part of the sphere away from the Transform gizmo, and drag to confirm that the sphere is locked to the XY plane.

4. Point to the Z-axis shaft, and drag.
   The Z shaft turns yellow, the X and Y shafts turn red and green, respectively, and the sphere moves along the Z axis.

5. Point to the Y shaft, and drag.
   The Y shaft turns yellow, and the sphere moves along only the Y axis.

6. Point to the red-and-green corner mark opposite the ends of the X and Y axes, and drag.
   The sphere moves along the XY plane.

7. Press the Spacebar to turn on Selection Lock on page 8079.

8. Drag the mouse anywhere in a viewport away from the selection.
   The sphere moves along the XY plane.
Point to the X shaft, and drag.

The sphere moves along only the X axis.

Experiment with other transformations, such as rotation and scale. Try different reference coordinate systems. Experiment with sub-object transformations.

**Interface**

**Change default colors** Customize menu > Customize User Interface dialog > **Colors panel** on page 8272 > Gizmos Element > Active Transform Gizmo and Transform Gizmo X/Y/Z.

**Enable/disable Transform Gizmo** Customize menu > Preferences > **Gizmos panel** on page 8354 > On check box.

---

**NOTE** When you turn off the Transform gizmo in Preferences, the standard axis tripod appears instead. To toggle display of either the gizmo or the tripod, press the X key or use Views menu > Show Transform Gizmo.

There are additional controls for each Gizmo in the **Gizmos panel** on page 8354 of the Preferences dialog.

---

**Transform Type-In**

Status bar > Transform Type-In

Edit menu > Transform Type-In

F12

Main toolbar > Right-click Select And Move, Select And Rotate, or one of the Select And Scale buttons.

Transform Type-In is a dialog that lets you enter precise values for move, rotate, and scale **transforms** on page 8750. You can use Transform Type-In with anything that can display an axis tripod or Transform gizmo.

You can also use the Transform Type-In boxes on the **status bar** on page 8064. To use the Transform Type-In boxes on the status bar, simply enter the appropriate values in the boxes and press Enter to apply the transformation. You can alternate between entering absolute transform values or offset values by clicking the Relative/Absolute Transform Type-In button to the left of the transform boxes.
If you choose Transform Type-In from the Edit menu, press F12, or right-click one of the transform toolbar buttons, Transform Type-In pops up as a dialog. The title of the dialog reflects the active transform. If Rotate is active, the dialog's title is Rotate Transform Type-In and its controls affect rotation. If Scale is active, its title is Scale Transform Type-In, and so on. You can enter either absolute transform values or offset values.

In most cases, both absolute and offset transforms use the active reference coordinate system on page 922. The exceptions are View, which uses the World coordinate system, and Screen, which uses World for absolute moves and rotations. Also, absolute scaling always uses the Local coordinate system. The dialog labels change to show the reference coordinate system being used.

When you use the Transform Type-In at a sub-object level, you transform the transform gizmo of the sub-object selection. So, for example, the absolute position values represent the absolute world position of the transform gizmo. If you've selected a single vertex, it's the absolute world position of the vertex. If multiple vertices are selected, the Transform gizmo is placed at the center of the selection, so the position you specify in the Transform Type-In sets the absolute position of the center of the selected vertices.

When multiple vertices are selected in Local transform mode, you end up with multiple transform gizmos. In this case, only the Offset control is available. Because the axis tripods are not scaled, the Absolute Scale control is not available at the sub-object level. Only Offset is available.

When you use the Transform Type-In for Absolute rotation, the state of the Center flyout is respected. You can perform absolute rotations about the pivot point of the object, the selection center, or transform coordinate center. See Choosing a Transform Center on page 907.

**Using Type-In with Sub-Object Selection**

You can use Transform Type-In with any sub-object selection or gizmo. The transform affects the axis tripod for the selection. Absolute and offset world coordinates are those of the object's or selection's coordinate system, whose origin is indicated by the axis tripod. If multiple vertices are selected, the tripod is at the center of the selection and its location is given in world coordinates. Because axis tripods cannot be scaled, Absolute Scale fields are unavailable when you are at a sub-object level.

See Basics of Creating and Modifying Objects on page 358 for information on sub-object selection and gizmos.
Procedures

To use transform type-in:

1 Select an object or a group of objects.

2 Choose a transform to perform on the objects (Move, Rotate, or Scale).

3 You can do any of the following, switching from one to another as required:
   - Type a value in an axis field and press Enter to apply the transform change to the object in the viewport.
   - Drag a spinner in an axis field to update the object in the viewport.
   - Drag the object to apply the transform and read the resulting change in the axis fields.
     For example, if Move is active, the fields read out both the absolute positions of the selected object in world space. If no object is selected, the fields turn gray.

Interface

Status bar

Absolute/Offset Mode Transform Type-In When this is off, 3ds Max treats values you enter into the X, Y, and Z fields as absolutes. When this is on, 3ds Max applies transform values you enter as relative to current values; that is, as an offset. Default=off.

X, Y, and Z Display and accept entry for values of position, rotation, and scale along each axis.

Absolute group (Dialog)
X, Y, and Z Display and accept entry for absolute values of position, rotation, and scale along each axis. Position and rotation are always displayed, as world scale is always local.

Offset group (Dialog)

X, Y, and Z Display and accept entry for offsets of the position, rotation, and scale values along each axis.

Displayed offset values revert to 0.0 after each operation. For example, if you enter 45 degrees in a Rotate Offset field, when you press Enter, 3ds Max rotates the object 45 degrees from its previous position, increases the Absolute field value by 45 degrees, and resets the Offset field to 0.0.

Offset labels reflect the active reference coordinate system. The Offset can be Offset: Local, Offset: Parent, and so on. If you use Pick to select the reference coordinate system of a particular object, the Offset will be named with that object.

Animating Transforms

You can animate changes in position, rotation, and scale (transforms) by turning on the Auto Key button and then performing the transform at any frame other than frame 0. This creates a key for that transform at the current frame.

Example: To animate an object moving among three points:

1. Turn on the Auto Key button on page 3373.
   
   The Auto Key button and the highlight border around the active viewport both turn red.

2. Drag the time slider to frame 25.

3. Move the object from its current position (point A) to another location (point B).
   
   3ds Max creates Move keys at frames 0 and 25. These appear on the track bar on page 8071. The establishing key at frame 0 describes the object’s original position, at point A. The key at frame 25 describes the object’s position at point B.

4. Drag the time slider to frame 50.
5 Move the object from point B to a third location (point C).
3ds Max creates a Move key at frame 50 that describes the object’s position at point C.

6 Click the Auto Key button to stop recording.

7 Click the Play button on page 8102.
The object moves from point A to point B over frames 0 to 25, and then proceeds to point C over frames 26 to 50.

8 The Play button has turned into a Stop button; click Stop to stop playback.

You can combine different transforms in a single animation sequence, so that an object appears to move as it rotates and changes in size.

See Animation Concepts and Methods on page 3368 for more information on animation techniques.
Transform Managers

3ds Max provides three controls, collectively referred to as the transform managers, for modifying the action of the transform tools.

The transform manager controls are as follows:

- The Reference Coordinate System drop-down list on page 922, which controls the orientation of the transform axes, is found to the right of the Move, Rotate, and Scale transform buttons on the main toolbar.

- The Transform Center flyout on page 930, which controls the center about which 3ds Max applies the transform, is found to the right of the Reference Coordinate System drop-down list.

- The Axis Constraint setting on page 910 lets you restrict the transform to a single axis or two axes (that is, a plane). The axis constraint tools appear on the Axis Constraints toolbar, which is off by default. You can open the toolbar by right-clicking an empty spot on the main toolbar and choosing Axis Constraints from the menu.

**TIP** You can also restrict transforms with the transform gizmos on page 889.

Definitions

Certain terms are used in the description of transforms and the transform managers.

- **An axis** is a straight line along which an object is moved or scaled, or about which an object is rotated. When you work in 3D, you use three axes, labeled X, Y, and Z, which are oriented 90 degrees from each other.

- **A coordinate system** specifies the orientation of the X, Y, and Z axes used by a transform. For example, in the World coordinate system, as seen from the Front view, the X axis runs horizontally from left to right, the Y axis runs from back to front, and the Z axis runs vertically, from bottom to top.

On the other hand, each object carries its own Local coordinate system. If the object has been rotated, its Local coordinate system might be different from the world coordinate system.

- The **transform center**, or pivot point, is the spot about which a rotation takes place, or to and from which scaling occurs.
Using the transform managers, you can specify any combination of axes, transform coordinate systems, and transform centers.

**Axis Tripod Icon**

An axis tripod appears in the viewports when you select one or more objects, to assist you visually in your transforms. This tripod consists of three lines, labeled X, Y, and Z, and shows you three things:

- The orientation of the tripod reveals the orientation of your coordinate system.
- The location of the junction of the three axis lines shows you where your transform center is.
- The highlighted red axis lines show you the axis or axes to which the transform is constrained. For example, if only the X axis line is red, you can move objects only along the X axis.

**NOTE** The Transform gizmo supplants the axis tripod for selections when a transform mode is active. Besides providing all of the above functions, it lets you specify the transform axis or axes without explicitly setting constraints; see Using the Axis Constraints on page 910. For more on the Transform gizmo, see Using Transform Gizmos on page 889.

You can toggle the display of the axis tripod in all viewports by choosing Views menu > Show Transform Gizmo, or by pressing the X key.

**Transform Manager Settings**

The state of the three transform managers (coordinate system, center, and axis constraints) is stored with each type of transform. When you switch from Move to Rotate to Scale, the transform managers change to whatever combination they were in when you last used that transform.

For example, if you click Rotate and set the transform managers to Local, Selection Center, and Y constraint, when you click Move, the controls might shift to View, Pivot Point, and XY constraint (whichever combination was set the last time you used Move). When you go back to Rotate, the controls revert to Local, Selection Center, and Y constraint.
To avoid surprises, always click the transform button first, and then set the transform managers. If, instead, you first set the transform managers, their settings are likely to change as soon as you choose a new transform button. One way to remember this is always to set the transform and managers by working from left to right on the toolbar. Alternatively, you can turn on Customize menu > Preferences > General tab > Reference Coordinate System group > Constant, which keeps the transform manager settings the same for all transforms.

Specifying a Reference Coordinate System

The reference coordinate system determines the orientation of the X, Y, and Z axes used by the transform. The type of transform system you use affects all transform operations.

You specify the transform coordinate system using the Reference Coordinate System list on page 922.

Creating a Local Axis

While modeling, it's often helpful to have a temporary, movable local axis so you can rotate or scale about an arbitrary center.

NOTE This technique does not work for animation. See Choosing a Transform Center on page 907 for animation tips.

TIP As an alternative to this method, you can use the Working Pivot on page 3766.

To create an adjustable local axis:

1. Create a Point helper object on page 2853.
2. From the Transform Coordinate System list, choose Pick, and then click the point object.
   The name of the point object appears in the list as the active coordinate system.

Now you can use the point object's coordinate system as an adjustable axis.

To use the adjustable axis:

1. Place the point object where you want the rotate or scale transform to be centered.
2 Select the object you want to transform.
3 Choose the point object’s name in the Transform Coordinate System drop-down list.
4 From the Use Center flyout on page 930 choose Use Transform Coordinate Center. For more information, see Choosing a Transform Center on page 907.
5 Proceed with the transform.

Choosing a Transform Center

The transform center affects scale and rotation transforms, but has no effect on position transforms.

3ds Max lets you choose from three types of transform center using the Use Center flyout on page 930 on the main toolbar. When you change the transform center, the junction of the axis tripod icon moves to the location you specify.

By default, 3ds Max sets the transform center to Use Pivot Point center for single objects. When you select multiple objects, the default transform center changes to Use Selection Center, because selection sets have no pivot point. You can change the transform center in either case, and 3ds Max remembers and restores the transform center setting separately for selections of single and multiple objects (during the current session).

TIP You can transform an object’s pivot with the Hierarchy panel > Adjust Pivot controls on page 3763. Alternatively, you can transform objects using the working pivot on page 3766.

For example, you might select a single object and choose Use Transform Coordinate Center, and then select multiple objects and choose Use Pivot Point Center. When you next select a single object, 3ds Max switches back to Use Transform Coordinate Center. Then, when you select multiple objects, the center switches back to Pivot Point.
1. User selects single object.
2. User clicks Use Transform Coordinate Center from Use Center flyout on Main toolbar.
3. User adds second object to selection.
4. Transform center changes to Use Selection Center when selection set contains more than one object.
5. User clicks Use Pivot Point Center while multiple objects still selected.
6. User selects single object.
7. Transform center returns to Use Transform Coordinate Center (see step 2).
8. User selects multiple objects.
9. Transform center returns to Use Pivot Point Center (see step 5).

Transforming About Snapped Points

While the transform center choices are often useful at the object level, they are not usually convenient when transforming sub-object selections. You can override the active transform center and perform the current transform about a temporary point by using snaps. When Snaps is active, and your selection is locked, the point you snap to will set the point about which the transform is performed. Using this technique, you can:

- Move relative to two snap points.
- Rotate about a snapped point.
- Scale about a snapped point.

For more details, see Snap Settings on page 2819.

Animation and the Transform Center

Because of the nature of keyframing, you can animate rotation and scale transforms properly only by using an object’s local pivot point. For example, while modeling, you can rotate an object that’s offset from the world origin around the world center coordinate system. The object sweeps around the origin in a large arc. However, if you attempt to animate this, the object rotates about its local axis and moves in a straight line from one end of the arc to the other.

To avoid this discrepancy, when Auto Key on page 8090 is on and either the Rotate or Scale button is active, the Use Center flyout is unavailable and set to Use Pivot Point. When Auto Key button is off, all transforms use the center settings previously described.

You can override this behavior by turning off Local Center During Animate on page 8349 in the Animation Preferences settings.

Keep in mind that this affects only the center of the transform. The orientation of the selected transform coordinate system is still in effect.
**Animating "Off-Center"**

You can animate a rotation or scale about an off-center point by linking your object as the child of a dummy helper object, and then rotating or scaling the dummy.

Another technique is to offset the pivot point of your object using the Hierarchy panel.

For information about linking, dummy objects, and the Hierarchy panel, see [Hierarchies on page 3618](#).

**Using the Axis Constraints**

Axis Constraints toolbar > Restrict to X, Y, Z, or a plane

Keyboard >

F5 restricts to X
F6 restricts to Y
F7 restricts to Z

F8 cycles through the three plane restrictions

The Restrict to ... buttons, also called the Axis Constraint buttons, are located on the Axis Constraints toolbar on page 8039, which is off by default.

You can turn on the Axis Constraints toolbar by right-clicking an empty spot on the main toolbar and choosing Axis Constraints from the pop-up menu. These buttons let you specify one or two axes about or along which the transform takes place. They help you avoid transforming an object in a direction you didn't intend.

**NOTE** It's generally easier to use the Transform gizmos than these buttons; see [Using Transform Gizmos on page 889](#). However, it is helpful to understand the concepts explained below.
Axis Constraint buttons

Only one axis constraint can be active at a time. When a button is turned on, transforms are constrained to the specified axis (or plane). For example, if you turn on the Restrict To X button, you can rotate an object only about the X axis of the current transform coordinate system.

The axis or axes to which you’re constrained are highlighted in red on the axis tripod icon in viewports, or in yellow on the Transform gizmo.

**NOTE** By default, axis constraints don’t apply when using Snap. You can override this by turning on Snaps Use Axis Constraint Toggle on the Axis Constraints toolbar on page 8039, or by turning on Use Axis Constraints in Snap Options on page 2828.

**NOTE** Constraints are set on a transform-by-transform basis, so select the transform before you select the axis constraint. If you do not want the constraints to change, turn on Customize menu > Preferences > General tab > Reference Coordinate System group > Constant.

The axis constraints are stored separately at object and sub-object levels. If you set these three controls one way while in sub-object mode and another way while in object selection level, when you return to sub-object mode, they’re restored to the way they were previously set. For example, if you're using XY constraints at object level, then switch to sub-object level and use Z constraint, when you return to object level, XY will be restored.
**Restrict to Plane Flyout**

The Restrict To Plane flyout, available from the Axis Constraints toolbar, lets you limit all transformations (move, rotate, scale) to the XY, YZ, or ZX planes (by default, parallel with the Top view).

You can also select planar constraint by using the Move Transform Gizmo on page 889. Instead of dragging one of the axis indicators, drag one of the plane indicators near the center of the gizmo.

When you move an object along a plane that is head-on to your view, the object moves along the single available axis shown in the view.

**Reset XForm Utility**

Utilities panel > Utilities rollout > Reset XForm button

Use the Reset XForm (Transform) utility to push object rotation and scaling values onto the modifier stack and align object pivot points and bounding boxes with the World coordinate system. Reset XForm removes all Rotation and Scale values from selected objects and places those transforms in an XForm modifier.

To reset the transform of a group, use the Transform button in the Reset group box of the Hierarchy > Pivot command panel.

**Procedures**

**To reset an object's transform:**

1. Select an object.
2. On the Utilities panel, click Reset XForm.
3. On the Utilities panel > Utilities rollout, click the More button and choose Reset XForm.
4 On the Reset Transform rollout, click Reset Selected. Object rotation and scaling are now carried by an XForm modifier placed at the top of the modifier stack.

When you apply the Reset Transform utility, an XForm modifier on page 2010 that carries the rotation and scale values is placed at the top of the Modifier Stack display. You can apply other modifiers above and below the XForm modifier. You can select the XForm modifier and add other Move, Rotate, and Scale transforms. You can delete the XForm modifier to completely remove the transforms from the object. You can collapse the object to absorb the rotation and scale values into the object mesh.

Interface

Reset Selected Removes all Rotation and Scale values from selected objects and places those transforms in an XForm modifier.

NOTE Reset Selected is not available if the object is contained in a Group on page 243.

Transform Commands

The basic transform commands are the most straightforward way to change an object’s position, rotation, or scale. These commands appear on the default main toolbar on page 8035. They are also available from the default quad menu on page 8052.
Select and Move

Main toolbar > Select and Move
Right-click an object. > quad menu > Transform quadrant > Move
Edit menu > Select and Move

Use the Select And Move button or the Move command on the Edit or quad menu to select and move objects.

To move a single object, you do not need to select it first. When this button is active, clicking an object selects it and dragging the mouse moves it.

The direction of the movement is determined both by your mouse and by the current reference coordinate system. To restrict object movement to the X, Y, or Z axis, or to any two axes, click the appropriate button on the Axis Constraints toolbar on page 8039, use the Transform gizmo on page 889, or right-click the object, and select the constraint from the Transform submenu.
Moving an object

See also:

■ Move Gizmo on page 892

Select and Rotate

Main toolbar > Select and Rotate
Right-click an object. > quad menu > Transform quadrant > Rotate
Edit menu > Select and Rotate
Use the Select and Rotate button or the Rotate command on the Edit or quad menu to select and rotate objects.

To rotate a single object, you don't need to select it first. When this button is active, clicking an object selects it and dragging the mouse rotates it.
When you are rotating an object about a single axis (as is usually the case), don't rotate the mouse, expecting the object to follow the mouse movement. Just move the mouse straight up and straight down. Up rotates the object one way, down rotates it the opposite way.

The center of rotation is determined by the Transform Center setting on page 922.

To restrict rotation about the X, Y, or Z axis, or to any two axes, click the appropriate button on the Axis Constraints toolbar on page 8039, use the Transform gizmo on page 889, or right-click the object, and select the constraint from the Transform submenu.

Rotating an object

See also:
- Rotate Gizmo on page 893

Procedures

This procedure illustrates the intuitive usage of the default Euler XYZ rotation controller on page 3453.
To animate object rotation interactively:

1. Add an object.

2. Move the time slider to a frame other than 0 and turn on Auto Key.

3. Choose Select And Rotate.

4. Rotate the object on any axis by any amount.

5. Move the time slider to a later frame.

6. Rotate the object on the same axis by an amount greater than 180 degrees.

7. Play back the animation.
   The rotation plays back exactly as you recorded it.

---

**Select and Scale**

Main toolbar > Select and Scale flyout
Right-click an object. > quad menu > Transform quadrant > Scale
Edit menu > Select and Scale

The Select And Scale flyout on the main toolbar provides access to three tools you can use to change object size.

From top to bottom, these are:

- Select and Uniform Scale on page 918
- Select and Non-Uniform Scale on page 919
- Select and Squash on page 920
In addition, the Scale command is available on the Edit menu and the Transform quadrant of the quad (right-click) menu; this activates whichever scale tool is currently chosen in the flyout.

**NOTE** The Smart Scale command activates the Select And Scale function and, with repeated invocations, cycles through the available scaling methods. By default, Smart Scale is assigned to the R key; you can use Customize User Interface on page 8249 to assign it to a different keyboard shortcut, a menu, etc.

### Select and Uniform Scale

Main toolbar > Select and Uniform Scale (on Select And Scale flyout)

Right-click an object. > Scale (selects current toolbar Scale mode)

The Select And Uniform Scale button, available from the Select And Scale flyout on page 917, lets you scale objects by the same amount along all three axes, maintaining the object's original proportions.

Uniform scale does not change an object's proportions.
To scale a single object, you don't need to select it first. When this tool is active, clicking an object selects it and dragging the mouse scales it.

See also:

- Scale Gizmo on page 895

Select and Non-Uniform Scale

Main toolbar > Select and Non-Uniform Scale (on Select And Scale flyout)
Right-click an object. > Scale (selects current toolbar Scale mode)

The Select And Non-Uniform Scale button, available from the Select And Scale flyout on page 917, lets you scale objects in a non-uniform manner according to the active axis constraint.

Non-uniform scale can change proportions with different values for different axes.
You can restrict the objects' scaling about the X, Y, or Z axis, or to any two axes, by first clicking the appropriate button on the Axis Constraints toolbar on page 8039, or with the Transform gizmo on page 889.

To scale a single object, you don't need to select it first. When this tool is active, clicking an object selects it and dragging the mouse scales it.

**IMPORTANT** Avoid applying non-uniform scale at the object level. Non-uniform scaling is applied as a transform and changes the axes of the object, so it affects other object properties. It also alters the properties passed hierarchically from parent to child. When you perform other operations on the object, such as rotation, inverse kinematic calculations, and other positioning operations, you might not get the results you expect. To recover from these problems, use the Hierarchy panel's Reset Scale button or the Utilities panel's Reset XForm utility. Either of these options will reset the axes to use the non-uniform scale as the fundamental scale for the object.

As an alternative to non-uniform scaling, consider using the XForm modifier on page 2010.

See also:
- Scale Gizmo on page 895

**Select and Squash**

Main toolbar > Select And Squash (on Select And Scale flyout)

Right-click an object. > Scale (selects current toolbar Scale mode)

The Select And Squash tool is useful for creating different phases of the “squash and stretch”-style animation often found in cartoons. The Select And Squash tool, available from the Select And Scale flyout on page 917, lets you scale objects according to the active axis constraint. Squashing an object always involves scaling down on one axis while simultaneously scaling up uniformly on the other two (or vice-versa).
Squash scales two axes in opposite directions, maintaining the object’s original volume.

You can restrict object scaling to the X, Y, or Z axis, or to any two axes, by first clicking the appropriate button on the Axis Constraints toolbar on page 8039.

When the Select And Squash tool is active, clicking an object selects it and dragging the mouse scales it.

**IMPORTANT** Avoid using Select And Squash at the object level. The non-uniform scaling that it effects is applied as a transform and changes the axes of the object, so it affects other object properties. It also alters the properties passed hierarchically from parent to child. When you perform other operations on the object, such as rotation, inverse kinematics calculations, and other positioning operations, you may not get the results you expect. To recover from these problems, use the Hierarchy panel’s Reset Scale button or the Utilities panel’s Reset XForm utility. Either of these options will reset the axes to use the non-uniform scale as the fundamental scale for the object.

As an alternative to non-uniform scaling with Select And Squash, consider using the XForm modifier on page 2010.

- Scale Gizmo on page 895

## Transform Coordinates and Coordinate Center

Controls for setting the coordinate system and the active center for transforms to use are on the default main toolbar on page 8035.

![Reference Coordinate System list](image)

See also:
- Moving, Rotating, and Scaling Objects on page 885

## Reference Coordinate System

Main toolbar > Reference Coordinate System list

The Reference Coordinate System list lets you specify the coordinate system used for a transformation (Move, Rotate, and Scale). Options include View, Screen, World on page 8768, Parent, Local on page 8621, Gimbal, Grid, Working on page 3766, and Pick.

In the Screen coordinate system, all views (including perspective views) use the viewport screen coordinates.

View is a hybrid of World and Screen coordinate systems. Using View, all orthographic views use the Screen coordinate system, while perspective views use the World coordinate system.
TIP The coordinate system is set on a transform-by-transform basis, so choose the transform before you specify the coordinate system. If you do not want the coordinate system to change, turn on Customize menu > Preferences > General panel > Ref. Coord. System group > Constant.

Interface

View In the default View coordinate system, X, Y, and Z axes are the same in all orthographic viewports. When you move an object using this coordinate system, you are moving it relative to the space of the viewport.

- X always points right.
- Y always points up.
- Z always points straight out of the screen toward you.
Different orientations of the View coordinate system:

1. Top viewport.
2. Front viewport.
3. Left viewport.
4. Perspective viewport.

**Screen** Uses the active viewport screen as the coordinate system.
- X is horizontal, running in a positive direction toward the right.
- Y is vertical, running in a positive direction upward.
- Z is depth, running in a positive direction toward you.

Because the Screen mode depends on the active viewport for its orientation, the X, Y, and Z labels on an axis tripod on page 905 in an inactive viewport show the orientation of the currently active viewport. The labels on that tripod change when you activate the viewport it is in.
The coordinate system in Screen mode is always relative to the point of view.

World Uses the world coordinate system. Seen from the front:
- X runs in a positive direction to the right.
- Z runs in a positive direction upward.
- Y runs in a positive direction away from you.
The World coordinate system is always fixed.

**NOTE** The world axis shows the current orientation of the viewport with respect to world coordinate system. You can find it in the lower-left corner of each viewport. The world axis colors are red for X, green for Y, and blue for Z. You can toggle the display of the world axis in all viewports by turning off Display World Axis on page 8311 on the Viewports panel of the Preference Settings dialog.

The world axis shows the current viewport orientation.
**Parent** Uses the coordinate system of the parent of the selected object. If the object is not linked to a specific object, it’s a child of the world, and the parent coordinate system is the same as the world coordinate system.

**Example of a Parent object coordinate system**

**Local** Uses the coordinate system of the selected object. An object’s local coordinate system is carried by its pivot point on page 8686. You can adjust the position and orientation of the local coordinate system, relative to its object, using the options on the Hierarchy command panel.

When Local is active, the Use Transform Center button is inactive and all transforms use the local axis as the center of transformation. In a selection set of several objects, each uses its own center for the transform.
Local uses an individual coordinate system specific to each object.

**Gimbal** The Gimbal coordinate system is meant to be used with the Euler XYZ Rotation controller on page 3453. It is similar to Local, but its three rotation axes are not necessarily perpendicular to each other.

When you rotate about a single axis with the Local and Parent coordinate systems, this can change two or three of the Euler XYZ tracks. The Gimbal coordinate system avoids this problem: Euler XYZ rotation about one axis changes only that axis’s track. This makes function curve editing easier. Also, absolute transform type-in with Gimbal coordinates uses the same Euler angle values as the animation tracks (as opposed to Euler angles relative to the World or Parent coordinate system, as those coordinate systems require).

For move and scale transforms, Gimbal coordinates are the same as Parent coordinates. When the object does not have an Euler XYZ Rotation controller assigned, Gimbal rotation is the same as Parent rotation.

The Euler XYZ controller can be the active controller in a List controller, too.

**Grid** Uses the coordinate system of the active grid.
Using an active grid coordinate system.

**Working** Uses the coordinate system of the working pivot on page 3766. You can use this coordinate system at any time, whether or not the working pivot is active. When **Use Working Pivot** on page 3769 is on, this is the default coordinate system.

**Pick** Uses the coordinate system of another object in the scene. After you choose Pick, click to select the single object whose coordinate system the transforms will use. The object's name appears in the Transform Coordinate System list.

Because 3ds Max saves an object's name in the list, you can pick an object's coordinate system, change the active coordinate system, and then use the object's coordinate system again at a later time. The list saves the four most recently picked object names.

When using Pick to specify an object as a reference coordinate system, you can press H to open the Pick Object dialog, which works like **Select From Scene** on page 206, and pick the object from there.

**NOTE** You can pick objects within an XRef scene as coordinate reference system.
Using another object as the coordinate system

**Use Center Flyout**

Main toolbar > Use Center flyout

The Use Center flyout provides access to three methods you can use to determine the geometric center for scale and rotate operations.

From top to bottom, they are:

[Use Pivot Point Center on page 931]
Use Pivot Point Center

Main toolbar > Use Pivot Point Center (on Use Center flyout)

The Use Pivot Point Center option, available from the Use Center flyout on page 930, lets you enable rotation or scaling of one or more objects around their respective pivot points on page 8686. When Auto Key on page 8090 is active, Use Pivot Point Center is automatically chosen and no other option is available. The axis tripods on page 905 show the centers that are currently being used.

**NOTE** The transformation center mode is set on a transform-by-transform basis, so select the transform before you select the center mode. If you do not want the center setting to change, turn on Customize menu > Preferences > General tab > Reference Coordinate System group > Constant.
Applying a rotation with the Pivot Point rotates each object around its own local axis.

**Rotating Multiple Linked Objects**

When rotating a chain of linked objects (that is, a hierarchy) with Use Pivot Point Center active, the rotation is applied equally to each object...
in the chain. This results in accumulated rotations, which makes it easy to animate such effects as fingers curling.

Use Selection Center

Main toolbar > Use Selection Center (on Use Center flyout)

The Use Selection Center button, available from the Use Center flyout on page 930, lets you enable rotation or scaling of one or more objects around their collective geometric center. If you transform multiple objects, 3ds Max calculates the average geometric center of all the objects and uses that for the transform center.
The *axis tripod* on page 905 shows the center that is currently being used.

**NOTE** The transformation center mode is set on a transform-by-transform basis, so select the transform before you select the center mode. If you do not want the center setting to change, turn on Customize menu > Preferences > General tab > Reference Coordinate System group > Constant.

With the Selection Center option, an averaged coordinate system is used to rotate the objects.

**Use Transform Coordinate Center**

Main toolbar > Use Transform Coordinate Center (on Use Center flyout)

The Use Transform Coordinate Center button, available from the Use Center flyout on page 930, lets you enable rotation or scaling of an object or objects around the center of the current coordinate system. When you designate another object as the coordinate system with the Pick function (see Specifying
a Reference Coordinate System on page 906), the coordinate center is the location of that object's pivot.

The axis tripod on page 905 shows the center that is currently being used.

**NOTE**  The transformation center mode is set on a transform-by-transform basis, so select the transform before you select the center mode. If you do not want the center setting to change, turn on Customize menu > Preferences > General tab > Reference Coordinate System group > Constant.

An example of the World coordinate center

**Transform Tools**

The transform tools can transform objects according to certain conditions. Some of them, such as Array, can also create copies of objects.

These tools (except for Array, Snapshot, Spacing Tool, and Clone And Align) are available on the default main toolbar on page 8035; the remainder are on the Extras toolbar on page 8041. Also, they all appear on the default Tools menu on page 8001.
See also:

- Moving, Rotating, and Scaling Objects on page 885
- Using Shift+Clone on page 996
- Creating Copies and Arrays on page 981

Transform Toolbox

Edit menu > Transform Toolbox

The Transform Toolbox contains functions for easy object rotation, scaling, and positioning as well as for moving object pivots.

Interface
Quick Navigation

- **Rotate group** on page 937
- **Size group** on page 938
- **Align Pivot group** on page 939
- **Object group** on page 939

**Rotate group**

Rotates the current selection (including sub-objects) clockwise and counter-clockwise based on the view direction; clockwise always rotates clockwise in the current view. Align the view roughly to any axis and click an arrow button to rotate the object by the amount specified by the Degrees value. If the Reference Coordinate System on page 922 is set to Local, you can rotate the object on its local axis by first aligning the view roughly to the object’s local axis. If the coordinate system is set to Screen, the object will be rotated accordingly.

The drop-down list on the left side is for quickly selecting a predefined rotation amount.

**NOTE** You can assign CUI shortcuts on page 8249 (PolyTools category) for both Rotate commands. When assigned as shortcuts, the Rotate functions work as follows:

- **Normal (no key)** Rotates 90 degrees.
- **Shift** Rotates 30 degrees.

[presets list] Opens a list of rotation-amount presets; click one to place it in the Degrees field.

[Rotate Counter-clockwise] Click to rotate the selection counter-clockwise (roughly) about the view direction by the Degrees amount.
Rotate Clockwise Click to rotate the selection clockwise (roughly) about the view direction by the Degrees amount.

Degrees The amount of rotation applied by either of the Rotate buttons. To change the value, use the drop-down list, keyboard, or spinner controls.

Size group

Sets the size in 3ds Max units for the selected object on a single axis or all axes simultaneously.

TIP You can use this feature to set an object’s size on any axis or all three axes to its previous size on one axis. First choose the axis and click Put Size, then choose a different axis or All and click Set Size.

Set Size Applies the Size value to the object on the current axis or axes, thus resizing it.

R Resets the object’s transform. Applies a Reset Xform on page 912 and converts it to the base geometry type, such as editable poly.

Size The size that is applied when you click Set Size. Edit this value with the keyboard or mouse (spinner), or retrieve the object’s current size with the Put Size button (see following).

X/Y/Z/All Choose the axis or axes on which to resize when you click Set Size. Also determines which axis size to retrieve with Put Size (see following).

Get Opens a small, non-modal dialog that shows the dimensions of the selected object’s bounding box on all three axes. If you change the size, the displayed values update automatically.
**Put Size** Places the dimension value specified by the current axis choice in the Size field. If All is chosen, has no effect.

**Align Pivot group**

These tools align the pivot on page 8686 of the selected object. Choose the location to move the pivot to and then click X, Y, or Z.

[align location] Choose the location to which the pivot moves when you click an axis button:

- **Min** Moves the pivot to the minimum value of the object's bounding box on the specified axis.
- **Max** Moves the pivot to the maximum value of the object's bounding box on the specified axis.
- **Center** Moves the pivot to the center of the object on the specified axis.
- **Origin** Moves the pivot to the center of the world on the specified axis.

**X/Y/Z** Specifies the axis to work on and also applies the operation.

- **Center** Moves the pivot to the center of the object on all three axes.
- **Origin** Moves the pivot to the center of the world on all three axes.

**Object group**

- **Center** Moves the object to the center of the world (origin).

**QClone (Quick Clone)** Makes a copy of the selected object and moves it to the side by the same amount as the object's width. Align the view roughly to any axis and apply.

Like the Rotate tool (see preceding), QClone works based on the direction the object is viewed in the viewport. In general it moves the clone to the right, except when the model is viewed from above or below, in which case it moves the clone toward the point of view.

Uses the following keyboard modifiers:

- **Normal (no key)** Makes a copy of the selected object.
- **Shift** Makes an instanced copy of the selected object.
- **Alt** Makes two copies or instances of the selected object. (Does not apply to use as a shortcut.)
If the distance the clone moves is too little or too much, reset the object’s transform first. Use the **R button** on page 938 in the Size group, or use **Reset Xform** on page 912.

---

**Mirror Selected Objects**

Main toolbar > Mirror Selected Objects

Tools menu > Mirror

Clicking Mirror displays the Mirror dialog, which enables you to move one or more objects while mirroring their orientation.

The Mirror dialog also allows you to mirror the current selection about the center of the current coordinate system. You can create a clone with the mirror dialog at the same time. If you mirror a hierarchical linkage, you have the option to mirror the IK limits.

![Mirroring an object](image-url)
The Mirror dialog uses the current reference coordinate system on page 922, as reflected in its name. For example, if Reference Coordinate System is set to Local, the dialog is named Mirror: Local Coordinates. There is one exception: If Reference Coordinate System is set to View, Mirror uses Screen coordinates.

As you adjust the various settings in the Mirror dialog, you see the results in the viewports.

For more information on using Mirror, see Mirroring Objects on page 1026.

**Procedures**

**To mirror an object:**

1. Make any object selection.

2. Click Mirror on the Main toolbar, or choose Tools menu > Mirror.
   The Mirror dialog opens.

3. Set the mirror parameters in the dialog and click OK.
   The active viewport changes to show the effect of each parameter as you set it. When you click OK, 3ds Max creates the choice of mirror that you see previewed.

**To make a clone using mirror:**

1. Make any object selection.

2. Click Mirror on the Main toolbar, or choose Tools menu > Mirror.
   The Mirror dialog opens.

3. In the Clone Selection group, choose Copy, Instance, or Reference.

4. Make any additional settings as desired and then click OK.
Interface

Mirror Axis group

The mirror axis choices are X, Y, Z, XY, XZ, and YZ. Choose one to specify the direction of mirroring. These are equivalent to the option buttons on the Axis Constraints toolbar on page 8039.

Offset Specifies the distance of the mirrored object's pivot point from the original object's pivot point.

Clone Selection group

Determines the type of copy made by the Mirror function. Default is No Clone.

No Clone Mirrors the selected object without making a copy.
Copy Mirrors a copy of the selected object to the specified position.

Instance Mirrors an instance on page 8611 of the selected object to the specified position.

Reference Mirrors a reference on page 8699 of the selected object to the specified position.

If you animate on page 3368 the mirror operation, mirroring generates a Scale key. If you set Offset to a value other than 0.0, mirroring also generates Position keys.

________

Mirror IK Limits Causes the IK constraints to be mirrored (along with the geometry) when you mirror the geometry about a single axis. Turn this off if you don’t want the IK constraints to be affected by the mirror command.

The end effectors used by the IK are not affected by the Mirror command. To successfully mirror an IK hierarchy, first delete the end effectors: Go to the Motion panel > IK Controller Parameters rollout > End Effectors group and, under Position, click the Delete button. After the mirror operation, create the new end effector using the tools on the same panel.

Array Flyout

Extras toolbar > Array flyout

The Array flyout, available from the Extras toolbar on page 8041, provides access to various tools for creating arrays of objects.

From top to bottom, these are:

Array on page 944

Snapshot on page 950
Array

Extras toolbar > Array
Tools menu > Array

The Array command displays the Array dialog, which enables you to create an array of objects based on the current selection.

A one-dimensional array

The items in the Array Dimensions group let you create one-, two-, and three-dimensional arrays. For example, a row of five objects is a single-dimension array, even though it takes up three-dimensional space in the scene. An array of objects that's five rows by three columns is a...
two-dimensional array, and an array of objects that's five rows by three
columns by two levels is a three-dimensional array.

**TIP** You can preview the array by turning on the Preview button. With Preview on, changing the array settings updates the viewports in real time.

For more information on using Array, see *Arranging Objects* on page 1009.

**Procedures**

**To create an array:**

1. Select the objects to array.
2. Click the Array button, or choose Tools > Array.
3. Choose Tools > Array.
4. On the Array dialog, select the type of object to output: Copy, Instance, on page 8611 or Reference on page 8699).
5. In the Preview group, click the Preview button to turn it on. This lets you see the results of the array operation in the viewports, with changes appearing in real time.
6. In the Array Transformation group, click the arrows to set Incremental or Totals array parameters for Move, Rotate, and Scale.
7. Enter coordinates for the array Transformation parameters.
8. Indicate whether you want a 1D, 2D, or 3D array.
9. Set Count to the number of copies on each axis.
10. Enter the appropriate values in the numeric fields for Incremental Row Offsets.
11. Click OK. The current selection is duplicated the specified number of times, with each object transformed as indicated.

**To replace an array:**

1. Undo the array to replace, using Edit > Undo Create Array, or press Ctrl+Z.
2 Change the coordinate system and transform center, if needed.

3 Click the Array button, or choose Tools > Array, and adjust any parameters on the Array dialog that is displayed.

4 Choose Tools > Array, and adjust any parameters on the Array dialog that is displayed.

5 Click OK to create a new array, which replaces the previous version. Repeat these steps to fine-tune the array.

Example: To create an array of objects that numbers 5 x 4 x 3:

1 Create a teapot with a radius of 10 units.

2 Choose Tools > Array to display the Array dialog.

3 In the Incremental set of parameters, set Move X (the upper-left field) to 50. This causes each object in the array to be positioned 50 units apart on the X axis.

4 In the Array Dimensions group, choose the 3D button to enable all the spinners in that group.

5 Set the 1D Count spinner to 5, the 2D Count spinner to 4, and the 3D Count spinner to 3.

   This creates a row of 5 objects that are 50 units apart, and then 4 rows of those five objects, and then 3 rows of the 5 x 4 matrix of objects, resulting in a box array.

6 In the 2D row, set the Y spinner to 80.

7 In the 3D row, set the Z spinner to 100.

8 Click OK.

   A box array of teapots appears. The first dimensional array is five teapots created along the X world axis, 50 units apart (as specified in the Array Transform group). The second dimensional array is four layers created along the Y world axis, 80 units apart (as specified in the Array Dimensions group). The third dimensional array is three layers created along the Z world axis, 100 units apart. The total number of objects in the array is 60.
Example: To create a 360-degree array:

1. Reset 3ds Max.

2. Near the top of the Front viewport (away from its center), create a long, thin box at the twelve-o’clock position (as if the viewport were a clock face).

3. From the User Center flyout on the main toolbar, choose Use Transform Coordinate Center.

5. Click the arrow button to the right of the Rotate label to enable the three Rotate fields in the Totals section.

6. Set the Z parameter to 360.0.

7. In the Array Dimensions group, choose 1D and set Count to 12.

8. Click OK.

   3ds Max creates an array of 12 boxes in a full circle.

Interface

![Array interface](image)
Array Transformation group

Specifies which combination of the three transforms to use to create the array. You also specify the extent, along the three axes, for each transform. You can specify the extent of the transform in increments between each object, or in totals for all objects. In either case, the distances are measured between the pivot points of the objects. The arrays occur using the current transform settings, so the group title changes depending on the transform settings.

Click the left or right arrow button for Move, Rotate, or Scale to indicate whether you want to set Incremental or Total array parameters.

Incremental

Move Specifies the distance between each arrayed object along the X, Y, and Z axes, in units.

Rotate Specifies the degree of rotation about any of the three axes for each object in the array, in degrees.

Scale Specifies the percentage of scale along any of the three axes for each object in the array, in percentages.

Totals

Move Specifies the overall distance, along each of the three axes, between the pivot points of the two outer objects in the resulting array. For example, if you'rearraying 6 objects and set Move X total to 100, the six objects will be arrayed in a row that's 100 units between the pivot points of the two outer objects in the row.

Rotate Specifies the total degrees of rotation applied to the objects along each of the three axes. You can use this, for example, to create an array that totals 360 degrees.

Re-Orient Rotates the generated objects about their local axes while rotating them about the world coordinates. When clear, the objects maintain their original orientation.

Scale Specifies the total scale of the objects along each of the three axes.

Uniform Disables the Y and Z spinners and applies the X value to all axes, resulting in a uniform scale.
**Type of Object group**

Determine the type of copies made by the Array function. The default is Copy.

**Copy** Arrays copies of the selected object to the specified position.

**Instance** Arrays instances of the selected object to the specified position.

**Reference** Arrays references of the selected object to the specified position.

**Array Dimensions group**

 Lets you add to the Array Transformation dimension. The additional dimensions are positional only. Rotation and scale are not used.

**1D** Creates a one-dimensional array, based on the settings in the Array Transformation group.

**Count** Specifies the total number of objects along this dimension of the array. For 1D arrays, this is the total number of objects in the array.

**2D** Creates a two-dimensional array.

**Count** Specifies the total number of objects along this second dimension of the array.

**X/Y/Z** Specifies the incremental offset distance along each axis of the second dimension of the array.

**3D** Creates a three-dimensional array.

**Count** Specifies the total number of objects along this third dimension of the array.

**X/Y/Z** Specifies the incremental offset distance along each axis of the third dimension of the array.

---

**Total in Array** Displays the total number of entities that the array operation will create, including the current selection. If you’re arraying a selection set, the total number of objects will be the result of multiplying this value times the number of objects in the selection set.

**Preview** Toggles a viewport preview of the current array settings. Changing a setting updates the viewports immediately. If the update slows down feedback with large arrays of complex objects, turn on Display As Box.
**Display as Box** Displays the array-preview objects as bounding boxes instead of geometry.

**Reset All Parameters** Resets all the parameters to their default settings.

---

**Snapshot**

Extra toolbar > Snapshot (on Array flyout)

Tools menu > Snapshot

Choosing Tools > Snapshot opens the Snapshot dialog. This enables you to clone an animated object over time.

---

Using an ice-cream cone animated along a path, Snapshot creates a stack of cones.

Snapshot spaces the clones equally in time. Adjustments in Track View let you space the clones equally along the path instead (see the second procedure, below).
Like other clone techniques, Snapshot creates copies, instances, or references. You can also choose a mesh option for use with particle systems.

**Particle Snapshots**

You can clone particle systems as static mesh objects. You can also produce clones of the particles themselves as meshes, when using the Snapshot dialog > Clone Method > Mesh option. This works with all configurations of particle systems, including those using MetaParticles. Usage is the same as with other types of objects.

**Procedures**

**To clone an object over time:**

1. Select an object with an animation path.
   
   Snapshot also shows the effect of any other transform animations, such as rotate or scale as well as parametric modifier animation.

2. Click the Snapshot button on the Extras toolbar > Array flyout, or choose Tools menu > Snapshot.

3. Set parameters in the dialog, and click OK.

**To space clones evenly by distance:**

1. Select an object with an animated position.

2. Open Track View and find the Position track for the original object.

3. Click Assign Controller and check that the track is using a Bezier Position controller. Do one of the following:
   
   - If the track is already using a Bezier Position controller, proceed to step 4.
   
   - If the track is not using a Bezier Position controller, change the controller on page 3897, then proceed to step 4.

4. Select all the transform keys and right-click one of the selected keys to display the Key Info dialog on page 3418.

5. Click Advanced to expand the dialog.
6 Click Normalize Time.
7 Set Constant Velocity on.
8 Choose Tools menu > Snapshot. The Snapshot dialog appears.
9 Set parameters in the dialog, and click OK.

Interface

**Snapshot group**

**Single** Makes a clone of the geometry of the object at the current frame.

**Range** Makes clones of the geometry of the object along the trajectory over a range of frames. Specify the range with the From/To settings and the number of clones with the Copies setting.

**From/To** Specifies the range of frames to place the cloned object along the trajectory.
Copies Specifies the number of clones to place along the trajectory. They are evenly distributed over the time period, but not necessarily over the spatial distance along the path.

Clone Method group

With the Copy, Instance, and Reference methods, the clone retains any animation within the object, so all the clones will be animated in the same way.

Copy Clones copies of the selected object.

Instance Clones instances on page 8611 of the selected object. Not available with particle systems.

Reference Clones references on page 8699 of the selected object. Not available with particle systems.

Mesh Use this to create mesh geometry out of particle system. Works with all kinds of particles.

Spacing Tool

Extras toolbar > Spacing Tool (on Array flyout)

Tools menu > Spacing Tool

The Spacing tool lets you distribute objects based on the current selection along a path defined by a spline or a pair of points.

The distributed objects can be copies, instances on page 8611, or references on page 8699 of the current selected object. You define a path by picking a spline or two points and by setting a number of parameters. You can also specify how the spacing between objects is determined and whether the pivot points of the objects align to the tangent of the spline.
The Spacing tool distributes the vases along the sides of the curved street. The vases are all the same distance from each other; fewer appear on the shorter side.

**TIP** You can use compound shapes containing multiple splines as the spline path for distributing objects. Before creating shapes, turn off Start New Shape on the Create panel. Then create your shapes. 3ds Max adds each spline to the current shape until you turn Start New Shape back on. When you select the compound shape so that the Spacing tool can use it as a path, objects are distributed along all of the splines of the compound shape. For example, you might find this technique useful in spacing light standards along a path defined by separated splines.

You can pick splines within an XRef scene as path reference.

For more information, see Using the Spacing Tool on page 1027.

**Procedures**

**To distribute objects along a path:**

1. Select the objects to distribute.
2 Click Spacing Tool, or choose Tools menu > Spacing Tool.

**NOTE** The Spacing tool is also available on rollouts for various components of the Railing object on page 482.

3 On the Spacing Tool dialog, click Pick Path or Pick Points to specify a path.
   If you click Pick Path, select a spline from your scene to use as the path.
   If you click Pick Points, pick a start and an end to define a spline as the path. When you're finished with the Spacing tool, 3ds Max deletes this spline.

4 Choose a spacing option from the Parameters list.
   The parameters available for Count, Spacing, Start Offset, and End Offset are dependent on the spacing option you choose.

5 Specify the number of objects to distribute by setting the value of Count.

6 Depending on the spacing option you choose, adjust the spacing and offsets.

7 Under Context, choose Edge to specify that spacing be determined from the facing edges of each object's bounding box, or choose Centers to specify that spacing be determined from the center of each object's bounding box.

8 Turn on Follow if you want to align the pivot points of the distributed objects to the tangent of the spline.

9 Under Type of Object, select the type of object to output (copy, instance on page 8611, or reference on page 8699).

10 Click Apply.
The Spacing tool gives you a choice of two basic methods for setting spacing: using a path, or specifying endpoints explicitly.

**Pick Path** Click this, and then click a spline in the viewport to use as the path. 3ds Max uses the spline as the path along which to distribute objects.

**Pick Points** Click this, and then click a start and an end to define a path on the construction grid. You can also use object snap to specify points in space. 3ds Max uses these points to create a spline as the path along which to distribute objects. When you’re finished with the Spacing tool, 3ds Max deletes the spline.

**Parameters group**

**Count** The number of objects to distribute.

**Spacing** Specifies the space in units between the objects. 3ds Max determines this spacing based on whether you chose Edges on page 960 or Centers on page 960.
**Start Offset** The number of units specifying an offset from the start of the path. Clicking the lock icon locks the start offset value to the spacing value and maintains the count.

**End Offset** The number of units specifying an offset from the end of the path. Clicking the lock icon locks the end offset value to the spacing value and maintains the count.

**Distribution drop-down list** This list contains a number of options for how to distribute the objects along the path, as follows:

- **Free Center** Distributes equally spaced objects along a straight line toward the end point of the path, beginning at the start of the path. A spline or a pair of points defines the path. You specify the number of objects and the spacing.

- **Divide Evenly, Objects at Ends** Distributes objects along a spline. The group of objects is centered at the middle of the spline. The Spacing tool evenly fills the spline with the number of objects you specify and determines the amount of space between objects. When you specify more than one object, there are always objects at the ends of the spline.

- **Centered, Specify Spacing** Distributes objects along a path. The group of objects is centered at the middle of the path. The Spacing tool attempts to evenly fill the path with as many objects as it can fit along the length of the path using the amount of space you specify. Whether there are objects at the ends of the path depends on the length of the path and the spacing you provide.

- **End Offset** Distributes the number of objects you specify along a straight line. The objects begin at an offset distance that you specify. This distance is from the end of the spline to its start point, or from the second pair of points to the first point. You also specify the spacing between objects.

- **End Offset, Divide Evenly** Distributes the number of objects you specify between the start of a spline or a pair of points and an end offset that you specify. 3ds Max always places an object at the end or its offset. When you specify more than one object, there is always an object placed at the start. The Spacing tool attempts to evenly fill the space with the objects between the end offset and the start.

- **End Offset, Specify Spacing** Distributes objects toward the start of a spline or a pair of points, starting at the end or its offset. 3ds Max always places an object at the end or its offset. You specify the spacing between objects and the offset from the end. The Spacing tool attempts to evenly fill the space with as many objects as it can fit between the end or its offset and the start. There might not always be an object placed at the start.
- **Start Offset**  Distributes the number of objects you specify along a straight line. The objects start at an offset distance that you specify. This distance is from the start of the spline to its end point, or from the first of a pair of points to the second. You also specify the spacing between objects.

- **Start Offset, Divide Evenly**  Distributes the number of objects you specify between the end of a spline or a pair of points, starting at an offset that you specify from the start. 3ds Max always places an object at the start or its offset. When you specify more than one object, there is always an object placed at the end. The Spacing tool attempts to evenly fill the space with the objects between the start or its offset and the end.

- **Start Offset, Specify Spacing**  Distributes objects toward the end of a spline or a pair of points, starting at the start. 3ds Max always places an object at the start or its offset. You specify the spacing between objects and the offset from the start. The Spacing tool attempts to evenly fill the space with as many objects as it can fit between the start or its offset and the end. There might not always be an object placed at the end.

- **Specify Offsets and Spacing**  Distributes as many equally spaced objects as possible along a spline or between a pair of points. You specify the spacing between objects. When you specify offsets from the start and end, 3ds Max distributes equally spaced objects between the offsets. There might not always be an object placed at the start and ends.

- **Specify Offsets, Divide Evenly**  Distributes the number of objects you specify along a spline or between a pair of points. If you specify one object, 3ds Max places it at the center of the path. If you specify more than one object, 3ds Max always places an object at the start offset and the end offset. If you specify more than two objects, 3ds Max evenly distributes the objects between the offsets.

- **Space from End, Unbounded**  Distributes the number of objects you specify along a straight line from the end toward the start of a spline or a pair of points. You specify the spacing between objects. 3ds Max locks the end offset so that it's the same as the spacing.

- **Space from End, Specify Number**  Distributes the number of objects you specify toward the start of a spline or a pair of points, starting at the end. The Spacing tool determines the amount of space between objects based on the number of objects and the length of the spline or the distance between the pair of points. 3ds Max locks the end offset so that it's the same as the spacing.

- **Space from End, Specify Spacing**  Distributes as many equally spaced objects as possible toward the start of a spline or a pair of points, starting
at the end. You specify the spacing between objects. 3ds Max locks the end offset so that it's the same as the spacing.

- **Space from Start, Unbounded**  Distributes the number of objects you specify along a straight line toward the end of a spline or a pair of points, starting at the start. You specify the spacing between objects. 3ds Max locks the start offset so that it's the same as the spacing.

- **Space from Start, Specify Number**  Distributes the number of objects you specify toward the end of a spline or a pair of points, starting at the start. The Spacing tool determines the amount of space between objects based on the number of objects and the length of the spline or the distance between the pair of points. 3ds Max locks the start offset so that it's the same as the spacing.

- **Space from Start, Specify Spacing**  Distributes as many evenly spaced objects as possible toward the end of a spline or a pair of points, starting at the start. You specify the spacing between objects. 3ds Max locks the start offset so that it's the same as the spacing.

- **Specify Spacing, Matching Offsets**  Distributes as many evenly spaced objects as possible along a spline or between a pair of points (and their offsets). You specify the spacing. 3ds Max locks the start and end offsets so that they're the same as the spacing.

- **Divide Evenly, No Objects at Ends**  Distributes the number of objects you specify along a spline or between a pair of points (and their offsets). The Spacing tool determines the amount of space between objects. 3ds Max locks the start and end offsets so that they're the same as the spacing.
**Context group**

1. Edge-to-edge spacing
2. Center-to-center spacing

*Edges* Use this to specify that spacing is determined from the facing edges of each object's bounding box.

*Centers* Use this to specify that spacing be determined from the center of each object's bounding box.

*Follow* Use this to align the pivot points of the distributed objects to the tangent of the spline.

**Type of Object group**

Determines the type of copies made by the Spacing tool. The default is Copy. You can copy, *instance* on page 8611, or *reference* on page 8699 objects.

*Copy* Distributes copies of the selected object to the specified position.

*Instance* Distributes instances of the selected object to the specified position.

*Reference* Distributes references of the selected object to the specified position.
TIP  You can use compound shapes containing multiple splines as the spline path for distributing objects. Before creating shapes, turn off Start New Shape under Shapes on the Create panel. Then create your shapes. 3ds Max adds each spline to the current shape until you click the Start New Shape button so that it's checked. When you select the compound shape so that the Spacing tool can use it as a path, objects are distributed along all of the splines of the compound shape. For example, you might find this technique useful in spacing light standards along a path defined by separated splines.

Clone and Align Tool

Extras toolbar > Clone and Align Tool (on Array flyout)

Tools menu > Clone and Align

The Clone And Align tool lets you distribute source objects based on the current selection to a second selection of destination objects. For example, you can populate several rooms simultaneously with the same furniture arrangement. Similarly, if you import a CAD file that contains 2D symbols that represent chairs in a conference room, you can use Clone And Align to replace the symbols with 3D chair objects en masse.

The distributed objects can be copies, instances on page 8611, or references on page 8699 of the current selected object. You determine the number of clones or clone sets by specifying any number of destination objects. You can also specify position and orientation alignment of the clones on one, two, or three axes, with optional offsets.

You can use any number of source objects and destination objects.

You can pick objects within an XRef scene as destination objects.

With multiple source objects, Clone And Align maintains the positional relationships among the members of each cloned group, aligning the selection center with the destination's pivot.

Procedures

To use the Clone And Align tool:

1  Create or load an object or objects to be cloned, as well as one or more destination objects.
2 Select the object or objects to be cloned.

3 Open the Clone And Align dialog.

**NOTE** The order of steps 2 and 3 can be reversed.

4 Do either of the following:
   - Click Pick once and then click each destination object in turn. Next, click Pick again to turn it off.
   - Click Pick List and then use the Pick Destination Objects dialog to pick all destination objects simultaneously.

5 On the Clone Parameters rollout, choose the type of clone, and, if appropriate, how to copy the controller. For details, see Clone Options Dialog on page 992.

6 Use the Clone Parameters rollout settings to specify position, orientation, and scale options.

7 At any time, when Pick is off, you can change the source selection in a viewport. This causes the dialog to lose focus; click it again to regain focus and refresh the viewport preview of the clone operation.

8 To make the clones permanent, click Apply, and then click Cancel or the close button (X, in upper-right corner) to close the dialog.
Interface

The Clone and Align tool takes the form of a non-modal dialog; it remains open while you work in the viewports. While the dialog is active, the results of the current settings appear as a preview in the viewports. Because of the
dialog's non-modal nature, you can change the selection of source and destination objects on the fly and see the results immediately in the viewports.

When the dialog focus is lost by activating another dialog or clicking in a viewport (that is, its title bar is gray rather than blue), the preview no longer appears in the viewports. To make the cloned objects permanent, click Apply when the dialog is active.

**Source and Destination Parameters rollout**

Designate source objects by selecting them in a viewport. If you do this with the Clone And Align dialog open, the dialog loses focus; click the dialog to regain focus and update the settings.

**Destination Objects** [label] This read-only field shows the number of destination objects. To change this value, use Pick, Pick List, and Clear.

**Pick** When on, each object you click in the viewports is added to the list of destination objects. Click again to turn off after picking all destination objects. To qualify as a valid destination object, an object must:

- not have been designated as a source or destination object.
- be selectable (frozen objects can’t be selected).
- not be a temporary cloned object.

**Pick List** Opens the Pick Destination Objects dialog, which lets you pick all destination objects simultaneously, by name. In the dialog, highlight the destination objects, and then click Pick.

**Clear All** Removes all destination objects from the list. Available only when at least one destination object is designated.

**Source Objects** [label] This read-only field shows the number of source objects. To change this value, keep the dialog open, make sure Pick is off, and then select source objects in the viewports. When you click the dialog, the field updates.

**Link to Destination** Links each clone as a child of its destination object.

**Clone Parameters rollout**

These settings let you determine the type of clone to create, and, if appropriate, how to copy the controller. For details, see **Clone Options Dialog** on page 992.
**Align Parameters rollout**

The Align Position and Align Orientation group names are followed by the current reference coordinate system on page 922, in parentheses, which they use as the coordinate system for positioning and aligning the clones. When the View coordinate system is active, alignment uses the World coordinate system.

The Offset parameters always use each destination object's Local coordinate system.

**Align Position group**

* X/Y/Z Position Specifies the axis or axes on which to align the clones' position. Turning on all three options positions each set of clones at the respective destination object's location.

* X/Y/Z Offset The distance between the destination object's pivot and the source object's pivot (or source objects' coordinate center). For an Offset value to take effect, the respective Position check box must be on.

**Align Orientation group**

* X/Y/Z Orientation Specifies the axis or axes about which to align orientation. Turning on all three options aligns each set of clones' orientation fully with that of the respective destination object.

* X/Y/Z Offset The angle by which the source objects are rotated away from the destination object's orientation about each axis. For an Offset value to take effect, the respective Orientation check box must be on.

---

**Match Scale** Use the X Axis, Y Axis, and Z Axis options to match the scale axis values between the source and destination.

This matches only the scale values you'd see in the coordinate display on page 8081. It does not necessarily cause two objects to be the same size. Matching scale causes no change in size if none of the objects has previously been scaled.

---

**Reset All Parameters** Returns all settings in the Align Parameters rollout to their default values.
Apply  Generates the clones as permanent objects. After clicking Apply, you can use Clone And Align to generate additional clones, using the results of previous clonings as source or destination objects if you like.

Cancel  Aborts the current cloning operation and closes the dialog.

Align Flyout

Main toolbar > Align flyout

The Align flyout, available from the Main toolbar on page 8035, provides access to six different tools for aligning objects.

From top to bottom, these are:

- Align on page 967
- Quick Align on page 972
- Normal Align on page 973
- Place Highlight on page 976
- Align Camera on page 978
- Align to View on page 979
Align

Main toolbar > Align (on Align flyout)

Keyboard > Alt+A

Interface on page 971

Align lets you align the current selection to a target selection. After selecting an object to align, you click Align, available on the Align flyout on page 966, and then select another object to align the first object to. This opens the Align dialog with the name of the target object on its title bar. When performing sub-object alignment, the title bar of the Align dialog reads "Align Sub-Object Selection."

Aligning objects along an axis
Left: X position, center
You can align the position and orientation of the bounding box of the source object to the bounding box of a target object.

You can use the Align tool with any selection that can be transformed. If an axis tripod is displayed, you can align the tripod (and the geometry it represents) to any other object in the scene. You can use this to align an object’s pivot point.

You can use objects within an XRef scene as references with all alignment tools on the Align flyout, except Align to View.

When performing sub-object alignment, the Current Object options and the Match Scale boxes are disabled. If you plan to align orientation for sub-objects, first switch to Local transform mode on the main toolbar so that the axis tripod is properly aligned with your sub-object selection.

Other alignment tools on the Align flyout are Quick Align on page 972, Normal Align on page 973, Place Highlight on page 976, Align to Camera on page 978, and Align to View on page 979.

**Procedures**

**To align an object with a point object:**

1. Create a point helper object and position it at a target location in your scene. Rotate it as necessary to adjust final orientation.

2. Select a source object.

3. On the Main toolbar, click Align, or choose Tools > Align.

   The Align cursor appears attached to a pair of cross hairs.

4. Move the cursor over the point object and click.

   The Align Selection dialog appears. If necessary, move the dialog out of the way so you can see the active viewport.

5. In the Align Position group, turn on X Position.

   The selected source object shifts to align with the X axis of the point object.

6. Turn on Y Position and Z Position.
The source object moves so its center is at the point object.

7 Turn on X Axis, Y Axis, and Z Axis in the Align Orientation group to reorient the object to match the coordinates of the point.

To align objects by position and orientation:

1 Select a source object (the object to move into alignment with the target object).

2 On the Main toolbar, click Align, or choose Tools > Align.
   The Align cursor appears. When over an eligible target object, the cursor also shows crosshairs.

3 Position the cursor over the target object and click.
   The Align Selection dialog appears. By default, all options in the dialog are turned off.

4 In the Current Object and Target Object groups, choose Minimum, Center, Pivot Point, or Maximum.
   These settings establish the points on each object that become the alignment centers.

5 Begin alignment by turning on any combination of X Position, Y Position, and Z Position.
   The source object moves in relation to the target object, along the axes of the reference coordinate system. Setting all three moves the objects as close as possible, given the Current Object and Target Object settings.

6 In the Align Orientation group, turn on any combination of X Axis, Y Axis, or Z Axis.
   The source object realigns accordingly. If the objects already share an orientation, turning on that axis has no effect. Once two axes are aligned in orientation, the third is automatic.

To align a gizmo to another object:

1 Display the gizmo level of the Sub-Object selection.
On the Main toolbar, click Align, or choose Tools > Align.

Choose Tools > Align.

Click to select a target object in the viewport. (You can select the same object containing the gizmo to align the gizmo to a part of its own object.)

Use the available settings in the Align dialog to adjust the transformation of the gizmo.

To align a sub-object selection of geometry to another object:

1. Do one of the following:
   - Convert the object to an editable mesh, and then make the sub-object selection at any level.
   - Apply a Mesh Select or Poly Select modifier, make a sub-object selection, apply an XForm modifier (The Mesh/Poly Select modifier by itself doesn’t allow transforms.), and then activate the Gizmo sub-object level of the XForm modifier.

On the Main toolbar, click Align, or choose Tools > Align, and then select a target object.

Use the Align dialog controls to perform the alignment.
Interface

Align Selection (Max Icon Box)

Align Position (World):

- X Position
- Y Position
- Z Position

Current Object:
- Minimum
- Center
- Pivot Point
- Maximum

Target Object:
- Minimum
- Center
- Pivot Point
- Maximum

Align Orientation (Local):
- X Axis
- Y Axis
- Z Axis

Match Scale:
- X Axis
- Y Axis
- Z Axis

Align Position group

X/Y/Z Position Specifies the axis or axes on which to perform the alignment. Turning on all three options moves the selection to the target object’s location.

Current Object/Target Object groups

Specify the points on the objects' bounding boxes to use for the alignment. You can choose different points for the current object and the target object. For example, you can align the current object’s pivot point on page 8686 with the center of the target object.

Minimum Aligns the point on the object's bounding box with the lowest X, Y, and Z values with the chosen point on the other object.

Center Aligns the center of the object's bounding box with the chosen point on the other object.
**Pivot Point** Aligns the object's pivot point with the chosen point on the other object.

**Maximum** Aligns the point on the object's bounding box with the highest X, Y, and Z values with the chosen point on the other object.

**Align Orientation (Local) group**

These settings let you match the orientation of the local coordinate systems between the two objects on any combination of axes.

This option is independent of the position alignment settings. You can leave the Position settings alone and use the Orientation check boxes to rotate the current object to match the orientation of the target object.

Position alignment uses world coordinates on page 8768, while orientation alignment uses local coordinates. on page 8621

**Match Scale group**

Use the X Axis, Y Axis, and Z Axis options to match the scale axis values between the two selected objects. This matches only the scale values you'd see in the Transform Type-In on page 899. It does not necessarily cause two objects to be the same size. There will be no change in size if neither of the objects has previously been scaled.

**Quick Align**

Main toolbar > Quick Align (on Align flyout)

Tools menu > Quick Align

Keyboard > Shift+A

Quick Align lets you instantly align the position of the current selection to that of a target object. If the current selection is a single object, Quick Align uses the two objects' pivots on page 8686. If the current selection comprises multiple objects or sub-objects, Quick Align aligns the source's selection center on page 933 with the pivot of the target object.
Procedures

To use Quick Align:

1. Select one or more objects or sub-objects to align.

2. Press Shift+A or choose Quick Align from the Tools menu or Main toolbar > Align flyout.
   The mouse cursor turns into a “lightning-bolt” symbol. When positioned over an acceptable alignment target, a crosshairs symbol also appears.

3. Click an object to which to align the selection from step 1.
   The alignment is performed.

Normal Align

Main toolbar > Normal Align (on Align flyout)
Tools menu > Normal Align
Keyboard > Alt+N

Normal Align uses the Normal Align dialog to align two objects based on the direction of the normal on page 8654 of a face or selection on each object. To open the Normal Align dialog, select the object to be aligned, click a face on the object, and then click a face on a second object. Upon releasing the mouse, the Normal Align dialog appears.

If you use Normal Align while a sub-object selection is active, only that selection is aligned. This is useful when aligning sub-object selections of faces, since otherwise there’s no valid face normal for the source object.

Normal Align respects smoothing groups and uses the interpolated normal, based on face smoothing. As a result, you can orient the source object face to any part of the target surface, rather than having it snap to face normals.

For an object with no faces (such as helper objects, space warps, particle systems, and atmospheric gizmos), Normal Align uses the Z axis and origin of the object as a normal. Thus, you can use a Point object on page 2853 with Normal Align.
Other alignment tools on the Align flyout are Align on page 967, Quick Align on page 972, Place Highlight on page 976, Align to Camera on page 978, and Align to View on page 979.

**Procedures**

To align normals:

1. Select a source object. This is the object that moves during alignment.

2. Click Normal Align on the Main toolbar, or choose Tools > Normal Align.

3. Drag across the surface of the source object.
   The Normal Align cursor appears, attached to a pair of cross hairs. A blue arrow at the cursor indicates the current normal.

4. Move the cursor and blue arrow until you locate the normal you want to use, then release.
   The blue arrow remains as reference to the source normal.

5. Drag across the surface of the target object.
   A green arrow at the cursor indicates the current normal.

6. Move the cross hairs and green arrow until you locate the normal you want to use as a target, then release.
   The source object moves into alignment with the target normal, and the Normal Align dialog appears.

7. Do one of the following:
   - Click OK to accept the alignment.
   - Using the dialog, make modifications to the alignment before clicking OK.
   - Click Cancel Align to cancel the alignment procedure.
Interface

The Normal Align dialog lets you adjust or cancel the current alignment, and contains the following controls:

**Position Offset group**

Lets you translate the source object perpendicular to the normal on the X, Y or Z axes.

X/Y/Z These three fields let you affect how much of an offset will be given to the selected faces.

**Rotation Offset group**

Lets you rotate the source object about the normal's axis. You see the rotation in real time.

Angle This field lets you define the angle for the rotational offset.

**Flip Normal** Determines whether the source normal matches the target normal's direction. This defaults to off, since you usually want the two normals to have opposing directions. When you turn this on or off, the source object flips 180 degrees.

**OK/Cancel Align** The Cancel button is labeled Cancel Align to make it clear that you're not only canceling the settings in the dialog, but canceling the original transform on page 8750 of the source object.
Place Highlight

Main toolbar > Place Highlight (on Align flyout)
Tools menu > Place Highlight
Keyboard > Ctrl+H

Place Highlight, available from the Align flyout on page 966, enables you to align a light or object to another object so that its highlight or reflection can be precisely positioned.

In Place Highlight mode, you can click and drag the mouse around in any viewport. Place Highlight is a viewport-dependent function, so use the viewport that you’re going to be rendering. As you drag the mouse in the scene, a ray is shot from the mouse cursor into the scene. If it hits a surface, you see the surface normal on page 8654 at that point on the surface.

When you designate a surface, any selected objects are positioned along a line that represents the ray reflected off the surface about the surface normal. The objects are positioned along this line based on their original distance from the surface point. For example, if the object is 100 units from the surface point before being moved, it will be positioned 100 units from the surface point along the reflected ray.

If the object is a light, the position of the highlight on the surface of the object will be the surface point that you’ve chosen.

**TIP** Place Highlight works with any kind of selected object. It can be used to move objects based on a combination of face normals and initial distance from the face. You can also use Place Highlight with a selection set that contains more than one object. All objects maintain their initial distance from the face. In this case it has nothing to do with highlights, but is simply being used to position objects.

**NOTE** Highlight rendering depends on the material’s specular properties and the type of rendering you use.
Place Highlight aligns a camera and a spotlight to the same face.

Other alignment tools on the Align flyout are Align on page 967, Quick Align on page 972, Normal Align on page 973, Align to Camera on page 978, and Align to View on page 979.

Procedures

To position a light to highlight a face:

1. Make sure the viewport you plan to render is active, and that the object you want to highlight is visible in it.
   The result of Place Highlight depends on what is visible in the viewport.

2. Select a light object.
3 Click Place Highlight, or choose Tools > Place Highlight.
   Choose Tools > Place Highlight.
   If the button is not visible on the toolbar, choose it from the Align flyout.

4 Drag over the object to place the highlight.
   When you place an omni, free spot, or directional light, 3ds Max displays a face normal for the face the mouse indicates.
   When you place a target spotlight, 3ds Max displays the light's target and the base of its cone.

5 Release the mouse when the normal or target display indicates the face you want to highlight.
   The light now has a new position and orientation. You can see the highlight illumination in shaded viewports that show the face you chose, and when you render those views.

### Align Camera

Main toolbar > Align Camera button (on Align flyout)
Tools menu > Align Camera

Align Camera, available from the Align flyout on page 966, lets you align a camera to a selected face normal.

Align Camera works similarly to Place Highlight on page 976, except that it operates on face normals instead of the angle of incidence, and occurs when you release the mouse button instead of dynamically acting during the mouse drag. Its purpose is to let you align a Camera viewport to a specified face normal.

Other alignment tools on the Align flyout are Align on page 967, Quick Align on page 972, Normal Align on page 973, Place Highlight on page 976, and Align to View on page 979.
**Procedures**

To use Align Camera:

1. Select the camera used for the viewport you want to align.

2. Click Align Camera or choose Tools menu > Align Camera.

3. In any viewport, drag the mouse over an object surface to choose a face. The chosen face normal appears as a blue arrow beneath the cursor.

4. Release the mouse to perform the alignment. 3ds Max moves the camera so it faces and centers the selected normal in the camera viewport.

**Align to View**

Main toolbar > Align to View (on Align flyout)

Tools menu > Align to View

Align to View, available from the Align flyout on page 966, displays the Align To View dialog, which lets you align the local axis of an object or sub-object selection with the current viewport.

You can use Align to View with any selection that can be transformed.

Other alignment tools on the Align flyout are Align on page 967, Quick Align on page 972, Normal Align on page 973, Place Highlight on page 976, and Align to Camera on page 978.

**Procedures**

To align the local axis of a selection with the current viewport:

1. Select the objects or sub-objects to align.

2. Click Align to View.
3 Specify the local axis of the selected object to align with the current viewport's Z axis.

4 Select the Flip check box when you switch the direction of the alignment. The alignment takes place while the dialog is displayed.

5 Click OK to complete the process.

**Interface**

The Align to View dialog contains the following options:

- **Align X, Align Y, Align Z** Specifies which local axis of the selected object will be aligned with the current viewport's Z axis.

- **Flip** Switches the direction of the alignment.
Creating Copies and Arrays

With 3ds Max, you can quickly create multiple versions of one or more selected objects during a transform operation. You do this by holding down the Shift key as you move, rotate, or scale the selection.

Portico created from arrays of columns

The general term for duplicating objects is cloning. This section presents all the methods and choices available for cloning objects. In addition to the transform method, the tools include the following:

- **Array** lets you set all three transforms, in all three dimensions, at the same time. The results are precise linear and circular arrays in 2D or 3D space.
Mirror produces a “reflected” clone about one or more axes. If you mirror an object without cloning, the result is a “flip” of the geometry, optionally to a new location.

Snapshot lets you create clones equally spaced over time or distance, based on an animation path.

Spacing Tool distributes objects based on the current selection along a path defined by a spline or pair of points.

You can animate any of the cloning techniques.

Overview of Copies, Instances, and References

To duplicate an object, you use one of three methods. For all three methods, the original and clone (or clones) are identical at the geometry level. Where the methods vary is in the way they handle modifiers (for example, Bend or Twist).

An object can be a copy of another.
Copy method: Creates a completely separate clone from the original. Modifying one has no effect on the other.

Instance method: Creates a completely interchangeable clone of the original. Modifying an instanced object is the same as modifying the original.

Reference method: Creates a clone dependent on the original up to the point when the object is cloned. Changing parameters for modifiers that were applied to the object before the object was referenced, will change both objects. However, a new modifier can be applied to one of the reference objects, and it will affect only the object to which it is applied.

Depending on the method used to create them, cloned objects are called copies, instances, or references.

The following discussion focuses on how you might use these methods.

Copies

Copies are the most familiar kind of clone object. When you copy an object, you create a new, independent master object and data flow resulting in a new, named object. The copy duplicates all of the data of the original object at the time it is copied. The copy has no connection to the original object.

Example of Using Copied Objects

If you modeled a basic building shape and wanted to create a group of varied buildings, you could make copies of the basic shape and then model different features on each building to distinguish them from each other.

Copying Actively Linked Objects

When you copy objects that are actively linked through the File Link Manager on page 7538, 3ds Max automatically converts the copies to editable mesh objects. If your selection contains several objects that instance another object, the resulting copies also instance the same object.

Instances

Instances are alike not only in geometry, but also in every other way as well. Instancing an object results in multiple named objects based on a single master object. Each named object instance has its own set of transforms, space warp bindings, and object properties, but it shares the object modifiers and master object with the other instances. The data flow for an instance branches just after evaluating object modifiers.
When you change one instance by applying or adjusting a modifier, for example, all the other instances change with it.

Within 3ds Max, instances derive from the same master object. What you’re doing “behind the scenes” is applying a single modifier to a single master object. In the viewport, what you see as multiple objects are multiple instances of the same definition.

**Example of Using Instanced Objects**

If you wanted to create a school of swimming fish, you might begin by making many instanced copies of a single fish. You could then animate the swimming motion by applying a Ripple modifier to any fish in the school. The whole school would swim with exactly the same motions.

**Instances of Actively Linked Objects**

Creating instances of actively linked objects is not recommended. Reliability issues can arise if the instanced object is deleted in the linked file.

**References**

*References* are based on the original object, as are instances, but can also have their own unique modifiers. Like instances, references share, at minimum, the same master object and possibly some object modifiers.

The data flow for a reference branches just after the object modifiers but then evaluates a second set of object modifiers unique to each reference. When you create references, 3ds Max displays a gray line, called the *derived-object line*, at the top of the modifier stack for all clones. Any modification made below the line is passed on to other references, and to the original object. New modifiers added above the line are not passed on to other references. Changes to the original object, such as in its creation parameters, are passed on to its references.

This effect is useful for maintaining an original that will affect all its references, while the references themselves can take on individual characteristics.

All shared modifiers reside below the derived-object line and are displayed in bold. All modifiers unique to the selected reference reside above the derived-object line and are not bold. The original object does not have a derived object line: its creation parameters and modifiers are all shared, and all changes to this object affect all references.
The results of changing or applying a modifier to a named object reference depends on where in the modifier stack it is applied:

- Applying a modifier to the top of the modifier stack affects only the selected named object.
- Applying a modifier below the gray line affects all references branching above that line.
- Applying a modifier at the bottom of the modifier stack affects all references derived from the master object.

References of Actively Linked Objects

Creating references of actively linked objects is not recommended. Reliability issues can arise if the referenced object is deleted in the linked file.

Example of Using Referenced Objects

In the example of modeling heads, you might want to keep a family resemblance in your characters. You could model basic features on the original, then model specifics on each reference.

At some point, if you wanted to see what your characters would look like as "cone-heads," you could apply a Taper modifier to the original head, and have all the other characters take on the same feature. You could give the original character a very pointed head, then apply a separate Taper to some referenced characters to reduce the point toward normal.

For swimming fish, you might choose to make all members of the school as referenced objects based on a single, original fish. You could still control the swimming motion from the original fish, and also add modifiers to individual fish in the school to vary their behavior.

Techniques for Cloning Objects

3ds Max provides several techniques for copying or duplicating objects; cloning is the general term for this process. These techniques can be used to clone any selection set.

- Clone
- Shift+Clone
■ Snapshot
■ Array
■ Mirror
■ Spacing Tool
■ Clone and Align Tool

**Shared Features**

While each technique has distinct uses and advantages in cloning objects, in most cases the cloning techniques share some similarities in how they work:

■ You can apply a transform when you clone. New objects are moved, rotated, or scaled as they are created.

■ The transform is relative to the current coordinate system, axis constraint, and transform center.

■ When cloning creates new objects, you have the choice of making them copies, instances, or references.

Each of the following items is discussed later in this chapter.

**Clone**

Using the Clone command on the Edit menu is the easiest method for copying an object in place; no transformation is involved. See Clone on page 992.
**Shift+Clone**

You can clone an object as you transform it interactively in the viewport. The process is referred to as Using Shift+Clone on page 996: the technique of holding down the Shift key while transforming a selected object with the mouse.

Quick and versatile, this technique is probably the one you’ll use most often to duplicate objects. Snap settings give you precise results.

How you set the center and axes for the transforms determines the arrangement of the cloned objects. Depending on the settings, you can create both linear and radial arrays.

You need a working knowledge of transform features to take full advantage of Shift+Clone. See Using Transforms on page 886.
Snapshot

Using an ice-cream cone animated along a path, Snapshot creates a stack of cones.

Snapshot on page 950 clones an animated object over time. You can create a single clone on any frame, or space multiple clones along the animation path. The spacing is a uniform time interval; it can also be a uniform distance.
A one-dimensional array

Array on page 1009 creates repeating design elements: for example, the gondolas of a Ferris wheel, the treads of a spiral stair, or the battlements along a castle wall.

Array gives you precise control over all three transforms and in all three dimensions, including the ability to scale along one or more axes. It is the combination of transforms and dimensions, coupled with different centers, that gives you so many options with a single tool. A spiral stair, for example, would be a combination of Move and Rotate around a common center. Another array using Move and Rotate might produce the interlocked links of a chain.
Mirror

Mirror on page 1026 produces a symmetrical copy around any combination of axes. There is also a "No Clone" option that performs the mirror operation without copying. The effect is a flip or move of the object to a new orientation.

Mirror has an interactive dialog. As you change settings, you see the effect in the active viewport; in other words, a preview of what the mirror will look like.

There is also a Mirror modifier that gives you parametric control of the mirror effect.
Spacing Tool

The Spacing Tool distributes the vases along the sides of the curved street.

The Spacing tool on page 953 distributes along a path defined by a spline or pair of points. You define a path by picking a spline or two points and by setting a number of parameters. You can also specify how the spacing between objects is determined and whether the insertion points of the objects align to the tangent of the spline.

Clone and Align Tool

The Clone And Align tool on page 961 lets you distribute source objects based on the current selection to a second selection of destination objects. For example, you can use Clone And Align to populate several rooms simultaneously with the same furniture arrangement. Similarly, if you import a CAD file that contains 2D symbols that represent chairs in a conference room, you can use Clone And Align to replace the symbols with 3D chair objects en masse.
Clone

Make a selection. > Edit menu > Clone

Make a selection. > Hold down Shift key. > Move, rotate, or scale the selection with the mouse.

With the Clone command you can create copies, instances, or references of a selected object or a set of objects.

Clone creates a copy, instance, or reference of an object.

The Clone command on the Edit menu creates a single copy of your selection. Alternatively, you can clone multiple copies by holding down the Shift key as you move on page 914, rotate on page 915, or scale on page 917 your selection. Either method displays the Clone Options dialog on page 992.

Clone Options Dialog

Make a selection. > Edit menu > Clone
Make a selection. Hold down Shift key. Move, rotate, or scale the selection with the mouse.

Scene Explorer on page 7888 > Paste a copied node.

Clone creates a copy, instance on page 8611, or reference on page 8699 of a selected object or set of objects. The Clone command on the Edit menu creates a single copy. You can clone multiple copies by holding down the Shift key as you transform the selection.

**Procedures**

**To clone an object without transforming it:**

1. Select an object, or set of objects.
2. From the Edit menu, choose the Clone command. The Clone Options dialog opens.

   **NOTE** All options are present except Number Of Copies.

3. Change the settings or accept the defaults, and then click OK. Each new, cloned object occupies the same space as the original. Select a clone by name to move or modify it.

**To clone an object with Scene Explorer on page 7888:**

**NOTE** Cloning objects with Scene Explorer requires that the new copies be hierarchical children of an existing object.

1. In Scene Explorer, highlight one or more objects.
2. Do either of the following:
   - Right-click one of the highlighted items and choose Copy Nodes.
   - From the Edit menu, choose Copy Nodes.

3. Do either of the following:
   - Right-click an item and choose Paste Nodes.
   - Highlight an object and from the Edit menu, choose Paste Nodes. The Clone Options dialog opens.
4 Change the settings or accept the defaults, and then click OK.
   The copied objects are cloned as children of the highlighted object.
   Each new, cloned object occupies the same space as the original. Select
   a clone by name to move or modify it.

To clone and transform an object:

1 On the main toolbar, click the Move, Rotate, or Scale
   button.

2 Select an object, multiple objects, group, or sub-object.

3 Hold down the Shift key and drag the selection.
   As you drag your selection, the clone is created, selected, and transformed.
   The original object is deselected and unaffected by the transform.
   When you release the mouse button, the Clone Options dialog opens.

4 Change the settings or accept the defaults, and then click OK.
Interface

![Clone Options Dialog]

**Object group**

**Copy** Places a copy of the selected object at the specified position.

**Instance** Places an instance of the selected object at the specified position.

**Reference** Places a reference of the selected object at the specified position.

**Controller group**

Lets you choose to copy or instance the transform controllers on page 8506 of the original object's child objects. This option is available only when the selection you are cloning includes two or more hierarchically linked objects on page 8599.

When cloning non-linked objects, transform controllers are simply copied.

Also, when cloning linked objects, the highest-level cloned object's transform controller is simply copied. This option applies only to the transform controllers of objects at levels below the top of the cloned hierarchy.

**Copy** Copies the cloned objects' transform controllers.
**Instance** Instances the cloned objects' transform controllers below the top level of the cloned hierarchy. With instanced transform controllers, you can change the transform animation of one set of linked children, and automatically have the change affect any cloned sets.

This allows you to animate all clones identically with a single animation setup. For example, consider a scene containing three objects named Torso, Thigh, and Calf. The objects are linked hierarchically so that Torso is the parent of Thigh and Thigh is the parent of Calf. Say you select all three objects and then clone them, and choose Clone Options > Controller > Instance. Thereafter, if you transform either Thigh or Calf object, the corresponding object in the other hierarchy is transformed identically, along with any child objects. However, if you transform either Torso object, the other hierarchy is not affected.

**Number of Copies** Specifies the number of copies of the object you want to create. Available only when you Shift+Clone an object.

Using Shift+Clone to generate multiple copies applies the transform successively to each additional copy. If you Shift+Move an object and specify two copies, the second copy is offset from the first copy by the same distance that the first copy is offset from the original. For Rotate, two copies of the rotated object are created, with the second copy rotated twice as far as the first. For Scale, two copies of the scaled object are created, with the second copy scaled from the first copy by the same percentage that the first copy was scaled from the original.

**Name** Displays the name of the cloned object.

You can use this field to change the name; additional copies use the same name followed by a two-digit number, starting at 01 and incrementing by one for each copy. So, for instance, if you Shift+Move an object and then specify the name building and two copies, the first copy will be named building and the second will be named building01.

**Using Shift+Clone**

Shift+Clone is the primary way to duplicate objects in 3ds Max. You hold down the Shift key and drag during any of the standard transform operations: Move, Rotate, or Scale.
To **Shift+Clone an object**:

1. On the main toolbar, click the Move, Rotate, or Scale button.

2. Select a transform coordinate system and constraints. Each transform carries its own settings. To avoid surprises, always click the transform button first, and then set your transform coordinate system and constraints.

   **NOTE** You can also use the Transform Gizmo to set axis constraints.

3. Select the object or set of objects you want to clone. The selection can be a single object, multiple objects, a group, or a sub-object selection.

4. Hold down the Shift key and drag the selection to apply the transform. As you drag, a clone is created and selected; it is now the object being transformed. The original object is no longer selected and is unaffected by the transform.

When you release the mouse button, the Clone Options dialog appears. Change settings in this dialog or accept the defaults, and then click OK.

Shift+Clone uses the Clone Options dialog on page 992 for any transform you choose.

- Cloning with Shift+Scale on page 1003

**Animating Shift+Clone**

You can animate any Shift+Clone operation. See Animating Shift+Rotate and Shift+Scale on page 1005.

**Cloning Without Transforming**

Cloning objects with Shift+Clone requires transforming them at the same time, by moving, rotating, or scaling them. In some cases, you might want to
clone an object without transforming it in any way. The Edit menu Clone command gives you this option, which lets you create only one clone at a time.

To clone objects without transforming:

1. Select the object or objects to clone.
2. Choose Edit menu > Clone. The Clone Options dialog appears. This is the same dialog used with Shift+Clone except that there's no Number Of Copies setting. The Clone command lets you create only one copy.
3. Change settings in this dialog or accept the defaults, and click OK.

**NOTE** The cloned object occupies the exact same space as the original, and is selected when cloning is complete. Use Select By Name on page 206 to select the original or reselect the clone.

**Cloning with Shift+Move**

Cloning objects while moving them is quick and easy. It produces a linear array of two or more objects.
Shift+Move creates a clone in a different location.

To clone with Shift+Move:

1. Click the Move button on the main toolbar.
2. Choose a coordinate system and axis constraint.
3. Make the selection you want to clone.
4. Hold down Shift and drag to move a clone of the selection away from the original.
5. Choose the number of copies you want to make on the Clone Options dialog, and whether you want them to be copies, instances, or references.
**About Arrays Created with Shift+Move**

Multiple clones produced by Shift+Move form an equally spaced linear array with these characteristics:

- The line of the array runs from the center of the original through the centers of the clones.
- The distance between each neighboring pair of copies is the same the distance between the original and the first clone.

By using snaps as you move the selection, you can make precise arrays.

An example of the Shift+Move array is a picket fence. From a single picket, you can generate long runs of fencing. You can array the fence along a major axis of the home grid, then group the pickets, rotate them to a particular angle, and move them into position.

You can also make three-dimensional arrays with Shift+Move. The main choice is the combination of axes to allow movement off the construction plane. For example, to build a stairway, you can create a box that forms the top step, then use Shift+Move to copy it diagonally downward, using an array to create a downward flight.

**Cloning with Shift+Rotate**

Cloning objects while rotating them produces a variety of effects, depending on how you set up the transformation.
Shift+Rotate creates a clone with a different orientation.

To clone with Shift+Rotate:

1. Click the Rotate button on the main toolbar.
2. Choose a coordinate system, transformation center, and axis constraint.
3. Make the selection you want to clone.
4. Hold down the Shift key and drag to rotate the selection.
5. Choose the number of copies you want to make on the Clone Options dialog, and whether you want them to be copies, instances, or references.

Effects of Transform Settings

Where you locate the transform center determines how 3ds Max positions clones when using Shift+Rotate.

- For all settings, the direction of rotation is constrained by the active axis or axes of the viewport’s coordinate system.
Each clone is rotated from the previous one by the same amount as the first clone from the original.

**Local Pivot at Center**

An object’s default pivot point is often located at its center or its base. When you use Shift+Rotate around an object’s default pivot point, the clones overlap evenly as each one is rotated the same amount. This is true for multiple objects with a local-pivot setting, since each object uses its own local center.

Clones of a circular object, like a sphere or cylinder, can be overlaid exactly on the original. You might need to move them away from the original to see them.

With angle snap on page 2816 set to divide a circle evenly, you can produce complex symmetrical objects from simple ones. For example, you can clone a tetrahedron around one axis, then clone the new set about another axis to produce a faceted star.

**Local Pivot at a Distance**

When you separate the local pivot from the original, clones create a wheel-like arrangement. Long shapes like petals or blades, cloned with the center near one end, can create flowers or propellers. See Adjust Pivot Rollout on page 3763.

You can move the local pivot any distance from the object, creating large circular arrays. Since direct animation is limited to the local pivot, this is a key technique in animating circular arrays. See Animating Shift+Rotate and Shift+Scale on page 1005.

**Selection Center**

For either single or multiple objects, the selection center is the geometric center of the bounding box on page 8528 enclosing the entire selection. Clones are arrayed around this center, forming wheel-like arrays.

For a single object, this center is usually different from its local center, but the effects are similar to those based on a local pivot.

**Coordinate Center**

Using the coordinate center, Shift+Rotate can produce circular arrays of any size.
The rotation takes place around the center of the home grid, the screen, or whichever coordinate system you choose. While clones can be created this way, the process cannot be directly animated. For details on overcoming this limitation, see Animating Shift+Rotate and Shift+Scale on page 1005.

**Cloning with Shift+Scale**

Cloning objects while scaling them can produce a variety of nested objects and arrays, depending on the center you choose.

![Shift+Scale creates a clone of a different size.](image)

To clone with Shift+Scale:

1. Click a Scale button on the main toolbar.
2. Choose a coordinate system, axis constraint, and transform center.
3. Make the selection you want to clone.
4. Hold down Shift and drag to scale the selection.
5 Use the Clone Options dialog to choose the number of clones you want to make and whether you want them to be copies, instances, or references.

**Effects of Transform Settings**

Transform settings determine how 3ds Max distributes clones of a selection during Shift+Scale. In all scaling operations, the transform center acts as the center of scaling:

- When clone objects decrease in size, they shrink toward the transform center.
- When clone objects increase in size, they expand away from the transform center.

The distance between cloned objects is scaled like the clones themselves, based on the initial distance from the original to the first clone. The spacing increases or decreases proportionately with respect to the transform center.

**Nested Copies**

When the selection center is used as the transform center for a single object, scaling occurs symmetrically around that center, producing nested copies.

- As you scale in toward the center, smaller and smaller copies are created.
- In the other direction, the original object is enclosed by increasingly larger copies.

Variations are possible, depending on the type of scale and axis limitations. For example, you can scale a flat box into a progressively stepped pyramid by using Squash on page 920 and cloning inward on the Z axis.

**Offset Centers**

For Shift+Scale, any center other than the local pivot has the effect of creating an array of progressively scaled objects. Again, objects scale down in size toward the center, while increasing in size further away. However, this effect is limited by the particular scale option and the axis constraints, as discussed next.
Axis Constraints

Uniform Scale is unaffected by axis constraints, which you can set with the Transform Gizmo. Copies are always arrayed in or out from the center of the current coordinate system.

For Non-Uniform Scale and Squash, scaling occurs only along the axis or axes set with the restricted axes.

NOTE The Restrict To ... buttons (also called the Axis Constraints buttons) are available on the Axis Constraints toolbar on page 8039, which is off by default. You can toggle display of this toolbar by right-clicking an empty area of a toolbar and choosing Axis Constraints from the Customize Display right-click menu on page 8239.

Animating Shift+Rotate and Shift+Scale

You can use the Auto Key button on page 8090 to animate Shift-clone. However, there are some restrictions.

When the Auto Key button is on, the transform center defaults to local pivot, and the Use Center flyout on page 930 on the toolbar is unavailable. If you choose one of the other centers and activate Auto Key, the center returns to the local pivot. This means you can’t directly animate about a non-local pivot center with Shift+Rotate and Shift+Scale. For example, you can’t use this method to create clones in an arc or circular array around a common center.

Using Non-Local Centers

To use a center separate from the object you’re cloning, you can do any of the following:

■ Use a dummy object.
■ Offset the local pivot.
■ Change the default animation center.

Using a Dummy Object as Center

In this procedure, you use the axis tripod of the dummy object as the center for rotation or scale.
To use a dummy object as center:

1. Create a dummy object on page 2840 at the center of rotation or scaling.

2. Link the object or objects you want to clone to the dummy object, which becomes the parent.

3. Select both the dummy and the objects, then transform them with Shift+Rotate or Shift+Scale.
   - For Shift+Rotate, the dummy's center becomes the pivot.
   - For Shift+Scale, the dummy and selected objects scale together toward the center of the dummy.

For details of dummy object use in hierarchies, see Using Dummy Objects on page 3651.

Offsetting the Local Pivot

In this procedure, you move the object's pivot to the center of rotation or scale. This works much like using a dummy object.

To offset the local pivot:

1. Select the object whose pivot you wish to move.

2. On the Hierarchy command panel, choose Pivot and then turn on Affect Pivot Only.

3. Move the local pivot of the original object to another location in your scene.

4. On the Hierarchy panel, click Affect Pivot Only again to turn it off. Shift+Rotate or Shift+Scale now animates around the offset center. This works with the default setting for local center.

NOTE Moving the local pivot can adversely affect linking and inverse kinematics. If this is a possibility, consider changing the default axis instead of moving the local pivot.
To change the default axis while animating:
In this procedure, you set 3ds Max to allow animation of transforms about any center on the Use Center flyout.

1 Choose Customize menu > Preferences and click the Animation tab of the Preference dialog.

2 In the Animate group, turn off Local Center During Animate. This changes the default and makes all the transform center options available when animating. You can now animate around either the selection or transform coordinate center, as well as local pivot.

**NOTE** Changing the default setting animates the rotation you see in viewports as a rotation plus translation, which might not be the effect you wanted.

---

**Cloning Objects Over Time with Snapshot**

The **Snapshot tool** on page 950 lets you clone an object along its animation path. You can make a single clone at any frame, or multiple clones spaced over a selected number of frames.
Snapshot can also clone a particle system’s particles.

Snapshot spaces the clones equally in time. Adjustments in Track View let you space the clones equally along the path instead.

Like other clone techniques, Snapshot creates copies, instances, or references. You can also choose a mesh option.

To clone an object with Snapshot, the object must already be animated. You can use Snapshot from any frame on the path. The Auto Key button has no effect on Snapshot, since Snapshot creates static clones, not animation. This is the general procedure:

**To clone an object with Snapshot:**

1. Select an object with an animation path, or a particle system. The animation can result from applying transforms, controllers, or any combination of effects.
On the **Array flyout** on page 943 click Snapshot, or choose Tools menu > Snapshot to display the Snapshot dialog.

**NOTE** The Array flyout is on the Extras toolbar, which is off by default. You can toggle display of this toolbar by right-clicking an empty spot on the main toolbar and choosing Axis Constraints from the *Customize Display right-click menu* on page 8239.

3 Set parameters in the dialog, and click OK.

## Arraying Objects

Array is a dedicated tool for cloning and precisely transforming and positioning groups of objects in one or more spatial dimensions. For each of the three transforms (move, rotate, and scale), you can specify parameters for individual objects in the array, or for the array as a whole. Many results you can get with Array would be laborious or impossible using Shift+Clone techniques.
A one-dimensional array

Creating an Array

This is the general procedure. For more details, see the topics that follow.

To create an array:

1. Select one or more objects to be in the array.
2. Choose a coordinate system and transform center.
3. Click Array on the Array flyout, or choose Array on page 944 from Tools menu.
   The Array dialog appears.

   NOTE The Array flyout is on the Extras toolbar, which is off by default. You can toggle display of this toolbar by right-clicking an empty spot on the main toolbar and choosing Axis Constraints from the Customize Display right-click menu on page 8239.
4 Set array parameters on this dialog, then click OK.

Reuse of Array Settings

Generally you should approach Array creation as an iterative process. The dialog settings are not interactive, so you get feedback only after creating the array. By revising the current settings and repeating the array, you develop a solution that meets your needs.

After creating an array and checking its result, you can undo the array using Edit menu > Undo Create Array or Ctrl+Z. This leaves the original selection set in place.

Repeating an Array

When you create an array, object selection moves to the last copy or set of copies in the array. By simply repeating current settings, you create a seamless continuation of the original array.

During a session, 3ds Max maintains all the dialog settings for your current array.

Array settings are saved only during the current session, not with the file. Be sure you’ve finished an array before you quit 3ds Max.

General Considerations

When you create an array, keep these points in mind:

- Array is relative to the current viewport settings for coordinate system and transform center.
- Axis constraints do not apply, because Array allows you to specify transforms along all axes.
- You can animate array creation. By changing the default Animate preferences setting, you can activate all the transform center buttons, allowing direct animation around either the selection or coordinate center, as well as local pivot. For information about changing the default setting, see the procedure, To change the default axis while animating on page 1006.
- To make an array of a hierarchically linked object, select all the objects in the hierarchy before you click Array.
Using the Array Dialog

The Array dialog provides two main control areas where you set the important parameters: Array Transformation and Array Dimensions.

You can set parameters in any order, but in practice it’s useful to start with Array Transformation. This creates the basic building block for the larger array, as defined by Array Dimensions.

These topics discuss specific strategies for using these controls:

Creating Linear Arrays on page 1018

Creating Circular and Spiral Arrays on page 1022

See also:

■ Array on page 944

Array Transformation

This area lists the active coordinate system and transform center. It’s where you set the transforms that define the first row of the array. You decide here on the distance, rotation, or scale of individual elements, and along what axes. You then repeat this row in other dimensions to produce the finished array.
Move, Rotate, and Scale Transforms

You set Move, Rotate, and Scale parameters along any of the three axes of the current coordinate system.

- **Move** is set in current units. Use a negative value to create the array in the negative direction of the axis.
- **Rotate** is set in degrees. Use a negative value to create the array in a clockwise direction around the axis.
- **Scale** is set as a percentage. 100 percent is full size. Settings below 100 decrease the size, and above 100 increase it.

Incremental and Totals

For each transform, you have the choice of whether to apply the transforms successively to each newly created element in the array or to the overall array.

For example, if you set Incremental > X > Move to 120.0 and Array Dimensions > 1D > Count to 3, the result is an array of three objects, each of whose transform centers is 120.0 units apart. However, if you set Totals > X > Move to 120.0 instead, the three elements are spaced 40.0 units apart for a total array length of 120.0 units.

- **Click arrows on either side of the transform labels to choose between Incremental or Totals.**

Incremental and Totals settings are toggles for each transform. When you set a value on one side, the other side is unavailable. However, the unavailable value updates to show the equivalent setting.

**Incremental:** Parameters set on this side apply to individual objects in the array. Here are examples:

- An Incremental Move X setting of 25 specifies a spacing of 25 units on the X axis between centers of arrayed objects.
- An Incremental Rotate Z setting of 30 specifies a progressive rotation of 30 degrees on the Z axis for each object in the array. In the finished array, each object is rotated 30 degrees farther than the one before it.
**Totals:** Parameters set on this side apply to the overall distance, number or degrees, or percentage scale in the array. Here are examples:

- A Totals Move X setting of 25 specifies a total distance of 25 units on the X axis between the centers of the first and last arrayed objects.
- A Totals Rotate Z setting of 30 specifies a combined rotation of 30 degrees on the Z axis divided equally among every object in the array.

**Type of Object**

**Copy** Creates new array members as copies of the originals.

**Instance** Creates new array members as instances of the originals.

**Reference** Creates new array members as references of the originals.

For further information, see [Overview of Copies, Instances, and References](#) on page 982.

**Array Dimensions**

The Array Dimensions controls determine the number of dimensions used in the array and the spacing between the dimensions.

**Count:** The number of objects, rows, or layers in each dimension.

**1D:** One-dimensional arrays form a single line of objects in 3D space, like a line of columns. 1D Count is the number of objects in a row. Spacing for these objects is defined in the Array Transformation area.
A one-dimensional array, with 1D Count=6

2D: Two-dimensional arrays form a layer of objects along two dimensions, like the rows of squares on a chess board. 2D Count is the number of rows in the array.
A two-dimensional array, with 1D Count=7 and 2D Count=4

3D: Three-dimensional arrays form multiple layers of objects in 3D space, like neatly stacked boxes. 3D Count is the number of layers in the array.
A three-dimensional array, with 1D Count=10, 2D Count=6, 3D Count=3

Incremental Row Offsets

These parameters become available when you choose a 2D or 3D array. These are distances along any of the three axes of the current coordinate system.

- If you set a Count value for 2D or 3D, but no row offsets, the array is created with overlapping objects. You need to specify at least one offset distance to prevent this.

- If some objects appear to be missing from the array, it is possible that some objects have been created exactly on top of other objects in the array. To determine whether this has occurred, use Select By Name on page 206 to see the full listing of objects in your scene. If objects are on top of one another and you don’t want this effect, click Ctrl+Z to undo the array, and try again.
Creating Linear Arrays

A linear array is a series of clones along one or more axes. A linear array can be anything from a line of trees or cars to a stairway, a picket fence, or a length of chain. Any scene requiring repeated objects or shapes is a candidate for a linear array.

Examples of linear arrays

For an explanation of interface terms used here, see Using the Array Dialog on page 1012. For the basic steps in making an array, see Arraying Objects on page 1009.

Creating Simple Linear Arrays

The simplest 2D linear array is based on moving a single object along a single axis. These are the basic choices to make on the Array dialog.

Make these choices in the Array Transformation group:

- Use Incremental Move settings where you know the spacing you want between objects.
Use *Totals Move* settings when you know the overall space or volume you want the array to occupy.

For either of these two types of arrays, enter a value for one axis. Leave the other transforms at their default values.

Make these choices in the Array Dimensions group:

- Choose 1D.
- Enter a Count value for the number of objects in the array. The Total In Array field updates to show you the current total of objects in the array you are designing.
- Click OK to create a linear array along the chosen axis, with the number of objects specified by Count.

**2D and 3D Linear Arrays**

Arrays in 2D and 3D have the same Array Transformation group setup as 1D, with the addition of Incremental Row Offsets settings for moving the additional dimensions apart.

- Set 2D or 3D and enter a Count value.
  - If you set 3D, the 2D values also become available. Both Count values are 1 by default, which has the same effect as 1D. Set the 2D and 3D Count values greater than 1 to produce a more complex array.
- Set a nonzero value for at least one Incremental Row Offsets setting for 2D and 3D. Otherwise, there will be no separation between the 1D row and the new clones.

A wide variety of linear arrays are possible. Experiment with moving along all three axes and varying the row offsets in 2D and 3D.
Using Rotation in Linear Arrays

You can rotate elements in a linear array by applying a Rotate value for a specified axis. When you add rotation to a linear array, the choice of transform center becomes important.
Using Scale in Linear Arrays

Linear array with progressive scaling

When you apply a Scale factor, 3ds Max scales each copy from the previous copy. Objects in the array become progressively smaller or larger, as in the illustration.
Scale and Movement in Nested Arrays

Using only Scale settings and the local pivot of an object produces nested arrays, like Russian dolls, just as it does when you Shift+Scale from the local pivot. However, with the Array tool, you can add movement as well. This means you can create increasingly larger or smaller copies and array them at the same time.

Using Uniform Scaling

By default, all axes are available for scaling.

If you turn on Uniform, only the Scale X field is active; the Y and Z fields are unavailable. The X value is applied as uniform scaling on all axes of the arrayed objects.

Creating Circular and Spiral Arrays

Creating circular and spiral arrays typically involves some combination of moving, scaling, and rotating copies along one or two axes and around a common center. The effects can vary from the uniform radial arrangement of bolts on a wheel hub to the complex geometry of a spiral staircase. You can model many circular patterns with these techniques.

See Using the Array Dialog on page 1012 for an explanation of interface terms used here. See Arraying Objects on page 1009 for the basic steps in making an array.

Using a Common Center

Both circular and spiral arrays require a common center for the arrayed objects. This can be the world center, the center of a custom grid object, or the center of the object group itself. You can also move the pivot point of an individual object and use that as the common center.
Circular Arrays

Circular arrays are similar to linear arrays, but based on rotation around a common center rather than movement along an axis. The following procedure makes a circle of objects on the XY plane of the home grid with the Z axis as the center.

To create a circular array:

1. On the main toolbar, choose a transform center to become the center of the array. In this case, choose Use Transform Coordinate Center so the center of the grid becomes the array center.

2. Select an object and position it at some distance from the center of the grid. This distance is the radius of the finished circle.
3 Choose Array from the Array flyout or the Tools menu to display the Array dialog.

**NOTE** The Array flyout is on the Extras toolbar, which is off by default. You can toggle display of this toolbar by right-clicking the main toolbar and choosing Axis Constraints from the Customize Display right-click menu on page 8239.

4 On the Array dialog, enter **360** in the Totals Rotate Z field.
   This is the total rotation for the array, a complete circle. To create a partial circle, enter a smaller value.

5 Choose 1D and enter a Count value (this can be any number) and click OK.
   3ds Max arrays that number of clones within the total rotational angle you specify.
Spiral Arrays

The simplest spiral arrays are rotated circular arrays with a movement along the central axis. The same circle is formed, but now the circle rises upward.

If $Z$ is the central axis, enter a value for Incremental Move $Z$. Each clone is then moved upward this amount as the circle is formed.

**Rotation in Spiral Arrays**

In spiral arrays, the direction of rotation determines the direction of the spiral: which way it winds up or down.

Enter a positive rotation for a counterclockwise spiral.

Enter a negative rotation for a clockwise spiral.

**Reorienting an Array**

By default, each object, when copied into the array, rotates around its own center to follow the main rotation around the common center. This is controlled by the Re-Orient option.
To cause objects to maintain their original orientation while being rotated, turn off Re-Orient. In effect, objects remain "facing the same direction" as the original object.

**Mirroring Objects**

The Mirror tool uses a dialog that either creates a mirrored clone of a selected object, or mirrors the orientation of the object without creating a clone. You can preview the effects of settings before committing to the operation.

**Mirroring an object**

This is the general procedure for mirroring an object. Begin by selecting the object.

- Click the Mirror button on the main toolbar, or choose Tools menu > Mirror. This displays the Mirror dialog. The title bar indicates the coordinate system currently in use.
For information on the Mirror dialog options, see Mirror Selected Objects on page 940.

**Mirrored Arrays**

You can combine the Mirror and Array tools by using them in succession. An entire array can be mirrored, or you can set up mirrored objects before creating an array.

**Animating Mirror**

When you use Mirror with Auto Key turned on, you see the transition occur as the mirrored object moves into place. For example, a cylinder mirrored to the other side of an axis appears to flatten and reshape itself. The object is, in fact, scaled from 100% to 0% to –100%. This effect is not visible unless the mirror operation is animated.

**Mirror Modifier**

The Mirror modifier on page 1516 provides a parametric method of mirroring an object or sub-object selection within the modifier stack. You can apply the Mirror modifier to any type of geometry. You can animate the mirror effect by animating the modifier’s gizmo.

### Using the Spacing Tool

The Spacing Tool distributes objects based on the current selection along a path defined by a spline or pair of points. The distributed objects can be copies, instances, or references of the current selected object. You define a path by picking a spline or two points and by setting a number of parameters. You can also specify how the spacing between objects is determined and whether the insertion points of the objects align to the tangent of the spline.
The Spacing Tool distributes the vases along the sides of the curved street. The vases are all at the same distance from each other; fewer of them appear on the shorter side.

For details on the Spacing Tool parameters, see Spacing Tool on page 953.

To distribute objects along a path:

1. Select one or more objects to distribute.

2. Choose Spacing tool from the Array flyout or the Tools menu.

   **NOTE** The Array flyout is on the Extras toolbar, which is off by default. You can toggle display of this toolbar by right-clicking an empty area on the main toolbar and choosing Axis Constraints from the Customize Display right-click menu on page 8239.

3. On the Spacing Tool dialog, click Pick Path or Pick Points to specify a path.
   If you click Pick Path, select a spline from your scene to use as the path.
If you click Pick Points, click a start point and an end point to define a spline as the path. When you’re finished with the Spacing Tool, 3ds Max deletes this spline.

4 From the drop-down list at the bottom of the Parameters group, choose a spacing option.
   The parameters available for Count, Spacing, Start Offset, and End Offset depend on the spacing option you choose.

5 Specify the number of objects to distribute by entering a Count value, or by using the spinner.

6 Depending on the spacing option you choose, adjust the spacing and offsets.

7 In the Context group, choose one of the following:
   ■ **Edges** specifies that spacing be determined from the facing edges of each object’s bounding box.
   ■ **Centers** specifies that spacing be determined from the center of each object’s bounding box.

8 To align the insertion points of the distributed objects to the tangent of the spline, turn on Follow.

9 In the Type Of Object group, choose the type of object to output (copy, instance, or reference) and click Apply.
Modifiers

Modifiers provide a way for you to sculpt and edit objects. They can change the geometry of an object, and its properties.

Example: effects of the Twist modifier on an object

The modifiers you apply to an object are stored in a stack on page 8641. By navigating up and down the stack, you can change the effect of the modifier, or remove it from the object. Or you can choose to “collapse” the stack and make your changes permanent.

There are other general things to know about using modifiers:

- You can apply an unlimited number of modifiers to an object or part of an object.
- When you delete a modifier, all its changes to the object disappear.
- You can move and copy modifiers to other objects using controls in the modifier stack display on page 8187.
- The order or sequence in which you add modifiers is important. Each modifier affects those that come after it. For instance, adding a Bend modifier on page 1165 before a Taper on page 1807 can give you distinctly different results than if you first added the Taper followed by the Bend.

See also:
- Modifier Stack Controls on page 8187

How Modifiers Differ from Transforms

Modifiers and transforms differ in how they affect an object and the order in which they are applied to an object.

Transforms

The transform is the most basic of 3D manipulations. Unlike most modifiers, transforms are independent of an object’s internal structure, and they always act in world space on page 8769. An object can carry any number of modifiers, but it always has only a single set of transforms.

The transforms of an object are expressed as a matrix of values that contain the following information:

- Position of the object center in world space
- Rotation of the object in world space
- Scale of the object along its local axes

The matrix is called the transformation matrix, and its information relates directly to the transforms Move, Rotate, and Scale. Applying one of these transforms alters the values in the transformation matrix.

Transforms have the following properties. They are:

- Applied to the entire object.
- Independent of their order of application. No matter how many times you transform an object, the results are stored as one set of values in the matrix.
Applied after all object-space modifiers have been evaluated, but before the world-space modifiers. See Using the Modifier Stack on page 1045.

Most transforms produce equal displacement along one or more axes of an object, or part of an object. For Move on page 914, Rotate on page 915, and Uniform Scale on page 918 transforms, the displacement is equal along all three axes. When you rotate a box, all sides remain parallel. In general, all vertices keep the same relative position to one another. The exceptions are Squash on page 920 and Non-Uniform Scale on page 919, which displace axes by different amounts.

**TIP** Use the XForm modifier on page 2010 if you want to transform an object at a specific location in the stack (that is, after some object-space modifiers but before others), or if you want to transform a sub-object selection. See Modifying at the Sub-Object Level on page 1054.

**Modifiers**

Most modifiers allow you to perform operations on the internal structure of an object in object space on page 8659. For example, when you apply a modifier such as Twist on page 1833 to a mesh object, the position of each vertex of the object is changed in object space to produce the twisting effect.

Modifiers can operate at the sub-object level, and are dependent on the internal structure of the object when the modifier is applied.

Modifiers have the following properties. They are:

- Applied to all of an object or part of an object (using a sub-object selection).
- Dependent on the order of application. Applying a Bend followed by a Twist produces a result different from applying a Twist followed by a Bend.
- Displayed as individual entries in the modifier stack, where you can turn them on or off, and change the order in which they're applied.

Some modifiers operate in world space. These use world-space coordinates, and are applied to the object after all object-space modifiers and transforms have been applied. Otherwise, they have the same overall properties as object-space modifiers.
Transforms, Modifiers, and Object Data Flow

Once you have defined an object, 3ds Max evaluates changes affecting the base object and displays the result in the scene. What these changes are, and the order in which they are evaluated, is called the object data flow.

Master Object

*Master object* refers to an object defined by a set of creation parameters and the original position and orientation of its pivot point. You never see the master object. What you see in the viewport is always the result of at least the following data flow:
Object creation parameters in the Modify panel and Track View
An example of master objects with different creation parameters.

**Object-Space Modifiers**

The object-space modifiers on page 1159 are the next group evaluated in the data flow. Each modifier is evaluated in the order it was placed on the modifier stack. The modifications all occur in the object’s object space and the result is called the modified object.
Object modifiers in the Modify panel and Track View
The effect of modifiers on a master object.

Object Transforms

Once the modified object has been evaluated, it is transformed within the world coordinate system. Transforms cover the position, rotation, and scale changes applied from the transform buttons on the toolbar.

The method of evaluating all modifiers first and then evaluating the combined transforms has ramifications for the way you work with 3ds Max. The effect of transforms is independent of the order in which they are applied. The order in which you apply modifiers, on the other hand, does affect the resulting geometry. If you want to apply a transform that is evaluated in a specific order in the modifier stack, use the XForm modifier on page 2010.
Transforming a modified object

Space Warps

Space warps on page 2887 are evaluated after transforms. They distort objects bound to the space warp based on the position of the object in world space. For example, a Wave space warp on page 2979 causes the surface of an object to undulate in the form of a wave. As the object or the space warp moves through world space, the waves move across the object’s surface.

Like space warps, world-space modifiers on page 1067 are evaluated after transforms. A world-space modifier is like a space warp bound to a single object.

Object Properties

Object properties are the last to be evaluated before the object is displayed. These are values specific to an object such as its name or settings you specify on the Object Properties dialog on page 283, such as shadow-casting properties; and materials you have applied to the object.

This is the end of the data flow, and the result is the named object you see in your scene.
Right-click an object and choose Properties to display its Object Properties dialog.

Object Properties affect the look of an object’s rendered output.

**Using Modifiers**

This section contains a number of topics intended to help you learn how to use modifiers and the Modify panel.
Using the Modify Panel

After adding objects to your scene from the Create panel, you often move to the Modify panel to change an object’s original creation parameters and to apply modifiers. Modifiers are the basic tools for reshaping and adjusting primitive geometry.

NOTE You can float on page 8555 or dismiss the command panel using the Customize Display right-click menu on page 8239. The default setting is to display the command panel docked at the right of your screen. If it is not displayed or you want to change its location and docking or floating status, right-click in a blank area on any toolbar, and choose from the shortcut menu.

The Modify panel stays in view until you click another command panel tab. The panel updates to show the options and controls that are available for the currently selected object or modifier.
Using Modifiers

Once you’ve applied modifiers to an object, you can use the Modifier Stack on page 8187 to find a particular modifier, change its parameters, edit its sequence in the modifier stack, copy its settings to another object, or delete it entirely.

You can find alphabetical lists of modifiers in Object-Space Modifiers on page 1159 and World-Space Modifiers (WSMs) on page 1067.

General Guidelines

You can generally do the following with the Modify panel:

- Modify anything you can select. This includes any object or set of objects, or any part of an object down to the sub-object level. For example, you can use the Mesh Select modifier to select a single face, then apply a Taper modifier to it.

- Apply an unlimited number of modifiers to an object or part of an object. The order or sequence in which you make modifications is important. Each modification affects those that come after it. See Using the Modifier Stack on page 1045.

**NOTE** Some modifiers can be applied only to certain types of objects.

Modifier Sub-Object Levels

In addition to its own set of parameters, a modifier typically has one or more sub-object levels that you access through the modifier stack on page 1045. The most common of these are a gizmo and a center.

**Gizmo** Displays in viewports as a wireframe that initially surrounds the selected object. A gizmo acts like a mechanical apparatus that transfers its modification to the object it’s attached to. To alter the effect of the modifier on the object, you can move, scale, and rotate the gizmo as you would any object.

**Center** The center is the modifier’s pivot point on page 8686. You can move a modifier’s center, which alters the effect of the modifier on the object.

Parametric Deformations and Other Modifier Types

One set of object-space modifiers is known as parametric deformations ("parametric deforms" on the Modifiers menu). Twist on page 1833 and Bend
on page 1165 are examples. Parametric deformations alter the selection passed to them without explicitly depending on topology.

Many other types of modifiers, however, perform operations on the explicit topology of sub-object selections. The Edit modifiers and Select modifiers are examples. When a topology-dependent modifier is present on the stack, you can adversely affect its results if you visit previous stack operations and change the number or order of sub-objects (such as faces or vertices) in the selection. If you try to do this, a warning alerts you to the situation.

You can safely edit the stack beneath the topology-dependent modifier, as long as you do not add or remove sub-objects from the selection on which it operates.

**Procedures**

**To use the Modify panel:**

1. Select an object in your scene.

2. Click the Modify tab to display the Modify panel.
   
   The name of the selected object appears at the top of the Modify panel, and fields change to match this object.
   
   The object's creation parameters appear in rollouts on the Modify panel, below the modifier stack display. You can use these rollouts to change the creation parameters for an object. As you change them, the object updates in the viewports.

3. Apply a modifier to an object (described in the next procedure).
After you apply a modifier, it becomes active, and rollouts below the modifier stack display settings specific to the active modifier.

To apply a modifier to an object:

1. Select the object.
2. Do one of the following:
   - Choose a modifier from the Modifier List. This is a drop-down list at the top of the Modify panel.
     - **TIP**: You can use the mouse or keyboard to choose a modifier from the Modifier List. To use the keyboard, first open the list with the mouse, and then type the first letter in the modifier’s name. From there you can use the arrow keys or the method described in the following paragraph to highlight the desired modifier, and then press Enter to assign the modifier. In many cases, several modifier names start with the same letter. You can go directly to a particular modifier if you type the first few letters (enough for a unique combination) in the desired modifier’s name quickly. For example, say you want to assign the Mirror modifier to an object. Typing \texttt{M} goes to Mesh Select, which isn’t anywhere near Mirror in the Modifier list, but typing \texttt{MI} goes directly to Mirror.
   - Choose a modifier from the Modifiers menu. This menu is organized into sets by functionality. Not all modifiers appear on the Modifiers menu.
   - If the modifier buttons are visible on the Modify panel and the modifier you want is one of them, click the button.
     - If the buttons are not visible but you want to use them, click the Configure Modifier Sets button on page 8210 (below the modifier stack display) and choose Show Buttons. A set of buttons with the names of modifiers appears between the modifier list and the stack display. Click Configure Modifier Sets again, choose the set of modifiers you want to use (for example, Free-Form Deformations), and then click the button for the modifier you want to apply.

Rollouts are now displayed below the modifier stack display, showing settings for the modifier. As you change these settings, the object updates in viewports.
To drag a modifier to an object:

1. Select an object that already has a modifier you would like to use on another object.

2. To copy the modifier without instancing it, drag the modifier's name from the stack display to the object in a viewport that you want to use the same modifier. To move the modifier, use Shift+drag; this removes it from the original object and applying it to the new one. To instance the modifier, use Ctrl+drag; this creates an instanced modifier applied to both the original object and the new one.

**NOTE** Instancing a modifier causes its name to be displayed in italics in the modifier stack. This indicates that the modifier is instanced, meaning that a change to the modifier parameters of one object will affect the other.

---

### Using the Modifier Stack

The modifier stack and its editing dialog are the keys to managing all aspects of modification. You use these tools to:

- Find a particular modifier and adjust its parameters.
- View and manipulate the sequence of modifiers.
- Copy, cut, and paste modifiers between objects, or sets of objects.
- Deactivate the effect of a modifier in the stack, the viewport display, or both.
- Select a modifier's components, such as gizmo or center.
- Delete modifiers.

**See also:**

- [Editing the Stack](#) on page 1049
- [Modifier Stack Controls](#) on page 8187
- [Modifier Stack Right-Click Menu](#) on page 8200
Examining the Modifier Stack

The modifier stack (or "stack" for short) is a list on the Modify panel. It contains the accumulated history of a selected object and any modifiers you have applied to it.

Internally, 3ds Max "evaluates" an object beginning at the bottom of the stack and applies changes to the object by moving sequentially to the top of the stack. You should therefore "read" the stack from bottom up to follow the sequence used by 3ds Max in displaying or rendering the final object.

Here is an example of stack entries for a capsule object (an extended primitive):

- At the bottom of the stack, the first entry always lists the object type (in this case, Capsule). You click this entry to display the original object creation parameters so you can adjust them. If you haven’t applied any modifiers yet, this is the only entry in the stack.

- Object-space modifiers appear above the object type. You click a modifier entry to display the modifier’s parameters so you can adjust them, or to delete the modifier.

  Modifiers are preceded by a plus or minus icon if they have sub-object (or sub-modifier) levels. See Using the Stack at Sub-Object Level on page 1057.

- At the top of the stack are world-space modifiers and space warps bound to the object. (In the illustration, Displace Mesh is a world-space modifier.) These always appear at the top, and are described as "bindings."
Basics of Using the Stack

With the stack feature, no modification has to be permanent. By clicking an entry in the stack, you can go back to the point where you made that modification. You can then rework your decisions, temporarily turn off the modifier, or discard the modifier entirely by deleting it. You can also insert a new modifier in the stack at that point. The changes you make ripple upward through the stack, changing the current state of the object.

Adding Multiple Modifiers

You can apply any number of modifiers to an object, including repeated applications of the same modifier. As you start applying object modifiers to an object, the modifiers "stack up" in the order they're applied. The first modifier appears just above the object type at the bottom of the stack.

■ 3ds Max inserts a new modifier in the stack just above the current selection, but always in the proper location. If you try to insert a world-space modifier between two object-space modifiers, 3ds Max automatically places it at the top of the stack.

■ If you select the object type on the stack and apply a new object-space modifier, it appears just above the object type and becomes the first modifier evaluated.

Effect of Stack Sequence

3ds Max applies modifiers in their stack order (beginning at the bottom and carrying the cumulative change upward), so a modifier’s location in the stack can be critical.

The following figure shows the difference between the objects based entirely on a reversal in the stack order of two modifiers. On the left-hand tube, a Taper modifier is applied before a Bend modifier, and on the right-hand tube, the Bend is applied first.
Results of reversing stack order of two modifiers

Using the Buttons

These buttons, found just below the modifier stack, help you manage the stack:

- **Pin Stack** Locks the stack and all Modify panel controls to the selected object’s stack. You can continue to edit the object even if you select a different object in the viewports.

- **Show End Result** When on, shows the effect of the entire stack on the selected object. When off, shows the effect of the stack only up to the currently highlighted modifier.

- **Make Unique** Makes an instanced object unique, or an instanced modifier unique to a selected object. See details in Editing the Stack on page 1049. This option is also available from the Modifier Stack right-click menu on page 8200.

- **Remove Modifier** Deletes the current modifier from the stack, eliminating all changes caused by that modifier.

- **Configure Modifier Sets** Click to display a pop-up menu that lets you configure how to display and choose modifiers on the Modify panel.
Editing the Stack

You can copy, cut, and paste modifiers within an object’s stack, or into the stacks of other objects. Among other features, you can give modifiers explicit names to help you remember the intended effect.

**To edit the stack:**

1. Choose an item in the stack.
2. Right-click.
   This displays the Modifier Stack right-click menu on page 8200, which is briefly introduced in this topic.

**Rearranging and Sharing Modifiers**

**To rearrange modifiers:**

The easiest way to move a modifier to a different location in the stack is simply to drag it there. Alternatively, you can use the following cut/copy and paste procedure.

1. Choose one or more modifiers, right-click, and choose Copy or Cut.
2. Choose a new location in the list, right-click, and choose Paste. The paste occurs immediately above the new location.

**To share modifiers with other objects:**

1. Choose one or more modifiers, right-click, and choose Copy.
2. Select a different object or group of objects.
3. Choose a location in the new stack, right-click, and choose Paste.
   You can also drag from the modifier stack display to an object in a viewport.

---

**TIP** Select world-space and object-space modifiers separately. Cut, Copy, and Paste are disabled if both types are selected. If you try to paste a world-space modifier into the section for object-space types, the paste occurs at the top of the world-space section. The reverse is also true.
Unique and Instanced Modifiers

By default, pasted modifiers are unique: they lose all connection with the modifier from which they were copied. Compare with an instanced modifier, which is shared between two or more objects. Changing a parameter on an instanced modifier automatically changes the same parameter on the other instanced objects.

To create an instance of a modifier:

- After copying or cutting the modifier, right-click and choose Paste
  Instanced.
  In the stack, the name of an instanced modifier appears in italics.

Any instance of a modifier controls all other instances. Use this feature when you want a number of objects to take on the same feature.

For example, copying an instanced Bend modifier on page 1165 to a number of trees would make them all bend identically. Changing Bend parameters on any one tree would change the bend on all the others.

To remove the instancing from a modifier:

- Select the instanced modifier and click Make Unique. This converts
  the modifier from instanced to unique.

Using Make Unique with Multiple Items

Assume you have a group of trees all sharing the same instanced Bend modifier. If you select two of them and click Make Unique on page 8206, a message asks, "Do you want to make the selected objects unique with respect to each other?"

- If you click Yes, the two trees become independent of one another. Each
  has a unique copy of the modifier and can be bent separately.

- If you click No, the two trees continue to share the same instanced modifier,
  but separately from the instance in the original group. The two trees can
  be bent together.

See How Instanced Modifiers Work on page 1063.
Collapsing the Stack

You can use Collapse All or Collapse To to collapse all or part, respectively, of an object's stack to an editable object that preserves the cumulative effect of the collapsed modifiers on the base object. You might choose to do this in these cases:

■ You've finished modifying an object and want to keep it as is.
■ You want to discard an object's animation tracks. Alternatively, you can Alt+right-click a selected object and choose Delete Selected Animation.
■ You want to simplify a scene and save some memory.

NOTE In most cases, collapsing all or part of the stack will save memory. However, collapsing some modifiers, such as Bevel, increases file size and memory use.

After you collapse an object's stack, you can no longer parametrically adjust either its creation parameters or the individual modifiers affected by the collapse. Animation tracks that were assigned to such parameters also disappear.

Collapsing the stack does not affect the object's transforms; it affects world-space bindings only if you use Collapse To. Collapsing the stack does not save memory if the stack contains no modifiers.

TIP Before you use either Collapse option, use Application menu on page 7989> Save > Save Selected to preserve a copy of the original parametric object.

To collapse the stack:

1 Right-click the modifier stack display.

2 If modifiers have been applied to the object, choose Collapse To or Collapse All.
   ◦ Collapse To Collapses the stack, up to and including the chosen modifier, into an editable object. Modifiers on the stack above the chosen modifier are not affected, and you can still adjust them individually.
   The resultant object type depends on the uppermost modifier that outputs a specific geometry type, if any. If the stack contains no such modifier, the result is an editable mesh on page 2192. If the collapsed portion of the stack contains a modifier that outputs a specific geometry type, and no other such modifier is above it, the result is that type of object. For example, if the topmost such collapsed modifier is Edit Poly, the resultant object is Editable Poly.
**Collapse All** Collapses the entire stack into an editable object, other than world-space bindings. Any world-space bindings on the stack are left intact.

The resulting stack list shows a single entry: Editable Mesh, unless any modifiers on the stack output a different type of geometry. For example, if the topmost such modifier is Edit Poly, the resultant object is Editable Poly.

If no modifiers are applied to the object, choose one of the Convert To options:
- Editable Mesh
- Editable Spline
- Editable Patch
- Editable Poly
- NURBS

**NOTE** Depending on the object type, not all Convert To options might be available.

---

**Edit Modifiers and Editable Objects**

To achieve highly detailed modeling effects, you can directly transform, modify, and align the geometry of objects at a sub-object level on page 8733, using the Modify panel on page 8184. The following table shows the different object types and their respective sub-objects.

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Sub-Object Geometry</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mesh</td>
<td>Vertex, Edge, Face, Polygon, Element</td>
</tr>
<tr>
<td>Poly</td>
<td>Vertex, Edge, Border, Polygon, Element</td>
</tr>
<tr>
<td>Spline</td>
<td>Vertex, Segment, Spline</td>
</tr>
<tr>
<td>Patch Surface</td>
<td>Vertex, Edge, Patch, Element, Handle</td>
</tr>
</tbody>
</table>
With the exception of NURBS, to gain access to an object’s sub-objects, in most cases you must first either convert the object into an editable object, or apply any of various modifiers to the object, such as Edit Mesh/Spline/Patch or Mesh/Spline Select. The Select modifiers simply let you specify sub-objects for modification by subsequently applied modifiers. The distinctions between transforming an object into an editable object and applying an Edit modifier to it are as follows:

<table>
<thead>
<tr>
<th>Method</th>
<th>Advantage</th>
<th>Disadvantage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Editable object</td>
<td>More efficient</td>
<td>Lose creation parameters</td>
</tr>
<tr>
<td></td>
<td>Can animate sub-objects</td>
<td></td>
</tr>
<tr>
<td>Edit/Select modifier</td>
<td>Keep creation parameters</td>
<td>Less efficient</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Cannot animate sub-objects</td>
</tr>
</tbody>
</table>

To convert a parametric object to an editable object, see any of the following topics:

- **Editable Mesh Surface** on page 2192
- **Editable Poly Surface** on page 2240
- **Editable Spline** on page 620
- **Editable Patch Surface** on page 2360

To apply an Edit modifier, see any of the following topics:

- **Edit Mesh Modifier** on page 1321
- **Edit Spline Modifier** on page 1424
- **Edit Patch Modifier** on page 1329

To apply a Select modifier, see the following topics:
Modifying at the Sub-Object Level

To achieve highly detailed modeling effects, you can directly transform, modify, and align the geometry of objects at the sub-object level on page 8733.

Sub-objects are the pieces that make up objects, such as vertices and faces. You can also access and transform the sub-object components of modifiers.

The particular geometry available at sub-object level depends on the object type. See Edit Modifiers and Editable Objects on page 1052 for details on each object type.
In a row of column sub-objects, a single column has been modified at the sub-object level.

Making a Sub-Object Selection

These are the general steps in setting up an object for sub-object selection. See Edit Modifiers and Editable Objects on page 1052 for more information.

1. Convert the object into an editable object such as an editable mesh, editable spline, editable poly, and so on. (Some modifiers you can apply
to the object, such as Edit Mesh, Mesh Select or Spline Select, also have sub-object levels.)

**TIP** Work in a wireframe viewport so you can see the geometry.

2. On the modifier stack display, click the plus icon to the left of the name of the modifier or editable object. This expands the object’s hierarchy, showing the names of the sub-object levels at which you can work.

3. On the stack display, choose the kind of sub-object geometry you want to work with: for example, Vertex, Face, or Edge. Each sub-object selection level has rollouts with their own sets of options.
   The sub-object level highlight is yellow by default.

4. Use standard selection techniques to select sub-object geometry, from a single sub-object to the entire object. By default, the sub-object selection highlights in red.

Once you make a sub-object selection of geometry, you can do any of the following:

- Apply any options supplied for the kind of object and the selection level.
- Apply standard transforms: Move, Rotate, Scale. For more information, see Transforming a Sub-Object Selection, following.
- Apply object-space modifiers (Bend, Taper, and Twist, for example) to perform useful modeling operations.
- Apply object-space modifiers (UVW Map or Smooth, for example) to perform useful surfacing operations.
- Bind a space warp on page 2887 to the selection. The rest of the object is unaffected by the warping.
- Use the toolbar commands Align on page 967, Normal Align on page 973, and Align To View on page 979 with face selections.

**Transforming a Sub-Object Selection**

Using an editable mesh, poly, patch, or spline, you can directly transform any sub-object selection. However, “Select” modifiers like Mesh Select on page 1500 and Spline Select on page 1741 enable only selection.
To transform a sub-object selection made with a Select modifier:

1. Add an XForm modifier on page 2010 to the stack, following (or somewhere above) the Select modifier.

2. In the stack, open the Select modifier and make a sub-object selection.

3. Choose XForm in the stack. You then transform the XForm gizmo, which applies the transform to the selection.

Selecting and Transforming Modifier Components

Most modifiers have sub-object components, such as a gizmo and center. Like sub-object geometry, these components can be accessed and transformed at sub-object level, directly modifying the object’s shape.

Other modifiers, like those for free-form deformation, have control points and lattices at a sub-object level. Moving these components creates the modeling effects of the modifier.

Using the Stack at the Sub-Object Level

With editable objects such as meshes and splines, or modifiers with sub-object levels such as Mesh Select and Spline Select, you can continue to model a single sub-object selection by applying any number of other modifiers. When you go back and change the original selection, the new selection is "passed up the stack" to the modifiers that follow.

Editable meshes and splines have "built-in" sub-object selection at their base level. But the selections you make with Mesh Select and Spline Select work exactly the same way on the stack.

This topic uses meshes for its examples. You can apply the same concepts to editable splines, patches, and poly objects.

Working at Two Levels

When you select an object and apply modifiers (for example, Bend and Taper), you’re working with the object as a single unit, or "whole object", at the object level.

When you make a sub-object selection, the stack display changes to show you are no longer working with the whole object. Consider the effect of a Mesh Select applied between Bend and Taper modifiers (Bend is below Taper). To the right of the Mesh Select and Taper modifiers, a sub-object icon (similar to
the sub-object button in the Selection rollout) appears to show that sub-object selection is now in effect.

The vertex sub-object selection made at the Mesh Select level is passed up the stack to the Taper modifier. This means the Taper modifier is applied only to the vertices selected at the Mesh Select level.

![Sub-object icon (in this case, for Vertex) to the right of modifier names in the stack display]

Sub-object selection carries upward through the stack. If you add more modifiers, each shows the sub-object icon to indicate this state.

By learning to "read the stack," you can move back and forth between the object and sub-object levels while you work on an object.

**Returning to Whole-Object Level**

When you finish modeling a certain sub-object selection, you can return to work on the whole object.

**To return the stack to object level:**

1. At any point in the stack, apply another Mesh Select modifier.

2. Leave this Mesh Select modifier at the top level (the object level, which highlights in gray). Any modifiers already on the stack above this modifier no longer show the sub-object icon. Any modifiers you add above the second Mesh Select now apply to the whole object.

3. To continue sending the sub-object selection up the stack, delete the second Mesh Select.

**Naming Sub-Object Selections**

Sub-object selections are often quite complex, involving a great many small elements that would be difficult to select a second time. For this reason, it's a good idea to name important selection sets using the Named Selection Sets list on page 185 on the main toolbar.
Named sub-object selections only appear at the type of level where they were first named. For example, if you select a set of vertices, you can name the selection at that vertex sub-object level. Then, when you later go to retrieve the named selection, you can access it only from the same modifier's vertex sub-object level.

Copying Sub-Object Selections

Once you name a sub-object selection set, you can copy it between modifiers in the same stack, or to the stack of another object of the same type. Editable meshes and Mesh Select (and their spline, patch, and poly counterparts) have buttons for Copy and Paste at each level of geometry, in the Modify panel > Selection rollout.

To copy/paste named sub-object selections:

1. Make a sub-object selection.
2. In the Selection rollout, click Copy. From the dialog, choose any available named selection set for that level of geometry.
3. Go to another Select modifier or to an editable mesh or poly, at the same level of geometry. Click Paste to complete the copy.

Modifying Multiple Objects

You can apply modifiers to multiple objects. In general, the process is parallel to modifying a single object. You make a selection set and apply an available modifier. The modifier then appears on a special stack that refers only to the commonality of that selection set.
The Principle of Commonality

When you select multiple objects, 3ds Max determines what the particular selected set of geometry has in common, if anything. Given any "commonality" among objects, 3ds Max presents the options as available modifiers. Unavailable modifiers represent areas where commonality does not hold.

You can apply modifiers to different categories of objects, depending on the modifier. For example, you might apply Bend to both a 3D object and a 2D...
shape. You can apply Mesh Select to a spline primitive and convert it to a mesh, but the reverse is not true: Spline Select is restricted to objects of the spline category.

**To modify multiple objects:**

1. Select two or more objects.
   - For selection sets, the name at the top of the Modify panel changes to read "Multiple Selected." If the objects are grouped, the group name appears.

2. Choose the kind of pivot point you want to use. See Using Pivot Points, (below).

3. Apply a modifier and adjust its parameters.
   - If you apply a Mesh Select modifier, you can select geometry on one or more of the objects to use as a sub-object selection set.

**Using Pivot Points**

The first item in the Modifier List is a toggle called Use Pivot Points. This toggle is available only when multiple objects are selected.

- When on, 3ds Max uses the pivot point of each object as the center of a modifier's operation. For example, if you bend a line of trees around the Z axis, each bends along its own trunk.

- When off, 3ds Max calculates a central pivot point for the entire selection set, and modifies the selection as a whole. For a Z-axis bend, trees at the end of a line would deform more than those at the center where the pivot is located.

**IMPORTANT** Choose the pivot setting before you apply the modifier. You can't change the pivot point afterward, although you can delete the modifier and start over without deselecting the selection set.
Original objects

Single modifier applied to all objects
when you apply a modifier to multiple objects, each object receives an identical version of the modifier. these are called instanced modifiers. they are interchangeable. a change to any one of the instances affects all the other instances. how instanced modifiers work on page 1063 covers instanced modifiers in detail.

**tip** sometimes you might apply modifiers to a selection set, perform some other operations, and select the set again, only to find its modifier stack is empty. this happens if you applied another modifier to an individual object in the original selection set. when you select the set again, the modifier stack is empty because all members of the set no longer have all modifiers in common. you can still access the instanced modifiers by selecting a single object in the set. the individual object's stacks still contain the modifiers you applied to the set as a whole.
In the stack, the name of an instanced modifier appears in *italic*.

**Objects sharing a single instanced modifier**

**Identifying Instanced Modifiers**

You can quickly lose track of which objects share the same modifier. An option on the Views menu highlights those objects.

**To identify objects sharing instanced modifiers:**

1. Select an object with an instanced modifier. Choose the instanced modifier in its stack.

2. Choose Views menu > Show Dependencies. Other objects with instances of the same modifier appear in a distinctive color (purple by default).

**Adjusting Instanced Modifiers**

You can make changes to an entire set of objects from a single instance. This is a major advantage of instanced modifiers.
To adjust instanced modifiers:

1. Select any object in a set of objects with instances of the same modifier.
2. Choose the instanced modifier in its stack.

   The single object highlights and the appropriate gizmos appear for the entire selection set. Adjustments to this modifier now affect the entire set.

Changing the parameter of an instanced modifier for one object affects all the objects sharing the modifier.

Making Instanced Modifiers Unique

At some point in your work, you might want to turn a modifier instance into a local copy that affects only a single object. To do so, click Make Unique on page 8206 on the Modify panel. This button appears beneath the modifier stack display. (Make Unique is also available as a pop-up menu choice when you right-click the instanced modifier's name in the stack display.)
To make an instanced modifier unique:

1. Select an object with an instanced modifier.
2. Choose the instanced modifier in its stack.
3. Click Make Unique beneath the modifier stack display. The modifier is no longer listed in italic text and if Show Dependencies is set, the highlight disappears from the other objects.

The modifier is now separate from the set of instanced modifiers. Adjustments you make to this modifier no longer affect other objects. Its parameters and gizmo remain unchanged from their original, instanced settings until you adjust them.

To make multiple modifier instances unique:

1. Select two or more objects with the same instanced modifier. The stack now shows what the objects have in common.
2. Choose the instanced modifier in the stack.
   There can be more than one instanced modifier in this stack. Click the one you want to make unique for each of the selected objects.
3. Click Make Unique.
4. Right-click and choose Make Unique from the menu. The modifier is no longer listed in italic text and if Show Dependencies is set, the highlight disappears from the other objects.
5. Click Yes to make the two objects become independent of one another. Click No for the two objects to continue to share the same instanced modifier, but separate from the instance in the original group.

The parameters for this modifier disappear, because the objects no longer share the modifier. For each object, the modifier is now separate from the set of instanced modifiers.

As with a single object, the parameters and gizmo are unchanged in the now unique modifiers.

■ To access the unique modifiers, select the objects individually.

NOTE If both the object and the modifier are instances, you can choose either in the stack before you click Make Unique.
World-Space Modifiers (WSMs)

World-space modifiers act as object-specific space warps. They are carried with the object, but like space warps use world space on page 8769 rather than object space for their effects. World-space modifiers eliminate the need for binding to a separate space-warp gizmo, making them convenient for modifying a single object or selection set.

You apply world-space modifier like you apply standard object-space modifier. You can access world-space modifiers from the Modifiers menu, the Modifier List in the Modify panel, and applicable modifier sets on page 8209. A world-space modifier is indicated by either an asterisk or the text “(WSM)” next to its name. (The asterisk or “(WSM)” distinguishes the world-space version from the object-space version of the same modifier, if one exists.)

When you assign a world-space modifier to an object, it appears at the top of the modifier stack, listed as a binding, in the same area as the space warp bindings.

Camera Map Modifier (World Space)

Modify panel > Select an object. > Modifier List > World-Space Modifiers > Camera Map (WSM)

Select an object. > Modifiers menu > UV Coordinates > Camera Map (WSM)

The Camera Map world-space modifier is similar to the Camera Map modifier on page 1180, in that it applies UVW mapping coordinates to the object based on a specified camera. As a result, if you assign the same map as a Screen environment to the background as you apply to the object, the object is invisible in the rendered scene.

The main difference between the world-space version of Camera Map and the object-space version is that, when you move the camera or the object using the object-space version, the object becomes visible, because the UVW coordinates are fixed to the object's local coordinates. When you move the camera or object using the world-space version, the object remains invisible because world coordinates are used instead.
Interface

![Camera Mapping Interface]

**Current Camera Object group**

**Label** Names the current camera used for mapping. If there is no current camera, reads "None."

**Pick Camera** Click this button, and then select the camera you want used for mapping.

**Channel group**

**Map Channel** Specifies use of a map channel on page 8627. Map channels are specified in the Material Editor on page 5641.

**Vertex Color Channel** Specifies use of the Vertex Color Channel (see UVW Map Modifier on page 1932).

**Displace Mesh Modifier (World Space)**

Select an object. > Modify panel > Modifier List > World-Space Modifiers > Displace Mesh (WSM)

The Displace Mesh world-space modifier (World Space) lets you see the effect of displacement mapping on page 6059 on editable mesh objects on page 2192 and objects with a Disp Approx modifier on page 1310 applied to them. If a displacement map is applied to the object, the mesh shows the effect of the displacement map. Displace Mesh replaces the mesh with its displaced version.
There are two main reasons for using Displace Mesh:

- As a visualization aid to see the effect of a displacement map in viewports, and to compare the placement of displaced objects with other objects in the scene. For example, if you use an animated displacement map to create waves on a water surface, you might temporarily apply Displace Mesh to see where the ripples meet the waterline of a boat. When you use Displace Mesh in this way, usually you delete it once you’ve obtained the effect you want.

- To obtain an editable mesh created from a displacement map
  To use the Displace Mesh this way, you apply it to the object that has a displacement map, then apply the Snapshot command on page 950 from the Tools menu, and choose Mesh as the clone method.

  Snapshot creates a permanently displaced mesh. As it does for other kinds of objects, Snapshot also leaves the original, displacement-mapped object in the scene. After applying Snapshot, you can delete the original object, or you can keep it in your scene to use for other purposes.

  **TIP** Use Disp Approx to displace editable meshes. Use Displace Mesh for previewing, as in the first item, but avoid using Snapshot. The mesh created by using Displace Mesh and Snapshot can have a high polygon count. This makes it slow to use interactively, and can cause smoothing problems, where the underlying mesh edges are visible.

**Interface**

The rollout for Displace Mesh lets you choose which surface approximation settings are used to produce the mesh.
Update Mesh Updates the mesh if you have changed the displacement mapping and want to see the results of the change. The mesh isn't updated automatically because that can become extremely time consuming.

Custom Settings When turned off, Displace Mesh uses default settings to subdivide the mesh for the purposes of displacement mapping. When turned on, the subdivision controls in this rollout are enabled. Default=off.

Subdivision Displacement Subdivides mesh faces to accurately displace the map, using the method and settings you specify in the Subdivision Presets and Subdivision Method group boxes. When turned off, the modifier applies the map by moving vertices in the mesh, the way the Displace modifier on page 1313 does. Default=on.

Split Mesh Affects the seams of displaced mesh objects; also affects texture mapping. When on, 3ds Max splits the mesh into individual faces before displacing them; this helps preserve texture mapping. When off, 3ds Max uses an internal method to assign texture mapping. Default=on.
TIP This parameter is required because of an architectural limitation in the way displacement mapping works. Turning Split Mesh on is usually the better technique, but it can cause problems for objects with clearly distinct faces, such as boxes, or even spheres. A box’s sides might separate as they displace outward, leaving gaps. And a sphere might split along its longitudinal edge (found in the rear for spheres created in the Top view) unless you turn off Split Mesh. However, texture mapping works unpredictably when Split Mesh is off, so you might need to add a Displace Mesh modifier and make a snapshot on page 950 of the mesh. You would then apply a UVW Map modifier on page 1932 and then reassign mapping coordinates to the displaced snapshot mesh.

Subdivision Presets group and Subdivision Method group

The controls in these two group boxes specify how the modifier applies the displacement map when Custom Settings and Subdivision Displacement are both turned on. They are identical to the surface approximation controls on page 2737 for NURBS surfaces.

Displace NURBS Modifier (World Space)

Select a NURBS object. > Modify panel > Modifier List > World-Space Modifiers > Displace NURBS (WSM)

The Displace NURBS world-space modifier (World Space) converts a NURBS object into a mesh. If a displacement map is applied to the object, the mesh shows the effect of the displacement map in viewports. There are two main reasons for using Displace NURBS:

- As a visualization aid to see the effect of a displacement map in viewports
  When you use Displace NURBS this way, you usually delete the modifier once you've obtained the effect you want.

- To obtain an editable mesh created from a displacement map on a NURBS object
  To use Displace NURBS this way, you apply it to the object that has a displacement map, then use the Snapshot command on page 950 from the Tools menu, and choose Mesh as the Clone Method.

  Snapshot creates a permanently displaced mesh. As it does for other kinds of objects, Snapshot also leaves the original, displacement-mapped object in the scene. After applying Snapshot, you can delete the original object, or you can keep it in your scene to use for other purposes.
Interface

The rollout for Displace NURBS lets you choose which surface approximation settings are used to produce the mesh.

**Animated Displacement Map** If you use an animated displacement map on the mesh, turn on this toggle to have the NURBS Modifier correctly update the mesh as the displacement map animates.
You can apply a displacement map on page 6059 using the Material Editor on page 5641.

**Update Mesh** Click to update the mesh if you have changed the displacement mapping and want to see the results of the change. The mesh isn’t updated automatically because that could become extremely time consuming.

**Viewport** Uses the tessellation that the NURBS object currently uses in viewports.

**Renderer** Uses the tessellation that the NURBS object currently uses for the renderer.

**Custom** Set the tessellation directly in the Tessellation Method group box.

**Base Surface, Surface Edge, Displaced Surface, and Lock** These controls are the same as in the surface approximation controls on page 2737 for NURBS objects.

**Tessellation Method group**

The controls in this group are the same as the surface approximation controls for NURBS objects.

---

**Ignore Surface Settings** When turned off, Displace NURBS uses the surface approximation settings for surface sub-objects. When turned on, Displace NURBS uses the settings in the Tessellation Method group and overrides settings for surface sub-objects. Default=off.

**Auto Weld** All vertices closer than the **Threshold** value are automatically welded together. This can simplify the mesh geometry. It is useful to turn this on when you have increased the Merge value in order to eliminate gaps between surface edges in the approximation of the NURBS object.

---

**Hair And Fur Modifier (World Space)**

Modify panel > Make a selection. > Modifier List > World-Space Modifiers > Hair And Fur (WSM)

The Hair And Fur modifier is the heart of the Hair And Fur feature. You apply it to any object that you want to grow hair from: either a mesh object or a spline object. If object is a mesh, the hair grows from the entire surface unless
you make a sub-object selection. If the object is a spline, hair grows between the splines.

When you select an object modified by Hair And Fur, hair is displayed in viewports. The hair itself as displayed in the viewports is not selectable, though hair guides are selectable when you work at the Guides sub-object level or style hair (see below).

**NOTE** Hair And Fur renders only in Perspective and Camera views. If you attempt to render an orthographic view, 3ds Max displays a warning that says the hair will not appear.

Hair And Fur renders by “tiles,” which are 2D projections of the 3D space that the hair or fur occupies. In Autodesk 3ds Max 2010, each tile is displayed in the rendered frame window as soon as it is generated. Also in Autodesk 3ds Max 2010, you can set the maximum memory that a tile uses at render time: see Hair And Fur Render Effect on page 7061.

Hair And Fur can take advantage of multiple processors, improving rendering time on multiprocessor systems.

**Components of the Hair And Fur Feature**

Hair And Fur in 3ds Max has a few different components in the interface:

- The Hair And Fur modifier is the main component. This is where you style the hair guides, and set parameters for size and coloration, kinkiness, frizziness, and so on.

- The Hair And Fur render effect on page 7061 more directly controls how hair is rendered. Typically you don't need to change the render effect parameters, unless you have special rendering requirements. A Hair And Fur render effect is automatically added to your scene when you apply the Hair And Fur modifier.

- A Hair Light Attributes rollout on page 5443 appears for all supported lights when a Hair And Fur render effect is active using the scanline renderer, and the render effect’s Use All Lights At Render Time toggle is turned on. Controls on this rollout let you fine-tune how hair shadows appear under specific lights. The following light types are not supported when rendering hair with the “buffer” method (see “Lighting Considerations,” below): Skylight, mr Area Omni, mr Area Spot, IES Sun, IES Sky, mr Sky and mr Sun. However, mr Area Omni, mr Area Spot, mr Sky, and mr Sun are supported for hair when you use the “mr prim” method and the mental ray renderer.
NOTE For the purposes of rendering shadows in hair, Direct lights are treated as point (omni) lights.

- There is also a Hair And Fur render element on page 6825, which you can use when you are doing your own compositing.

Growth Objects

You can grow Hair either from a surface or from splines.

To grow hair from a surface, select the object and then apply the Hair And Fur modifier. You can use either geometric primitives or an editable surface type such as Polymesh.

To grow hair from splines, you can draw several splines and combine them into a single object (or turn off Start New Shape during creation), and then apply the Hair And Fur modifier. You will see some preview interpolated hairs appear in viewports. The order of the spline sub-objects is important because Hair uses this order to interpolate hair in between the splines. If the interpolation seems incoherent, you might need to physically rearrange the splines.

Using a spline emitter, Hair interpolates hair growth between pairs of splines in logical, numerical order.

Left: Splines in sequential order result in predictable hair growth.
Right: Splines in nonsequential order can produce undesirable results.

TIP To check the numerical order of splines, go to the Editable Spline level of the modifier stack and access the Spline sub-object level. Then click each spline in turn and check its ID number at the bottom of the Selection rollout. It also can help to make sure that each spline’s first vertex is where the hair roots should be.
Guide Hairs

Storing and manipulating millions of dynamic, simulated hairs is demanding on today’s technology. Therefore, just as standard 3D graphics technology uses boundaries such as surfaces to describe solid objects, Hair uses hair “guides” to describe basic hair shape and behavior.

Guides (yellow) occur at each polygon corner. Hairs (red) are interpolated between guides.

When the growth object is a surface, Hair And Fur generates guide hairs at the corners of polygons. When the growth object is a spline, the spline sub-objects are themselves the guides.

For surface-grown hair, you can manipulate the guides with styling tools on page 1095 to form a “control volume” that gets populated by interpolated hairs. The hairs can then be further manipulated with distorting controls such as Kink on page 1131 and Frizz on page 1126, which can be driven by maps or solid textures.
Frizz settings affect the hairs but not the guides.

By default, a percentage of hairs are displayed in the viewports, but surface-grown guides do not appear except when you are working at the Guides sub-object level. You can adjust the viewport display of guides and hairs with settings on the Display rollout on page 1143.

Guides are also used to calculate dynamics. After this calculation, hair interpolation takes place when you render. This is when parameters such as Frizz, as well as displacement and coloration, are calculated. You don't have control of every single hair, but this two-phase process makes the creation of realistic hair computationally feasible on a typical computer.

**Styling Hair**

The Hair And Fur modifier's growth settings have a great effect on the hair’s appearance and behavior, but you can also manipulate the guides directly (or in other words, style the hair).

For surface-grown hair, use the tools on the Styling rollout on page 1095. First, select the surface whose hair you want to edit, and then on the Modify panel, either click the Style Hair button on the Styling rollout or choose the Guides...
sub-object level from the Selection rollout on page 1082 or the modifier stack display.

After guides have been styled, hair is interpolated between neighboring guide pairs.

Mesh-based hair guides before and after styling.

With spline growth, you style the hair by editing the growth splines in the viewports.
Copying and Pasting Hair

You can copy and paste a Hair And Fur modifier from one stack to another, but you need to line up the objects as closely as possible, because Hair uses proximity to determine how to position copied guides. If the objects have significantly different geometry, the transfer of guides can be inaccurate.

Copying and pasting the Hair And Fur modifier automatically adjusts the hair scaling. Copying from a large object to a small object, for instance, results in a smaller default size in the copied modifier.

If you copy an object that has Hair And Fur in its modifier stack, Hair will also copy the modifier’s data to a new modifier that will track the new object.

Textures, Vertex Maps, and Shaders

You can control many Hair And Fur modifier parameters with maps. If you apply a map to a parameter that is not a color, such as Density, Hair uses the texture as a grayscale map that is multiplied by the parameter value (0.0 to 100.0).

You apply a map by clicking the square button to the right of the parameter. After applying a map, the letter “M” appears on the button. To place this map in the first slot in the Material Editor, Shift+click the button. To disable the map temporarily, Ctrl+click the button. A disabled map is indicated by a lower-case “m”.

Lighting Considerations

When you render using the default “buffer” method, Hair And Fur provides its own default lighting (a single omni light), unless you have one or more supported lights in the scene.
Supported lights for the scanline renderer and “buffer” method include spotlights, omni lights, direct lights (which are treated as omni lights for hair purposes), and photometric lights except for IES Sun and IES Sky. Supported lights for the mental ray renderer and “mr prim” method include the lights supported by the scanline renderer, and these mental ray light types: mr Area Omni Light, mr Area Spotlight, mr Sky, and mr Sun.

If supported lights exist in the scene, by default they are used to light the hair, and the internal default omni light is not used. This is because in the Hair And Fur render effect on page 7061, the Use All Lights At Render Time option is on by default. Also, any supported lights set to cast shadow-mapped shadows will cast shadows from rendered hair.

For Hair’s “buffer” render to consider only certain lights, select the lights you’d like Hair to use, go to the Hair And Fur render effect, turn off Use All Lights At Render Time, and then click Add Hair Properties. This causes only the designated lights to illuminate the hair. It also adds a Hair Light Attr rollout on page 5443 to each of the designated lights. This lets you fine-tune the light’s shadow settings for Hair.

With the “buffer” method, you can also raytrace your scene.

NOTE The other rendering methods provided are “geometry” and “mr prim.” The “geometry” method creates actual geometry for the rendered hair at render time. The “mr prim” method uses a mental ray shader to generate hair, and is for use only with the mental ray renderer. Use the Hair And Fur render effect to choose the rendering method.

Loading and Saving

Hair And Fur data in your scene is automatically saved when you save your MAX scene file. The state data for the hair can consume quite a bit of space, so your scene file will probably be significantly larger than it was before you applied hair.

Animating Hair

You cannot keyframe hair styling. You can keyframe Modify panel parameters to create special effects such as hair growing. But to animate hair motion, you can use the Frizz Animation parameters or use dynamics.

To animate frizz, use the Frizz Anim. on page 1131, Anim. Speed, and Frizz Anim. Dir. parameters. It’s not necessary to keyframe these to create animation; just set them to values other than the defaults.
To animate with dynamics, use the Dynamics rollout on page 1136. See To
generate a precomputed dynamics simulation with Hair on page 1137. A gravity
force is built in to Hair And Fur. You can add space warps to act as external
forces (for example, Wind).

- Hair And Fur Render Effect on page 7061
- Hair And Fur Render Element on page 6825
- Hair Light Attributes Rollout on page 5443

Procedures

To use the Hair And Fur modifier:

This procedure lists the essential steps for growing hair on an object. For more
information, see other Hair And Fur topics in this help, and the tutorials in
the Autodesk 3ds Max Tutorials, available from Help menu > Tutorials.

1. Apply the Hair And Fur modifier to a mesh or spline object.
   The hairs appear in the viewports as brown lines.

2. Set the modifier parameters according to the desired results (see Topics
   in this Section, following). Available settings include the number of hairs,
   length, thickness, and coloring.

3. Activate a Perspective or Camera viewport, and then render the scene.
   Hair cannot render in an orthographic viewport.

To apply hair to a limited area of a high-resolution object:

An efficient working method for applying hair to part of a high-poly-count
object is to use a low-poly proxy object.

1. Create the object to which you wish to apply hair.

2. Make a copy of the object in the same location as the original, remove
   any geometry where hair shouldn't grow, and reduce the polygon count.
   For example, you could use the MultiRes modifier on page 1537.

3. If the original object is to move, make the low-resolution proxy object a
   child of the original object.
4 Apply the Hair And Fur modifier to the low-resolution proxy object and adjust as necessary.

5 Make the low-resolution proxy object non-renderable (see General Panel (Object Properties Dialog) on page 283). The hair will still render.

Selection Rollout (Hair And Fur)

Select an object with the Hair And Fur modifier applied. > Modify panel > Selection rollout

The Selection rollout provides tools for accessing different sub-object levels and display settings and for creating and modifying selections, and displays information about selected entities.

When you first apply the Hair And Fur modifier to an object, the entire object is affected by the modifier. You can specify that the only part of an object should grow hair by accessing a sub-object level and making a selection.

Clicking a button here is the same as choosing a sub-object level in the modifier stack display. Click the button again to turn it off and return to the Object selection level.

Interface

NOTE Controls on this rollout are available only when the growth object is a mesh. If the growth object is a spline, the Selection controls have no effect, and sub-object levels for the Hair And Fur modifier are not visible in the modifier stack.
Guides Accesses the Guides sub-object level, which lets you edit the styling guides using tools on the Styling rollout on page 1095. When you click Guides, the Style Hair button on the Styling rollout is automatically turned on, and vice versa.

Face Accesses the Face sub-object level, which lets you select a triangular face beneath the cursor; region selection selects multiple triangular faces within the region.

Polygon Accesses the Polygon sub-object level, which lets you select polygons beneath the cursor. Region selection selects multiple polygons within the region.

Element Accesses the Element sub-object level, which lets you select all contiguous polygons in an object by clicking once. Region selection lets you select multiple elements.

By Vertex When on, you can select a sub-object only by selecting a vertex that it uses. When you click a vertex, all sub-objects that use the selected vertex are selected.

Ignore Backfacing When on, using the mouse to select sub-objects affects only those facing you. When off (the default), you can select any sub-objects under the mouse cursor, regardless of their visibility or facing. If there are more than one sub-object under the cursor, repeated clicking cycles through them. Likewise, with Ignore Backfacing off, region selection includes all sub-objects, regardless of the direction they face.

NOTE The state of the Backface Cull setting on the Display panel does not affect sub-object selection. Thus, if Ignore Backfacing is off, you can still select sub-objects, even if you can’t see them.

Named Selection Set group

Copy Places a named selection into the copy buffer.

Paste Pastes a named selection from the copy buffer.
**TIP** You can use this to grow hair from an existing selection lower on the stack. However, because the Hair And Fur modifier outputs an editable mesh, the copied sub-object selection should be from a mesh-based modifier. For example, if your base object is an editable poly, you can use tools such as Ring, Loop, and Grow to make a procedural edge selection, and then Ctrl+click the Polygon button on the Selection rollout to convert the selection to polygons. Next, apply a Mesh Select modifier (*not* Poly Select), and go to the Polygon sub-object level; the Mesh Select modifier inherits the Editable Poly selection. Use the Named Selection Sets field on the main toolbar to name the selection, and then use the Mesh Select modifier’s Copy function on the named selection. Finally, apply the Hair And Fur modifier, go to the Poly sub-object level, and paste the selection.

---

**Update Selection** Recalculates the area from which hair is grown, based on the current sub-object selection, and refreshes the display. When you access a sub-object level within the Hair modifier and make a selection, the area of hair growth doesn't automatically update. Click Update Selection to view the results of a change in sub-object selection.

**Tools Rollout (Hair And Fur)**

Select an object with the Hair And Fur modifier applied. > Modify panel > Tools rollout

This rollout provides tools for accomplishing a variety of tasks with Hair, including creating a hairstyle from an existing spline object, resetting the hair, and loading and saving general presets for the modifier as well as specific hairdos. Here you can also specify an object from the current scene to be used as hair, such as a flower or group of flowers for creating a garden.

**Using Instanced Hair**

Besides the built-in hair strands, which are created at render time, you can assign any source object as hair strands, using the Instance Node controls on the Tools rollout. For example, in the following illustration, the original orientation of the source object affects its orientation when it is used as hair strands.
Rotating the source object affects the hair orientation.

The next illustration shows how increasing the Frizz Root value creates greater amounts of distortion in the resulting instanced hairs. This image also shows how a raised pivot in the source object causes the root of the hair to go below the surface of the growth object (the red square). Compare this with the previous illustration, in which the pivot rests at the base of the source object.

Frizz causes the instanced hairs to change shape.

The next illustration shows the effect of the Merge Material check box. On the left side, Merge Material was left on, with the result that the flower model
retained its original material and coloring when used as hair. On the right, Merge material was turned off, so the flower-hairs took on the material of the flower pot growth object.

In the next illustration, the Root Thick setting, from left to right, is 2.0, 10.0, 20.0, and 30.0. With instanced geometry, the Root Thick value affects the thickness of the resulting object uniformly along its height, while the Tip Thick value has no effect. (The Root Thick and Tip Thick settings are on the General Parameters rollout on page 1111.)
Increasing Root Thick affects the overall thickness of the hair geometry.
From left to right: Root Thick = 2.0, 10.0, 20.0, and 30.0

The final illustration, below, shows how the instanced hair aligns itself faithfully to the guides, no matter how they’re styled. The styled hair was brushed from the center, and the instances align perfectly in all directions, face up, without twisting or other distortion. This makes it easy to style instances as scales, for example.
Top left: The original styled hair
Top right: The instanced hair (arrows) conforms to the styling.
Bottom: Close-up view of instanced hair
Interface

Recomb From Splines Lets you use a spline object to style the hair. Click this button and then select an object that is made up of spline curves. Hair will turn the curves into guides and populate each guide of the selected growth mesh with a replica of the closest curve.

This tool is particularly useful for creating a specific style and length, such as short hair with a part on the side, without having to manually groom the hair in the Style dialog. For optimal control, position the splines fairly closely together and use as many as possible.
Hair and guides are recombed by the spline object (white).

**Spline Deform group**

Spline deformation lets you style or animate hair by having it conform to the shape of a spline on page 577.

**Pick** Click to choose the spline you will use to deform the hair, then click the spline in a viewport, or press H and use the Pick Object dialog to select the spline.

When no spline is picked, the label of this button shows “None.” When a spline is in active use, the label shows the name of the spline you picked.

The deformation applies to all hair guides, and is a one-time operation: while splines are active, the guides are “locked” to the spline, and moving a point on a spline deforms the closest guides. However, the base of the spline (for example, where it’s attached to the head) does not move. If you deform the spline near the base of the guide, you will move the spline away from the base, because the base is fixed and will not follow the deformation.
**TIP** Clicking Recomb From Splines readjusts the hair (but not the guides) to align to the spline deformation better. However, you can’t animate Recomb From Splines.

Left: The spline picked to deform hair  
Right: Hair deformed by the spline

Animating the spline (for example, by animating the position of its vertices) animates the deformed hair, but not if you later alter the hair position by styling. This includes animating a modifier applied to the spline. The spline can be a *spline cage*: in other words, an Editable Spline object that consists of multiple splines.

Left and right: Spline cage formed of two spiral spline sub-objects  
Middle: Hair deformed by the spline cage

3ds Max interpolates between the spline shapes in the spline cage, and the shape of a hair depends on its proximity to one or another spline sub-object in the cage.

**TIP** One way to create a spline cage is to style hair, then click Tools rollout > Convert group > Guides -> Splines.
To stop using spline deformation, click the Clear Spline button (labeled “X”).

**Reset Rest** Performs an averaging of hair guides using the growth mesh’s connectivity.

This function is particularly useful after using Recomb From Splines. It’s also advantageous when you change the size ratios of polygons in the growth object. For example, if you stretch part of the mesh by moving some vertices, by default the larger polygons will contain fewer hairs per unit area. Use Reset Rest to redistribute the number of hairs on the surface for more even coverage.

![Even hair distribution before resizing polygons](image1)
![Uneven hair distribution after moving edges, altering polygon size ratios](image2)
![After using Reset Rest, distribution is again evened out.](image3)

**Regrow Hair** Discards any styling information, resetting the hair to its default state, retaining all current Modify panel settings.

**Presets group**

Lets you load and save hair presets. Each preset contains all current Modify panel settings (except Display settings), but *not* any styling information.

**Load** Opens the Hair Presets dialog, which contains a list of presets in the form of named swatches. To load a preset, double-click its swatch. Several sample presets are included with 3ds Max.
Save Creates a new preset. You're prompted for a preset name; after entering one, Hair renders the swatch, as shown by a message on the status bar. You can abort the creation of the preset by clicking the Cancel button on the status bar during rendering. If you enter an existing preset name, Hair asks you to confirm overwriting the preset.

Hairdo group

Lets you copy and paste hairdos. Each hairdo contains all the current Modify panel settings (except Display settings) and styling information. This lets you apply all hair settings from one object to another.

Copy Copies all hair settings and styling information into a paste buffer.

Paste Pastes all hair settings and styling information to the current Hair-modified object.
Instance Node group

Lets you specify an object to use as custom hair geometry. The hair geometry is not instanced from the original object, but all hairs created from it are instances of each other, to save memory.

**NOTE** Hair does not use animation from instance objects. If an object is animated, Hair uses its state at the first animation frame.

**Pick** To specify a hair object, click the Pick button and then pick an object to use. Thereafter, the button shows the name of the object you picked. To use a different instance object, or to use a modified version of the original object, click this button and then pick the new object.

**TIP** In order for the instances to be properly scaled and fit to the hair, place the model's pivot at the “root” of the object. Hair will then scale your model appropriately so that the height of each instance matches the length of the hair it has been applied to. Any part of your model that extends below the pivot will intersect the surface. This can be useful; if the hair grows at an oblique angle to the growth surface, you can raise the pivot in the original model to make sure the instanced hairs will extend all the way to the growth surface.

Also, bear in mind that the instancing engine will be deforming your model as it fits it to the hairs. Make sure that your model has enough divisions along the Z (vertical) axis for the deformation to look as smooth as it needs to; the number of subdivisions should be approximately equal to the Hair Segments value. Hair doesn't perform automatic subdivision on the geometry.

**X** To stop using the instance node, click the Clear Instance button (labeled “X”).

**Merge Material** When on, combines the material applied to the growth object and the material applied to the hair object into a single Multi/Sub-Object material and applies it to the growth object. When off, the growth object's material is applied to the instanced hair. Default=on.

**NOTE** The merged material is instanced from the instance node, so that changing the original material affects the resulting material applied to the hair.

Convert group

Use these controls to convert guides or hair generated by the Hair And Fur modifier to 3ds Max objects that you can operate on directly.
**Guides -> Splines** Copies all guides to a new, single spline object. The original guides are left intact.

**Hair -> Splines** Copies all hairs to a new, single spline object. The original hairs are left intact.

**Hair -> Mesh** Copies all hair to a new, single mesh object. The original hairs are left intact.

---

**Render Settings** Opens the Effects panel and rollout on page 7058 and adds a Hair And Fur render effect on page 7061 to the scene, if one doesn't already exist.

**NOTE** The Hair And Fur render effect settings are global, so even if you click Render Settings to open the effect settings from different Hair And Fur modifiers, you'll get the same render-effect settings.

---

**Styling Rollout (Hair And Fur)**

Select an object with the Hair And Fur modifier applied. > Modify panel > Styling rollout

The Guides sub-object level of the Hair And Fur modifier on page 1073 lets you style hair interactively in viewports. Interactive styling controls are on the Styling rollout, which has a Style Hair button that you can also click to begin styling.

**Styling with Hair Guides**

Styling tools aren't available until you click Style Hair to turn it on, or choose the Guides sub-object level in either the Selection rollout or the modifier stack.

Each guide hair has 15 segments and 14 vertices (there's an additional, non-selectable vertex at the root); for a tool to affect a guide, at least one of its vertices must be selected. To select vertices, click Select (in the Styling group) to turn it on, then use standard 3ds Max selection tools to select a portion of the guides. For example, you might drag a selection rectangle to select vertices on adjacent hair guides. By default, selected guides are displayed as orange, and unselected guides are displayed as yellow.

Selections you make this way are constrained by the buttons at the top of the Selection group: Select Hair By Ends, Select Whole Guide (the default), Select Guide Vertices, or Select Guide By Root. As these names imply, the constraints
affect how the Hair Brush modifies hair guides. The best way to get a feel for
the difference between selection constraints is to practice using the various
selection constraints with tools such as Translate. The Hair Brush uses a
combination of these constraints and IK to alter guide geometry.

Left: Hair guide before styling
Center: Translating while Select Whole Guide is active
Right: Translating while Select Hair By Ends is active

Once you've made a selection, typically you will click Hair Brush (also in the
Styling group, to the left of Select), and then use the brush in conjunction
with one of the tools at the bottom of the Styling group: Translate, Stand,
Puff Roots, Clump, Rotate, or Scale.

While you style, only selected guides are affected, and in addition, only guides
that fall within the brush area are affected at any given time. You can change
the brush size using the slider in the Styling group, or by holding down
Ctrl+Shift and dragging the mouse.

The Hair Cut tool on the Styling rollout (between Hair Brush and Select) cuts
hair guides by scaling them based on the brush location.

Interface

NOTE Controls on this rollout are available only when the growth object is a mesh.
If the growth object is a spline, the Styling controls have no effect. Instead, you
can style the hair by editing the underlying spline object.
Hair And Fur Modifier (World Space)
Style Hair / Finish Styling Click Style Hair to begin styling. Click Finish Styling to turn off styling mode. When you turn this button on, a brush is immediately available and by default the active tool is Translate. Turning on Style Hair turns on the Guides sub-object level in the Selection rollout on page 1082, and vice versa.

Selection group

Select Hair by Ends You can select only the vertex at the end of each guide hair.

Select Whole Guide (The default.) Selecting any vertex on a guide hair selects all vertices on the guide hair. When you first turn on Style Hair, Hair activates this mode and selects all vertices of all guide hairs.

Select Guide Vertices You can select any vertices on a guide hair.

Select Guide by Root You can select only the vertex at the root of each guide hair, and doing so selects all vertices on the guide hair.

Vertex display drop-down list Chooses how selected vertices are displayed in viewports.

- **Box Marker** (The default.) Selected vertices display as small squares.
- **Plus Marker** Selected vertices display as small plus signs.
- **X Marker** Selected vertices display as small Xes.
- **Dot Marker** Selected vertices display as dots.

Selection Utilities The buttons labeled “Selection Utilities” are for handling selections.
**Invert Selection** Inverts the vertex selection.
Keyboard shortcut: Ctrl+I

**Rotate Selection** Rotates the selection in space.

**Expand Selection** Expands the selection by growing its area incrementally.

**Hide Selected** Hides selected guide hairs.

**TIP** If interactive styling in viewports seems to be slow, try hiding those guides you aren’t working on.

**Show Hidden** Unhides any hidden guide hairs.

**Styling group**

**Hair Brush** (The default.) In this styling mode, dragging the mouse affects only selected vertices within the brush area.
While Hair Brush is on, a brush gizmo is displayed in viewports. In the active viewport, the brush appears as a circle, but as you can see in the other viewports, the brush is actually a three-dimensional cylindrical region.
In the active viewport, the brush appears to be a circle.
Inactive viewports show the brush to be a cylindrical region.

**Hair Cut** Lets you trim the guide hairs. To cut hair, follow this suggested procedure:

1. In Selection mode, choose any selection method.
2. Drag the mouse to select guide hairs to trim.
3. Turn on Hair Cut.
4. Resize the brush using the slider.
5. Position the brush circle over hairs to cut, and then click to cut the hairs. Hairs with vertices inside the brush circle are shortened so that their endpoints touch the brush circle.
NOTE  Cutting hair doesn’t actually remove vertices; it only scales the guide hairs. You can restore guide hairs to their original length with Scale or one of the Pop commands on page 1105.

Left: Hair guides before cutting
Right: Hair guides after cutting

Select  Goes into selection mode, where you can use 3ds Max selection tools to select guide vertices according to the constraints chosen in the Selection group (Whole Guide, Ends, and so on).

Distance Fade  Available only for Hair Brush. When on, the effect of brushing fades toward the edges of the brush, giving a gentler effect. When off, brushing affects all selected vertices equally, giving a hard-edged effect. Default=on.

Ignore Back Hairs  Available only for Hair Brush and Hair Cut. When on, hairs on back faces are not affected by the brush. Default=off.

Brush size slider  Drag this slider to change the size of the brush.
Keyboard shortcut: Ctrl+Shift+drag
The styling buttons below the Brush Size Slider are available only while Hair Brush is on.
**Translate** Moves selected vertices in the direction that you drag the mouse.

**Stand** Pushes selected guides toward a perpendicular orientation to the surface.

Left: Guide hairs before styling with Stand  
Right: Guide hairs after styling with Stand (on the right)

**Puff Roots** Pushes selected guide hairs toward a perpendicular orientation to the surface. The bias for this tool is closer to the root of the hair than to the endpoint.

Left: Hair guides before puffing roots  
Right: Hair guides after puffing roots
**Clump** Forces selected guides to move towards each other (drag mouse leftward) or farther apart (drag mouse rightward).

Left: Hair guides before clumping  
Right: Hair guides after clumping (at the right)

**Rotate** Rotate or swirls guide hair vertices around the cursor location (at the center of the brush).

Left: Hair guides before rotating  
Right: Hair guides after rotating (at the forelock)

**Scale** Scales selected guides larger (drag mouse rightward) or smaller (drag mouse leftward).
Left: Hair guides at original lengths
Right: Hair guides after scaling shorter

Utilities group

**Attenuate Length** Scales selected guides according to the surface area of underlying polygons. This is useful, for example, in applying fur to an animal model, which typically has smaller polygons in areas with shorter hair. For example, the polygons on an animal's paws are usually smaller than the ones on the chest, and the chest fur tends to be longer.

**Pop Selected** Pops selected hairs out along the surface normal.
**Right: Hair guides after using Pop Selected**

**Pop Zero-Sized** Works like Pop Selected, but only operates on zero-length hairs.

**Left: Hair guides on top of head were scaled to zero length.**

**Right: Using Pop Zero affects only the zero-length hair guides.**

**Recomb** Makes a guide parallel to the surface, using the guide's current direction as a hint.

Here's a suggested procedure: Turn on Hair Brush, select guides using Select Whole Guide, and then move the guides around not worrying about skin penetration or hair shape. You're just trying to indicate the direction of the hair flow. Click Recomb frequently, and you will soon start to see hair flowing smoothly wherever you want it to. Once you have this flow, you can do your other styling. With the Recomb tool, you probably won't need to use Comb Away. Once you have the flow as you like it, you can go in and start styling in scale, cut guides, and move some of the tips around, “shaping” or “styling” the hair.
Left: Hair guides in their default position
Right: Hair guides after clicking Recomb

**Reset Rest** Performs an averaging of hair guides using the growth mesh’s connectivity.
This function is particularly useful after using Recomb.

**Toggle Collisions** When on, styling takes hair collisions into account. When off, styling ignores collisions. Default=off.
For collisions to be used while styling, you need to have already added at least one collision object using the Dynamics rollout on page 1136. If no collisions are specified, this button has no effect.

_TIP_ If you collisions are enabled and styling interaction seems slow, try turning off Toggle Collisions.

**Toggle Hair** Toggles viewport display of generated (interpolated) hair. This doesn't affect display of the hair guides. Default=on (hair is displayed).
**Lock**  Locks selected vertices with respect to the orientation to and distance from the nearest surface. Locked vertices can be selected, but they can't be moved.

This is useful for creating different types of hair shapes. For example, to make a braid, you would comb hair down some straight tubes, and then lock the vertices to the tubes. Then, in 3ds Max, when you twist the tubes, the hairs will follow. Locked vertices are no longer dynamic, although they will follow whatever the surface does, but if other vertices on the same guides aren't locked, they can still move freely, as usual.

**Unlock**  Unlocks all locked guide hairs.

**Undo**  Reverses the most recent action.

Keyboard shortcut: Ctrl+Z

**Hair Groups group**

**Split Selected Hair Groups**  Splits the selected guides into a group. This can be useful for creating a part or a cowlick, for example.

**Merge Selected Hair Groups**  Recombines selected guides.

If you don't use Split Selected Hair Groups, then when you render hair, the generated hairs are interpolated across a styled part. When Split Selected Hair Groups is on, there is no interpolation between the split group and other hairs. To remove this effect and make the part less “clean,” click Merge Selected Hair Groups.
Quad Menu for Hair Styling

While you are styling hair at the Guides sub-object level, right-clicking a viewport displays a quad menu that contains shortcuts to many styling controls that are also found on the Styling rollout on page 1095.

Utilities quadrant

The first two choices are shortcuts to the buttons in the Hair Groups group:

- **Merge Hairgroups** on page 1108
- **Split Hairgroups** on page 1108

The other choices in this quadrant are shortcuts to the buttons in the Utilities group:

- **Unlock** on page 1108
- **Lock** on page 1108
Styling quadrant

The choices in this quadrant are shortcuts to most of the controls in the Styling group:

- **Ignore Back** on page 1102
- **Soft Falloff** on page 1102
- **Scale** on page 1104
- **Rotate** on page 1104
- **Clump** on page 1104
- **Puff** on page 1103
- **Stand** on page 1103
- **Translate** on page 1103
- **Cut** on page 1101
  To exit Cut mode and return to the hair brush, choose one of the other styling modes in this quadrant.

**TIP** While the brush is active, you can resize it in viewports by holding down Ctrl+Shift and dragging the mouse.

Selection Utils quadrant

These choices are shortcuts to the buttons under “Selection Utilities” in the Selection group:

- **Invert Selection** on page 1099
Selection quadrant

These choices are shortcuts to the buttons at the top of the Selection group that constrain how you can select hair guides:

- **Tip** on page 1098
- **Guide** on page 1098
- **Verts** on page 1098
- **Root** on page 1098

**General Parameters Rollout (Hair And Fur)**

Select an object with the Hair And Fur modifier applied. > Modify panel > General Parameters rollout

This rollout lets you set the hair count and density, the length, thickness at the root and tip, and various other comprehensive parameters.
Interface

Hair Count
The total number of hairs generated by Hair. In some cases this is an approximate count, but the actual count is usually very close to the specified quantity. Default=15000. Range=0 to 10000000 (ten million).

Top: Hair Count=1000
Bottom: Hair Count=9000
By default, Hair normalizes density to surface area; that is, larger polygons receive more hairs than smaller ones. If you edit the growth object in a way that changes the polygon-size ratios, use Reset Rest on page 1092 to adjust the hair distribution automatically.

**Hair Segments** The number of segments per hair. Default=5. Range=1 to 150. This is equivalent to spline segments; with more segments, curly hair looks more natural, but the generated mesh object is larger. For perfectly straight hair, set Hair Segments to 1.

**Left:** Hair Segments=5  
**Right:** Hair Segments=60

**Hair Passes** Sets the number of transparency passes. Default=1. Range=1 to 20.

Hair's buffer render on page 7064 has a fairly novel way of handling hair transparency. Instead of resolving actual hair transparency, the hair is rendered multiple times (as opaque hair) with different random seeds. These buffers are then blended together. As you increase the Hair Passes value, the transparency (or wispiness) of the hair increases. In addition, increasing the value increases the actual number of rendered hairs as well, although the apparent density, or fill, seems about the same because of the additional transparency. Render time also increases linearly.
NOTE For best results when using the “mr prim” hair rendering method (see Hair And Fur Render Effect on page 7061) with the mental ray renderer, be sure to set the Trace Depth > Max. Depth value (see Rendering Algorithms Rollout (mental ray Renderer) on page 6741) higher than the Hair Passes value.

Density The numeric value sets the overall hair density; that is, it acts as a percentage multiplier of the Hair Count value. Default=100.0. Range=0.0 to 100.0.

This attribute is also mappable via the map button to the right of the spinner. Mapping lets you add a texture map to control the amount of hair. An area of the map whose gray value is 50% will reduce the amount of hair grown in that area by 50%. To change the overall hair count, use the Hair Count value (see above).
Top: Density=100.0 + map
Bottom: The bitmap used to control density

**TIP** For optimal efficiency, use the Hair Count value to set the actual number of hairs, leave Density at 100.0, and use mapping to create uneven hair distribution. Simply lowering the Density value without specifying a map causes hairs to be created and then discarded, which unnecessarily increases rendering time.

**Scale** Sets the overall scaling for the hairs. Default=100.0. Range=0.0 to 100.0.
At the default value of 100.0, the hairs are full size. Reduce this value to make the hairs smaller. To make the hairs larger, use the styling tools on page 1095. Default=100.0. Range=0.0 to 100.0.
This attribute is also mappable via the map button to the right of the spinner. Mapping allows you to add a texture map to control the length of the hair. An area of the map whose gray value is 50% will cut the hair grown in that area to 50% of its original length, with no shape change.
NOTE The default size of the hairs depends on the size of the object to which the modifier is applied. The larger the object, the greater the initial size.

**Cut Length** The numeric value sets the overall hair length as a percentage multiplier of the Scale value. Default=100.0. Range=0.0 to 100.0.
This attribute is also mappable via the map button to the right of the spinner. Mapping allows you to add a texture map to control the length of the hair. An area of the map whose gray value is 50% will cut the hair grown in that area to 50% of its original length, with no shape change.
This parameter is more computationally expensive than a density map, since each curve is re-parameterized on the fly, and should not be confused with a density map. It's really more useful as an animated effect for growing hair (for example, creating a wolfman character).

**Rand. Scale** Introduces random scaling into the rendered hairs. Default=40.0. Range=0.0 to 100.0.
At the default value of 40.0, 40 percent of the hairs are scaled down randomly by varying amounts. At 0.0, no random scaling is introduced.

**Root Thick** Controls the thickness of the hair at its root. With instanced hair, this controls the overall thickness as a multiplier of the original object’s dimensions on the X and Y axes in object space.

This setting affects both native hair and instanced hair. With instanced hair, Root thick controls the overall thickness of the hair, not just at the root.

**Tip Thick** Controls the thickness of the hair at its tip.

This setting affects native hair only, not instanced hair. To create tapering in instanced hair, apply the tapering when modeling the object to be instanced within Hair.

Hair is translucent if its width is less than one pixel. On the other hand, setting Root Thick and Tip Thick to small values (close to or less than 1.0) can be a good way to obtain translucent hair.

**Displacement** Displaces the hair roots from the surface of the growth object. Default=0.0. Range=–999999.0 to 999999.0.

When you render an object with a high polygon count, but use a low-polygon proxy object to grow the hair, adjusting Displacement can help make the hair seem to grow from the high-polygon object, rather than floating above it.
Another use for this setting can be animating the hair falling onto or moving away from the growth object.

**Interpolate** When on, hair growth is interpolated among the guide hairs, and the surface is fully populated with hair according to the General Parameters settings. When off, Hair generates only one hair per triangular face on the growth object, up to the limit imposed by the Hair Count setting. Default=on.

**Material Parameters Rollout (Hair And Fur)**

Select an object with the Hair And Fur modifier applied. > Modify panel > Material Parameters rollout

The parameters on this rollout apply to buffer-rendered hair on page 7064 generated by Hair. In the case of geometry-rendered hair on page 7064, the hair coloring is derived from the growth object. In the case of hair rendered by “mr prim”, all parameters apply except Self Shadow and Geom. Shadow. With instanced hair, Hair uses the material from the instanced object.

You can apply a map to any value by clicking the blank button to the right of the parameter. Values in the map act as multipliers to the base value.

**TIP** If you apply a colored texture map to a color attribute such as Tip Color, start by setting the base color to white. Because the map acts as a multiplier, not doing so can lead to unexpected results. For example, if Tip Color is set to yellow and you apply a blue texture map, the hair will be black: this is because if you multiply those RGB values, they zero each other out.
**Interface**

**Occluded Amb.** Controls the bias of the ambient/diffuse contributions of the illumination model. A setting of 100.0 renders the hair with flat lighting. A value of 0.0 is lit only by scene light sources, typically resulting in a higher-contrast solution. Default=40.0. Range=0.0 to 100.0.
**Tip Fade** Applies only to mr prim on page 7064 rendering (with the mental ray renderer). When on, the hair fades to transparent toward its tip. When off, the hair is equally opaque for its entire length.

**Tip Color** Hair color at the tips, farthest from the growth object surface. To change the color, click the color swatch and use the Color Selector.

**Root Color** Hair color at the roots, closest to the growth object surface. To change the color, click the color swatch and use the Color Selector.
Tip Color=red
Root Color=blue
Hue Variation=0.0

The Tip Color and Root Color attributes are also mappable via the map buttons to the right of the spinners. These let you add texture maps to control the hair coloring, separately at the tip and base. The UVW mapping used for the texture is the same as that of the growth object.

For results closest to the map colors, set Tip Color and Root Color to white. Alternatively, set a different color to tint the map coloring.

Left: The texture map used for the hair (center and right)
Center: The map applied to Tip Color and Root Color causes the hair to use the same coloring.
Right: Setting Tip Color and Root Color to orange adds an orange tint to the hair.

Hue Variation The amount by which Hair varies the color of the hairs. The default value results in natural-looking hair. Default=10.0. Range=0.0 to 100.0.
**Value Variation** The amount by which Hair varies the brightness of the hairs. The default value results in natural-looking hair. Default=50.0. Range=0.0 to 100.0.

**Top: Hue/Value Variation=0.0**

**Middle: Value Variation=100.0**

**Bottom: Hue Variation=100.0**

**Mutant Color** The color for mutant hairs. Mutant hairs are randomly selected, based on the Mutant % value (see following), and receive this color. One example of mutant hairs are the gray hairs that appear as we age.

**Mutant %** The percentage of hairs that receive the mutant color (see above). You can animate the Mutant % value to produce, for example, a rapidly aging character. Default=0.0. Range=0.0 to 100.0.
Left: Mutant % = 30.0
Right: Mutant % = 0.0
Both: Color = brown, Mutant Color = white

**Specular** The brightness of highlights on the hairs.

**Glossiness** The relative size of highlights on the hairs. Smaller highlights result in glossier-looking hair.

The combined results of the Specular and Glossiness settings appear in a graph to the right of the two parameters.
Left: Specular=0.0, Glossiness=0.0
Center: Specular=100.0, Glossiness=75.0
Right: Specular=100.0, Glossiness=0.1

**Specular Tint** This color tints specular highlights. Click the color swatch to use the Color Selector. Default=white.

**Self Shadow** Controls the amount of self-shadowing; that is, hairs casting shadows on other hairs within the same Hair And Fur modifier. A value of 0.0 disables self shadowing, while a value of 100.0 results in maximum self-shadowing. Default=100.0. Range=0.0 to 100.0.
NOTE You can adjust the shadow characteristics by changing the Hair Light Attr rollout on page 5443 settings for lights that illuminate the hair.

**Geom. Shadow** The amount of shadow contribution hair receives from geometry in the scene. Default=100.0. Range=0.0 to 100.0.

**Geom. Mat. ID** The material ID assigned to geometry-rendered hair on page 7064. Default=1.

### mr Parameters Rollout (Hair And Fur)

Select an object with the Hair And Fur modifier applied. > Modify panel > mr Parameters rollout

Lets you assign a mental ray shader on page 6385 to generate hair. 3ds Max passes the object’s UV coordinate data, including map channels, to the mental
ray shader; strictly speaking, the shader generates hair from this UV and mapping data, not from the object geometry itself. (Multiple map channels are supported.)

When you use a mental ray shader for hair, you must render your scene using the mental ray renderer on page 6675 and set the Hair And Fur render effect on page 7061 method to “mr prim”.

Aside from the “mr prim” option that you can choose as a render effect (see Hair And Fur Render Effect on page 7061), no mental ray hair shaders are provided with 3ds Max. This feature is meant to support third-party hair shader products or custom-coded hair shaders.

NOTE When you assign a mental ray shader, the shader controls supersede other Hair And Fur material settings. On the other hand, if you use this rollout to assign a shader that is not supported, the renderer uses the regular Hair And Fur material settings. (“Geometric” settings such as Hair Count, Hair Segments, and so on, still apply.)

Interface

Apply mr Shader When on, lets you apply a mental ray shader to generate hair.

[shader button] Enabled only when “Apply mr Shader” is on. Click to display a Material/Map Browser on page 5724 and assign the shader.

When no shader is assigned, this button is labeled “None”. When a shader is assigned, the button's label shows the shader's name.

Frizz Parameters Rollout (Hair And Fur)

Select an object with the Hair And Fur modifier applied. > Modify panel > Frizz Parameters rollout

Frizz displacement is accomplished by doing a Perlin noise lookup at the hair's rest position root, and then displacing the hair much the way bump mapping displaces a surface normal. The frequency of the noise function is set by the
Frizz X/Y/Z Frequency parameters. The magnitude of the displacement is controlled with Frizz Root and Frizz Tip. If you set dynamics mode on page 1140 to Live, the viewports show the effects of changing these settings in real time.

1. Frizz Root/Tip=0.0
2. Frizz Root=50.0, Frizz X/Y/Z Freq=14.0
3. Frizz Root=150.0, Frizz X/Y/Z Freq=60.0
4. Frizz Tip=30.0, Frizz X/Y/Z Freq=14.0
5. Frizz Root=50.0, Frizz Tip=100.0, Frizz X/Y/Z Freq=60.0
Frizz actually calculates two noise fields, both of which use the same frequency settings and tip/root amplitudes. One of the noise fields is static relative to the hair. The Anim parameters let you animate the second noise field through the hair over time. This is useful for things like grassy fields, where it would be overkill to compute real dynamics. These parameters give you a similar result, at a small fraction of the computational overhead.

All Frizz/Kink settings=0.0; this reference image provided for comparison with the Frizz and Kink illustrations (below).
**Interface**

**Frizz Root** Controls the displacement of the hair at its root. Default=15.5. Range=0.0 to 360.0.

**Frizz Tip** Controls the displacement of the hair at its tip. Default=130.0. Range=0.0 to 360.0.
Frizz Root=30.0, Frizz Tip=100.0, Frizz X/Y/Z Freq=14.0

Top: Styled
Bottom: Unstyled

Left: Differing values for Frizz Root and Frizz Tip result in curved hairs.
Right: When Frizz Root=Frizz Tip, the hairs are straight.

Chapter 9  Modifiers
**Frizz X/Y/Z Frequency** Controls the frequency of the frizz effect on each of the three axes. Default=14.0. Range=0.0 to 100.0.

Like frizz, Frizz Anim displaces the hair with a noise field. The difference is that you can move the noise field to create animated displacement, resulting in wavy movement without having to resort to dynamics.

**Frizz Anim.** Sets the amplitude of the wavy motion. Default=0.0. Range=–9999.0 to 9999.0.

**Anim. Speed** This multiplier controls the speed at which the animating noise field moves through space. This value is multiplied by the X, Y, and Z components of the Frizz Anim Dir attribute to determine the per-frame offset of the animating noise field. Default=0.0. Range=–9999.0 to 9999.0.

**Frizz X/Y/Z Anim. Dir(ection)** Sets the direction vector of the frizz animation. Default=0.0. Range=–1.0 to 1.0.

This vector is not normalized before use. This means that you can apply small tweaks to the values to achieve fine control over the speed of the animation on a given axis. To reduce confusion it’s a good idea to keep these directions either –1, 0, or 1. Once you’ve got the animation close to what you want, you can diverge from these and adjust the values to achieve the exact result you need.

**Kink Parameters Rollout (Hair And Fur)**

Select an object with the Hair And Fur modifier applied. > Modify panel > Kink Parameters rollout

Kink displacement works similarly to Frizz, but evaluates noise lookups along the whole length of the guide. The result is a noise pattern that works on a larger scale than the Frizz noise. The effect is similar to crimped hair.
1. All settings=0.0 (no kink)
2. Kink Root=0.5 (rest=0.0)
3. Kink Tip=10.0, Kink Root=0.0, Kink X/Y/Z Freq=4.0,
4. Kink Tip=10.0, Kink Root=0.0, Kink X/Y/Z Freq=50.0,
Interface

**Kink Root** Controls the amount of kink displacement of the hair at its root. Default=0.0. Range=0.0 to 100.0

Kink Root=0.5, Kink Tip=0.0, Kink X/Y/Z Freq=4.0

Top: Styled
Bottom: Unstyled
**Kink Tip** Controls the amount of kink displacement of the hair at its tip. Default=0.0. Range=0.0 to 100.0

**Kink X/Y/Z Frequency** Controls the frequency of the kink effect on each of the three axes. Default=0.0. Range=0.0 to 100.0.

---

**Multi Strand Parameters Rollout (Hair And Fur)**

Select an object with the Hair And Fur modifier applied. > Modify panel > Multi Strand Parameters rollout

Some degree of clumping gets naturally created when you use Frizz at low frequencies, but you can go a bit further here with the Multi Strand parameters. For each hair that is normally rendered, Multi Strand renders a clump of additional hairs scattered around the original hair. The Splay settings control the degree of scattering at the roots and tips, and Multi Strand Count controls the number of hairs to create for the clump. You can use Splay to shape the clump by spreading or compressing the roots and tips.
**TIP** For each original hair, Multi Strand creates a cluster of hairs around that hair, offset at the bottom by the Root Splay factor. The hair is offset in the plane tangent to the root of the hair, which is not necessarily the surface of the object. To make sure Multi Strand hairs actually make contact with the surface, make the growth surface a bit smaller than the rendered surface.

1. Multi Strand Count=0, Hair Count=500
2. Multi Strand Count=10, Root Splay=0.1, Tip Splay=0.1, Hair Count=500
3. Multi Strand Count=10, Root Splay=0.4, Tip Splay=0.1, Hair Count=500
4. Multi Strand Count=10, Root Splay=0.0, Tip Splay=1.0, Hair Count=500
Interface

Count | The number of hairs per clump.
Root Splay | Provides a random offset for each hair in a clump, at the root.
Tip Splay | Provides a random offset for each hair in a clump, at the tip.
Randomize | Randomizes the size of each hair in a clump.

Dynamics Rollout (Hair And Fur)

Select an object with the Hair And Fur modifier applied. > Modify panel > Dynamics rollout

For hair to seem natural in an animation, it must respond to the motion of the body it's attached to and to external influences such as wind and gravity. Hair's Dynamics functions let the hair behave like real-world hair, in interactive (Live) or Precomputed mode.

Designating Collision Surfaces

Hair dynamics uses guide hairs to calculate collision. To reduce computation, you have to explicitly designate the objects with which hair will collide. The object from which the hair grows is a special case: to have hair collide with this object (for example, a human head), simply turn on Use Growth Object.

If there is a collision object that you want more than one Hair modifier to interact with, you have to add that object as a collision object for each different Hair And Fur modifier.

There are two different methods for calculating collision: Sphere and Polygon. Spherical collision uses a bounding sphere for collision objects; polygonal collision uses the collision object’s actual geometry. The Polygon option is more accurate, but the Sphere option is quicker to calculate.
Procedures

Example: To view hair dynamics in real time:

1 Apply the Hair And Fur modifier to an object.

2 On the Dynamics rollout (scroll the command panel down to view it), set Mode to Live.

3 Move the object around.
The hair moves realistically.

4 On the Tools rollout, click Regrow Hair.
The hair resumes its default position, growing straight out of the object.

5 Click the Play Animation button.

6 The hair settles and droops, as if affected by gravity. Note that, as the animation repeats, the effects of gravity are cumulative; the hair animation doesn’t restart at the first frame.

7 On the Tools rollout, click Regrow Hair again.

8 Add a Wind space warp to the scene.

9 On the Dynamics rollout, set Dynamics Params > Gravity to 0.0.

10 In the External Forces group (at the bottom of the Dynamics rollout), click Add and then select the Wind space warp.

11 Play the animation again.
This time, the hair isn’t affected by gravity, but simply blown by the wind. Again, the effect is cumulative and the animation doesn’t repeat.

All of this animation takes place only in real time; no keyframes are set, so it can’t be rendered. To learn how to set up a renderable dynamics simulation with Hair, see the following procedure.

To generate a precomputed dynamics simulation with Hair:

1 Apply the Hair And Fur modifier to an object.

2 Set up the animation. It could simply be motion of the growth object, or you could use the Dynamics rollout > External Forces group to add space warps, such as Wind, that should affect the hair. Actually, because
the hair is affected by its own gravity by default, you don’t need to set up any explicit animation at all to see hair dynamics.

3 On the Modify panel > Dynamics rollout, use the Collisions group to set objects the hair should collide with. Also set other simulation parameters in the Dynamics Params group.

4 In the Stat Files group, click the ellipsis (...) button. Use the Save As dialog to specify the location and name of the stat files to be generated.

**NOTE** When you run the simulation, Hair will generate a separate stat file for each animation frame.

**IMPORTANT** If you plan to render the animation with a networked render farm, make sure the path you specify can be seen in exactly the same way from each node on the render farm. If stat files aren’t found, hair will be stiff and just oriented to the skin as it moves. If the wrong stat files are found, hair can float right off an object.

**TIP** If using Windows XP, click the My Network Places button to set a path using the Universal Naming Convention (UNC), even if it’s on a local drive. Such a path can be accessed readily by other computers on the network.

The path and stat file name appear in the text field next to the ellipsis button.

5 In the Simulation group, set the frame range for the simulation and then click Run.

Hair runs the dynamics simulation and generates a stat file for each frame in the animation. It also automatically sets the mode to Precomputed, so when you play or render the animation, it reads the stat files and uses the information for the hair positioning in each frame.

6 Play the animation.

The dynamics simulation stored in the stat files appears in the viewports.

7 In the Mode group, choose None, and then play the animation again.

The dynamics animation no longer appears. However, it’s still stored in the stat files, and will reappear if you choose Precomputed.

8 Make sure Precomputed is on, and then render the animation.
Interface
**Mode group**

Chooses the method Hair uses to generate dynamics. Live mode is suitable for experimentation, but for best results when rendering animation with Hair, use Precomputed mode.

- **None** Hair doesn’t simulate dynamics.
- **Live** Hair simulates dynamics interactively in the viewports, but doesn’t generate animation keyframes or stat files for the dynamics. For best results with Live mode, turn off Display rollout > Display Hairs group > As Geometry.

  For some methods of using live dynamics, see this procedure: Example: To view hair dynamics in real time: on page 1137.

  If you press ESC while using live dynamics, 3ds Max displays a dialog that asks whether you want to stop live dynamics. Both Freeze and Stop reset the mode to None, but Freeze freezes the hair in its current position. You can use this as a starting point for precomputed dynamics, or as a point from which you style the hair.

- **Precomputed** Lets you generate stat files for rendering dynamics-animated hair. Available only after setting a name and location for stat files (see following and To generate a precomputed dynamics simulation with Hair: on page 1137).

**Stat Files group**

Stat files let you record and play back a Hair-generated dynamics simulation. For a workflow example, see this procedure: To generate a precomputed dynamics simulation with Hair: on page 1137.

**Text field** Displays the path and file name for the stat files.

... (ellipsis) button Click to choose a name prefix and location for stat files using the Save As dialog.
Hair adds a four-digit frame number (with leading zeroes) and the file name extension ".stat" to the name you provide (for example, hair_test0001.stat).

Delete all files Deletes stat files from the target directory. The files must have the name prefix you assigned using the ... button.

**TIP** You can still use stat files even if you move them to another location. Follow this procedure:

1. Open the MAX file used to generate the stat files.
2. On the Modify panel > Dynamics rollout, click the ... [ellipsis] button.
3. Use the Save As dialog to navigate to the directory with the stat files, and then click any stat file. Its name appears in the File Name field.
4. Edit the File Name field to delete the four-digit extension after the stat file name. For example, if the stat file name is test0033.stat, delete the "0033" so that it reads test.stat.
5. Click the Save button. The new stat file path appears in the Stat Files field.

Now, when you play or render the animation, Hair uses the stat files as originally generated.

**Simulation group**

Determines the extent of the simulation, and lets you run it. These controls become available only after you choose Precomputed mode and specify stat files in the Stat Files group. Set Start and End to the frames at which to begin and end the simulation, and then click the Run button. 3ds Max then computes the dynamics and saves the stat files.

**Start** The first frame to consider in calculating the simulation.

**End** The final frame to consider in calculating the simulation.

**Run** Click to run the simulation and generate the stat files within the frame range indicated by Start and End.

To abort a simulation while it's running, click Cancel on the status bar.

**Dynamics Params group**

These controls specify the basic parameters for the dynamics simulation. The Stiffness, Root Hold, and Dampen values can be mapped: click the map button
to the right of the spinner to assign a map. Grayscale values in the map multiply the parameter’s value at that hair location.

**Gravity** Lets you specify a force that moves hair vertically in world space. Negative values pull hair up while positive values pull it down. To cause hair not to be affected by gravity, set the value to 0.0. Default=1.0. Range=–999.0 to 999.0.

**Stiffness** Controls the magnitude of the effect of dynamics. If you set Stiffness to 1.0, the dynamics will have no effect. Default=0.4. Range=0.0 to 1.0.

**Root Hold** Comparable to stiffness, but affects the hair only at the roots. Default=1.0. Range=0.0 to 1.0.

**Dampen** Dynamic hair carries velocity forward to the next frame. Increasing dampening increases the amount by which these velocities are diminished. Thus, a higher Dampen value means that hair dynamics will be less active (the hair can also start to get “floaty”). Default=0.0. Range=0.0 to 1.0.

**Collisions group**

Use these settings to determine which objects hair collides with during a dynamic simulation and the method by which collision is calculated.

- **None** Collisions are not considered during the dynamic simulation. This can cause the hair to penetrate its growth object as well as other objects it comes into contact with.

- **Sphere** Hair uses a spherical bounding box to calculate collisions. This method is faster because it requires less computation, but can cause inaccurate results. It’s most effective when the hair is seen from a distance.

- **Polygon** Hair considers each polygon in the collision objects. This is the slowest method, but the most accurate.

**Use Growth Object** When on, hair collides with the growth (mesh) object.

**Objects list** Lists the names of scene objects with which hair should collide.

**Add** To add an object to the list, click Add and then click the object in a viewport.

**Replace** To replace an object, highlight its name in the list, click Replace, then click a different object in a viewport.

**Delete** To remove an object, highlight its name in the list, then click Delete.
**External Forces group**

This group lets you specify space warps on page 2887 that will affect the hair during the dynamics simulation. For example, you can add a Wind space warp on page 2926 to cause the hair to be blown by a breeze.

**NOTE** Hair dynamics already has a built-in gravity force, so it’s not necessary to add one.

**Objects list** Lists the names of forces that dynamically affect the hair.

**Add** To add a space warp to the list, click Add and then click the warp's icon in a viewport.

**Replace** To replace a space warp, highlight its name in the list, click Replace, then click a different warp's icon in a viewport.

**Delete** To remove a space warp, highlight its name in the list, then click Delete.

**Display Rollout (Hair And Fur)**

Select an object with the Hair And Fur modifier applied. > Modify panel > Display rollout

These settings let you control how hairs and guides display in the viewports. By default, Hair displays a small percentage of the hairs as lines. Alternatively, you can display the hairs as geometry, and you can also choose to display the guides.
Interface

Display Guides group

Display Guides toggle When on, Hair displays guides in the viewports, using the color shown in the color swatch. Default=off.

**NOTE** At the Guides sub-object level, guides always appear in the viewports.

Guide Color Click to display the Color Selector and change the color used to display guides.

Guides do not reflect some settings made to the hair, such as Frizz. Use the Guides display mainly to see where hair will appear on the growth object. Hair places one guide at each vertex on the growth surface.

Display Hairs group

Display Hairs toggle When on, Hair displays hairs in the viewports. Default=on.

Override When off, 3ds Max displays hairs using an approximation of their rendered color. When on, displays hairs using the color shown in the color swatch. Default=off.

Color swatch Click to display the Color Selector and change the color used to display hairs when Override is on.

**NOTE** When hair is displayed as geometry (see below), the color setting is ignored.
**Percentage** The percentage of total hairs displayed in the viewports. Lower this value to improve real-time performance in the viewports.

**Max. Hairs** The maximum number of hairs displayed in the viewports, regardless of the Percentage value.

**As Geometry** When on, displays the hairs in the viewports as the actual geometry to be rendered, rather than the default lines. Default=off.

### LS Colors Modifier (World Space)

Select a Lightscape mesh object. > Modify panel > Modifier List > World-Space Modifiers > LS Colors (WSM)

The LS Colors modifier converts Lightscape radiosity values to 3ds Max vertex colors.

When you import a Lightscape model into 3ds Max, the radiosity values are kept as irradiances; that is, they describe the intensity of light falling on a mesh in physical units. This modifier converts the physical units to RGB colors. In conjunction with the Lightscape Mesh modifier on page 1486, this modifier can be used to produce meshes suitable for game engines.

**See also:**

- Lightscape Files (LP, LS, and Other Formats) on page 7756
**Interface**

**Brightness** Controls the brightness of the displayed image on your monitor. The setting of this control does not affect the actual lighting levels in the model. Default=50.0.

**Contrast box** Controls the contrast between light and dark regions in the model. Default=50.0.

**Daylight** Determines whether you want natural daylight to be used in the calculation. Default=on.

**Exterior Scene** Turn on for exterior daylight simulations. Default=off.

**TIP** Use the logarithmic exposure control on page 7215 to control the brightness and contrast of the colors when you render.

**Use exposure control** When on, disregards the settings of Brightness, Contrast, Daylight, and Exterior, and instead uses the settings of the active exposure control. If no exposure control is active in the scene, this toggle is disabled. Default=off.
The three radio buttons that follow choose how to handle irradiance values.

- **Convert light falling on the surface**  When chosen, converts the irradiance values directly to RGB values. In order to properly render the mesh, the vertex colors need to be interpolated and multiplied by the color of the material on the mesh.

- **Convert light reflecting from the surface**  When chosen, takes the irradiance values and multiplies them by the material's ambient color, then converts the result to RGB. To properly render the mesh, you need to interpolate the vertex colors over the faces. If textures are displayed by multiplying them by the vertex colors, they will not be correctly displayed unless the material color is white. By default, this is the active option.

- **Convert light reflecting from the surface, except for textured materials**  When chosen, takes the irradiance values and multiplies them by the material's ambient color, and then converts the result to RGB, unless a texture is applied to the material's ambient component. If the ambient component has a map, this method converts the irradiance value directly to the vertex color. To properly render the mesh, you need to interpolate the vertex colors over the faces, unless the material is textured. If textures are displayed by multiplying them by the vertex colors, they will be correctly displayed.

**Add to colors**  When on, the result of the color conversion is added to existing vertex color values, if there are any. Default=off.

**Use self-illumination**  When on, the material's self illumination is included in the final vertex colors. Default=on.

## MapScaler Modifier (World Space)

Select an object. > Modify panel > Modifier List > World-Space Modifiers > MapScaler (WSM)

Select an object. > Modifiers menu > UV Coordinates > Map Scalar (WSM)

MapScaler maintains the scale of a map applied to an object. This lets you resize the object without altering the scale of the map. Typically, you might use this to maintain the size of a map regardless of how the geometry is scaled.
MapScaler sets the scale of a map on an object.

This differs from the MapScaler (OSM) modifier on page 1487, which maintains the scale of the map with respect to the object size when scaled with a Select And Scale tool. See the latter’s definition for other differences between the two versions.

**NOTE** This world-space modifier is for use primarily with vertically oriented objects, such as walls in an architectural model, or objects with large, flat surfaces. While you can apply the MapScaler to any object, the results are less realistic on curved surfaces, especially complex ones, which can show cracks in the finished texture.
Interface

Scale Represents the size of one repetition of the texture pattern. Size is measured in current system units. Repetitions occur across the object in the U and V directions. Default=1.0.

NOTE When the Use Real-World Texture Coordinates switch is active in the General Preferences dialog, the scale setting defaults to 1.0. If Use Real-World Texture Coordinates is turned off, scale defaults to 100.0.

U/V Offset Specify horizontal and vertical offsets respectively. Available only when Wrap Texture is off.

Wrap Texture When on, Map Scaler attempts to wrap the texture evenly around the object. This option requires more computing, but usually produces the most satisfactory results. Default=on.

Wrap Using Smoothing Groups When turned on, textures are wrapped around corners when they share the same smoothing groups. Curved walls will map smoothly while sharp corners get a new texture origin. This switch is only available when the Wrap Textures switch is turned on. Default=off.

Channel Specifies the map channel on page 8627. Default=1.
Up Direction group

World Z Axis Aligns the map with the Z axis of the world.
If you choose this option and then rotate the object, the mapping is not fixed to the object.

Local Z Axis Aligns the map with the local Z axis of the object.
With this option, the mapping remains fixed to the object.

PatchDeform Modifier (World Space)

Select an object. > Modify panel > Modifier List > World-Space Modifiers > PatchDeform (WSM)

The PatchDeform world-space modifier lets you deform an object based on the contours of a patch object. It works the same as the PathDeform (World Space) on page 1150, but uses a patch instead of a curve. With the exception of the Move to Patch button, its parameters are the same as those in the object-space PatchDeform modifier on page 1567.

PathDeform Modifier (World Space)

Select an object. > Modify panel > Modifier List > Animation Modifiers > PathDeform (WSM)

The PathDeform world-space modifier deforms an object based on a shape, spline or NURBS curve path. With the exceptions noted in the Interface section, this world-space modifier works the same as the object-space PathDeform modifier on page 1569.

Procedures

The first two examples, below, demonstrate the basic differences in orientation and the relationship between the object and its path when using the PathDeform modifier and the PathDeform (WSM) modifier.
Example: To use the PathDeform modifier to curve text:

1 In the Top viewport, create a circle that's 100 units in radius.

2 In the Front viewport, create a text shape with six or seven letters, and a size of 25.

3 Apply an Extrude modifier to the text shape, and set the Amount to -5.0.

4 On the Main toolbar, set the Reference Coordinate System to Local.
Looking at the axis tripod for the extruded text object, you can see that its Z axis runs from back to front relative to world space.

5 Apply a PathDeform on page 1569 object-space modifier to the text object.
Click the Pick Path button, and then select the circle.
A circular gizmo appears. The circle runs through the local Z axis of the text object. Because of its orientation, its effect is minimal, but you can see a slight wedge-shaped deformation from the top view.

6 In the Path Deform Axis group, choose the Y option, and then the X option.
The circle gizmo rotates to run through the specified axes, deforming the text object differently with each change.

7 Adjust the Percent spinner to view its effect, and then set it to zero. Try the same with Stretch, Rotation, and Twist, and then restore them to their original values.

TIP Use the Ctrl key with Twist to amplify the effect.

8 Turn on Flip to switch the direction of the path, and then turn it off.

9 Go to the Gizmo sub-object level, and move the gizmo path around.
The text object is further deformed by its relative position to the gizmo.
10 Select the original circle shape, and change its radius.
   The deformation of the text object alters because its gizmo is an instance of the shape object.

Example: To use the PathDeform world space modifier:

This procedure continues from the previous one.

1 Select the text object, and then remove the Path Deform modifier from the stack.
2 Apply a Path Deform (WSM) modifier.
3 Click Pick Path, and select the circle.
   The text object flips around and moves in world space. Note that its orientation and deformation are difficult to analyze because there's an offset distance between the path and the object.
4 Click Move to Path.
   The text object is transformed so that its local Z axis is aligned with the path and its position is at the first vertex of the path.
   In the following steps, you'll use various controls to re-orient the text object so that it's at the front of the circle and readable from the Front viewport.
5 Choose the X option in the Path Deform Axis group to place the length of the text object along the path.
6 Adjust the Percent spinner to –25 to move the text to the front of the circle.
7 Adjust the Rotation spinner to –90 to rotate the text so it faces the Front viewport.
8 Turn on Auto Key, go to frame 100, and set Percent to –125.
9 Play the animation to watch the text run around the circle.
Example: To create a growing vine:

1. Use the Line tool and, optionally, Editable Spline to create a path along which the vine will grow.

2. Create a Cone, and apply the Path Deform (WSM) modifier.
3 Pick the path, and then click Move to Path. (The local Z axis of the cone should be along the path.)

Go to frame 100, and turn on Auto Key.

Increase the Stretch value to stretch the cone along the path until it reaches the end. There won't be enough height segments in the cone, but you can fix that in step 7.

Turn off Auto Key.

In the stack, click Cone, and then in the Parameters rollout increase the Height Segments setting until the stretched cone is smooth on the path.

Play the animation.

The cone grows along the path, like a vine.

Interface

Because this is a world-space rather than an object-space modifier, the object is affected in world-space coordinates, and also by the position of the path relative to the object. Thus, if you transform the object relative to the path, or vice-versa, it has an effect on the deformation.

Generally speaking, the Path Deform world-space modifier leaves the path in place while moving the object to the path, while the Path Deform object-space modifier leaves the object in place while moving the path to the object.
For all parameters except the following, refer to the PathDeform modifier on page 1569.

**Path Deform group**

**Move to Path** Moves the object from its original position to the start of the path.

When you first pick a path, the object is deformed by the path based on the offset distance between the first vertex in the path and the object's location. Thus, as you adjust the Percent spinner, for example, the result will be distorted depending on the offset distance.

**IMPORTANT** Using the Move To Path button applies a transform to the object that's not removed if you later remove the Path Deform binding from the object. However, you can undo on page 240 the transform immediately after it's been performed.

**NOTE** If the Auto Key button is on when you perform Move To Path, transform keys are created.
Point Cache Modifier (World Space)

Select an object. > Modify panel > Modifiers List > World-Space Modifiers > Point Cache (WSM)

The world-space version of the Point Cache modifier works exactly the same as the Point Cache modifier on page 1574, except that it uses world-space coordinates instead of local-space coordinates. Use this version when animating with world-space modifiers such as PatchDeform (WSM) modifier on page 1150 or PathDeform (WSM) modifier on page 1150.

Subdivide Modifier (World Space)

Make a selection. > Modify panel > Modifier List > World-Space Modifiers > Subdivide (WSM)

Make a selection. > Modifiers menu > Radiosity Modifiers > Subdivide (WSM)

The Subdivide (WSM) modifier is similar to the object-space Subdivide modifier on page 1756, and has the same parameters. In the world-space version of Subdivide, the size limit is on the mesh after it is transformed into world space coordinates.

Surface Mapper Modifier (World Space)

Make a selection. > Modify panel > Modifier List > World-Space Modifiers > Surface Mapper (WSM)

The Surface Mapper (WSM) modifier takes a map assigned to a NURBS on page 2416 surface and projects it onto the modified object or objects. Surface Mapper is especially useful for seamlessly applying a single map to a group of surface sub-objects within the same NURBS model. You can also use it for other kinds of geometry.

The NURBS surface's map is projected onto the other geometry in the direction of the NURBS surface's normals, or opposite the normals if the modified object is on the other side of the NURBS surface.
Procedures

To use the surface mapper world-space modifier:

1. Create the NURBS surface to use for projection, and transform it so it wraps the objects you want to map.

2. Use the Material Editor on page 5641 to assign a mapped material to the NURBS surface.

3. Select the objects you want to map.

4. Use the Material Editor to assign the same material to the objects you want to map.

5. Apply the Surface Mapper world-space modifier.

6. In the Parameters rollout, turn on Pick NURBS Surface, and then click the NURBS projection surface in a viewport. 3ds Max now uses the NURBS surface's normals to project the texture onto the modified objects.

TIP To fine-tune the map placement on the mesh, you can use the NURBS surface's Edit Texture Surface dialog on page 2719.
Source Texture Surface group

These controls let you choose the NURBS surface to project.

Pick NURBS Surface Picks the NURBS surface to use for projection. Click to turn on this button, then click the NURBS surface in an active viewport.

Surface Shows "<none>" before you pick a NURBS surface; shows the name of the surface after you pick one.

Map Channels group

These controls let you choose which map channels on page 8627 to use.

Input Channel Selects the NURBS surface map channel to use before projection.

Output Channel Selects the modified object’s map channel to use after projection.
**Update Options group**

These controls let you choose how to update the mapping displayed in viewports. They have no effect if Show Map In Viewport on page 5696 is turned off.

*Always* Updates viewports whenever the mapping changes.

*Manually* Updates viewports only when you click Update.

*Update* Updates viewports. This is unavailable unless you've chosen Manually.

**SurfDeform Modifier (World Space)**

Select an object. > Modify panel > Modifier List > World-Space Modifiers > Surf Deform (WSM)

Select an object. > Modifiers menu > Animation Modifiers > Surf Deform (WSM)

The SurfDeform (WSM) modifier works the same as the PathDeform (WSM) modifier on page 1150, except that it uses a NURBS Point or CV surface instead of a curve.

**Object-Space Modifiers**

Object-space modifiers directly affect an object's geometry in local space on page 8621.

When you apply an object-space modifier, it appears directly above the object with other object-space modifiers in the modifier stack on page 8187. The order in which the modifiers appear in the stack can affect the resulting geometry.

**Affect Region Modifier**

Modify panel > Make a vertex sub-object selection. > Modifier List > Object-Space Modifiers > Affect Region

Make a vertex sub-object selection. > Modifiers menu > Parametric Deformers > Affect Region

The Affect Region modifier is a surface modeling tool, primarily used with vertex sub-object selections while surface modeling. With Affect Region,
transforming a selection of vertices can also transform vertices in the region that surrounds the selection. This can help you form a bubble or indentation in the surface of an object. The easiest way to see this modifier’s effect is with a shallow, flat box object with plenty of subdivisions. The Affect Region modifier has a two-part, arrow-shaped gizmo, plus numeric controls.

When you apply the Affect Region modifier, it assigns an arrow-like gizmo consisting of two points connected by a line. The base of the arrow is the start point. The length and direction of the arrow defines the amount of movement of the vertices. Any vertices within Falloff distance of the base of the arrow are translated in the direction of the arrow.

Because no points on the mesh are directly selected, this modifier doesn’t depend on the topology of the input object. You can apply it to any renderable object. However, you can limit the effect by using a selection modifier like Mesh Select on page 1500 or Volume Select on page 1992 to pass a sub-object selection up the stack.

**NOTE** The Affect Region modifier is ideal for simple animated effects, especially when you need to use interactive parameters. However, for fine-tuned modeling, you’ll probably prefer the expanded capabilities of Soft Selection on page 2014 in Editable Mesh on page 2192, Editable Poly on page 2240, Edit Mesh on page 1321, Mesh Select on page 1500, Volume Select on page 1992, the HSDS modifier on page 1464, and NURBS on page 2436.
Affect Region modifier applied

Procedures

Example: To form a bubble over the surface of a plane:

1. Create a plane with 15 width and length segments.
2. Set the length and width of the plane to 50 units.
3. Apply the Affect Region modifier.
4. In the Parameters group, set Falloff to 50.
5. Adjust the parameters to achieve different effects.

Interface

NOTE The parameters of this modifier are similar to those of the Soft Selection function on page 2014 of an Editable Mesh.
**Modifier Stack**

![Modifier Stack Image]

**Point sub-object level** At this sub-object level, the base and tip of the gizmo arrow are points that can be selected. You can select, translate, and animate these two points together or individually.

For more information on the stack display, see *Modifier Stack* on page 8187.

**Parameters rollout**

![Parameters Rollout Image]

**Parameters group**

**Falloff** Sets the radius of affected vertices, in units, from the base of the gizmo arrow. (Spinner value range: float, 0.0 to 999,999.0)

**Ignore Back Facing** Affects only those vertices whose face normals are in the same general direction as the gizmo arrow. When turned off, all vertices in the Falloff group are affected.
Curve group

Pinch  Affects the tangency of the curve where it meets the arrow tip. Positive values produce a pointed tip while negative values produce a dimple. (Spinner value range: float, -999,999.0 to 999,999.0)

Bubble  Changes the curvature of the affected vertices. A value of 1.0 produces a half-dome. As you reduce this value, the sides of the dome slope more steeply. Negative values lower the base of the curve below the base of the arrow gizmo. (Spinner value range: float, -999,999.0 to 999,999.0)

Attribute Holder Modifier

Create or select an object. > Modify panel > Modifier List > Object-Space Modifiers > Attribute Holder

Create or select an object > Modifiers menu > Animation > Attribute Holder

The Attribute Holder modifier is an empty modifier that provides a readily accessible user interface on the Modify panel to which you can add custom attributes on page 307. It has no user interface of its own; the interface consists solely of those attributes you assign to it. In essence, Attribute Holder is a stripped-down version of Parameter Collector on page 325 that can collect only custom attributes and appears on the Modify panel instead of a floating dialog.

Procedures

Example: To collect different custom attributes in an Attribute Holder modifier:

Before undertaking this procedure, you should be familiar with basic usage of the Parameter Wiring dialog on page 3612.

1  Add a small box to an empty scene. Make it about 20.0 units on a side.

2  Apply a Taper modifier and an Attribute Holder modifier, in that order. In the modifier stack, the Attribute Holder modifier should be highlighted.

3  From the Animation menu, choose Parameter Editor.
In Parameter Editor, on the Attribute Rollout, make or ensure the following settings:

■ Add to Type=Selected Object's Current Modifier
■ Parameter Type=Float
■ UI Type=Slider
■ Name=Box Height

On the Float UI Options rollout, keep all the default settings.

On the Attribute Rollout, click Add.
The Custom Attributes rollout appears on the Modify panel, containing the new Box Height slider.

Add another attribute:

■ Add to Type=Selected Object's Current Modifier
■ Parameter Type=Integer
■ UI Type=Spinner
■ Name=Box Height Segs
■ Integer UI Options > Range=From 1 to 50.

Add two more Float/Spinner attributes named Taper Amount and Taper Curve.
The Attribute Holder modifier now has four custom attributes, but they don't do anything because they're not connected. You'll use Parameter Wiring to hook them up.

Close the Parameter Editor dialog.

In the active viewport, right-click the box and choose Wire Parameters.
From the pop-up menu that appears, choose Modified Object > Box (Object) > Height.
A rubber-band dashed line appears connecting the mouse cursor to the box.

You can't connect this “wire” directly to the custom attribute, so just left-click in an empty part of the viewport to open the Parameter Wiring dialog.
The hierarchy list on the left side, Box01, is expanded to the box's Height parameter, which is highlighted.
On the right side, expand this path: Object > Box01 > Modified Object > Attribute Holder > Custom Attributes, and then click Box Height to highlight it.

Click the Two-way Connection button (double-headed arrow), and then click Connect.

Similarly, connect Height Segments on the left side to Box Height Segments on the right.

Close the Parameter Wiring dialog.

Right-click the box again, choose Parameter Wiring, choose Modified Object > Taper > Amount, and then left-click to open the Parameter Wiring dialog.

The Amount parameter is highlighted on the left side of the dialog.

On the right side, click the Attribute Holder's Taper Amount parameter, and then connect them.

Connect Curvature on the left side to Taper Curve on the right side, and then close the dialog.

All the parameters are now hooked up.

Experiment with changing the values on the Custom Attributes rollout.

The Attribute Holder modifier lets you change the box's creation parameters as well as the Taper modifier's settings without switching back and forth in the modifier stack. In this way you can access, in one convenient location, as many different parameters from different levels in an object's modifier stack, or even from different objects, as you like.

You might notice that you can't set the taper to curve inward. You can resolve this by reopening Parameter Editor, clicking Edit/Delete, and then modifying the Taper Curve attribute to allow negative values. The change takes effect immediately, with no rewiring required.

### Bend Modifier

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Bend

Make a selection. > Modifiers menu > Parametric Deformers > Bend

The Bend modifier lets you bend the current selection up to 360 degrees about a single axis, producing a uniform bend in an object's geometry. You can
control the angle and direction of the bend on any of three axes. You can also limit the bend to a section of the geometry.

Bend applied to a streetlight model

**Procedures**

**To bend an object:**

1. Select an object and apply the Bend modifier.

2. On the Parameters rollout, set the axis of the bend to X, Y, or Z. This is the axis of the Bend gizmo, not the axis of the selected object. You can switch between axes at any time, but the modifier carries only one axis setting.

3. Set the angle of the bend along the chosen axis. The object bends to this angle.

4. Set the direction of the bend. The object swivels around the axis.
You can reverse angle and direction by changing a positive value to a negative value.

To limit the bend:

1. Turn on Limit Effect in the Limits group.
2. Set values for the upper and lower limits. These are distances in current units above and below the modifier's center, which is at zero on the gizmo's Z axis by default. You can make the upper limit zero or positive, and the lower limit zero or negative. If the limits are equal, the result is the same as turning off Limit Effect.
   The bend is applied between these limits. The surrounding geometry, while unaffected by the bend itself, rotates to keep the object intact. This is analogous to bending a pipe, where the unbent sections rotate but remain straight.
3. At the sub-object level, you can select and move the modifier's center.

The Limit settings remain on either side of the center as you move it. This lets you relocate the bend area to another part of the object.

Interface

Modifier Stack

Gizmo sub-object You can transform and animate the gizmo like any other object at this sub-object level, altering the effect of the Bend modifier. Translating the gizmo translates its center an equal distance. Rotating and scaling the gizmo takes place with respect to its center.

Center sub-object You can translate and animate the center at this sub-object level, altering the Bend gizmo's shape, and thus the shape of the bent object. For more information on the stack display, see Modifier Stack on page 8187.
Parameters rollout

**Bend group**

*Angle* Sets the angle to bend from the vertical plane. Range=-999,999.0 to 999,999.0.

*Direction* Sets the direction of the bend relative to the horizontal plane. Range=-999,999.0 to 999,999.0.

**Bend Axis group**

*X/Y/Z* Specifies the axis to be bent. Note that this axis is local to the Bend gizmo and not related to the selected entity. Default=Z.

**Limits group**

*Limit Effect* Applies limit constraints to the bend effect. Default=off.

*Upper Limit* Sets the upper boundary in world units from the bend center point beyond which the bend no longer affects geometry. Default=0. Range=0 to 999,999.0.

*Lower Limit* Sets the lower boundary in world units from the bend center point beyond which the bend no longer affects geometry. Default=0. Range=-999,999.0 to 0.
Bevel Modifier

Select a shape. > Modify panel > Modifier List > Bevel

The Bevel modifier extrudes shapes into 3D objects and applies a flat or round bevel to the edges. A common use for this modifier is to create 3D text and logos, but you can apply it to any shape.

Bevel takes a shape as the base of a 3D object. You then extrude the shape up to four levels and assign an outline amount for each level.

Beveled text

Procedures

Example: To create beveled text:

This example produces typical 3D beveled text, with equal bevels in front and back.

1 Create text on page 600 using default settings.
   Font=Arial, Size=100.0.
2 Apply the Bevel modifier.
3 Type -1.0 in the Start Outline field.
4 For Level 1, do the following:
   ■ Type 5.0 for Height.
   ■ Type 2.0 for Outline.
5 Turn on Level 2, and do the following:
   ■ Type 5.0 for Height.
   ■ Type 0.0 for Outline.
6 Turn on Level 3 and do the following:
   ■ Type 5.0 for Height.
   ■ Type -2.0 for Outline.
7 If needed, turn on Keep Lines From Crossing.
Interface

Parameters rollout

- Capping
  - Start
  - End

- Cap Type
  - Morph
  - Grid

- Surface
  - Linear Sides
  - Curved Sides
  - Segments: [1]
  - Smooth Across Levels
  - Generate Mapping Coords.
  - Real-World Map Size

- Intersections
  - Keep Lines From Crossing
  - Separation: [1.0]

- Bevel Values
  - Start Outline: [0.0]
  - Level 1:
    - Height: [0.0]
    - Outline: [0.0]
  - Level 2:
    - Height: [0.0]
    - Outline: [0.0]
  - Level 3:
    - Height: [0.0]
    - Outline: [0.0]
Capping group

You can determine whether or not the beveled object is capped at either end with the check boxes in the Capping group.

**Start** Caps the end with the lowest local Z value (bottom) of the object. When turned off, the bottom is open.

**End** Caps the end with the highest local Z value (top) of the object. When turned off, the end is left open.

Cap Type group

Two radio buttons set the type of cap used.

**Morph** Creates cap faces suitable for morphing.

**Grid** Creates cap faces in a grid pattern. This cap type deforms and renders better than morph capping.

Surface group

Controls the side curvature, smoothing, and mapping of the surface.

The first two radio buttons set the interpolation method used between levels; a numeric field sets the number of segments to interpolate.

**Linear Sides** When active, segment interpolation between levels follows a straight line.

**Curved Sides** When active, segment interpolation between levels follows a Bezier curve. For visible curvature, use multiple segments with Curved Sides.

**Segments** Sets the number of intermediate segments between each level.

![Four-level bevels with 1 and 2 segments](image)
Bevels with linear and curved sides

Rounding and smoothing the bevel object sides

**Smooth Across Levels** Controls whether smoothing groups are applied to the sides of a beveled object. Caps always use a different smoothing group than the sides.

- When turned on, smoothing groups are applied to the sides. The sides appear rounded.
- When turned off, smoothing groups are not applied. The sides appear as flat bevels.

**Generate Mapping Coordinates** When turned on, mapping coordinates are applied to the beveled object.
**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material’s Coordinates rollout on page 6201. Default=on.

**Intersections group**

Prevents sharp corners from overlapping neighboring edges.

Bevel works best with rounded shapes or shapes with corners greater than 90 degrees. Acute angles (less than 90 degrees) produce extreme bevels and often overlap nearby edges.

**Keep Lines From Crossing** Prevents outlines from crossing over themselves. This is accomplished by inserting extra vertices in the outline and replacing sharp corners with a flat line segment.

- **Using Keep Lines From Crossing:**
  - Left: Off
  - Right: On
**Separation** Sets the distance to be maintained between edges. The minimum value is 0.01.

---

**Changing the Separation value**

**Bevel Values rollout**

Contains the parameters that set the height and bevel amount of up to four levels.

A beveled object requires a minimum of two levels: a start and an end. You add more levels to vary the amount and direction of bevel from start to end.

You can think of bevel levels as layers on a cake. The Start Outline is the bottom of the cake and the Level 1 parameters define the height and size of the first layer.

Turning on Level 2 or Level 3 adds another layer to the beveled object with the height and outline specifying the amount of change from the previous level.

The last level on is always the top of the object.

You must always set the Level 1 parameters.
**Start Outline** Sets the distance the outline is offset from the original shape. A non-zero setting changes the original shape's size.

- Positive values make the outline larger.
- Negative values make the outline smaller.

**Level 1** Includes two parameters that indicate the change from the Start level.

**Height** Sets the distance of Level 1 above the Start level.

**Outline** Sets the distance to offset the Level 1 outline from the Start Outline. Levels 2 and Level 3 are optional and allow you to change the bevel amount and direction.

**Level 2** Adds a level after Level 1.

**Height** Sets the distance above Level 1.

**Outline** Sets the offset distance of the Level 2 outline from Level 1.

**Level 3** Adds a level after the previous level. If Level 2 is not on, Level 3 is added after Level 1.

**Height** Sets the distance above the previous level.

**Outline** Sets the offset distance of Level 3 from the previous level.

Traditional beveled text uses all levels with these typical conditions:

- Start Outline can be any value, usually 0.0.
- Level 1 Outline is a positive value.
- Level 2 Outline is 0.0. No change from Level 1.
- Level 3 Outline is the negative of Level 1. Returns Level 3 to the same size as the Start Outline.

---

**Bevel Profile Modifier**

Select a shape. > Modify panel > Modifier List > Bevel Profile

The Bevel Profile modifier extrudes a shape using another shape path as the "beveling profile." It's a variation on the **Bevel modifier** on page 1169.

**IMPORTANT** Bevel Profile fails if you delete the original beveling profile. Unlike a loft object, which incorporates the shape, Bevel Profile is simply a modifier.
**NOTE** Although this modifier might seem similar to a loft object with varying scale settings, it’s actually different because it uses different outline values as distances between line segments rather than as scale values. This more complex method of resizing a shape results in some levels having either more or less vertices than others, and generally works better with text, for example.

Bevel Profile creates an object using an open spline.
Bevel Profile creates an object using a closed spline, yielding a different result.

**Procedures**

**To use the Bevel Profile modifier:**

1. Create the shape you want to bevel (preferably in the Top viewport).
2. In the Front (XZ) viewport, create a shape to use as the beveling profile.
3. Select the first shape and apply the Bevel Profile modifier.
4. Click the Pick Profile button in the Bevel Profile modifier, and then click the profile shape.
Interface

Modifier Stack

For more information on the stack display, see Modifier Stack on page 8187.

Parameters rollout

Bevel Profile group

Pick Profile Selects a shape or NURBS curve to be used for the profile path.

Generate Mapping Coords Assigns UV coordinates.

Real-World Map Size Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=on.
Capping group

Start Caps the bottom of the extruded shape.
End Caps the top of the extruded shape.

Cap Type group

Morph Selects a deterministic method of capping that provides the same number of vertices for morphing between objects.
Grid Creates gridded caps that are better for cap deformations.

Intersections group

Keep Lines From Crossing Prevents beveled surfaces from self intersecting. This requires more processor calculation and can be time-consuming in complex geometry.
Separation Sets the distance that sides should be kept apart to prevent intersections.

Camera Map Modifier (Object Space)

Select one object. > Modify panel > Modifier List > Object-Space Modifiers > Camera Map
Select one object. > Modifiers menu > UV Coordinates > Camera Map
The Camera Map modifier (object-space version) assigns planar mapping coordinates based on the current frame and the camera specified in the Camera Map modifier. This differs from the Camera Map (WSM) modifier on page 1067 that updates the object’s mapping coordinates on every frame.
Left: The texture of an object with a camera map modifier matches the background when seen by the camera the modifier uses.

Right: When seen by a camera not used by camera map, the object’s texture is based on object geometry.

**Blending an Object into the Background**

In the Procedures section (below), you’ll be blending an object into the background using the Camera Map modifier. If the background uses the same image as the object’s texture map, then the object blends with the background at the frame where the modifier is applied and a camera is specified. The object becomes visible if either the camera or object moves. In order to make the illusion work, you must assign the same map to the background that you assign to the object.

**Mapping Coordinates**

Because the accuracy of mapped objects depends partly on the complexity of the mesh, the “blend to background” effect works best when applied to an object with a relatively high density of triangular faces. The necessary density also depends on the distance of the object from the camera.
A simple box might look fine when it occupies only a small portion of the background, but up close the mapping will look distorted without adequate tessellation. Some experimentation is required to get an ideal mapping and still minimize the complexity of the geometry. (In general, for a box object that’s filling a quarter of the screen, a tessellation of 4x4x4 works well.)

**NOTE** When using the Camera Map modifier, apply the modifier to a single object at a time. If it’s applied to a selection set, only the first item in the selection will be mapped properly.

Use Camera Map (WSM) on page 1067 if you want to move the camera and maintain the match to the background.

**Using the Plate Match/MAX R2.5 Rendering Filter**

Prior to 3ds Max 3, the antialiasing affected only geometric edges, with the filtering of bitmaps being controlled in the Bitmap Map parameters (pyramidal, summed area, or no filtering). Antialiasing filters affect every aspect of the object, filtering textures along with geometric edges. While antialiasing provides superior results, it produces inconsistencies when rendering objects that are supposed to match the environment background. This is because the antialiasing filters do not affect the background by default. You can turn on background antialiasing in Customize > Preferences > Rendering > Background Antialiasing > Filter Background. To correctly match an object’s map to an unfiltered background image, you need to use the Plate Match/MAX R2.5 filter so the texture is not affected by the antialiasing.

There are three ways you can render objects in 3ds Max to blend seamlessly into a background environment:

- By assigning a Matte/Shadow Material
- By assigning a 100% self-illuminated diffuse texture to an object using Camera Mapping
- By assigning a 100% self-illuminated diffuse texture using Environment/Screen projection

The Plate Match/MAX R2.5 antialiasing should be used whenever trying to match foreground objects with an unfiltered background or when trying to match the antialiasing qualities of the 3ds Max 2.5 renderer.
Procedures

The following steps show how to apply the Camera Map modifier, and how to set up your scene.

To apply the Camera Map modifier:

1. Create a scene with a camera and one or more objects. Make sure the object you want to map is visible in the Camera viewport.

2. Select the object, and apply the Camera Map modifier. Be sure to use the Object-Space version of the Camera Map modifier.

3. If you have animation in the scene, move to the frame where you want the object map to match the background. For example, if the camera is animated, the mapping will match only at this frame.

4. On the Camera Mapping rollout, click Pick Camera, and then select the camera used for the rendered view.

To assign a background image to the Camera viewport:

NOTE This procedure is not necessary for successful rendering, but if you want to see the effect in a viewport, follow these steps.

1. Activate the Camera viewport and turn off the grid.

2. Choose Views menu > Viewport Background.

3. On the Viewport Background dialog that displays, click the Files button, and choose the same bitmap that you plan to apply as a background for the rendered scene, and as a diffuse map on the object.

4. In the Aspect Ratio group, choose Match Rendering Output.

5. Turn on Display Background, and click OK. The dialog is dismissed and the map is displayed in the viewport.

To assign a mapped material to the object:

1. In the Material Editor, create a standard material to whose Diffuse component you've assigned the same bitmap as you assigned to the background.

2. At the Diffuse Map level of the material, turn on the Show Map In Viewport button.
3 Select the object, and click Assign Material To Selection.
The map on the object in the viewport matches the viewport background,
but the shading makes the object visible. To make the object truly
invisible, go to the next step.

4 At the top level of the object’s material, set Specular Level and Glossiness
to 0. Turn off Self Illumination Color, and set Self Illumination to 100.
The object is now camouflaged against the background.

To assign the background to the rendered background:
1 Choose Rendering menu > Environment.

2 In the Environment dialog that displays, click the button below
"Environment Map" to open the Material/Map Browser.

3 Under the Browse From group box, choose Material Editor.

4 Turn off Root Only, find the map in the list window, highlight it, and
choose OK.

5 Choose Copy in the dialog, and click OK.

6 In the Exposure Control rollout on the Environment dialog, make sure
the exposure is set to <no exposure control> or the turn off the Active
switch.
   If this is not done, you will be able to see the object in the rendering.

7 Render the Camera viewport.
The mapped object is camouflaged against the background in the rendered
scene.
Interface

Pick Camera To apply the UVW coordinates, click this button, and then select the camera through which you're going to view the scene.

Map Channel Turn on and choose a map channel to use. Map channels are specified in the Material Editor.

Vertex Color Channel Uses the Vertex Color channel.

Cap Holes Modifier

Select a mesh object. > Modify panel > Modifier List > Cap Holes
Select a mesh object. > Modifiers menu > Mesh Editing > Cap Holes

The Cap Holes modifier builds faces in the holes in a mesh object. A hole is defined as a loop of edges, each of which has only one face. For example, one or more missing faces from a sphere would produce one or more holes. The modifier works best on reconstructing planar holes, but can do a reasonable job on non-planar holes as well.
Cap Holes used to make the cake appear solid

**NOTE** This modifier can cap holes in a sub-object selection passed up the stack. It caps any part of the hole that’s adjacent to, or within the selected geometry, whether vertex, edge, or face.

**Tips**

- If the Cap Holes modifier doesn’t appear to work, remove it, apply a Mesh Select modifier on page 1500 to select the faces surrounding the hole, then apply Cap Holes to the sub-object selection.

- The Cap Holes modifier creates faces with invisible edges unless you turn on All New Edges Visible before you apply it.

**Procedures**

Example: To cap a hole in a sphere:

1. Create a sphere.
2. Apply an Edit Mesh modifier to the sphere.
3. In the stack display, choose the Face selection level.
4. Select and delete a contiguous group of faces.
5. Turn off the Face selection level.
6. Apply a Cap Holes modifier.
The hole you created should be filled.

**TIP** Turning on Smooth With Old Faces makes the cap less visible.

### Interface

![Parameters Interface](image)

**Smooth New Faces** Assigns the same smoothing group number to all new faces. If possible, this will be a smoothing group number not used elsewhere in the object.

**Smooth With Old Faces** Smooths new triangular faces using the smoothing groups from bordering old faces. This smooths only one level in from the perimeter of the border of the hole, so you might need to use both this and the Smooth New Faces option to properly smooth a large hole.

**NOTE** When Smooth With Old Faces is turned on, the faces in the capped holes inherit a material face ID from one of the surrounding faces. When this item is turned off, the faces in the capped holes are assigned a new ID.

**Triangulate Cap** Makes all of the edges visible in the new faces.

### Cloth and Garment Maker Modifiers

Cloth provides you with advanced tools for creating realistic fabrics and tailor-made clothing for characters and creatures.
The Cloth system comprises two modifiers:

- The **Cloth modifier** on page 1204 is responsible for simulating the motion of cloth as it interacts with the environment, which may include collision objects (a character or a table, for example) and external forces, such as gravity and wind.

- The **Garment Maker modifier** on page 1266 is a specialized tool for creating 3D garments from 2D splines, similarly to the way real clothes are made, by stitching together flat pieces of cloth.

You can model clothing in two ways: by creating the cloth objects with standard 3ds Max modeling methods and applying the Cloth modifier to them, or by designing virtual clothing patterns with splines and stitching together these various virtual panels to form a full garment using the Garment Maker modifier. With Garment Maker, you can even import spline patterns from external applications and use these as your pattern panels.
Cloth and Garment Overview

Cloth is an advanced cloth-simulation engine that lets you create realistic garments for your characters and other creations. Cloth is designed to work in concert with the modeling tools in 3ds Max and can turn just about any 3D object into clothing; it also allows you to build garments from scratch.

Before you begin working with Cloth, we recommend that you read this overview. It provides background information on cloth-simulation technology, so you can begin to grasp exactly the way Cloth works. It will give you a better overall understanding of how to set up Cloth scenes, the way the cloth behaves, and the array of advanced controls you will have at your disposal.

As an artist and creator, you can use this knowledge to tailor (no pun intended) how Cloth will affect and interact with your scenes, and how you can best take advantage of this software.

Cloth-Simulation Technology

Cloth simulation is the process of replicating the movement and deformation of a piece of fabric or clothing to mimic how cloth would react in the real world. To make cloth simulation work, first you need a cloth object, such as a tablecloth or a pair of pants. Next, you need something for the fabric to interact with. This can be a collision object such as a table top or character's leg, or a force such as wind or gravity.

Limitations

While Cloth is designed to help you create clothing for your models, you should be aware that, by its very nature, cloth simulation is only an approximation of how real fabric would react under certain circumstances; this system does have some limitations.

One of the most important aspects of working with Cloth is the amount of time it can take to create a simulation. If you're looking to create a fully physically correct simulation, you might run into problems. Even with a fast computer, cloth dynamics at that level of accuracy (and geometric detail) could take virtually forever. So you must learn to scale your simulations back to a reasonable level. This doesn't mean you can't get believable clothing; it simply means that there are tradeoffs you should be willing to make.
Tradeoffs

In order to create a believable simulation, you need to balance time against quality and accuracy. The more time you have, the more accuracy and quality your simulation can have. There's no reason to make a model with 10,000 polygons if you can define the form equally well with 3,000. The same rule applies to cloth simulations.

Internal and External Forces

When simulating cloth, different forces come into play. Some internal forces like bend, stretch, and shear allow the fabric to deform in a realistic manner. External forces such as gravity, wind, and collisions make the cloth interact with its environment. To obtain a good-looking simulation, most or all of these things need to come into play. Without these forces, a piece of cloth will remain a flat, lifeless plane.

Collision Detection

When putting a shirt or pair of pants on a character, you don't want any part of the body to protrude through the fabric. The desired result is to have the garment deform around the mesh (rather than through it) so there are no intersections. This is done with collision detection; with Cloth, you tell the simulation system which objects will act as cloth, and which ones will act as collision objects.

Basically, virtual feelers are sent out from the vertices of the cloth objects to see if there are any other objects that they might collide with. When one of the feelers hits something, the simulation knows that it must deform the fabric. It is important to remember that a cloth mesh with more vertices has more feelers and can do a better job of collision detection. This is critical, because if you are working with a high-poly character (collision object), you will need to increase the density of your cloth, or the high-poly mesh will protrude through the lower-poly cloth object. The reason is that there aren't enough feelers to detect all of the detail in the collision object.

The alternative to this is to add one or more low-polygon proxy meshes for the character so there doesn't need to be such high density cloth objects that will slow down simulation. We'll cover the mesh density a bit more in the next section.

Lastly, if you are simulating with fast-moving cloth objects, you might need to increase the Density value to give you the benefit of more feelers. You also might adjust the Step size to check more often for collision objects in the way.
Clothing and Pattern Design Overview

Traditionally, sewing patterns are cut from flat pieces of cloth and stitched together. The place where one piece of cloth is sewn to another is called a seam. Patterns are generally symmetrical, where the left side of the garment matches the right.

Skirt

The simplest is a skirt pattern with two pieces, with a similar shape for the front and back. The back shape is a little larger than the front to account for the hips and buttocks.

The shapes are sewn together at the sides to form a simple skirt.
The bottom edge of a garment is called a hem. In the skirt pattern, the waistline and hem are slightly curved. When a person puts on the skirt, the curve sits flat on the waist, while the skirt falls in folds to the hem. Because both the waistline and hem are curved, the skirt falls to the same length all the way around.

**Shirt**

A shirt pattern is slightly more complicated. A simple T-shirt pattern is made of two pieces, one for the front and another for the back. The collar on the back piece is higher than the collar on the front. You sew seams up the sides and at the shoulders, leaving the arm hole open.
You can also add sleeves to the shirt. A sleeve pattern is bell-shaped.

It might not be immediately obvious how this pattern turns into a sleeve. The large hump of the bell fits over the shoulder, to give room for it to move.
Pants

A pants pattern has a curved shape at the top to accommodate the hips. The longer straight edge is the outside seam, while the shorter edge is the inseam. The curve near the top fits around the belly or buttocks, and under the crotch area.
Each piece is cut twice. The two front pieces are sewn together along the crotch, and the two back pieces are sewn together in the same way. Then the front is attached to the back at the outside seams and inseams.
Darts

Darts are diamond-shaped holes inside a panel or V-shaped cutouts at an edge of a garment panel (see figure below), which when closed up cause the garment to assume a curved shape.
Darts used to be a common part of women’s everyday clothing, especially in blouses and dresses. However, darts are not needed with loose garments or stretchy clothing. Today, they are used mostly in formal wear and tailored garments.

**Clothing Design and Techniques**

One way to create clothing is to lay out a pattern and put it together with Garment Maker. Garment Maker is a modifier that is used to make seams, lay out cloth panels and define fabric densities. You can use Garment Maker to create seams for the pattern either in a traditional, flat layout or in a visual, easy-to-use 3D layout.

In the real world, clothes are made by cutting out shapes from pieces of cloth and sewing them together along seams with thread. Garment Maker emulates this approach. First you must create a pattern that will define the shapes of the panels. Clothing patterns typically use shapes that we don’t encounter in everyday life. Those of us who aren’t an experienced clothing designers might have a hard time creating these shapes from scratch. It’s often best to start out with a pattern made by somebody else. Cloth includes a variety of patterns
for shirts, pants, jackets and so forth. You can also buy software that will generate these patterns in DXF format.

One program that does this is PatternMaker, available from http://www.patternmaker.com. When you want to move beyond editing the patterns included with Cloth, it’s often helpful to use such applications to help create patterns and familiarize yourself with the process.

![Shirt pattern and shirt sewn together with Garment Maker](image)

**Modeling Clothing**

Garment Maker is a useful tool for putting together patterns and adjusting seams, but you can also achieve good results by modeling with the standard 3ds Max tools and using Cloth on top of these meshes. You can create clothing with polygons, patches, or NURBS.

**IMPORTANT** Keep in mind that modeled clothing must not have any overlapping vertices or interpenetrating faces. This type of geometry can cause the simulation to fail. Using Garment Maker, you will not run into this problem. If you are careful in creating your mesh, then this is an easy rule to follow.

**Pros and Cons**

When designing clothing, Garment Maker is usually the best way to go. It lets you define seams, seam strength, pleats, and other clothing parameters that cannot be defined with clothing modeled via other methods. Either methods lets you define separate portions of your clothing with different fabrics, but Garment Maker gives you greater control over this. The advantage to using modeled clothing is that it can sometimes be a faster setup with familiar methods and it’s a great way to repurpose older clothing models you have.
made in the past. Using polygon-modeled clothing can result in overly regular creases and folds. Garment Maker uses a Delaunay mesh, which tends to avoid this problem. However, the irregular triangulation can result in rendering artifacts for low-resolution clothes, so it is advisable to apply the **HSDS modifier** after Cloth on garments created with Garment Maker and subdivide all the triangles once.

**NOTE** MeshSmooth does not give good results with Garment Maker meshes.

**Left: Garment Maker Delaunay mesh**  
**Right: Modeled quad mesh**

### How Cloth Works

Cloth exists within 3ds Max as a pair of modifiers: Garment Maker and Cloth. Between these two, you can turn just about any 3D object into a cloth object, or you can create clothing in a more traditional method from 2D patterns, and then sew the panels together. However, before getting into the specifics of the two modifiers, it’s useful to discuss how to preplan for using Cloth. This includes how geometry affects Cloth behavior as well as the density of the meshes you use as fabric.
Effect of Geometry on Cloth

Ideally, the way you model your cloth should not affect how it behaves. However, in practice, the nature of the cloth geometry impacts the simulation. First of all, the density of the mesh defines how fine the folds are that can develop. If you create a plane with only nine vertices, when you drape it over a sphere, you are obviously not going to get much detailed folding.

In addition to this aspect, there is the nature of the edges in the mesh. Folding can occur only at edges between triangles, so the regularity or irregularity of the mesh also dictates the resulting deformation. For example, a plane all of whose triangle hypotenuse edges are aligned will result in a cloth with folds aligned along those edges. Garment Maker creates meshes with an irregular layout (but with fairly equal-sized and close-to-equilateral triangles) that avoids this folding bias. However, this can also result in rendering artifacts with low-resolution cloths, so it is advisable to apply the HSDS modifier after Cloth on garments created with Garment Maker and subdivide all the triangles once.

NOTE MeshSmooth does not give good results with Garment Maker meshes.

Left: A low-density shirt.
Right: The same shirt with HSDS applied, above Cloth in the modifier stack

NOTE There should never be any modifiers that can alter topology between Garment Maker and Cloth. For example, you can use Unwrap UVW, but not modifiers such as Edit Mesh, MeshSmooth, or HSDS.

The type of geometry you work with can have a great impact on how the cloth will react. You're probably accustomed to using triangular and quadrilateral polygons for modeling. Garment Maker uses a Delaunay mesh subdivision
that promotes non-uniform deformation. When using quad polygons for cloth simulation be careful of getting uniform or symmetrical results.

Left: A quad mesh
Right: A Delaunay mesh

**Cloth Mesh Density**

It is important to think about how dense your mesh has to be to achieve the result you want. Making the mesh too dense will slow down the system, while having your mesh at too low resolution might not give you the folds or detail you want to see.

For example, if you applied a Bend modifier to a cylinder with only a few height segments, the result would be angular and unsmooth. On the other hand, if you created the cylinder with 1,000 height segments, you’d be wasting resources. The same is true for Cloth. You must find a balance between level of detail and performance that is appropriate for your scene.

Low, medium, and high-density meshes and the way they deform
Notes on the HSDS Modifier

Using the HSDS modifier to add detail to your model can be an effective solution that lets you simulate with a lower resolution mesh, and still get high-quality results. However, if you choose to use the HSDS modifier on top of your Cloth garments, you may want to apply an Edit Mesh modifier below it to weld the vertices together along the seams. This prevents the mesh from coming apart at the seams as it is subdivided.

Shown above is how the modifier stack should look when using HSDS. The intermediate Edit Mesh modifier is used to weld the panel edge vertices together. If you want to preserve the seam creases, you should apply further Mesh Select and Smooth modifiers to reselect the panels and apply different smoothing groups across the garment.

Pattern-Making Software

Below is a list of traditional pattern-making software that you can use to create patterns for import into 3ds Max and use with Cloth. After ensuring that your Internet connection is active, click the software names to display the makers' Web sites.

- Fashion CAD
- PatternMaker
- Wild Ginger Software
- Autometrix
Cloth Modifier

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth

The Cloth modifier is the heart of the Cloth system, and is applied to all objects in your scene that need to be part of the Cloth simulation. This is where you define cloth and collision objects, assign properties, and execute the simulation. Other controls include creating constraints, interactively dragging the cloth, and erasing parts of the simulation.

Left: Cloth modifier not yet applied
Right: Cloth modifier applied and simulated

See also:

- Object Properties Dialog (Cloth) on page 1222
- Cloth and Garment Maker Modifiers on page 1187
Basic Concepts

In a Cloth simulation, you will let Cloth know which objects will be part of the simulation, and which objects will not. Once you have done this, you define what the objects are made of. You can specify what is made of cloth, and what is a solid, collision object.

Because Cloth is a modifier, an instance of it is assigned to each object to be included in the Cloth simulation. This includes all cloth and collision objects. Be aware that two cloth objects with two separate applications of the Cloth modifier will not interact with one another. There are a couple of ways to include objects in the simulation:

- Select all of the objects at once and apply the Cloth modifier to them.
- Apply Cloth to one or more objects and then add objects with the Add Objects button, available on both the Object rollout and the Object Properties dialog on page 1222.

Units of Measure

IMPORTANT The following information is necessary only if you change the system unit after applying the Cloth modifier. If you change the system unit before applying Cloth, the modifier automatically adjusts the cm/unit setting.

It is important to think about size in doing clothing simulations. A very large flag behaves differently from a handkerchief. If the scale is off, then the simulation will be off. Because Cloth deals with real-world physics, it works in real-world units. This means that Cloth needs to know the relationship between units in 3ds Max and units in its own world.

For example, suppose you create a plane that is 10 x 10 3ds Max units. If you want this plane to behave like a 10-inch x 10-inch handkerchief, you would tell Cloth that 1 3ds Max unit=1 inch. If you want it to behave like a 10-foot x 10-foot bed sheet, you would tell Cloth that 1 3ds Max unit=1 foot.

Except as noted at the start of this section, Cloth ignores the 3ds Max System Units Setup (under Customize menu > Units Setup > System Units Setup). Cloth has its own units setup, which is determined by the cm/unit parameter on page 1241 on the Simulation Parameters rollout. This tells Cloth how many centimeters (cm) correspond to each 3ds Max unit. One inch equals 2.54 cm,
so the default setting of 2.54 means that one 3ds Max unit corresponds to 1 inch.

Following is the procedure to follow to determine what setting to use here.

1 Use the measure utility or tape helper to measure some dimension of your cloth (or character) in 3ds Max units (call this number x).
2 Decide how big you want this object to be in the real world. Convert this number to centimeters. If you have the dimension in inches, simply multiply by 2.54 (call this number y).
3 \[ \text{cm/unit} = \frac{y}{x} \]

Here is a quick example: You import a file, man.obj, into 3ds Max, and want to put a shirt on him.

1 Using the Measure utility, you find that the man is 170 3ds Max units tall. So \( y = 170 \).
2 You determine that this man is about 6 feet tall.
   - 6 feet = 72 inches.
   - And 72 inches = 72 \times 2.54 = 182.88 cm. So \( x = 182.88 \)
3 So now you have the values to make sure the shirt behaves correctly. \[ \text{cm/unit} = \frac{170}{182.88} = 0.929 \] Or you can round the spinner's value up to 1.0, since pinpoint accuracy is not needed here.

**Fabric Behavior**

Cloth provides many different ways to set up fabric behaviors. You can make your cloth behave like leather, silk, burlap, and anything in between.

**The Simulation**

Once all of your parameters are set and you’re ready to go, it’s time to simulate. In many cases, you will first perform a local simulation to fit your fabric to your character. Once your fabric is in place, you can simulate over time.

Running a simulation in Cloth is very freeform. You are able to make many changes and edits to a simulation, making it more of a work in progress than a click and a “hope for the best” scenario.
Constraints

You can constrain fabric in various ways to create different fabric effects during simulations. Cloth can constrain cloth to have extra drag as it flies through the air, or can cause it to be affected by a space warp in the scene. Linking a portion of the fabric to an animated object or attaching to a surface are other common constraints. If you wanted to create a pair of pants you would constrain the top portion of the pants to the waist of the character or a curtain can be constrained to a rod. Constraints are a very important and robust part of Cloth. Cloth has the ability to make multiple groups of constrained vertices for great flexibility. You can constrain many different parts of a piece of clothing to different nodes' surfaces or other cloth objects.

You build constraints in Cloth at the modifier's Group sub-object level on page 1244. At this level, you can see vertices of all selected objects, both cloth and collision. You can then select these and place them in groups. Once a group is defined, you can then attach or "constrain" the selection set to another object, or have it affected by some external force.

Tearing Cloth

You can tear cloth. For an example of how to do so, see this procedure on page 1211.

Cloth tears during the course of a simulation under a couple of circumstances:

- The forces affecting the cloth pull it in a way that causes it to tear. A Strength or Tear Threshold value (they are the same) lets you set how easily cloth is torn.
- The cloth collides with a collision object that is set to Cuts Cloth. See Collision Properties on page 1234.

You must specify where the cloth will tear before you run the simulation. There are a few different ways to do this:

- In either Cloth or Garment Maker, set a seam to be tearable. See Seams Sub-Object Level (Cloth) on page 1263, Curves Sub-Object Level (Garment Maker) on page 1287, and Seams Sub-Object Level (Garment Maker) on page 1294.
- In the Cloth modifier, use the Group sub-object level to choose vertices that will tear, and then click Make Tear to create the tear. See Group Rollout (Cloth) on page 1245.
With the Cloth modifier, choose two cloth elements that will tear apart, then at the Group sub-object level, join their edges by choosing vertices and then clicking Weld. See Group Rollout (Cloth) on page 1245.

Tearing Cloth and the Point Cache Modifier

If you use a Point Cache modifier on page 1574 to optimize a Cloth animation, there is a chance that tears will not be smoothed correctly before tearing occurs. To fix this problem, you can add a Welder modifier on page 2004 to the stack. Place the Welder above the Point Cache modifier.

Procedures

Example: To use the Keep Shape option:

If your cloth object starts out with 3D shape that you'd like to retain during the simulation, you can use the Keep Shape option and setting to preserve this shape, or even reverse it. This simple procedure provides an example of how to use Keep Shape.

1 In the Top or Perspective viewport, add a Plane primitive object of about 90 x 90 units, with 20 x 20 segments.

2 Apply a Bend modifier, set Angle to 250.0, and set Bend Axis to X. This produces the initial tubular shape.

3 Copy the bent plane twice so you have three planes in a row. Rename the planes as follows:
   - don't keep shape
   - keep shape
   - reverse shape
4 Select all three planes and apply the Cloth modifier.

5 On the Simulation Parameters rollout, turn off Gravity and set cm/unit to 0.5.
   Turning off Gravity keeps the cloth objects from falling during the simulation, so they stay in view, and lowering the cm/unit setting compensates for the planes’ relatively large size.

6 On the Object rollout, click Object Properties.
   This opens the Object Properties dialog.

7 In the Objects In Simulation list, highlight all three planes (by dragging), and then, above the Cloth Properties group, choose Cloth. Also set U Bend to 500.0.
   This sets V Bend also to 500.0 automatically.
   Using high Bend values allows the simulation to proceed more quickly.
   Next, you’ll set different Keep Shape properties separately for each object.

8 Highlight the reverse shape object in the list and set the Bend % value to -100.0.

   NOTE The default value is 100.0.
Click OK to exit the dialog.

Select the *don't keep shape* object and note that Object rollout > Selected Objects Manip group > Use Target State is off.

Select both the *reverse shape* and the *keep shape* objects, but not *don't keep shape*, and then turn on Use Target State.

On the Object rollout, click Simulate Local.

After a few seconds, the *don't keep shape* object starts to flatten out, the *keep shape* object doesn't change, and the *reverse shape* object has, in fact, reversed its shape, effectively creating a negative bend angle.

**TIP** You can also use Use Target State with Grab State to maintain or reverse a shape created with a previous cloth simulation or shape-changing modifier.
Example: To tear a piece of cloth:

1. In the Top viewport, create a Plane. Make it about 150 units on each side. Set its Length Segments and Width Segments both equal to 7.

2. Also in the Top viewport, create two dummy objects: one on each side of the plane.

   ![The plane flanked by two dummy objects]

3. Turn on Auto Key. Go to frame 100, then animate each dummy object so it moves about 300 units away from the plane along its X axis: move the left-hand dummy to the left, and the right-hand dummy to the right.

4. Turn off Auto Key.
5 Go back to Frame 0.

6 Select the plane. Go to the Modify panel, and apply a Cloth modifier to the plane.

7 On the Object rollout, click Object Properties. 3ds Max opens the Object Properties dialog for cloth. In the list of objects, click Plane01 to highlight it, choose the Cloth radio button to make Plane01 behave as cloth, and then click OK (keep all the default Cloth Property settings).

8 In the Modifier stack, go to the Group sub-object level.

9 Select the vertices along the left-hand side of the plane, and then on the Group rollout, click Make Group. Click OK to accept the default name of Group01. With Group01 still highlighted in the Group list, click Node, and then in a viewport click the left-hand dummy object to assign it to this group.

10 Repeat step 9 for the right-hand column of vertices and the right-hand dummy object.

11 Select the two center columns of plane vertices, and then on the Group rollout, click Make Tear. Click OK to accept the default name of Group03.
Central vertices selected to create a tear in the cloth

3ds Max creates a new Weld constraint that comprises the vertices at the center of the cloth plane.

After clicking Make Tear

12 On the Modifier stack, go back to the top Cloth level.
13 In the Object rollout > Simulation group, click Simulate.  
3ds Max animates the dummies pulling at the cloth. As this happens,  
the cloth tears along the vertices that you set to tear.
Cloth tearing in the center as its edges are pulled apart

Depending on the position of the dummy objects, the tear you see in your example might differ from the one shown in these illustrations.
To run a cloth simulation with a networked render farm:

A complex cloth simulation can require extensive computation and take a long time. Cloth includes commands that make it easy to run a simulation on a networked machine (part of a render farm), freeing up your machine for working on other parts of the scene.

1. Set up the simulation.
2. For each cloth object in the simulation, select the object, and then on the Selected Object rollout click Set and specify a path and file name for the cache.
   For best results, specify a mapped drive and turn on Force UNC Path. This specifies the path using the Universal Naming Convention so that it can be found by all computers in the network. Also, it’s probably a good idea to keep all the cache files in the same directory.
3. On the Simulation Parameters rollout, turn on Sim On Render.
4. Save the scene file.
5. On the Render Setup dialog, turn on Net Render, and then click Render. Submit the job to a single Server.

Unlike rendering, network Cloth simulation cannot be split up among multiple Server machines.

NOTE You needn’t render the entire animation to trigger the cache creation; a single frame suffices.

As soon as the Server machine starts the render, it begins computing the simulation and saving it to disk. At any point you can load the simulation in its current state from the cache file to check its progress by clicking the Load button.

Object Rollout (Cloth)

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth > Object rollout

The Object rollout is the first rollout you see on the Command panel once you apply the Cloth modifier. It comprises mostly controls to create a Cloth simulation and adjust fabric properties.
Object Properties  Opens the Object Properties dialog on page 1222, where you can define which objects to include in the simulation, whether they are cloth or collision objects, and the parameters associated with them.

Cloth Forces  Add forces (that is, space warps in the scene) such as wind to the simulation. Click Cloth Forces to open the Forces dialog. To add forces to the simulation, in the Forces In Scene list on the left side, highlight the forces to add, and then click the > button to move them to the Forces In Simulation list, thus adding them to the simulation. Thereafter, the forces affect all cloth objects in the simulation.

To remove forces from the simulation, in the Forces In Simulation list on the right side, highlight the forces to remove, and then click the < button to move them to the Forces In Scene list.

Simulation group

To run a cloth simulation, click any of the three Simulate buttons in this group. To halt a simulation, press Esc or if the Cloth Simulation dialog is open (i.e., Progress on page 1219 is on), click the Cancel button.

Simulate Local  Starts the simulation process without creating animation. Use this to drape the clothes on a character or sew the panels of a garment together.

Simulate Local (damped)  Same as Simulate Local, but with a large amount of damping added to the cloth. When sewing a garment together, sometimes the panels come together at high speed, causing problems. Using a damped simulation alleviates this problem.

Simulate  Creates a simulation over the active time segment. Unlike Simulate Local, this creates animation data in the form of a simulation cache at every frame.
The simulator advances by a time step called $dT$. The initial value is the Step setting on page 1242 on the Simulation Parameters rollout. When the simulator encounters certain situations, it decreases $dT$ in order to overcome the obstacles. Sometime later, the simulator increases $dT$ again up to the maximum Step value you set. The current value of $dT$ appears on the Cloth Simulation dialog that shows the progress of the simulation as it takes place (see following).

When the simulator decreases $dT$, it shows "$dT$ decreased" on the Cloth Simulation dialog along with one of the following messages (explanation follows each message):

- **could not solve equations** – The solver could not solve the equations of motion.
- **cloth has become over-stretched** – In attempting to solve one step, some edges of the cloth became too elongated, indicating a failure of the solver.
- **cloth-solid collision velocity was too large** – The speed of the cloth relative to that of the collision object is too high.
- **cloth-cloth collision velocity was too large** – The speed of colliding cloth parts is too high.

**Progress** When on, opens the Cloth Simulation dialog during the simulation. The dialog shows the progress of the simulation, including information about time, and messages about errors or time step size adjustments.

![Cloth Simulation Dialog](image)

The Cloth Simulation dialog shows information about the simulation while it's running.

**Simulated Frames** Shows the number of frames simulated so far.

**Erase Simulation** Deletes the current simulation. This deletes the cache of all cloth objects and sets the Simulated Frames count back to 1.
**Truncate Simulation** Deletes animation created by the simulation after the current frame.

For example, if you've simulated an animation to frame 50 but want to keep only animation keys from frames 0 to 30, set the time slider to frame 30, then click this button. The simulation is then deleted from frame 31 on.

**Selected Object Manip group**

**Set Initial State** Updates the first frame of the selected cloth object's cache to the current position.

**Reset State** Resets the selected cloth object's state to the state before Cloth in the modifier stack. When you click this, the simulation is erased; that is, Simulated Frames returns to 1.

**Delete Object Cache** Deletes the cache for selected non-cloth objects. If an object is simulated as cloth, and is then turned into a collision object (or inactive) via the Object Properties dialog, it will retain the cloth motion in its cache.

This is useful for simulating clothes in layers. For example, you may simulate a character's pants, then turn the pants into a collision object for simulating a coat. By simulating in layers, you avoid the problems of cloth-to-cloth collision detection. If you want to remove the cached motion from the selected object(s), click this button.

**Grab State** Grabs the current state from the top of the modifier stack and updates the cache for the current frame.

Following is an example of how this might be used:

1. Simulate to frame 100. When you play back the simulation, you see a collision object poking through the cloth at frame 24.
2 Add an Edit Mesh modifier after Cloth and pull the cloth vertices so the object doesn't poke through.

3 Go down the stack to Cloth and click Grab State. The vertices are now moved twice as far as you intended because the vertex displacement was applied once by Cloth, and again with Edit Mesh.

4 Remove the Edit Mesh modifier. The vertices should now be where you want them.

Grab Target State Lets you specify the target shape for Keep Shape on page 1233. Grabs the current deformation from the top of the modifier stack and uses that mesh to define the target bend angles between triangles. Also turns on Use Target State on page 1221.

**NOTE** Only the bend angles from the Target State mesh are used, not the edge lengths.

**TIP** To add some natural creasing to your cloth, drop the cloth on the floor, click Grab Target State, and then run the simulation. After clicking Grab Target State and before running the simulation, click Reset State (unless you want the cloth to stay on the floor!).

Reset Target State Resets the default bend angles to the mesh below Cloth in the stack.

**NOTE** For Garment Maker on page 1266 objects, the target bend angles will depend on the output method set in the Garment Maker modifier. To see what is actually being used, use Show Target State on page 1222.

Use Target State When on, preserves the shape of the mesh as stored by Grab Target State on page 1221. It uses the Bend % and Stretch % settings in the Keep Shape on page 1233 group on the Object Properties dialog for Cloth.

If multiple cloth objects with different Use Target State settings are selected, this check box appears unavailable, but you can click it to make the setting for all selected objects.

**NOTE** In previous versions, this check box was labeled Keep Shape and was found on the Object Properties dialog for Cloth.
Create Keys Creates keys for a selected cloth object. The object is collapsed to an editable mesh, and any deformation is stored as vertex animation.

Add Objects Lets you add objects to the simulation without opening the Object Properties dialog. Click Add Objects, and then click an object to add. To add multiple objects at once, press H and use the Pick Objects dialog.

Show Current State Shows the current state of the cloth at the end of the last simulation time step. If the simulation is cancelled, the last time step could lie between two frames. If the simulation is allowed to successfully finish, the last time step corresponds to the last frame.

Show Target State Shows the current target state of the cloth; that is, the desired bend angles used by the Keep Shape option.

Show enabled solid collision When on, highlights all groups of vertices for which Solid Coll on page 1254 is on. This is handy for seeing exactly which vertices will be involved in solid-object collisions.

Show enabled self collision When on, highlights all groups of vertices for which Self Coll on page 1254 is on. This is handy for seeing exactly which vertices will be involved in cloth-to-cloth collisions.

Object Properties Dialog (Cloth)

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth > Object rollout > Object Properties button

Use the Object Properties dialog to specify which objects are included in a Cloth simulation, whether they are cloth or collision objects, and define parameters associated with them.
Interface

Cloth and Garment Maker Modifiers | 1223
Objects in Simulation

The list below the caption “Objects in Simulation” shows the objects currently included in the Cloth simulation.

To change an object’s role and properties, first highlight its name in the list. You can highlight multiple object names using standard methods: Ctrl+click, Shift+click, and dragging.

Add Objects Click to open a Select From Scene dialog on page 206 that lets you select objects from your scene to be added to the Cloth simulation. After you add an object, the object name appears in the Objects In Simulation list, and an instance of the Cloth modifier is applied to the object.

Remove Removes objects highlighted in the Objects In Simulation list from the simulation. You cannot remove an object that is currently selected in 3ds Max.

Choosing the Role of an Object

Three radio buttons in the Object Properties dialog, to the right of the Objects In Simulation list, let you choose how the Cloth simulation treats each individual object.

Inactive Choose to make the highlighted object inactive in the simulation. The object can still be in the simulation, but it will not react to anything. This option is helpful for testing how different objects react, and for isolating dynamic effects.

When you first add an object to the Cloth simulation, by default it is Inactive.

Cloth Choose to make the highlighted object behave as a cloth object. Once you designate an object as Cloth, you can set its parameters in the Cloth Properties group on page 1225.

NOTE Each cloth object can actually have two sets of properties. See the following section, “High-Level Cloth Options,” for more details.

Collision Object Choose to make the highlighted object behave as a collision object. Cloth objects bounce off, wrap around, or are torn by collision objects. Once you designate an object as a Collision Object, you can set its properties in the Collision Properties group on page 1234.
High-Level Cloth Options

Use Panel Properties When on, tells Cloth to use the cloth properties specified at the Panel sub-object level on page 1259. This allows you to define different cloth properties on a panel-by-panel basis. Default=off.

While this option is on, controls in the Cloth Properties group are unavailable.

Property 1 / Property 2 These two radio buttons let you assign two different sets of cloth properties to a Cloth object.

If you assign both Property 1 and Property 2 sets, you can then use the Property Assignment group on page 1238 settings to interpolate or animate between the sets.

Three options can be set only for Property 1, and are unavailable in the Property 2 set. Both sets use the same settings for these options. The options are Use Cloth Depth/Offset, Use Edge Springs, and Use Solid Friction.

Cloth Properties

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth > Object rollout > Object Properties button > Object Properties dialog > Highlight an object in the list. > Choose Cloth. > Cloth Properties group

Cloth Properties control how a cloth object behaves in a Cloth simulation.

The 3ds Max interface provides a few different ways to set cloth properties. Setting these values here in the Object Properties dialog for cloth applies them to the object globally. You can also apply these values locally at either the Group sub-object level on page 1244 or the Panel sub-object level on page 1259.

If you turn on Use Panel Properties (see Object Properties Dialog (Cloth) on page 1222), 3ds Max disables the global settings in this group. Setting properties locally for panels is useful mainly when you are modeling a multi-panel garment created by the Garment Maker modifier on page 1266.

You can assign two sets of properties to a single cloth object: Property 1 and Property 2. If both sets are assigned, you can then use the Property Assignment group on page 1238 to interpolate or animate between the sets. See also High-Level Cloth Options on page 1225.
Interface

Presets group
Sets the Cloth Properties parameters to the preset chosen from the drop-down list. Any presets that are built into the system or that have been previously saved and loaded will show up here.

**Load** Loads presets from your hard drive. Click this button and then navigate to the directory with your presets to load them into Cloth Properties. Presets have the file name extension `.sti`.

**Save** Saves Cloth Properties parameters to a file to be loaded at a later time. By default, all Cloth preset files are saved to your `\scenes\cloth` folder.

![Cloth Properties](image)

**U Bend** / **V Bend** Resistance to bending. The higher this value is set, the less the fabric will be able to bend. A cotton fabric might bend more easily than leather, so a value of 15.0 for both U and V Bend might be good for cotton, while 50.0 would work well for leather.

By default, the U Bend and V Bend parameters are locked together so that changing one sets the other to the same value. You can set different values for the two only when Anisotropic on page 1232 is off. We recommend that you do this only for Garment Maker on page 1266 objects.
Left: U and V Bend=50, simulating a burlap material
Right: U and V Bend=2.5, simulating silk or other light fabric

**U B-Curve / V B-Curve** Resistance to bending as the fabric folds. The default value of 0 sets the bend resistance to be constant. A setting of 1 makes the fabric very resistant to bending as the angle between triangles approaches 180 degrees. You never want two adjacent triangles to pass through each other, so you can increase this value to prevent this from happening.

By default, the U B-Curve and V B-Curve parameters are locked together so that changing one sets the other to the same value. You can set different values for the two only when Anisotropic on page 1232 is off. We recommend that you do this only for Garment Maker on page 1266 objects.

**U Stretch / V Stretch** Resistance to stretching. The default value of 50.0 is a reasonable value for most types of cloth. A larger value will be stiffer, while a smaller one will be stretchy like rubber.

By default, the U Stretch and V Stretch parameters are locked together so that changing one sets the other to the same value. You can set different values for the two only when Anisotropic on page 1232 is off. We recommend that you do this only for Garment Maker on page 1266 objects.

**U Compress / V Compress** Resistance to compression. Although these values default to 50.0, like their counterpart Stretch values, assigning values lower than the Stretch values can give good results, because when cloth is compressed along the length of its fibers, it tends to buckle rather than shrink.

By default, the U Compress and V Compress parameters are locked together so that changing one sets the other to the same value. You can set different
values for the two only when Anisotropic on page 1232 is off. We recommend that you do this only for Garment Maker on page 1266 objects.

**Shear** Resistance to shearing. Higher values result in stiffer cloth fabrics. Shear defines how much the individual triangles can deform. If you were to lay the edges of the triangle out in a straight line, this value would represent how long this line can stretch. With a high value, this length will be only the sum of the length of all of the sides at rest. A low value allows this length to be greater than that of all of the triangle sides at rest. This length of stretched sides is not on a one-to-one basis. One side of the polygon can stretch more than another, as long as the total shear value is not exceeded.

**Density** The weight of the cloth per unit area (in gm/cm²). Higher values mean heavier cloth like denim. Use smaller values for lighter cloth like silk.

**Damping** The larger this value, the more sluggishly the fabric will react. With a lower value, the fabric will behave with more spring. Cloth with more damping will come to rest sooner than cloth with less damping. High damping results in cloth that behaves as though it is moving through oil. Excessive damping can cause simulation instabilities.

---

**TIP** Begin by setting Damping to 0.01. If your simulation requires more damping, try increasing this value gradually.

---

**Plasticity** The tendency of the cloth to keep its current deformation (that is, the bend angles).

This is different from **Keep Shape** on page 1233, which determines the extent to which the cloth tends to keep its original deformation (or the one defined by the Target State). If you set Plasticity to 100.0, the cloth will not attempt to change the angles between triangles. If you want stiffer cloth, but you don’t want the cloth to “balloon” up, increase the Plasticity value.

**Thickness** Defines the virtual thickness of a fabric for the purpose of detecting cloth-to-cloth collisions. This value is irrelevant if cloth-to-cloth collisions are disabled. Larger values keep the cloth separated by greater distances. Be careful not to use too large or small values in this field. Very large values will interfere with the natural behavior of the cloth. Very small values will cause the simulator to take too long to calculate. This distance is measured in cm (centimeters) and should be smaller than the size of the triangles that make up the cloth object. A setting of 0.0 will let Cloth automatically assign a reasonable value for thickness.
**Repulsion** The amount of force used to repel other cloth objects. This value is irrelevant if cloth-to-cloth collisions are disabled. The simulator will apply a repulsion force scaled by this value to keep the cloth from coming in contact with other cloth objects. Increase this value if there are a lot of collisions between different parts of cloth, or if the cloth is tending to interpenetrate.

**Air Res.** Resistance to air. This value will determine how much the air will affect the cloth. A higher Air Resistance value is useful for a tightly woven fabric, while a lower value is suitable for a loose-knit garment.

**Dyn. Fric.** Dynamic friction between the cloth and solid objects. A larger value will add more friction and cause the fabric to slide less across an object. A lower value will allow the fabric to slip off an object easily, similarly to how silk behaves.

**Static Fric.** Static friction between the cloth and solid objects. When the cloth is in a stationary position, this value will control its ability stay where it is, or slip away.

**Self Fric.** Friction between the cloth and itself. This is similar to dynamic and static friction, but applies to cloth-to-cloth or self-collisions. A larger value will cause more friction between the cloth and itself.
**Seam Force** Not presently used and kept only for backward compatibility with older versions of the former product, called Stitch. This was a global seam strength, but seam strength is now defined on a seam-by-seam basis at the Seams sub-object level.

**U Scale** Controls how much to shrink or expand the cloth along the U direction (as defined by Garment Maker). For non-Garment Maker meshes, this applies a uniform scaling to the cloth along both axes, and the V Scale parameter is ignored. A value of less than 1 will shrink the fabric at simulation time, while a value of more than 1 will stretch it.

**V Scale** Controls how much to shrink or expand the cloth along the V direction (as defined by Garment Maker). A value of less than 1.0 will shrink the fabric at simulation time, while a value of more than 1.0 will stretch it.

**Depth** Collision depth for the cloth object. If a portion of cloth reaches this depth inside a collision object, then the simulation will no longer try to push the cloth out of the mesh. This value is measured in 3ds Max units.

To specify a Depth value specific to the cloth object, use this setting and be sure to turn on Use Cloth Depth/Offset on page 1233.

**Offset** The distance maintained between the cloth object and the collision object. A very low value can cause the collision mesh to protrude from under the cloth. A very high value causes the fabric to appear to be floating above the collision object. This value is measured in 3ds Max units.

To specify an Offset value specific to the cloth object, use this setting and be sure to turn on Use Cloth Depth/Offset on page 1233.

**Cling** The extent to which the cloth object adheres to a collision object. Range=0.0 to 99999.0. Default=0.0.

You can use this parameter to simulate effects such as wet cloth. A setting of 1.0 should be just enough to hold the default material onto a surface against its own weight.

**Layer** Indicates the correct “order” of cloth pieces that might come in contact with each other. Range=–100 to 100. Default=0.

If your garments and/or panels are all correctly oriented to begin with, then cloth-to-cloth collision detection should keep items from interpenetrating. However, the initial state of a garment or panel might have some interpenetration that cannot be resolved. For example, suppose you make a jacket with Garment Maker where the front right panel is supposed to sit on top of the front left panel. When you sew together the garment (generally with self-collision off), the front panels will interpenetrate, so to make sure that the right panel sits outside the left panel, you might have to use constraints or Live Drag. Using the Layers option on the panels can help here.
Here is the logic of layers: When two pieces of cloth (A and B) are in collision-detection range, their layers (layerA and layerB) are compared and the following rules are applied:

- If either layerA or LayerB is 0, then Cloth uses the regular cloth-to-cloth collision method.
- If layerA=layerB, then Cloth uses the regular cloth-to-cloth collision method.
- If abs(layerA) > abs(layerB) then piece A is pushed to the appropriate side of piece B. Which side? If layerB > 0, then to the side indicated by the face normals. If layerB<0 then to the opposite side.

The sign of the Layer value indicates what the "outside" of that piece of cloth is. A positive sign means "The side that the normals face is the outside".

---

**Based on** This text field displays the name of the preset that the initial Cloth Property values are based on. If you have not chosen a preset, it displays “default.”

When you modify some parameters and save a preset, 3ds Max saves the file using the name of the last preset you loaded.

---

**Inherit Velocity** When on, the cloth inherits the velocity of the mesh at the start of the simulation. This can be useful if you are generating a simulation in stages: generating one simulation, and then generating another that begins where the first one ended. Turning on Inherit Velocity can help create a smooth transition between the two simulations. Default=off.

**Use Edge Springs** Enables an alternative method for calculating stretch. When on, stretch force is based on springs along triangle edges. When off, the stretch and shear forces are calculated in a more sophisticated manner to more accurately reflect the underlying physics. Default=off.

**Anisotropic (unlock U,V)** When on, you can set different U and V values for the Bend, B-Curve, and Stretch parameters. The U and V directions are defined by Garment Maker on page 1266 and do not apply to non-Garment Maker meshes, for which setting different U/V values might result in unexpected behavior. Default=off.
Use Cloth Depth/Offset When on, uses the Depth on page 1231 and Offset on page 1231 values set in Cloth Properties. When on, the cloth object ignores the collision object Depth and Offset values. Default=off.

Use Collision Obj Friction When on, uses the friction of the collision object to determine friction. Values for collision can be assigned either to the cloth or the collision objects. This enables you to set different friction values for each collision object. Default=off.

Keep Shape group

These settings preserves the shape of the mesh based on the values of Bend % and Stretch %. In normal operation, when Cloth creates a simulation, it tries to "flatten out" the cloth. To enable these settings, turn on Use Target State on page 1221.

Bend % Modulates the target bend angles to a value between 0.0 and the angles defined by the target state on page 1221. A negative value inverts the angles. Range=–100.0 to 100.0. Default=100.0.

Stretch % Modulates the target stretch angles to a value between 0.0 and the angles defined by the target state on page 1221. Range=0.0 to 100.0. Default=100.0.

Pressure group

A closed volume of cloth (for example, a polymesh based on a sphere) can behave as if it is filled with gas.

Pressure The pressure of the gas filling the mesh. Increase this value to observe the pressure effect. At pressures near 100.0, the cloth volume behaves much like a balloon; lower values slow down the effect of gravity. Default=0.0.
**Damping** Increase the Damping value to slow down the effect of the pressure force. Default=0.0.

**Track Volume** When Track Volume is on, Pressure changes as the cloth volume changes. This models real-world gas, where compressing the volume increases the pressure, and so on. Default=off.

While Track Volume is on, the Pressure value sets only the pressure at the start of the simulation.

**Cap Holes** If there are holes in the mesh, turning on Cap Holes adjusts the pressure so the mesh behaves as if the holes were capped. Default=off.

**Collision Properties**

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth > Object rollout > Object Properties button > Object Properties dialog > Highlight an object in the list. > Choose Collision Object. > Collision Properties group

Collision Properties control how a collision object behaves in a Cloth simulation. Cloth objects bounce off, wrap around, or are torn by collision objects.

**Interface**

![Collision Properties Interface](image)

**Depth** Collision depth for the collision object. If a portion of cloth reaches this depth inside a collision object, then the simulation will no longer try to push the cloth out of the mesh. This value is measured in 3ds Max units.

**Offset** The distance maintained between the cloth object and the collision object. A very low value can cause the collision mesh to protrude out from under the cloth. A very high value will look like the fabric is floating on top of the collision object. This value is measured in 3ds Max units.
**Dyn. Fric.** Dynamic friction between the cloth and this particular solid object. A larger value will add more friction and cause the fabric to slide across an object less. A lower value will allow the fabric to slip of an object very easily, similarly to how silk would react. This value is only used for interaction with cloth objects that have Use Solid Friction enabled, otherwise the friction value is taken from the cloth’s own properties.

**Static [Friction]** Static friction between the cloth and solid objects. When the cloth is in stationary position, this value will control its ability stay where it is, or slip away. This value is only used for interaction with cloth objects that have Use Solid Friction enabled otherwise the friction value is taken from the cloth’s own properties.

**Enable Collisions** Enables or disables collisions for this object while still allowing it to be in the simulation. This means the object can still be used for making surface constraints.

**Cuts Cloth** When on, the Collision Object can cut the cloth if it intersects with the cloth during the course of a simulation. The cloth object must be set up to have a tear along either a seam or a group of vertices. Default=off.

**TIP** When you turn on Cuts Cloth, turn off Enable Collisions. This gives the most realistic results for most models.

---

**Selected Object Rollout (Cloth)**

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth > Selected Object rollout

The Selected Object rollout lets you control the simulation caches, control and optionally animate the cloth properties with a texture map or interpolation, and specify a bend map. This rollout appears only when a single object in the simulation is selected.
Cache group

Use these settings for network simulation. When you render with Sim On Render on page 1243 on, Cloth can run the simulation on a networked machine, leaving your local machine free for other work. For a procedure, see To run a cloth simulation with a networked render farm: on page 1216.

[Text field] Shows the current path and file name for the cache file. You can edit this field, but the path must exist; the file will be created if necessary. For any cloth object for which you have not specified a file name, Cloth creates one based on the object name.

Force UNC Path If the text field path is to a mapped drive, converts the path to UNC format on page 8753. This makes the path readily accessible to any computer on the network. To convert cache paths for all cloth objects in the current simulation to UNC format, click the All button.

Overwrite Existing When on, Cloth can overwrite existing cache files. To enable overwriting for all cloth objects in the current simulation, click the All button.

Set Lets you specify the path and filename of the cache file for the selected object. Click Set, navigate to the directory, enter the file name, and then click Save.

Load Loads the specified file into the selected object’s cache.

Import Opens a file dialog to load a cache file other than the specified one.

Load All Loads the specified cache file for every cloth object in the simulation.
Save Saves the current cache, if any, using the specified file name and path. If no file is specified, Cloth creates one based on the object name.

Export Opens a file dialog to save the cache to a file other than the specified one. You can save in the default CFX format or in PointCache2 format.

Extra Cache To create a second cache in PointCache2 format, turn on Extra Cache and click Set to specify a path and file name. This file is also created when you render with Sim On Render on.

**Property Assignment group**

Interpolate Interpolates between the two different property settings in the Object Properties dialog on page 1222 (as determined by the Property 1 and Property 2 radio buttons at the top right corner). You can use this slider to animate between these two properties to adjust the type of fabric settings the garment is using.

Texture Map Set a texture map and apply the Property 1 and Property 2 settings to the cloth object. You can add a grayscale texture map in this slot to blend between the two properties set in the Object Properties dialog. Black will represent property 1 and white property 2. Any grayscale value will blend between these two properties. You can drag a texture map onto this button.
Cloth object with a burlap material in Property 1 and silk in Property 2 being controlled by a Checker procedural map

**Mapping Channel** Lets you specify the mapping channel the Texture map will work from, or choose Vertex Color to use that instead. Vertex color can be particularly useful in conjunction with the new painting tools in 3ds Max. You can paint vertex colors directly onto your object and use the painted areas for material assignment.

**Bend Map group**

The Bend Map option lets you use a texture map, map channel, or vertex colors to modulate the target bend angles. The value of this is that you can paint deformations onto your cloth, or use some kind of noise map to add irregularity to the cloth.

**Bend Map** Toggles the use of the Bend Map option.
Set the strength of the modulation with the numeric value. In most cases, the value should be less than 1.0. Range=0.0 to 100.0. Default=0.5.
Choose the map type for the Bend map:

- **Vertex Color**
  Uses the Vertex Color channel for modulation.

- **Map Channel**
  Uses a map channel other than Vertex Color for modulation. Set the channel with the spinner.

- **Texture Map**
  Uses a texture map for modulation. To specify a texture map, click the button (labeled None by default) and then use the Material/Map Browser to choose the map. Thereafter the map name appears on the button.

### Simulation Parameters Rollout (Cloth)

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth > Simulation Parameters rollout

The Simulation Parameters rollout settings let you specify general properties of the simulation such as gravity, start and end frames, and sewing-spring options. These settings apply to the simulation on a global scale, that is, to all objects in the simulation.
**Interface**

![Simulation Parameters](image)

**cm/unit** Determines how many centimeters there are per 3ds Max system unit.

Cloth automatically sets cm/unit to the equivalent of 2.54 centimeters per inch (the default system unit in 3ds Max). For example, if you set the system unit to one foot, Cloth automatically sets cm/unit to 30.48 (12x2.54).

Size and scale are important when doing cloth simulation because a 10-foot curtain behaves much differently from a one-foot square handkerchief, even if they are made from the same fabric.

**Earth** Click this button to set the Gravity value to that of planet Earth.

**Gravity** When on, the Gravity value (see following) affects cloth objects in the simulation.
[Gravity value] The force of gravity in cm/sec\(^2\). A negative value applies gravitational force downward. A positive value (i.e., no sign) means gravity will act to move cloth objects upward. The default value is set to be the same as Earth's gravity: -980.0 cm/sec\(^2\).

**Step** The maximum size of the time step the simulator takes.
This value is measured in seconds. The value must be less than the length of one frame (less than 0.033333 for 30 fps animation). A value of 0.02 is generally the largest value you want to use. Reducing this value causes the simulator to take longer to calculate, but will in general give better results. The simulator will automatically reduce its time steps as needed, but this is the maximum value that it will try. This value works in conjunction with the Subsample parameter: The actual maximum value=Step value divided by Subsampl value.

**Subsample** The number of times per frame that 3ds Max samples the position of solid objects. Default=1.
At the default value, Cloth samples the solid objects in the simulation once every frame. Increasing this value should help when objects are moving or rotating quickly, but be aware that the higher you set the value, the slower the simulation will be.

**Start Frame** The frame at which the simulation starts. If you change this value after the simulation has been performed, the cache will be moved to this frame. Default=0.

**End Frame** When on, determines the frame at which the simulation will stop. Default=100.

**Self Collision** When on, detects cloth-to-cloth collisions. Leaving this off will speed up the simulator, but will allow cloth objects to interpenetrate.
The numeric setting specifies the extent to which Cloth tends to avoid self-colliding cloth objects, at the cost of simulation time. Range=0 to 10. Default=0.
This is a maximum limit. If Cloth needs fewer calculations to resolve all collisions, it will use fewer. In most cases, a value greater than 1 isn't necessary.

**Check Intersections** (Discontinued feature. This check box has no effect.)

**Solid Collision** When on, the simulator takes into account cloth-to-solid object collisions. This is almost always left on.

**Use Sewing Springs** When on, uses the sewing springs created with Garment Maker to pull the fabric together.
This works only with objects that have been made with Garment Maker on page 1266. Turn this option off once the garment has been pulled together.
When off, Cloth will identify vertices that are sewn together and will always keep them coincident. When on, there is always a chance for the vertices to come apart if the sewing springs are not strong enough (actually, there will always be some slight gap between the vertices in this case).

**Show Sewing Springs** Toggles the visual representation of the sewing springs in the viewports. These do not render.

**Sim on Render** When on, triggers the simulation at render time. Use this for generating a simulation with a network computer, which lets you continue to work on other aspects of your scene with your own computer. See a procedure [here](#) on page 1215.

After the render is completed, Cloth writes a cache for each cloth object. You can specify this cache file on the **Selected Object Rollout (Cloth)** on page 1235 (which is available only when a single object is selected). If you do not specify a name, 3ds Max creates one.

The numeric value indicates the priority of the simulation; the simulations are run in ascending order. For modifiers with the same priority, the order is undefined.

**NOTE** Each object has its own cache file, which is temporarily created when the MAX file is opened. On saving the file, the cache is incorporated into the MAX file. When Sim On Render is on, the cache file specified is created and written to, but is not read from as you change the time slider. The cache file must be [loaded into the internal cache file](#) on page 1237 before you can see it.

**Advanced Pinching** When on, Cloth tests for cloth pinched between two parts of the same collision object.

This option helps with cloth colliding with small features of the collision objects, such as fingers. There is a significant performance hit for high-resolution collision objects.

**Tension** Lets you visualize the compression/tension in the fabric by means of vertex coloring. Stretched cloth is indicated by red, compressed by blue, neutral by green. The numeric setting lets you change the range of tension/compression illustrated by a complete traversal from red to blue. The higher this value, the more gradual the shading. This works only for Garment Maker objects.

**Weld group**

Controls how cloth is smoothed across a tear that you set up, before the cloth has been torn.
The difference between these two options is primarily in whether they are compatible with a Point Cache modifier. See Point Cache Modifier (Object Space) on page 1574.

- **Verts**  When chosen, Cloth welds the vertices before tearing occurs. This creates a smooth mesh; however, its topology changes when the tear occurs, so when you choose this option you can’t use a Point Cache modifier with the Cloth animation.

- **Normals**  (The default.) When chosen, uses face normals to generate smoothing. The topology of the Cloth object does not change, so when this option is chosen, you can use a Point Cache modifier with the Cloth animation.

### Group Sub-Object Level (Cloth)

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth > Modifier stack > Highlight the Group sub-object level

Groups let you select groups of vertices and constrain them to surfaces, collision objects, or other cloth objects.

At the Group sub-object level, all selected objects that are part of the Cloth simulation are shown with their vertices visible so that you can select them in an efficient fashion.

When you create or select a group at this sub-object level, the Group Parameters rollout on page 1252 becomes available.

**IMPORTANT**  The concept of a group for Cloth can be applied to both the cloth objects and to the collision objects in the simulation. And when created, groups can then be given unique properties. For example, a group on a collision object can have a different collision offset from the rest of the object. This is a powerful feature when working with groups.

**NOTE**  You can select groups of vertices explicitly, with the mouse in the viewports, and you can also specify a soft selection or use a texture map to select vertices using controls on the Group Parameters rollout. See Soft Selection group on page 1258. In addition, named selection set on page 217 tools are available at this level.
**Groups and Constraints**

The main reason for creating a group is to make it a *constraint*. A group becomes a constraint when you assign its vertices to behave in a particular way: for example, to follow another object or another piece of cloth. Until you make a group into a constraint, the group is described as *unassigned*.

You create and manage groups, and constrain them, using the controls on the Group rollout on page 1245. You can fine-tune the behavior of an individual group using the controls on the Group Parameters rollout on page 1252.

**Group Rollout (Cloth)**

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth > Modifier stack > Highlight the Group sub-object level > Group rollout

The Group sub-object rollout is for selecting groups of vertices and constraining them to surfaces, collision objects, or other cloth objects.
Interface

[Group management buttons]

1246 | Chapter 9  Modifiers
Make Group Makes a group out of selected vertices. Select the vertices to include in the group, and then click this button. Name the group, and it will then show up in the list below for you assign to an object.

Delete Group Deletes the group highlighted in the list.

Detach Removes any constraint assigned to the group and sets it back to being unassigned (that is, without any constraint). Any unique properties assigned to this group will remain in effect.

Initialize Constraints that involve attaching the vertices to another object (Node, SimNode, Surface and Cloth constraints) contain information regarding the relative positions of the group vertices to the other object. This information is created upon the creation of the constraint. To regenerate this information, click this button.

Change Group Lets you modify the vertex selection in the group. To use, follow this procedure:
1. Choose the group in the list.
2. Change the selection of vertices.
3. Click Change Group.

Rename Renames the highlighted group.

[Constraint creation buttons]

Node Constrains the highlighted group to the transforms of an object or node in the scene. To use, click Node, and then select the node for constraining.
The node cannot be an object in the simulation; for that purpose, use the SimNode constraint on page 1248.

**NOTE** Node and SimNode simply constrain the group to an object's transforms, not to the object itself. They need not be near each other. When the cloth and the constraining object should be in close proximity, such as with clothing on a character mesh, use the Surface constraint instead (see following).

**Surface** Attaches the selected group to the surface of a collision object in the scene. To use, click Surface, and then select the node for attaching.

**TIP** This constraint is best suited for when the cloth and the constraining object should be in close proximity, such as with clothing on a character mesh.

**Cloth** Attaches the selected group of cloth vertices to another cloth object.

**Preserve** This group type preserves the motion from below the Cloth modifier in the modifier stack. For example, you might have a dress that you've skinned to a skeleton. You want the upper portion of the dress to be unaffected by the Cloth simulation (that is, to retain its deformation defined by the skinning), and the lower part to be simulated. In this case, you'd make a Preserve constraint from the upper vertices.

**Drag** This group type locks the vertices in place or adds a damping force to selected group. When Group Parameters rollout > Soft on page 1253 is off, you can use this constraint for “nailing” vertices in place so that they do not move at all. When Soft is on, the vertices will have a drag force applied where the amount of drag is controlled by the Strength and Damping values, also on the Group Properties rollout.

**SimNode** This option works the same as the Node option on page 1247, except that the node must be part of the Cloth simulation.

**Group** Attaches one group to another. This is recommended only for single-vertex groups. (that is, groups that contain only one vertex). With this, you can make one cloth vertex stick to another cloth vertex. Select one group, click this button to open the Pick Group dialog, and then choose another group.

**NoCollide** Causes collisions between the currently selected group and another group to be ignored. When you click this button, you're prompted to choose another group. You could use this option to prevent the simulator from processing collisions between cloth and the body under an arm or between the legs.
**Forcefield** Allows you to link a group to a space warp and have the space warp affect the vertices.

**Sticky Surf** The group sticks to a surface only after it has collided with that surface. **Solid Coll** on page 1254 must be enabled for this constraint to work.

**Sticky Cloth** The group sticks to a surface only after it has collided with that surface. **Self Coll** on page 1254 must be enabled for this constraint to work.

**Weld** Click to make an existing group into a Weld constraint. You must first highlight the name of the group in the Group list. Weld *does not* create a tear; it only welds vertices that are in close proximity. Use Weld if you create a tear by modeling two elements with matching edges and then applying the Cloth modifier later.

**Make Tear** Click to make a vertex selection into a tear with a Weld constraint. First, select the vertices, and then click Make Tear.

**Clear Tears** Click to remove all tears from the Cloth modifier. You cannot remove individual tears.

**NOTE** Deleting a Weld constraint does not remove a tear: instead, it causes the mesh to break along those vertices, because the Weld constraint holds vertices together until tearing occurs.

**[Group list]**

Shows all current groups. The number of vertices associated with the highlighted group is shown below the list. To assign, copy, paste, delete, or edit a created group, first highlight the group name in the list.
**Copy** Copies a named selection set to the copy buffer.

**Paste** Pastes the named selection set from copy buffer.

**Shrink** Click to shrink the current vertex selection. 3ds Max removes the outer row and column from the selection.

**Grow** Click to grow the current vertex selection. 3ds Max adds an outer row and column to the selection.

**Ring** Select two vertices, and then click Ring to select the vertices that are perpendicular to these two.

Ring also works with selections of more than two vertices, but the results might not be what you expect. This is especially likely if Ignore Backfacing is turned off, as it is by default.
**Ring selection based on two vertices**

**Loop** Select two vertices, and then click Loop to select the vertices that are parallel to these two.

Loop also works with selections of more than two vertices, but the results might not be what you expect. This is especially likely if Ignore Backfacing is turned off, as it is by default.

**Element** Select one or more vertices, then click Element to select all the vertices in an element. An element corresponds to an Element in the underlying geometry: use this option with Editable Poly, Editable Patch, or Editable Mesh objects.

**Get Stack Selection** Gets a sub-object selection from below the Cloth modifier on the stack, and applies it to the Group vertex selection. For example, if you...
create an Editable Poly object, make a vertex sub-object selection for the Editable Poly object, apply the Cloth modifier, and then at the Group level click Get Stack Selection, the vertex selection is identical to the one you made for the Editable Poly object.

If the underlying selection is of a different sub-object type, such as Edge or Poly, clicking Get Stack Selection creates a selection whose vertices correspond to vertices in the underlying selection: for example, all vertices that belong to the Edges or the Polys selected below.

---

**Ignore Backfacing** When on, you can select only vertices that face you in a viewport. When off (the default), you can select any vertices under the mouse cursor, regardless of whether they face you in the viewport.

---

**Group Parameters Rollout (Cloth)**

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth > Modifier stack > Highlight the Group sub-object level > In a viewport, select vertices. > Group rollout > Click Make Group > Group Parameters rollout

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth > Modifier stack > Highlight the Group sub-object level > Group rollout > In the Group list, highlight the name of an existing group. > Group Parameters rollout

The Group Parameters rollout appears after you use Make Group on a vertex selection to create at least one group. Thereafter, highlight the group in the Group rollout list to display and edit the group's settings with the Group Parameters rollout.

**Interface**

**Constraint Parameters group**

If the currently highlighted group is unassigned (that is, not a constraint), then controls in this group are not available.
On When on, enables the constraint specified for the current group in the group list on the Group rollout, using remaining settings in this group box.

Soft Sets the constraint type to soft. A soft constraint uses springs between vertices. When off, the constraint is hard or rigid. The constraint types Node, Surface, Preserve, Drag, and SimNode can be hard or soft. Cloth, Group, and Forcefield constraints are always soft.

ID Uses a Material ID to attach the group to an object. This option applies only to Surface and Cloth constraints. If, when the constraint is created or initialized, the cloth vertices are not over a triangle, then the constraint will be created to the center of the nearest triangle that has the requisite Material ID. This could mean that several vertices might be constrained to the center of the same triangle. In this case, you should only use soft constraints. A hard constraint would pull all those cloth vertices to the same exact point on the triangle, which would look strange.

Offset The variance in the distance between a constrained group and its constraining, or target, object. The default value is 1.0 with Rel on (see following). This sets the constrained group to maintain its original distance from the target object. When set to 0.0, the constraint seeks to set the distance to the target object to zero.
  ■ rel Specifies the offset as a ratio of the original value. Available only with the Surface and Cloth constraint types. For example, if you want to move a constrained vertex by half its original distance, turn on the Rel. check box and set Offset to 0.5. Default=on.

Strength The stiffness of the springs used if the constraint is soft.
  ■ vc Sets vertex colors to determine the strength of the constraint. Default=off.

Damping The damping of the springs if the constraint is soft.
1-to-1 (The default.) When the mesh density is changed in Garment Maker, the group selection is reassigned. The 1-to-1 option selects the vertex closest to the original vertex.

Blob When the mesh density is changed in Garment Maker, the group selection is reassigned. The Blob option selects the original vertex and the ones created within a certain radius of it. The radius can be left at default or auto, or it can be set manually.

- **Radius**  When on, lets you set the radial distance used by the Blob option. When off, Blob uses an automatic radial value. Default=off; default value = 2.0.

**Behavior Settings group**

**Behavior Settings** Toggles the availability of the other settings in this group. When off, the other settings have no effect.

**Solid Coll** When on, the group vertices are used in solid-collision detection.

**Self Coll** When on, the group vertices are used in self-collision detection.

**Layer** Indicates the correct "order" of cloth pieces that might come in contact with each other. Range=–100 to 100. Default=0.

If your garments and/or panels are all correctly orientated to begin with, then cloth-to-cloth collision detection should keep items from interpenetrating. However, the initial state of a garment/panel might have some interpenetration that cannot be resolved. For example, suppose you make a jacket with Garment Maker where the front right panel is supposed to sit on top of the front left
panel. When you sew together the garment (generally with self-collision off), the front panels will interpenetrate, so to make sure that the right panel sits outside the left panel, you might have to use constraints or Live Drag. Using the Layers option on the panels can help here.

Here is the logic of layers: When two pieces of cloth (A and B) are in collision-detection range, their layers (layerA and layerB) are compared and the following rules are applied:

- If either layerA or LayerB is 0, then Cloth uses the regular cloth-to-cloth collision method.
- If layerA=layerB, then Cloth uses the regular cloth-to-cloth collision method.
- If abs(layerA) > abs(layerB) then piece A is pushed to the appropriate side of piece B. Which side? If layerB > 0, then to the side indicated by the face normals. If layerB<0 then to the opposite side.

The sign of the Layer value indicates what the "outside" of that piece of cloth is. A positive sign means "The side that the normals face is the outside".

Keep Shape When on, preserves the shape of the mesh based on the Bend % and Stretch % settings. In normal operation, when Cloth creates a simulation, it tries to "flatten out" the cloth. Default=off.

- Bend % Modulates the target bend angles to a value between 0.0 and the angles defined by the target state on page 1221. A negative value inverts the angles. Range=–100.0 to 100.0. Default=100.0.
- Stretch % Modulates the target stretch angles to a value between 0.0 and the angles defined by the target state on page 1221. A negative value inverts the angles. Range=0.0 to 100.0. Default=100.0.

Presets group

Sets the Cloth Properties parameters to the preset selected in the drop-down list. Any presets that are built into the system or that have been loaded will show up here.
**Load** Loads presets from the hard drive. Click this button and then navigate to the directory with your presets to load them into your Cloth Properties. Presets have the file name extension `.sti`.

**Save** Saves your Cloth Properties parameters to a file that you can then load at a later time.
**[Group properties]**

*Use These Properties* Turn on to set the cloth properties for the individual group, using the controls on this rollout. Default=off.
Get From Object  Click to sets the cloth properties of the group to be the same as the object to which the group belongs.

The remaining Properties controls are the same as those found in the Cloth Properties group on page 1225 of the Object Properties dialog for Cloth.

**Soft Selection group**

![Soft Selection controls](image)

The Soft Selection controls apply on a per-group basis to permit soft selection of vertices neighboring the explicitly selected group members. This works the same as soft selection of vertices in other parts of 3ds Max. For details, see *Soft Selection Rollout* on page 2014. Alternatively, you can select vertices for a group based on a texture map.

![Use Texture Map](image)

**Use Texture Map**  When on, Cloth uses a texture map to specify a soft selection of vertices that belong to the current group. Click the button (by default,
labeled “None”) to choose a texture map. Use the Mapping Channel controls to choose a map channel or vertex color channel. You can add a grayscale texture map in this slot to blend between unselected and fully selected pixels in the group. Black represents unselected and white represents fully selected. Any grayscale value blends between the two. You can drag a texture map onto this button.

NOTE For a texture map to apply to a group, at least one vertex must be explicitly selected. However, when Use Texture Map is on, the group’s explicit vertex selection has no effect.

Panel Sub-Object Level (Cloth)

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth > Modifier stack > Highlight the Panel sub-object level

At the Panel sub-object level, you can select one panel (cloth section) at a time and change its cloth properties.

A panel, which must be created by the Garment Maker modifier on page 1266, is a closed spline that is not enclosed by another spline. If a closed spline is enclosed by another spline, it forms a hole in the outer spline.

NOTE To be able to select a panel at this sub-object level, you must first use Object Properties on page 1222 to specify that the object is cloth. Also, to be able to change settings on this rollout, first turn on Object Properties > Use Panel Properties on page 1225.
Interface
**Presets group**

**Presets** Sets the selected panel's properties parameters to the preset selected in the drop-down list. Any presets that are built into the system or that have been previously saved and loaded will show up here. Presets have the file name extension `.sti`.

**Load** Load presets from a specified location on your hard drive. Click this button and navigate to the directory with your presets to load them into your Cloth Properties.

**Save** Save your Cloth Properties parameters to a file to be loaded at a later time. By default, Cloth preset files are saved to the `cloth` folder inside 3ds Max install directory.
These Properties controls are the same as those found in the Cloth Properties group on page 1225 of the Object Properties dialog for Cloth.
**Keep Shape group**

![Keep Shape](image)

**Keep Shape** When on, preserves the shape of the mesh based on the Bend % and Stretch % settings (see following). In a normal operation, when Cloth creates a simulation, it tries to "flatten out" the cloth.

**Bend %** Modulates the target bend angles to a value between 0.0 and the angles defined by the target state on page 1221. A negative value inverts the angles. Range=-100.0 to 100.0. Default=100.0.

**Stretch %** Modulates the target stretch angles to a value between 0.0 and the angles defined by the target state on page 1221. A negative value inverts the angles. Range=-100.0 to 100.0. Default=100.0.

**Layer** Sets the layer for the selected panel. See Behavior Settings group on page 1254.

**Seams Sub-Object Level (Cloth)**

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth > Modifier stack > Highlight the Seams sub-object level

The Seams sub-object rollout is used to define seam properties.
Interface

**On** Turn the seam on or off to make it active or inactive.

**Crease angle** Creates a crease at your seam. The angle value will determine the angle of the crease that will be between the two panels. (Can be positive or negative depending on which way you want to crease)

Left: High crease angle

Right: Low crease angle

**Crease Strength** Increase or decrease the strength of your seam. This value will effect how much the seam will resist bending in relation to the rest of the cloth object. A value of 2.0 means that the cloth will have twice the resistance to bending that it would otherwise have (as defined by the object/panel/vertex group properties).
Sewing Stiffness  The amount of force with which the panels will be pulled together at simulation time. A larger value will pull the panels together harder and faster.

Tearable When on, sets the selected seam to be tearable. Default=off.

- Tear Threshold  Sets a threshold value for tearing the seam. This value is equivalent to the Strength value of a Weld constraint at the Group sub-object level on page 1244. Default=10.0.

Enable All  Sets all seams on selected garment to be active.

Disable All  Sets all seams on selected garment to be off. This button deactivates the On check box for all seams.

Faces Sub-Object Level (Cloth)

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Cloth > Modifier stack > Highlight the Faces sub-object level

The Faces sub-object rollout enables interactive dragging of cloth objects while they are simulated locally. This sub-object level is useful for positioning cloth within your scenes in a more interactive way.

NOTE  If you position your cloth incorrectly, you can restore the original position by returning to the Object level and clicking the Reset State button.

Interface
Simulate Local  Starts local simulation of the cloth. In order for the real-time interactive feedback with the cloth to occur, this button must be on.

Live Drag!  When active you can drag selected faces as the local simulation is taking place.

Live Rotate!  When active, you can rotate selected faces as the local simulation is taking place.

Sim on mouse down  Runs the local simulation only when the left mouse button is clicked. This mode is usually preferred since you can start and stop the local simulation simply by releasing the mouse button. As a result, it makes it far easier to position and rotate the faces of your cloth within your scene.

Ignore Backfacing  When on, you can select only faces facing you. When off (the default), you can select any faces under the mouse cursor, regardless of visibility or facing.

**Garment Maker Modifier**

Select a shape object (spline or NURBS curve). > Modify panel > Modifier List > Object-Space Modifiers > Garment Maker

Garment Maker is a modifier that is designed to put together 2D patterns that you can then use with Cloth on page 1204. With Garment Maker you can take a simple, flat, spline-based pattern and convert it to a mesh, arrange its panels, and create seams to sew the panels together. You can also specify internal seam lines on page 1274 for creases and cuts.

- Cloth Modifier on page 1204

**Basic Concepts**

**Splines**

When you start working with Garment Maker, you begin either by importing or drawing traditional 2D splines in the 3ds Max Top viewport. To use a spline
with Garment Maker and eventually Cloth, it must be a closed shape. This does not mean that you cannot have splines inside of splines, but if you have multiple spline shapes inside of one another, the inner splines are treated as "holes" in the fabric, as shown below.

Two closed splines - one with a nested spline inside

Resulting geometry after applying Garment Maker
TIP For best results, when applying Garment Maker to multiple splines, first combine the splines into a single object.

Also, to keep your patterns precise, no rounding of boundary edges and corners, you must break the splines at the corner vertices. This is also important because it directly impacts the segments of the splines that are to be used to create seams between the individual panels. To understand this better, take a look at the following example.

In the image below are two rectangular splines to which a user might want to apply Garment Maker. After applying Garment Maker, the idea is to then create a seam between the two panels along the inner edge. First, it should be noted that both splines are closed shapes and have been attached so they are part of the same editable spline object.

When Garment Maker is assigned, look what happens:
Garment Maker seems to have "chopped" corners of the rectangular splines off, altering the pattern. Beyond that, if the user tried to select the edges of the panels that make up the seam, they will not be able to. This is because Garment Maker currently has only a single spline to work with for each panel.

To keep the pattern clean, do the following:

1. Access the Vertex sub-object level of the editable spline.
2. Select the vertices where seams are to be created.
3. Click Break to create unique segments that Garment Maker can use to create a seam.

Shown below are the results when all of the vertices are selected and then broken.
All vertices in both panels selected and then "broken"

Garment Maker applied to “broken” splines

The corners are now preserved. When the user goes to select the edges between the panels to act as seams, they will be selected independently of the other panel edges and highlight in red. This is what you want in order to create seams.
Garment Panels

Garment Maker’s Panels sub-object level lets you arrange the panels of the pattern around the character. You can then create seams where the panels should connect and be “sewn” together. This lets you create the seams you need while seeing how the clothing will look around your character. Creating seams like this is in many cases far superior to making them in a flat layout because it allows you to visualize what is being done.
Pattern Creation

To make patterns you can use the basic 2D spline tools in 3ds Max. Cloth comes with several patterns, but after you learn to use them, you will most likely want to start making your own. Patterns can take advantage of many features that real sewing patterns have, such as darts and multi-segment seams. To learn about other pattern making software, see Pattern-Making Software on page 1203.

Tricky Assemblies

As you begin to move beyond the basic patterns for your garments, there are a number of rules that you should follow in order to work effectively with Cloth:

- Always create your pattern splines in the Top viewport. Garment Maker assumes that the pattern is laid out this way.
- When seaming garments with MultiSegment edges, you must take care of the order in which the seams are made.
NOTE A MultiSegment comprises two or more individual segments acting as a single segment; you create it with Garment Maker.

When creating a seam you cannot use:

- A MultiSegment that has multiple gaps in it, unless all but one of those gaps are bridged by another seam.
- A segment or MultiSegment that forms a closed loop (that is, a path directly, or via seams, completely encloses the MultiSegment).

Both these issues arise in the common sleeve assembly shown below. The sleeve needs to be sewn to the armhole. When assembled, both the sleeve and the armhole form closed loops. The sleeve forms a loop via the seam along its underside. The armhole is closed by two seams: one across the shoulder and one down the side.

Now, since you cannot seam closed loops together, it therefore follows that both the armhole and sleeve must be left open when creating the seam connecting them. So the order is as follows:

1 Because the sleeve is one segment and the armhole is two segments, you must make a MultiSegment out of those two segments first.

2 When dealing with MultiSegment seams, the order of creation is important. If you attempt to create seams in the wrong order, you might get a “Seamline topology is wrong” error, and the seams will not be created. When dealing with MultiSegment seams, create the minimum number of seams necessary to make the MultiSegment seam match the topology of the other piece to that you are going to connect.

In this case, you have an arm seam that is open at the bottom, and a MultiSegment that is open at both the top and the bottom. If you closed the side of the garment, you'd end up with the situation illustrated in the center image below, where the seam is twisted (it cannot be "untwisted" by reversing the seam). By closing the top of the armhole MultiSegment with a seam at the shoulder, you'll create proper topology to make the MultiSegment seam.

3 Next, you can seam up the sleeve to the armhole. See the leftmost image below.

4 Finally, you can add the seam down the side of the garment and across the underside of the sleeve (the order is irrelevant here).
Left: Seam created for shoulder first and then for the MultiSegment, producing the desired result.

Middle: Seam created at the bottom of the body MultiSegment first, resulting in an irreversible MultiSegment seam from the arm to the body.

Right: No seams made on the body to connect its MultiSegment, resulting in a seam topology error.

Internal Seam Lines

When drawing panels, you can use extra open splines to define seam lines within the panels, also known as internal seam lines. Triangulation always occurs along these internal seam lines, so you can use them to help define the structure of the cloth panel, and as crease lines on page 1296. Also, you can specify that an internal seam line should be cut on page 1290, so that the cloth separates along the line during the simulation.

To create an internal seam line, simply specify a Material ID of 2 for the internal spline, which should not be closed. Also, for best results, keep its endpoints away from other splines in the shape. And, as with outside seam lines, an internal spline should not cross over itself or other splines.
Left: Open spline, set to Material ID 2, specifies internal seam line.  
Center: At Garment Maker > Curves or Seams sub-object level, seam line is selected 
and Cut is turned on.  
Right: Cloth separates along cut line during simulation.

Procedures

To place garment panels automatically:

The Garment Maker modifier provides tools for positioning garment panels 
on a humanoid character model. This automatic placement is approximate; 
further adjustment is typically necessary.

1. Load or create your character model.
2. Create your panels as splines or NURBS curves parallel to the world XY 
   plane (that is, create them in the Top viewport).

Shirt panels, as seen in the Top viewport
When applying Garment Maker to multiple splines, for best results, first combine the splines into a single object. You can still manipulate the separate pieces within the Garment Maker modifier at the Panels sub-object level.

3 Apply the Garment Maker modifier. Set parameters as necessary.

4 On the Main Parameters rollout, click the None button, and then click the character model. The object’s name appears on the button.

5 Below this button, click the Mark Points On Figure button. A character outline appears in the corner of each viewport. Superimposed on the outline are seven asterisk-shaped points; the one at the center-top of the chest is highlighted in red.
The character outline lets you mark points for positioning panels.

6 Click the corresponding point on the front of your model.
As you move the mouse cursor over the surface of the model, a red circle shows where the marker will be placed. When you click, an axis tripod appears on the surface at that location, and the next point on the character outline, at the center of the pelvic region, is highlighted in red.
7 Continue to click at each location on your model that corresponds to the highlighted marker on the character outline until you’ve designated all seven points.

All seven points are marked on the character model.

To finish, right-click in the viewport.

8 Go to the Panels sub-object level and select a panel.
The front shirt panel is selected.

9 At the bottom of the Panels rollout, choose a Level, and then in the Panel Position group, click the button corresponding to the desired position for the panel.

The panel moves to the designated position.
Adjust as necessary. For example, in the above illustration, Level should probably be set to Top At Neck. To correct this, you would choose Top At Neck, and then click Panel Position > Front Center again.
Of course, you can also move the panel manually; in fact, in most cases it will probably be necessary to do so. Panel Position serves primarily as a starting point for placing panels.

11 Continue selecting panels and placing them, adjusting as necessary.

All panels placed with Panel Position. Note that sleeve panels need to be rotated 90 degrees, and cuff panels need to be rotated and moved to the wrists.

**Main Parameters Rollout (Garment Maker)**

Select a shape object (spline or NURBS curve). > Modify panel > Modifier List > Object-Space Modifiers > Garment Maker > Main Parameters rollout

The Main Parameters rollout is the first rollout you see on the Modify panel once you apply the Garment Maker modifier.

This rollout comprises mostly controls to create and adjust the mesh. The remaining rollouts are available at the sub-object levels.
Interface

**Density** Adjusts the relative density of the mesh (in other words, the number of triangles per unit area). Possible values range between 0.01 and 10.0. A value of 10.0 creates a very dense mesh, while 0.01 creates a comparatively low-resolution mesh.

For best results, use the lowest possible density to achieve the desired result. This speeds up simulation time and overall performance.
Auto mesh When on, Garment Maker updates the mesh automatically if you change the density or add/remove seams. This setting is active at all sub-object levels, so it's recommended you leave it on to see changes as you make them. The only time you might want to turn off Auto Mesh is while creating the seams at the Curves sub-object level. Re-meshing can take some time, so you might want to define a number of seams before re-meshing.

Preserve When on along with Auto mesh, Garment Maker preserves the 3D shape of the object. When off, if you change the Density value, the panels are flat.

Relax When on, relaxes the default mesh to produce a smoother result. Default=off. (The default mesh is a standard Delaunay triangulation.)

Mesh It! Applies a change in the Density value. If Auto mesh is off when you change the Density value, you must click the Mesh It! button to apply the change.

TIP Sometimes in an error condition Mesh It! will no longer respond. If this happens, go to the spline level in the modifier stack, and then return to the Garment Maker level.

Mesh It and Preserve Applies a Density change and also preserves the 3D shape of the object. This lets you change the density of the cloth or the

---

Cloth and Garment Maker Modifiers | 1283
The following setting, comprising three radio buttons, determines how the cloth panels are passed up the modifier stack to the Cloth modifier:

- **Arranged Panels** With this option, the mesh passed up the stack will be have the panels arranged/bent around the figure as they were placed by the user in panels sub-object mode.

- **Preserved Surface** When both Auto mesh and Preserve are on, or when you click Mesh It And Preserve, Garment Maker takes a snapshot of the mesh at the top of the stack (where Cloth is applied). This snapshot is passed up the stack when you choose Preserved Surface. This way, if you change the Density value, the mesh will retain its deformation. Once a snapshot has been taken, at the Panel sub-object level, the panels will have the Use Preserved check box on. This means you can move the panels around while maintaining their deformation. Also note that once a snapshot has been taken, Garment Maker automatically chooses the Preserved Surface option.

- **Flat Panels** Displays all the panels as flat surfaces. This mode defines the texture coordinates of the garment vertices. With this output mode active, you can adjust texture coordinates at the Panel sub-object level by moving and rotating the panels.

**Stretch Map Coords** When on, the UV coordinates are based on the square bounding rectangle whose edge is the longer edge of the actual bounding box, and so have an aspect ratio of 1:1. When off, the UV coordinates do not maintain a 1:1 aspect ratio but use the actual bounding box.
Figure group

Use these controls to specify locations for each panel on the figure to be clothed.

[counter] Click this button, labeled “None” by default, and then click the object, or figure, to which the clothing is to be applied. Typically this is a character model. Thereafter, the name of the object appears on the button.

Mark Points on Figure After specifying a figure using the “None” button (see preceding), use this control to specify locations on the figure for automatically positioning panels in the garment.

When you click Mark Points On Figure, this character outline appears in the corner of each Viewport:
The character outline lets you mark points for positioning panels.

As each point highlights in red, click the corresponding location on your figure. When you do so, an axis tripod appears on the object surface and the next point on the outline highlights. During this process you can manipulate the viewport as usual, zooming, panning, and rotating freely. You can continue clicking points as long as you like; to stop, right-click in the viewport, or turn the button off.

**NOTE** If you return to marking points later, 3ds Max starts again where you left off earlier.

The points highlight in this order:

1. Upper Chest
2. Pelvis
3. Neck
4. Right shoulder
5. Left shoulder
6. Right hand
7. Left hand
After setting the points, you can use the Panel Position on page 1293 and Level on page 1294 controls at the Panels sub-object level to place the panels automatically.

**Curves Sub-Object Level (Garment Maker)**

Select a shape object (spline or NURBS curve). > Modify panel > Modifier List > Object-Space Modifiers > Garment Maker > Curves sub-object level > Curves rollout

Use the Curves sub-object level to stitch your pattern panels together.

You can also connect seams in the Seams sub-object mode with a more three-dimensional representation of the panels. The Curves sub-object level provides a flat layout to work in that can be useful for more complex patterns.

You can create and delete seams and adjust the way your pattern fits together.

**Interface**

![Curves sub-object level interface](image)
Create Seam Creates a seam between two segments. Select two segments of the panels you would like to sew together, and click Create Seam. This will make a seam between these two panels that will be sewn together at simulation time. Seams get a randomly-generated color to distinguish them from the panels.

Top: Segments selected  
Bottom: Seam made between two panels

Delete Seam Deletes selected seam. (Selected seam is colored red).

Reverse Seam Reverses or flips a twisted seam.  
When creating seams, the first vertex on each segment is used to line up the resulting seam panel. Sometimes you can end up with a twisted seam and will need to use Reverse Seam to untwist it.
A twisted seam that needs to be reversed

Make MultiSegment A MultiSegment is a combination of two or more segments that will be treated as one segment for the purpose of creating seams. Select the segments you want to combine then click this button. Note that if the segments are not contiguous, the gaps must be bridged by seams before this MultiSegment can be used in a seam.

Break MultiSegment Break apart selected MultiSegments.

On Turns the selected seam on or off, making it active or inactive.

Crease angle Creates a crease at the selected seam. The angle value determines the target angle of the crease between the two panels or along an internal seam line on page 1274.

Left: High crease angle
Right: Low crease angle

Crease Strength Increase or decrease the strength of the selected seam. This value affects how much the seam will resist bending in relation to the rest of the cloth.
the cloth object. A value of 2.0 means that the cloth will have twice the resistance to bending that it would otherwise have (as defined by the object/panel/vertex group properties).

**Sewing Stiffness** The amount of force with which the panels are pulled together at simulation time. A larger value pulls the panels together harder and faster.

**Cut** Applies only to an internal seam line on page 1274. Makes a cut in the fabric at this seam line.

**Tearable** When on, sets the selected seam to be tearable. Default=off.

**Tear Threshold** Sets a threshold value for tearing the seam. This value is equivalent to the Strength value of a Weld constraint at the Group sub-object level on page 1244. Default=10.0.

**Seam Tolerance** The amount of difference in length between two edges that is permitted in the formation of a seam. The two segments that comprise a seam should be about the same length. If they have different lengths, the difference must be within this tolerance range. If you seam together two segments that are significantly different in length, the cloth will tend to bunch up (which could be a desired effect). In order to allow the creation of such a seam, the Seam Tolerance will need to be increased. The default value is 0.06, which means that the two segment lengths must be within 6 percent of each other's lengths.

**Draw Seams** Shows the seams in the viewport; hides them when off.

**Show Mesh** Shows the mesh in the viewport, or hides it to work on your pattern. When this option is off, the mesh is represented with a bounding box.

### Panels Sub-Object Level (Garment Maker)

Select a shape object (spline or NURBS curve). > Modify panel > Modifier List > Object-Space Modifiers > Garment Maker > Panels sub-object level > Panels rollout

The Panels sub-object level of the Garment Maker modifier lets you position and bend the panels of your pattern to fit your object or figure.

You can also use these controls to adjust the texture mapping of your garment.
Density Controls the mesh density of a selected panel. This value is applied as a multiplier of the Main Parameters rollout > Density setting on page 1282. You can increase the density of a particular panel by raising this value.

If Main Parameters rollout > Auto Mesh is off when you change this value, go back to the Main Parameters rollout (Cloth level in modifier stack) and click Mesh It! on page 1283 to update the mesh. For this reason, it is recommended that you leave Auto Mesh on. The only time you might want to turn off Auto Mesh is while creating the seams at the Curves sub-object level. Re-meshing can take some time, so you might want to define a number of seams before re-meshing.

Different Density settings applied to separate panels

Mat ID Set the material ID for the selected panel. Using this option enables you to assign different materials to select portions of the clothing.

Position group

Reset Resets the position of the selected panels to their original locations (that is, the locations immediately after Garment Maker was applied).

Reset All Resets the position of all panels to their original locations.

Deformation group

Most controls in this group are available only when one or more panels are selected.

Reset Removes the deformation of the selected panels (restoring the flat state).
Reset All Removes the deformation from all panels.

Use Preserved Turn this on to override the None or Curved deformation options. When on, the panel gets its shape from the preserved mesh instead of the deformation options.

None Makes this panel flat.

Curved Use the value in the Curvature field to bend the panel.

Curvature Sets the amount of curve or bend of a panel. The higher this value is, the more the panel will curve.

X-axis Sets the axis for the curvature to the panel's local X axis.

Y-axis Sets the axis for the curvature to the panel's local Y axis.

Panel Position group

These buttons move the selected panel to a specified position. These positions are determined by 3ds Max based on the positions you set with the Mark Points On Figure on page 1285 controls at the Garment Maker object level. The positions are:

- Front Center
- Front Right
- Front Left
- Back Center
- Back Right
- Back Left
- Right Side
- Left Side
- Right Arm
- Left Arm

NOTE The terms Front, Back, Right, and Left refer to the character's orientation.
**Level group**

Sets where the top of the panel should go. Garment Maker derives these locations from the locations you specify with the Mark Points On Figure on page 1285 controls. The choices are:

- Top at neck
- Top at shoulder
- Top at underarm
- Top at waist

If you change the setting here, it affects the subsequent Panel Position results.

**Adjusting Texture Coordinates**

When Garment Maker is in Flat Panels mode (that is, the Main Parameters rollout > Flat Panels option on page 1284 is chosen), the texture coordinates are defined by the positions of the panels. Imagine the panels are being cut out of a large piece of fabric. The location and orientation of a panel in that large piece of fabric determine how the texture is aligned on it. By moving and rotating a panel, you can change its texture coordinates. Remember, you must be in Flat Panels mode to do this.

**Seams Sub-Object Level (Garment Maker)**

Select a shape object (spline or NURBS curve). > Modify panel > Modifier List > Object-Space Modifiers > Garment Maker > Seams sub-object level > Seams rollout

At the Seams sub-object level, you can define and edit seams and their properties.

Seams behave the same as curves, but at this level the mesh is displayed three-dimensionally instead of in a flat layout. Also, at this level the mesh is always updated when you add or remove a seam.
Create Seam Creates a seam between two segments. Select two segments of the panels you would like to sew together and then click Create Seam. This creates a seam between the two panels that will be sewn together at simulation time.
Right: Seam created between the two segments

**Delete Seam** Deletes selected seam. (Selected seam is colored red).

**Reverse Seam** Reverses or flips a seam that has been made with a twist in it. When creating seams, the first vertex on each segment is used to line up the resulting seam panel. Sometimes you can end up with a twisted seam and will need to use Reverse Seam to untwist it.

![A twisted seam that needs to be reversed](image)

**Make MultiSegment** A MultiSegment is a combination of two or more segments that will be treated as one segment for the purpose of creating seams. Select the segments you want to combine then click this button. Note that if the segments are not contiguous, the gaps must be bridged by seams before this MultiSegment can be used in a seam.

**Break MultiSegment** Break apart selected MultiSegments.

**On** Turns the selected seam on or off, making it active or inactive.

**Crease angle** Creates a crease at the selected seam. The angle value determines the target angle of the crease between the two panels or along an internal seam line on page 1274.
Crease Strength Specifies the strength of the selected seam. This value affects the extent to which the seam resists bending in relation to the rest of the cloth object. A value of 2.0 means that the cloth will have twice the resistance to bending that it would otherwise have (as defined by the object/panel/vertex group properties).

Sewing Stiffness The amount of force with which the panels are pulled together at simulation time. A larger value will pull the panels together harder and faster.

Cut This applies only to an internal seam line on page 1274. Makes a cut in the fabric at this seam line.

Tearable When on, sets the selected seam to be tearable. Default=off.

Tear Threshold Sets a threshold value for tearing the seam. This value is equivalent to the Strength value of a Weld constraint at the Group sub-object level on page 1244. Default=10.0.

Seam Tolerance The amount of difference in length between two edges that is permitted in the formation of a seam. The two segments that comprise a seam should be about the same length. If they have different lengths, the difference must be within this tolerance range. If you seam together two segments that are significantly different in length, the cloth will tend to bunch up (which may be a desired effect). In order to allow the creation of such a seam, the Seam Tolerance will need to be increased. The default is 0.06, which means that the two segment lengths must be within 6%.

Remove All Deletes all seams.
Draw Seams  Shows the seams in the viewport; hides them when turned off.

Show Mesh  Show the mesh in the viewport, or hide it to work on your pattern. When this option is off, the mesh is represented with a bounding box.

Troubleshooting and Error Codes in Garment Maker

When you are working with Garment Maker, you may encounter errors if your splines are set up incorrectly. This topic lists the common error messages you might see, and how to correct the problems they report.

Cannot remesh: the number of panels has changed:  This error occurs when the user has modified the original pattern, and added new closed splines to it. The only way to correct this is to delete the original Garment Maker modifier and reapply a new one.

Number of boundary curves has changed:  Users will get this error if they add or remove splines from the pattern after the initial application of Garment Maker. To correct it, delete the original Garment Maker modifier and reapply a new one.

Boundary splines do not form a closed loop:  In this case, the splines that the user has tried to apply Garment Maker to don't form closed loops. Often, this is caused by an extra vertex and segment attached to one of the splines, and usually this segment is so small you cannot see it. It can be difficult to find the offending part. To remedy this situation, select all the vertices, weld them, then re-break them at the corners.

Splines form overlapping loops:  When a user gets this error, it means that some panel loops overlap others (in the XY plane of the local view). If you create the shape in the Top view this should not happen (provided you don't create overlapping loops). Most commonly, this occurs when the user create the splines in a viewport other than Top and on a plane other than the XY plane.

Unable to create seam:  This error happens in when trying to create a seam in two cases:

- One (or more) of the segments/MultiSegments in the attempted seam forms a closed loop (for example, if you make a MultiSegment from the armhole segments, that MultiSegment forms a closed loop if you create seams at the shoulder and below the armhole). You will have to delete one of the seams so that the MultiSegment is no longer closed. For an armhole, you generally keep the seam below the armhole open when you join it.
with the sleeve. You can then close the seam. For the same reason, the sleeve cannot be seamed at the underside before joining to the armhole.

- A MultiSegment in the attempted seam contains segments that are not contiguous and that are not linked by any seam.

**Seam line topology is wrong:** This error usually occurs when you try to make a closed loop into a seam. The loop might be natural, or it might be the result of seams created earlier.

For example, when creating a shirt, if you first create the sleeve seam along the length of the sleeve, and then attempt to sew the sleeve to the armhole, this message appears. This is because a loop has been created in the spline that defines the top of the sleeve. The solution in this example is to create the seams in the correct order:

1. Shoulder-front to shoulder-back
2. Sleeve to armhole
3. Side-front to side-back
4. Along the length of the sleeve

See *Tricky Assemblies* on page 1272 for more information.

**CrossSection Modifier**

Select a spline object with spline cross sections. > Modify panel > Modifier List > CrossSection

Make a selection. > Modifiers menu > Patch/Spline Editing > CrossSection

The CrossSection modifier creates a "skin" across multiple splines. It works by connecting the vertices of 3D splines to form a skin. The resulting object is another spline object that can be used with the Surface modifier on page 1763 to create a patch surface. These two modifiers, when used together, are sometimes referred to collectively as “Surface Tools.”
CrossSection uses splines to create a model of a boat.

CrossSection can build a skin across various-shaped splines with different vertex counts and open/closed status. The more different the splines in vertex count and complexity, the more likely the skin will have discontinuity.

**NOTE** Similar functionality is provided by the Editable Spline object on page 620. At the Editable Spline > Segment and Spline sub-object levels, you can create a spline cage using Connect Copy and Cross Section. Using this method, you need to region-select the created vertices to transform them. Also, this method lets you define the ordering of the spline more easily than does the CrossSection modifier.

**Procedures**

**Example: To explore the CrossSection modifier:**

1. On the Create panel, click Shapes, then click Circle.
2. Drag in the Top viewport to create a circle about 100 units in radius.
3 On the Modify panel, choose Edit Spline from the Modifier List.

4 In the modifier stack display, turn on Spline sub-object, then select the circle.

5 In the Front viewport, Shift+Move the spline up to copy it.

6 Shift+Move the copy up to create a third circle.

**NOTE** The order that you attach or clone splines is important: this is the order that CrossSection uses to create the skin.

7 On the Modify panel, choose CrossSection from the Modifier List. CrossSection joins the vertices of the three circles. A basic spline cylinder is displayed.

8 On the Modify panel, on the Modifiers List, choose Surface to add the Surface modifier. The spline cylinder is transformed into a patch surface by the Surface modifier.

9 To edit the model's surface, change the splines using controls in the Edit Spline modifier. Or, since the output of the Surface modifier is a patch surface, add an Edit Patch modifier and use patch edit controls to change the surface.
An Edit Patch modifier above the Surface modifier was used to create the image.

Example: Using the CrossSection modifier to skin several splines with different shapes:

1. On the Create panel, click Shapes.
2. On the Object Type rollout, turn on Start New Shape, then click NGon.
3. In the Top viewport, create two five-sided circular NGons.
4. On the Create panel, with Shapes still active, click Line.
   Create two lines, each with four vertices. Create the vertices left-to-right.
On the main toolbar, click Select And Move, then move the objects in the viewport to order them along the Z axis with the NGons at the bottom and the lines above the NGons.

Select the bottom NGon.

On the Modify panel, choose Edit Spline from the Modifier List.

In the Geometry rollout, click Attach.

Select the remaining NGon and lines in an ascending order, as numbered in the image.
NOTE  The order of selection is important. The CrossSection modifier uses
the selection order to define the skin.

Example continued: Lining up the vertices:

1  On the Modify panel, choose the Vertex sub-object level in the
   stack display.
   Lining up the first vertex of each spline is important to prevent the surface
   from twisting.

2  Use Ctrl+click to select the rightmost vertex of each line and the
   bottommost vertex of each NGon.

3  On the Geometry rollout, click Make First.

Aligning the first vertex is important. This is where the seam forks, going
from a closed to an open spline.

Example continued: Using CrossSection and Surface to "skin" the shapes:

1  On the Modify panel, choose CrossSection from the Modifier List.
   The CrossSection modifier connects the splines at the vertices.

2  On the Modifiers List, choose Surface.
   The Surface modifier generates a patch surface based on the splines.

3  In the modifier stack display, choose the CrossSection modifier.
4 On the CrossSection Parameters rollout, toggle between Linear and Smooth. Notice how the splines change.

5 On the Modify panel, toggle the Show End Result On/Off Toggle button to display the final patch surface. The toggle won’t remain on if the CrossSection modifier is current. Drop down to the Editable Patch in the stack and turn on the Show End Result toggle if you like.

**TIP** When you use CrossSection, draw splines in a consistent direction. A twisted surface results when lines are created from vertices that are not lined up.

**Interface**

| Linear/Smooth/Bezier/Bezier Corner | Determines what type of curve will be used through the spline vertices. |

**Delete Mesh Modifier**

Modify panel > Make a sub-object selection. > Modifier List > Delete Mesh

Modify panel > Make a sub-object selection. > Modifiers menu > Mesh Editing > Delete Mesh

Delete Mesh provides parametric deletion based on the current sub-object selection level in the stack. The possible choices are faces, vertices, edges, and objects. Apply the Delete Mesh modifier to delete the geometry specified at that sub-object level.
Delete Mesh used to remove the faces where the handle joins the cup.

For example, you can apply a Mesh Select modifier on page 1500, select a row of faces in a cylinder, and then apply a Delete Mesh modifier to delete those faces. To undo the deletion, you can simply remove the Delete Mesh modifier.

**TIP** Try applying a Delete Mesh modifier following an animated Vol. Select modifier on page 1992.

### Procedures

**Example: To delete a row of faces in a cylinder:**

1. Create a cylinder on page 403.
2. Apply a Mesh Select modifier and select a row of faces in the cylinder.
3. Apply the Delete Mesh modifier to delete those faces.

   To undo the deletion, remove the Delete Mesh modifier.

### Interface

This modifier has no parameters.
Delete Patch Modifier

Modify panel > Make a patch selection. > Modifier List > Delete Patch
Make a selection. > Modifiers menu > Patch/Spline Editing > Delete
Delete Patch provides parametric deletion based on the current sub-object
level in the stack. The possible choices are vertices, edges, patches, and
elements. Apply the Delete Patch modifier to delete the geometry specified at
that sub-object level.

For example, you can apply a Patch Select modifier, select a row of patches in
a patch sphere, and then apply a Delete Patch modifier to delete those patches.
To undo the deletion, remove the Delete Patch modifier.

Delete Patch used to remove sections of a patch sphere.

Procedures

Example: To delete a patch in a sphere:
1. Create a sphere.
2 Right-click the sphere, and choose Convert To > Convert To Editable Patch on the quad menu.

3 On the Modify panel, in Editable Patch, choose the Patch sub-object level, and select a patch.

4 In the Modifier List, choose the Delete Patch modifier. This deletes the selected patch.
To undo the deletion, remove the Delete Patch modifier.

**Interface**

There are no parameters for this modifier.

**Delete Spline Modifier**

Modify panel > Select a spline sub-object. > Modifier List > Delete Spline
Modify panel > Select a spline sub-object. > Modifiers menu > Patch/Spline Editing > Delete Spline

The Delete Spline modifier provides parametric deletion of spline geometry based on the current sub-object selection level in the stack. The possible selection levels include vertices, segments, and splines. Apply the Delete Spline modifier to delete the geometry specified at that sub-object level.
Delete Spline used to remove a segment in the middle of a spline.

Procedures

To use the delete spline modifier:

1. Create a shape that contains multiple splines.
2. Apply a Spline Select modifier on page 1741 and select a section of the spline for deletion.
3. Apply a Delete Spline modifier to delete the section.

To undo the deletion, remove the Delete Spline modifier.

Interface

This modifier has no parameters.
Disp Approx Modifier

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Disp Approx

Make a selection. > Modifiers menu > Surface Deformers > Disp Approx

Make a selection. > Modifiers menu > NURBS Editing > Disp Approx

The Disp Approx modifier (short for Displacement Approximation) lets you make the displacement mapping settings on an object in the modifier stack on page 8187. It converts its input object to an editable mesh on page 2192, so you can use this modifier to add displacement mapping to geometry primitives on page 388 and any other kind of object that can convert to an editable mesh.

Using an image to displace the surface of a cylinder
Displacement mapping on page 6059 uses a map to change surface geometry. You apply the map using the Material Editor on page 5641.

You don’t need to apply this modifier to NURBS on page 2416 surfaces, patches on page 2408, editable meshes on page 2192, or editable polymeshes on page 2240, because you can apply displacement mapping directly to these kinds of objects.

Procedures

To apply displacement mapping:

1. Select an object other than a NURBS surface, patch, editable mesh, or editable poly.
2. Apply the Disp Approx modifier.
   Now you can apply displacement mapping to the object. The Displacement Approx. rollout has parameter that you can adjust, but displacement mapping will work using the default settings.
3. Go to the Material Editor. Apply a Standard material to the object.
4. In the material’s Maps rollout, click the Displacement button, then use the Material/Map Browser to apply a displacement map.
Interface

Subdivision Displacement Subdivides mesh faces to accurately displace the map, using the method and settings you specify in the Subdivision Presets and Subdivision Method group boxes. When turned off, the modifier applies the map by moving vertices in the mesh, the way the Displace modifier on page 1313 does. Default=on.

Split Mesh Affects the seams of displaced mesh objects; also affects texture mapping. When on, the mesh is split into individual faces before displacing them; this helps preserve texture mapping. When off, texture mapping is assigned using an internal method. Default=on.
TIP  This parameter is required because of an architectural limitation in the way
displacement mapping works. Turning Split Mesh on is usually the better technique,
but it can cause problems for objects with clearly distinct faces, such as boxes, or
even spheres. A box’s sides might separate as they displace outward, leaving gaps.
And a sphere might split along its longitudinal edge (found in the rear for spheres
created in the Top view) unless you turn off Split Mesh. However, texture mapping
works unpredictably when Split Mesh is off, so you might need to add a Displace
Mesh modifier on page 1068 and make a snapshot on page 950 of the mesh. You
would then apply a UVW Map modifier on page 1932 and then reassign mapping
coordinates to the displaced snapshot mesh.

Subdivision Presets and Subdivision Method group boxes

The controls in these two group boxes specify how the modifier applies the
displacement map when Custom Settings and Subdivision Displacement are
both turned on. They are identical to the Surface Approximation controls on
page 2737 used for NURBS surfaces.

Displace Modifier

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers >
Displace

Make a selection. > Modifiers menu > Parametric Deformers > Displace

The Displace modifier acts as a force field to push and reshape an object’s
geometry. You can apply its variable force directly from the modifier gizmo,
or from a bitmapped image.
Displace used to change the surface in the container

There are two basic ways to use the Displace modifier:

- Apply displacement effects directly by setting Strength and Decay values.
- Apply the grayscale component of a bitmapped image to generate the displacement. Lighter colors in the 2D image push outward more strongly than darker colors, resulting in a 3D displacement of the geometry.

The Displace space warp on page 2930 has similar features. It’s useful for applying effects to a large number of objects or a particle system.

**Force Distribution**

Displace distributes its force through four different gizmos: Planar, Cylindrical, Spherical, and Shrink Wrap. Gizmos are also used as mapping coordinates for applying bitmaps. Sphere and Shrink Wrap have the same effect when modeling, but differ in the way they map.

The Spherical and Shrink Wrap gizmos begin with a uniform field around them. The Cylinder and Planar gizmos are both directional. Cylinder pushes at right angles to its axis, and Planar pushes at right angles to its surface.
By default, gizmos are centered on the object. However, you can transform any of these shapes and use it directly as a tool to deform the geometry of an object.

**Modeling Options**

Displace is a versatile modifier with many possible applications. Here are some options:

- Produce interior modeling effects by scaling down the gizmo and moving it inside the object. The outward force shapes the geometry from within.
- Animate the modeling process. One result is a roving, magnetic-like field that pushes and pulls on a surface.
- Add additional Displace modifiers to an object, using each one to create a different modeling effect.
- Collapse a finished model into a plain mesh. This reduces the object's complexity and removes all modifiers, but keeps the modeled surface intact.

**Procedures**

**To displace an object:**

1. Select an object and apply the Displace modifier.
2. In the Parameters rollout > Map group, select one of the four gizmo types.
3. In the Displacement group, set values for Strength and Decay. Vary these settings to see the effect of the displacement on the object.

Depending on the object and the complexity of the bitmap, you might need to use dense geometry to see the effect clearly. Try a test run and, if necessary, add tessellation in the areas of greatest detail.

**To apply a bitmap as a displacement map:**

1. In the Parameters rollout > Image group, click the Bitmap button (which is labeled "None" until a map has been chosen). Use the file dialog to choose a bitmap.
2. Adjust the Strength value. Vary the strength of the field to see the effect of the bitmap displacing the object's geometry.
After you get the image you want from bitmapped displacement, you can apply an **Optimize modifier** on page 1557 to reduce the complexity of the geometry while retaining the detail.

**To model with the displace modifier:**

1. Apply Displace to the object you want to model. Choose a gizmo from the Map group.
2. Increase the Strength setting until you begin to see a change in the object.
3. Scale, rotate, and move the gizmo to concentrate the effect. As you do this, adjust the Strength and Decay settings to fine-tune the effect.

**Interface**

**Displacement group**

![Displacement group interface](image)

**Strength** When set to 0.0, Displace has no effect. Values greater than 0.0 displace object geometry or particles away from the position of the gizmo. Values less than 0.0 displace geometry toward the gizmo. Default=0.0.

**Decay** Varies the displacement strength with distance.

By default, Displace has the same strength throughout world space. Increasing Decay causes the displacement strength to diminish as distance increases from the position of the Displace gizmo. This has the effect of concentrating the force field near the gizmo, similar to the field around a magnet repelling its opposite charge. Default=0.0.

**Luminance Center** Determines which level of gray Displace uses as the zero displacement value.

By default, Displace centers the luminance by using medium (50 percent) gray as the zero displacement value. Gray values greater than 128 displace in the outward direction (away from the Displace gizmo) and gray values less than 128 displace in the inward direction (toward the Displace gizmo). Use the
Center spinner to adjust the default. With a Planar projection, the displaced geometry is repositioned above or below the Planar gizmo. Default=0.5. Range=0 to 1.0.

**Image group**

![Image group](image)

Lets you choose a [bitmap](#) on page 8523 and [map](#) on page 8631 to use for displacement. Both are assigned and removed in the same way.

**Bitmap button** Assigns a bitmap or map from a selection dialog. After you make a valid choice, these buttons display the name of the bitmap or map. This button is labeled "None" until you choose a map.

**Remove Bitmap/Map** Removes the bitmap or map assignment.

**Blur** Increase this value to blur or soften the effect of the bitmapped displacement.
Map group

Contains mapping parameters for bitmapped displacement. See UVW Map modifier on page 1932.

The four mapping modes control how Displace projects its displacement. The type of Displace gizmo and its location in the scene determine the final effect.
Displace gizmos: Planar, Cylindrical, Spherical, and Shrink Wrap

**Planar** Projects the map from a single plane.

**Cylindrical** Projects the map as if it were wrapped around the cylinder. Turn on Cap to project a copy of the map from the ends of the cylinder.

**Spherical** Projects the map from a sphere, with singularities at the top and bottom of the sphere where the bitmap edges meet at the sphere's poles.

**Shrink Wrap** Projects the map from a sphere, as Spherical does, but truncates the corners of the map and joins them all at a single pole, creating only one singularity at the bottom.

**Length, Width, Height** Specifies the dimensions of the Displace gizmo's bounding box. Height has no effect on Planar mapping.

**U/V/W Tile** Sets the number of times the bitmap repeats along the specified dimension. The default value of 1.0 maps the bitmap exactly once; a value of 2.0 maps the bitmap twice, and so on. Fractional values map a fractional portion of the bitmap in addition to copies of the whole map. For example, a value of 2.5 maps the bitmap two and a half times.

**Flip** Reverses the orientation of the map along the corresponding U, V, or W axis.

**Use Existing Mapping** Has Displace use mapping set earlier in the stack. This has no effect if the object is not mapped.
Apply Mapping Applies the Displace UV mapping to the bound object. This lets you apply material maps to the object using the same mapping coordinates as the modifier.

Channel group

Specifies whether to apply the displacement projection to a mapping channel or a vertex color channel, and which channel to use. For more information on these channels, see UVW Map modifier on page 1932.

Map Channel Choose this to specify a UVW channel to use for the mapping, and use the spinner to its right to set the channel number.

Vertex Color Channel Choose this to use the vertex color channel for the mapping.

Alignment group

Contains controls for adjusting the mapping gizmo's size, position, and orientation.

X, Y, Z Flips the alignment of the mapping gizmo along its three axes.

Fit Scales the gizmo to fit the object's bounding box.

Center Centers the gizmo relative to the object's center.

Bitmap Fit Displays a Select Bitmap dialog. The gizmo is scaled to fit the aspect ratio of the bitmap you select.

Normal Align Turns on Pick mode to let you select a surface. The gizmo is aligned to the normal of that surface.

View Align Orients the gizmo in the same direction as the view.
Region Fit  Turns on Pick mode to let you drag two points. The gizmo is scaled to fit the specified area.

Reset  Returns the gizmo to its defaults.

Acquire  Turns on Pick mode to let you choose another object and acquire its Displace gizmo settings.

Edit Mesh Modifier

Create or select an object > Modify panel > Modifier List > Object–Space Modifiers > Edit Mesh

Create or select an object > Modifiers menu > Mesh Editing > Edit Mesh

The Edit Mesh modifier provides explicit editing tools for different sub-object levels of the selected object: vertex, edge, and face/polygon/element. The Edit Mesh modifier matches all the capabilities of the base Editable Mesh object, except that you cannot animate sub-objects in Edit Mesh. See Editable Mesh on page 2192 for a complete parameter reference.

When possible, it’s far more efficient and reliable to perform explicit modeling at the Editable Mesh level rather than store those edits within the Edit Mesh modifier. The Edit Mesh modifier must copy the geometry passed to it, and this storage can lead to large file sizes. The Edit Mesh modifier also establishes a topological dependency that can be adversely affected if earlier operations change the topology being sent to it.

There are, however, situations where using the Edit Mesh modifier is the preferred method.

- You want to edit a parametric object as a mesh, but want to retain the ability to modify its creation parameters after the edit.

- You want to store your edits temporarily within Edit Mesh until you are satisfied with the results, before collapsing them permanently to an editable mesh object.

- You need to make edits across several objects at once, but do not want to convert them to a single editable mesh object.

- You have a modifier in the stack that must remain parametric, and the mesh must be edited after the modifier is applied.
NOTE Collapsing an object that has an Edit Mesh modifier applied to it results in an Editable Mesh object.

Edit Normals Modifier

Select a mesh, patch, spline or NURBS object. > Modify panel > Modifier List > Edit Normals
Select a mesh, patch, spline, or NURBS object. > Modifiers menu > Mesh Editing > Edit Normals

The Edit Normals modifier gives you explicit and procedural, interactive control over each of an object's vertex normals on page 8654. It is meant to be used primarily with mesh objects destined for output to game engines and other 3D rendering engines that support specified normals. The results are visible in the viewports and in rendered images.

The orientation of a vertex normal affects how neighboring surfaces reflect light. By default, normals are set so that reflection of light in 3ds Max follows the rules of real-world physics: The angle of reflection equals the angle of incidence. But by reorienting vertex normals, you can set the angle of reflection to be anything you want. The Edit Normals modifier lets you specify vertex normals' directions, combine and separate them, change the type, and copy and paste values among normals.

WARNING Don't apply an Edit Normals modifier to the low-res object used in normal bump projection on page 6856. Normal bump projection relies on the low-res object having standard normals, and altering them causes normal bump maps to have unpredictable results.

Types of Normals

Three types of normals are available with the Edit Normals modifier:

- **Unspecified**: These are the normals that the modifier derives from smoothing groups and initially assigns to the modified mesh vertices. 3ds Max calculates the direction of an unspecified normal based on the average facing of all polygons to which it belongs that are in its smoothing group. By default, each vertex has as many normals as the number of unique smoothing groups used by surrounding polygons. For example, each side of a box uses a different smoothing group by default, so each vertex at which three sides meet (typically a corner) has three different normals: one perpendicular to each of the three sides. On the other hand, a sphere
uses a single smoothing group, so each of its vertices has one normal, perpendicular to the average facing of the polygons that share it. By default, unspecified normals are displayed as blue.

- **Specified:** These are normals that are intended for use by particular corners of particular faces, without regard to smoothing groups. For instance, you might create a box, apply Edit Normals, select a group of normals at a particular vertex, and click Unify. Now those three faces are told specifically to use that one unified normal, and they ignore their smoothing groups at that vertex. But specified normals are not set to explicit values; they ignore smoothing groups, but they're still based on the face normals of the faces that use them. Specified normals are displayed as cyan.

- **Explicit:** These are normals that are set to particular values. For instance, if you use the Move or Rotate command to change a normal from its default value, it has to be made explicit, so it won't be recomputed based on the face normals. Explicit normals are green by default.

**NOTE** Explicit normals are also considered to be specified.

**NOTE** A selected normal is always red. When not selected, its color indicates as type, as noted above. You can find the customizable color entries on page 8272 for these normal types in the Elements > Geometry list. The three entry names are:
- Normals - Explicit
- Normals - Specified
- Normals - Unspecified

**Usage Examples**

Following are two instances in which a 3D artist creating content for output to a game engine might find practical use for the Edit Normals modifier:

- An artist is working on a knight with a chrome shield. The chrome shield has a DirectX cube map shader on page 8716 on it so that the artist can see the reflections in the viewport. The artist would like to make the reflections in the shield look "dented" by fights in battle. The artist applies the Edit Normals modifier to the shield object. He then adjusts several of the normals slightly, viewing the results in real time, thanks to the pixel shader. He then exports the character with a custom export tool designed to handle normal information.
A game artist is working on an object that will explode in the game. To do this, the game engine requires the object to be split into multiple objects: the broken pieces that will result from the explosion. When the object is broken apart in 3ds Max (using Slice), the normals are pointing in different directions; this makes it easy to see the seams between the broken pieces. To fix this, the artist selects all the pieces of the breaking object and applies the Edit Normal modifier to all of them at once. She then selects the normals across the seam and unifies them so they are pointing in the same direction. The artist then exports to the game engine.

**Usage Notes**

Please observe the following notes and precautions when using the Edit Normals modifier:

- Edit Normals supports both poly objects (polygon-based) and mesh objects (triangle-based). If you apply Edit Normals to a poly object, the result is a poly object. If you apply Edit normals to any other object type, the result is a mesh object.

- Edit Normals also supports embedding of edited-normal data when collapsing the stack, and when converting from poly object to mesh object, but not when converting from a mesh object to any other object type. If you apply Edit Normals to a primitive object, adjust the normals, and then collapse the stack (or convert to Editable Mesh), 3ds Max embeds any changes to the normals in the mesh object, including selection status. Primitive objects are mesh-based, so if you convert the same object to Editable Poly, the edited normals are lost. On the other hand, if you convert a primitive object to Editable Poly, apply Edit Normals, adjust the normals, and then collapse the stack, resulting in a poly object, the normals are retained. You can subsequently regain access to embedded, edited normals in a collapsed object by applying another Edit Normals modifier.

- Any modifiers that change topology will remove changes applied to the normals with the Edit Normals modifier. These include MeshSmooth, Tessellate, Slice, Mirror, Symmetry, Face Extrude, and Vertex Weld. Oddly enough, it also means that the Normal modifier (used to flip face orientations) will not support the edited normals. Since Turn To Poly can be used to modify face topology, it also strips off the edited normals.

- All compound objects strip off the edited normals from their operands.

- The good news: All deformation and map modifiers preserve the normals. For instance, if you apply a Bend, the normals should be bent along with
the geometry. Map modifiers, such as Unwrap UVW, won't affect the normals at all.

■ However, a few geometric modifiers do not fully support the new normals. They won't strip them away, but neither will they correctly deform any explicit normals. Modifiers in this category include Push and Relax.

■ The Smooth modifier correctly modifies any non-specified normals, while leaving the specified and explicit normals alone.

■ Like Mesh Select and Poly Select, Edit Normals “inherits” attributes from below it in the stack. For example, if you create a box, apply an Edit Normals modifier, change some normals, and then apply a second Edit Normals modifier, the top Edit Normals “inherit” the user-specified normals from the pipeline, just as Mesh Select adopts the current selection when you apply it. But the top Edit Normals modifier ignores any subsequent changes to the original Edit Normals modifier, just as Mesh Select ignores any changes made to the selection below it in the stack after it is applied.
The Edit Normals modifier is useful mainly at the sub-object level, Normal, so this level is active by default as soon as you apply the modifier to an object. At this point, you can see the normals as lines emanating from the mesh vertices, select and transform them, copy and paste them, and change their settings on the Modify panel.

You can transform normals only by moving and rotating them, not by scaling them. However, moving a normal effectively rotates it, so in most cases you’ll have better control by using the Rotate tool.

The following command reference includes keyboard shortcuts, which are available when the Keyboard Shortcut Override Toggle on page 8420 (on the toolbar) is on. In addition, you can use Ctrl+0 (zero) to access the object level of the modifier.
Select By group Lets you specify how to select normals in the viewport:

- **Normal (Ctrl+1):** Click a normal to select it.
- **Vertex (Ctrl+2):** Click a mesh vertex to select all of its normals.
- **Edge (Ctrl+3):** Click a mesh edge to select the normals associated with the neighboring polygons.
- **Face (Ctrl+4):** Click a mesh face (or polygon) to select the associated normals.

Of course, with all of these methods, you can also use region selection to select multiple normals at once.

**Ignore Backfacing** When on, selection of sub-objects affects only those facing you. When off (the default), you can select any sub-object(s) under the mouse cursor, regardless of their visibility or facing. If there are more than one sub-object under the cursor, repeated clicking cycles through them. Likewise, with Ignore Backfacing off, region selection includes all sub-objects, regardless of the direction they face.

**Show Handles** Enables the display of handles, which are small squares at the end of each normal. Turn this on to make it easier to select normals.

**Display Length** Specifies the length of each normal. This is for display purposes only; the length has no effect on the normal's functionality.

**Unify (U)** Combines all selected normals at each vertex into a single specified normal on page 1322. By default, with Unify/Break To Average off, Unify sets the direction for each unified normal to be perpendicular to the averaged surface at that point. With Unify/Break To Average on, Unify sets the direction be the average of the combined normals at each location.

**Break (B)** Separates all selected, unified normals into their original components. With Unify/Break To Average off, Break orients each separated normal perpendicular to its respective face, thus splaying out the normals at each vertex if the connected faces are at different angles (as with a sphere). With Unify/Break To Average on, each separated normal uses the orientation of the original normal.

Break converts any selected normals to specified normals.

**Unify/Break to Average** Determines normal orientation as the result of a Unify or Break operation. See the descriptions above for details. Default=off.
Average group

These controls give you different methods of averaging vertex normals; that is, setting them all to the same absolute angle, which is the average of their combined angles.

**Selected** Sets selected normals to the same absolute angle: the average angle of all of them. If Use Threshold is on, averages only normals whose distance from each other is less than that specified in the Average Threshold spinner (to the button’s right).

**Use Threshold** Activates the Average Threshold setting, and causes the Selected to average only normals whose distance from each other is less than the specified value.

**Target** Enters an interactive mode in which you specify pairs of normals to average. Click Target, and then select a normal. When the mouse cursor is over a normal, it changes to a + cursor. After clicking the first normal, a rubber-band dashed line connects the normal to the mouse cursor. Click a second normal to average the angles of the two normals.

The pixels spinner to the right of the Target button sets the maximum distance in screen pixels between the mouse cursor and the target normal.

---

**Copy Value** (Ctrl+C) Copies the selected normal’s orientation to the copy buffer. Available only when a single normal is selected.

Use Copy Value and Paste Value to apply a normal’s orientation to one or more others within the same Edit Normals modifier. You cannot copy normals between modifiers.

**Paste Value** (Ctrl+V) Applies the paste buffer contents to the current selection. Available only after Copy Value has been used to place a normal’s orientation in the copy, and one or more target normals are selected.

**Specify** (S) Converts selected normals to specified normals on page 1323.

**Reset** (R) Causes all selected normals to revert to unspecified on page 1322 status, and returns them to their initial, calculated positions. Also breaks apart unified normals.

**Make Explicit** (E) Converts selected normals to explicit normals on page 1323.

[Selection Display] When one normal is selected, shows its ID number. When 0 or more than one normal is selected, shows the number of normals selected.
**Edit Patch Modifier**

Create or select an object > Modify panel > Modifier List > Object-Space Modifiers > Edit Patch

Create or select an object > Modifiers menu > Patch/Spline Editing > Edit Patch

The Edit Patch modifier provides editing tools for different sub-object levels of the selected object: vertex, handle, edge, patch, and element. The Edit Patch modifier matches all the capabilities of the base Editable Patch object, except that you cannot animate sub-objects in Edit Patch. See Editable Patch on page 2360 for a parameter reference.

Other than the inability to animate sub-objects with Edit Patch, the main difference between Edit Patch and Editable Patch is that the modifier incorporates the ability of the Surface modifier to generate a patch object from a spline cage. For details, see Spline Surface on page 1330.

When possible, it's far more efficient and reliable to perform explicit editing on an Editable Patch object rather than store those edits within the Edit Patch modifier. The Edit Patch modifier must copy the geometry passed to it, and this storage can lead to large file sizes. The Edit Patch modifier also establishes a topological dependency that can be adversely effected if earlier operations change the topology being sent to it.

There are, however, situations where using the Edit Patch modifier is the preferred method.

- You want to edit a parametric object as a patch, but want to retain the ability to modify its creation parameters after the edit.
- You want to store your edits temporarily within Edit Patch until you are satisfied with the results, before committing them permanently to an editable patch.
- You want to streamline your workflow with the Spline Surface tools, which are unique to Edit Patch.
- You need to make edits across several patch objects at once, but do not want to convert them to a single editable patch object.
- You have a modifier in the stack that must stay parametric, and the resulting patch must be edited after the modifier is applied.
Procedures

To create a patch object using the Cross Section and Spline Surface tools:

This procedure describes how to simplify the workflow of building objects using a spline cage to which a patch surface is applied, a method described in the Surface modifier on page 1763 topic as “Surface Tools.”

1. Create a spline object.
   Make sure that the spline vertices form valid three-sided or four-sided polygons. Vertices on splines that cross one another should be coincident.
   To make spline vertices coincident, drag vertices over each other with 3D Snap turned on. 3D Snap must have the Vertex or End Point option turned on. With 3D Snap turned on, you can snap to vertices on existing splines as you create new splines. You can also select vertices and use the Fuse option in an Editable Spline to make vertices coincident.

2. Convert the spline object to an Editable Spline, if necessary, or apply an Edit Spline modifier.

3. Use the Cross Section command on page 633 in Edit/Editable Spline to add splines connecting different splines in the spline object, thus creating a spline cage.
   This replaces the previous workflow of using the CrossSection modifier.

4. Apply the Edit Patch modifier to the spline object.
   By default, in Edit Patch the Geometry rollout > Spline Surface group > Generate Surface option is on, causing the modifier to create patches over all valid three- and four-sided polygons in the spline cage.
   This replaces the previous workflow of using the Surface modifier.

5. Adjust the Spline Surface settings and edit the object as necessary. If you modify the spline object, for best results, edit at the Vertex sub-object level, and be sure to select all vertices at an intersection before moving them.
Interface

Spline Surface group

The Geometry rollout > Spline Surface group is found only in the Edit Patch modifier; it's not available in the Editable Patch object. The group becomes available when the object to which the Edit Patch modifier is applied consists of splines. Its controls replicate the functionality of the Surface modifier on page 1763.

For best results, apply the Spline Surface controls after creating a spline cage with the CrossSection modifier on page 1299 or the Editable Spline Cross Section command on page 633. The latter approach approximates the Surface Tools workflow (described in the Surface Modifier topic), but with a simpler modifier stack; instead of additional CrossSection and Surface modifiers, the stack need contain only an Editable Spline object and an Edit Patch modifier. Alternatively, you can use the Edit Spline modifier's Cross Section command.

Generate Surface Creates a patch surface using existing splines to define the patch edges. Default=on.

Threshold Determines the overall distance that is used to weld the vertices of the spline object. All vertices/vectors within the threshold distance of each other are treated as one. Threshold uses units set in the Units Setup dialog on page 8366. Default=1.0.

NOTE Spline control handles are also treated as vertices, so setting high Threshold levels can produce unexpected results.

Flip Normals Reverses the facing direction of the patch surface. Default=off.

Remove Interior Patches Removes interior faces of an object that you would not normally see. These are the faces created within the caps or other interior patches of the same type of a closed polygon. Default=on.
**Use Only Selected Segs** Only segments selected in the Edit Spline modifier or the editable spline object will be used by the Surface modifier to create patches. Default=off.

**NOTE** Segment Sub-Object does not have to be left on in the Edit Spline modifier or editable spline object.

---

**Edit Poly Modifier**

Create or select an object. > Modify panel > Modifier List > Object-Space Modifiers > Edit Poly

Create or select an object. > Modifiers menu > Mesh Editing > Edit Poly

Create or select an object. > **modeling ribbon** on page 2025 > Polygon Modeling panel > Apply Edit Poly Mod

The Edit Poly modifier provides explicit editing tools for different sub-object levels of the selected object: vertex, edge, border, polygon, and element. The Edit Poly modifier includes most capabilities of the base Editable Poly object, except for Vertex Color information, Subdivision Surface rollout, Weight and Crease settings, and Subdivision Displacement rollout. Edit Poly lets you animate sub-object transforms and parameter changes. In addition, because it's a modifier, you can retain the object creation parameters and change them later. For detailed information about animating with Edit Poly, see these procedures on page 1340.

Edit Poly gives you these options:

- Transform or Shift+Clone the selection, as with any object.
- Use the options supplied on the Edit rollouts to modify the selection or object. Later topics discuss these options for each of the polymesh components.
- Pass a sub-object selection to a modifier higher in the stack. You can apply one or more standard modifiers to the selection.

**TIP** You can exit most Edit Poly command modes, such as Extrude, by right-clicking in the active viewport.
Overriding Actions with Press/Release Keyboard Shortcuts

While working with poly objects, you can use a “press/release keyboard shortcut” to temporarily override the current operation and perform a different one. As soon as you release the keyboard shortcut, you return to the previous operation.

For example, you might be working at the Polygon sub-object level, moving polygons, and need to rotate the object to access a different part of it. Instead of having to exit the Polygon sub-object level, rotate the object and then re-enter the sub-object level, you could simply press and hold 6, rotate the object, release the key, and immediately return to moving polygons.

To see a list of press/release keyboard shortcuts, go to Customize > Customize User Interface > Keyboard panel, open the Group drop-down list, and choose Edit Poly or Editable Poly. The actions in boldface are the ones that you can assign as press/release shortcuts. Not all are assigned; for information about assigning keyboard shortcuts, see Keyboard Panel on page 8250.

Differences Between Edit Poly and Editable Poly

Functionality in Edit Poly is mostly the same as that of Editable Poly. Please note the following differences:

- Edit Poly is a modifier, with all properties that modifier status entails. These include the ability to place Edit Poly above a base object and other modifiers
on the stack, to move the modifier to different locations in the stack, and to apply multiple Edit Poly modifiers to the same object, each containing different modeling or animation operations.

- Edit Poly has two distinct modes of operation: Model and Animate. See Edit Poly Mode rollout on page 1342.

- Delete Isolated Vertices is now an option on the Edit Geometry rollout. Previously, it appeared as a dialog every time you deleted contiguous polygons. Now you can set it and forget it.

- Edit Poly eliminates the Full Interactivity switch; this feature is on all the time.

- Edit Poly provides two new ways of obtaining an existing selection from lower in the stack: Use Stack Selection on page 1350 and Get Stack Selection on page 1355.

- In addition to the Settings dialogs from Editable Poly, Edit Poly gives you an Align Geometry dialog on page 1422, available from the Settings button on the Edit Poly Mode rollout on page 1342.

- Edit Poly lacks Editable Poly's Subdivision Surface and Subdivision Displacement rollouts. There are no Weight or Crease settings for vertices, edges, or borders. If you need to use Weight and Crease settings with Edit Poly, apply a Meshsmooth modifier on page 1505, set Iterations to 0, and then make the settings as desired. Also, there is no provision for setting vertex properties such as color.

- In Animate mode, you begin a slice operation by clicking Slice, not Slice Plane. You still need to click Slice Plane to move the plane around. You can animate the slice plane.

- In some cases, several Undo commands on page 240 might be required to revert from changes made with certain Edit Poly operations, such as Extrude.

  For example, if you extrude a polygon using the Extrude Polygons dialog on page 2349, there will be three Undo actions. The first undoes the Commit, which happens automatically when you click the dialog OK button at the end; the second undoes the change in height (from 0 to the height you set); and the third undoes the entry into the Extrude operation.

Following is a table showing the Edit Poly functions that are and are not animatable. Functions that are not animatable are unavailable in Animate mode. Functions marked “Yes” can be animated explicitly in Animate mode.
Functions marked “Proc” cannot be animated explicitly, but can be animated procedurally. This means they can be applied to different parts of the Edit Poly object at different points in the animation by means of an animated sub-object selection passed up the stack. For further information, see this procedure on page 1341.

**Edit Poly Workflow**

Edit Poly differs from other Edit modifiers in 3ds Max in that it provides two different modes, available on the Edit Poly Mode rollout: one for modeling and another for animating. By default, Edit Poly operates in Model mode, whose functionality is mostly the same as that of Editable Poly. Alternatively, you can work in Animate mode, which makes available only functions that you can animate.

Each Edit Poly modifier can preserve any number of keyframes animating a single operation type, such as transforming faces, on the same sub-object selection. To animate other parts of the object, or to animate a different operation on the same sub-object selection, just use another Edit Poly modifier.

You’ll find functions specific to the active sub-object level on a special rollout, leaving the Edit Geometry rollout with functions that can be used at most sub-object levels, as well as at the object level.

Also, many commands are accompanied by a Settings button, which gives you a second way to use the command:

- In Direct Manipulation mode, activated by clicking the command button, you apply the command by manipulating sub-objects directly in the viewport. An example of this is Extrude: You click the Extrude button, and then click and drag sub-objects in the viewports to extrude them.

**NOTE** Some buttons, such as Tessellate, operate on the mesh immediately, with no viewport manipulation required.

- Interactive Manipulation mode is well suited to experimentation. You activate this mode by clicking the command’s Settings button. This opens a non-modal settings dialog and places you in preview mode, where you can set parameters and see the results immediately in the viewport on the current sub-object selection. You can then accept the results by clicking OK, or reject them by clicking Cancel. You can also use this mode to apply the same or different settings to several different sub-object selections in a row. Make the selection, optionally change the settings, click Apply, and then repeat with a different selection.

**IMPORTANT** When you click Apply, the settings are “baked into” the selection, and then applied again to the selection as a preview. If you then click OK to exit, you will have applied the settings twice. If your intention is to apply them only once, simply click OK the first time, or click Apply, and then Cancel.
NOTE  Changes implemented in Interactive Manipulation mode with editable poly objects cannot be animated. However, they can with Edit Poly objects.

- Poly Select Modifier on page 1582
- Turn To Poly Modifier on page 1830
- Editable Poly Surface editable poly on page 2240

Procedures

To animate an Edit Poly operation on a sub-object selection:

1. Select an object.
2. Apply the Edit Poly modifier.
3. Go to the first frame at which to set a key and turn on Auto Key.
4. On the Modify panel > Edit Poly Mode rollout, choose Animate.
5. Make a sub-object selection.
6. Perform an operation on the selection, such as a transform or extrusion.
7. Proceed to the next keyframe and continue to change settings for the current operation and sub-object selection.

   If you change the selection, the existing animation is applied to the new selection, and lost from the previous one. If you change the operation, any changes from the previous animation are frozen (that is, “baked” into the model) at the current frame, and only new keyframes are recorded in the current Edit Poly modifier.

   To animate different sub-object selections using different operations, use multiple applications of the Edit Poly modifier.
To apply an Edit Poly operation to an animated sub-object selection:

This procedure demonstrates procedural animation with Edit Poly: the ability to change the location of application on an object during an animation using an existing, animated sub-object selection.

1. Select an object.
2. Create an animated sub-object selection. One way to do this is to apply a Volume Select modifier on page 1992 and animate the gizmo's transform, or animate the modifier effect by using an animated texture map.
3. Apply the Edit Poly modifier.
4. Go to the same sub-object level in Edit Poly, and then, on the Selection rollout, turn on Use Stack Selection.
5. Scrub the time slider.
   The animated selection appears on the Edit Poly object.
6. On the Modify panel > Edit Poly Mode rollout, choose Animate.
7. Perform an operation on the sub-object selection, such as a chamfer or extrusion. You needn't turn on Auto Key or use Set Key.

**NOTE** With Use Stack Selection on, you can't change the selection.

Now, when you play the animation, the Edit Poly effect moves along with the animation of the sub-object selection.

If you decide to animate a different function procedurally, first click Edit Poly Mode rollout > Cancel.

**Example: To apply an Edit Poly operation procedurally to an animated model:**

Edit Poly lets you layer an animated sub-object operation on top of an existing animation. Try this brief example:

1. Create an animated model, such as a box with an animated Bend modifier.
2. Apply an Edit Poly modifier, and on the Edit Poly Mode rollout, choose Animate. Also turn on Auto Key.
3. Go to the Polygon sub-object level.
4. Go to frame 20 and extrude a polygon.
5. Play the animation.
The extrusion animation plays “on top” of the existing animation. This isn’t possible with the Edit Mesh modifier.

**Interface**

**Stack Display**

For more information on the stack display, see Modifier Stack on page 8187.

**Show End Result** Because Edit Poly is a modifier, if you apply further modifiers and then return to the Edit Poly stack entry, Show End Result is on by default, and you can still see the results of any modifiers above Edit Poly on the stack. This is different from the Editable Poly object, where if you apply a modifier such as Symmetry on page 1803 and then return to the Editable Poly stack entry, you cannot see the effect of the modifier on the object’s geometry. While at a sub-object level, if you turn on Show Cage on the Edit Poly Mode rollout, you can see the final object as a white mesh, the original sub-object selection as a yellow mesh, and the original Edit Poly object as an orange mesh.

**Edit Poly Mode rollout**

This rollout provides access to Edit Poly’s two modes of operation: Model, for modeling, and Animate, for animation of modeling effects. For example, you can animate the Taper and Twist settings for polygons extruded along a spline.

During and between sessions, 3ds Max remembers the current mode for each object separately. The same mode remains active at all sub-object levels.

Edit Poly Mode also gives you access to the current operation’s Settings dialog, if any, and lets you commit to or cancel out of modeling and animation changes.

**Model** Lets you model using the Edit Poly functions. Operations in Model mode cannot be animated.
**Animate** Lets you animate using the Edit Poly functions. In addition to choosing Animate, you must turn on Auto Key on page 8090 or use Set Key on page 8093 for animating sub-object transforms and parameter changes. Alternatively, in Animate mode you can apply a single command, such as Extrude or Chamfer, to an animated sub-object selection passed up the stack.

**TIP** If you use Set Key to animate with Edit Poly, be sure to turn on Key Filters > Modifiers.

**NOTE** The Edit Poly modifier can store any number of keyframes animating a single operation, such as transforming polygons, on the same sub-object selection. Use additional Edit Poly modifiers to:
- animate other parts of the object
- animate repeated applications of the same operation on the same sub-object selection
- animate repeated applications of a different operation on the same sub-object selection

For example, say you want to animate a polygon extruding from an object from frame 1 to 10, and then moving back to the original position over the next 10 frames. You can accomplish this with a single Edit Poly modifier using the Extrude function, setting one keyframe at 10 and another at 20. However, say you want to animate a polygon extruding outward, and then animate movement of one of the resultant side polygons. In that case, you’d need two Edit Poly modifiers: one for the extrusion, and another for the poly transform.

**TIP** While modeling in Animate mode, you can use Commit on page 1344 to freeze the animation at the current frame.

**[label]** Shows the current command, if any. Otherwise, it shows <No Current Operation>.

When you're working in Model mode using direct manipulation (that is, working in the viewports), the label shows the current operation during drag operations, and then returns to the unavailable state.

When you're working in Model mode using a Settings dialog, or in Animate mode using direct manipulation or a Settings dialog, the label continually shows the current operation.
Commit In Model mode, using a Settings dialog, accepts any changes and closes the dialog (same as the OK button on the dialog). In Animate mode, freezes the animated selection in its state at the current frame and closes the dialog. Any existing keyframes are lost.

**TIP** Commit lets you use animation as a modeling aid. For example, you could animate a vertex selection between two positions, scrub between the two to find a suitable in-between position, and then use Commit to freeze the model at that point.

**Settings** Toggles the Settings dialog for the current command.

**Cancel** Cancels the most recently used command.

**Show Cage** Toggles the display of a two-color wireframe that shows the editable poly object before modification or subdivision. The cage colors are shown as swatches to the right of the check box. The first color represents unselected sub-objects, and the second color represents selected sub-objects. Change a color by clicking its swatch. The Show Cage toggle is available only at sub-object levels.

The cage displays the original structure of the edited object.
Typically this feature is used in conjunction with the MeshSmooth modifier on page 1505 because it lets you easily toggle visibility of the unsmoothed base object while simultaneously viewing the smoothed result, but it works with any modifier.

**TIP** Show Cage is also particularly helpful when used with the Symmetry modifier on page 1803.

### Selection rollout

The Selection rollout provides tools for accessing different sub-object levels and display settings and for creating and modifying selections. See Selection Rollout (Edit Poly Modifier) on page 1346.

### Soft Selection rollout

Soft Selection controls apply a smooth falloff between selected sub-objects and unselected ones. When Use Soft Selection is on, unselected sub-objects near your selection are given partial selection values. These values are shown in the viewports by means of a color gradient on the vertices, and optionally on the faces. They affect most types of sub-object deformations, such as the Move, Rotate, and Scale functions and any deformation modifiers (such as Bend) applied to the object. This provides a magnet-like effect with a sphere of influence around the selection.

For more information, see Soft Selection Rollout on page 2014.

### Edit (sub-object) rollout

The Edit (sub-object) rollouts provide sub-object-specific functions for editing an Edit Poly object and its sub-objects. For specific information, click any of the following links:

- Edit Poly (Object) on page 1357
- Edit Poly (Vertex) on page 1359
- Edit Poly (Edge) on page 1368
- Edit Poly (Border) on page 1389
- Edit Poly (Polygon/Element) on page 1395
**Edit Geometry rollout**

The Edit Geometry Rollout (Polymesh and Edit Poly) provides global functions for editing an Edit Poly object and its sub-objects.

**Paint Deformation rollout**

Paint Deformation lets you stroke elevated and indented areas directly onto object surfaces. For more information, see Paint Deformation Rollout (Polymesh) on page 2333.

**Selection Rollout (Edit Poly Modifier)**

Select an Edit Poly object. > Modify panel > Selection rollout

The Selection rollout provides tools for accessing different sub-object levels and display settings and for creating and modifying selections. It also displays information about selected entities.

When you first access the Modify panel with an Edit Poly object selected, you're at the Object level, with several functions available as described in Edit Poly (Object) on page 1357. You can toggle the various sub-object levels and access relevant functions by clicking the buttons at the top of the Selection rollout.

Clicking a button here is the same as choosing a sub-object type in the modifier stack display. Click the button again to turn it off and return to the Object selection level.
NOTE You can convert sub-object selections in three different ways with the use of the Ctrl and Shift keys:

- To convert the current selection to a different sub-object level, clicking a sub-object button on the Selection rollout with Ctrl held down. This selects all sub-objects at the new level that touch the previous selection. For example, if you select a vertex, and then Ctrl+click the Polygon button, all polygons that use that vertex are selected.

- To convert the selection to only sub-objects all of whose source components are originally selected, hold down both Ctrl and Shift as you change the level. For example, if you convert a vertex selection to a polygon selection with Ctrl+Shift+click, the resultant selection includes only those polygons all of whose vertices were originally selected.

- To convert the selection to only sub-objects that border the selection, hold down Shift as you change the level. The selection conversion is inclusive, meaning:
  - When you convert faces, the resulting selection of edges or vertices all belong to selected faces that bordered unselected faces. Only the edges or vertices that bordered unselected faces are selected.
  - When you convert vertices to faces, the resulting selection of faces had all of their vertices selected and bordered unselected faces. When you convert vertices to edges, the resulting selection contains only edges all of whose vertices were previously selected and only edges of faces that did not have all vertices selected; that is, of faces around the border of the vertex selection.

Face selection (left) converted to vertex border (center) and edge border (right)
When you convert edges to faces, the resulting selection of faces had some but not all of their edges selected, and were next to faces with no edges selected. When you convert edges to vertices, the resulting vertices are on previously selected edges, but only at intersections where not all edges were selected.

Conversion commands are also available from the quad menu.
**Interface**

- **Vertex** Accesses the Vertex sub-object level, which lets you select a vertex beneath the cursor; region selection selects vertices within the region.

- **Edge** Accesses the Edge sub-object level, which lets you select a polygon edge beneath the cursor; region selection selects multiple edges within the region.

- **Border** Accesses the Border sub-object level, which lets you select a sequence of edges that borders a hole in the mesh. A border comprises only connected edges with faces on only one side of them, and is always a complete loop. For example, a default box primitive doesn't have a border, but the teapot object has a couple of them: one each on the lid, the body, and the spout, and two on the handle. If you create a cylinder and delete one end, the row of edges around that end forms a border.

When Border sub-object level is active, you can't select edges that aren't on borders. Clicking a single edge on a border selects that whole border.
You can cap a border, either with the Cap function on page 1392 or by applying the Cap Holes modifier on page 1185. You can also connect borders between objects with the Connect compound object on page 695.

NOTE
The Edge and Border sub-object levels are compatible, so if you go from one to the other, any existing selection is retained.

**Polygon** Accesses the Polygon sub-object level, which lets you select polygons beneath the cursor. Region selection selects multiple polygons within the region.

**Element** Accesses the Element sub-object level, which lets you select all contiguous polygons in an object. Region selection lets you select multiple elements.

NOTE
The Polygon and Element sub-object levels are compatible, so if you go from one to the other, any existing selection is retained.

**Use Stack Selection** When on, Edit Poly automatically uses any existing sub-object selection passed up the stack, and prevents you from manually changing the selection.

**By Vertex** When on, you can select sub-objects only by selecting a vertex that they use. When you click a vertex, all sub-objects that use the selected vertex are selected.
Not available at the Vertex sub-object level.

**Ignore Backfacing** When on, selection of sub-objects affects only those facing you. When off (the default), you can select any sub-object(s) under the mouse cursor, regardless of their visibility or facing. If there are more than one sub-object under the cursor, repeated clicking cycles through them. Likewise, with Ignore Backfacing off, region selection includes all sub-objects, regardless of the direction they face.

NOTE The state of the Backface Cull on page 166 setting on the Display panel does not affect sub-object selection. Thus, if Ignore Backfacing is off, you can still select sub-objects even if you can’t see them.
**By Angle** When on, selecting a polygon also selects neighboring polygons based on the angle setting to the right of the check box. This value determines the maximum angle between neighboring polygons to select. Available only at the Polygon sub-object level.

For example, if you click a side of a box and the angle value is less than 90.0, only that side is selected, because all sides are at 90-degree angles to each other. But if the angle value is 90.0 or greater, all sides of the box are selected. This function speeds up selection of contiguous areas made up of polygons that are at similar angles to one another. You can select coplanar polygons with a single click at any angle value.

**Shrink** Reduces the sub-object selection area by deselecting the outermost sub-objects. If the selection size can no longer be reduced, the remaining sub-objects are deselected.

**Grow** Expands the selection area outward in all available directions. For this function, a border is considered to be an edge selection.

![Grow and Shrink](image)

With Shrink and Grow, you can add or remove neighboring elements from the edges of your current selection. This works at any sub-object level.

**Ring** Expands an edge selection by selecting all edges parallel to the selected edges. Ring applies only to edge and border selections.
Ring selection adds to the selection all the edges that are parallel to the ones selected originally.

**TIP** After making a ring selection, you can use Connect on page 1383 to subdivide the associated polygons into new edge loops.

[Ring Shift] The spinner next to the Ring button lets you move the selection in either direction to other edges in the same ring; that is, to neighboring, parallel edges. If you have a loop selected, you can use this function to select a neighboring loop. Applies only to Edge and Border sub-object levels.
Left: Original loop selection

Upper right: Ring Shift up moves selection outward (from center of model).

Lower right: Ring Shift down moves selection inward (toward center of model).

To expand the selection in the chosen direction, Ctrl+click the up or down spinner button. To shrink the selection in the chosen direction, Alt+click the up or down spinner button.

**Loop** Expands the selection as far as possible, in alignment with selected edges.
Loop applies only to edge and border selections, and propagates only through four-way junctions.
Loop selection extends your current edge selection by adding all the edges aligned to the ones selected originally.

[Loop Shift] The spinner next to the Loop button lets you move the selection in either direction to other edges in the same loop; that is, to neighboring, aligned edges. If you have a ring selected, you can use this function to select a neighboring ring. Applies only to Edge and Border sub-object levels.
Left: Original ring selection

Upper right: Loop Shift up moves selection outward.

Lower right: Loop Shift down moves selection inward.

To expand the selection in the chosen direction, Ctrl+click the up or down spinner button. To shrink the selection in the chosen direction, Alt+click the up or down spinner button.

Get Stack Selection Replaces the current selection with the sub-object selection passed up the stack. You can then modify this selection using standard methods.

If no selection exists in the stack, all sub-objects are unselected.
Preview Selection

This option lets you preview a sub-object selection before committing to it. You can preview at the current sub-object level, or switch sub-object levels automatically based on the mouse position. The choices are:

- **Off**  No preview is available.
- **SubObj**  Enables previewing at the current sub-object level only. As you move the mouse over the object, the sub-object under the cursor highlights in yellow. To select the highlighted object, click the mouse. To select multiple sub-objects at the current level, press and hold Ctrl, move the mouse to highlight more sub-objects, and then click to select all highlighted sub-objects.

To deselect multiple sub-objects at the current level, press and hold Ctrl+Alt, move the mouse to highlight more sub-objects, and then click a selected sub-object. This deselects all highlighted sub-objects.

_Polygon sub-object selection preview with Ctrl held down_
- **Multi**  Works like SubObj, but also switches among the Vertex, Edge, and Polygon sub-object levels on the fly, based on the mouse position. For example, if you position the mouse over an edge, the edge highlights, and then clicking activates the Edge sub-object level and selects the edge.

To select multiple sub-objects of the same type, press and hold Ctrl after highlighting a sub-object, move the mouse to highlight more sub-objects, and then click to activate that sub-object level and select all highlighted sub-objects.

To deselect multiple sub-objects at the current sub-object level, press and hold Ctrl+Alt, move the mouse to highlight more sub-objects, and then click a selected sub-object. This deselects all highlighted sub-objects. Note that this method does not switch sub-object levels.

**NOTE** When Ignore Backfacing on page 1350 is off, you’ll see back-facing vertices and edges highlight while previewing a sub-object selection.

**Selection Information**

At the bottom of the Selection rollout is a text display giving information about the current selection. If 0 or more than one sub-object is selected, the text gives the number and type selected; for example, “4 Polygons Selected.”

If one sub-object is selected, the text gives the identification number and type of the selected item; for example, “Polygon 73 Selected.”

When using Preview Selection on page 1356, a second line gives additional information about the identity or number of highlighted sub-objects.

**Edit Poly (Object)**

Select an Edit Poly object. > Modify panel

Edit Poly (Object) functions are available when no sub-object levels are active. These functions are also available at all sub-object levels, and work the same in each mode, except as noted below.
Interface

Edit Geometry rollout

For detailed descriptions of these controls, see Edit Geometry Rollout (Polymesh and Edit Poly) on page 1409.

Paint Deformation rollout

Paint Deformation lets you stroke elevated and indented areas directly onto object surfaces. For more information, see Paint Deformation Rollout (Polymesh) on page 2333.
**Edit Poly (Vertex)**

Select an Edit Poly object. > Modify panel > Selection rollout > Vertex

Select an Edit Poly object. > Modify panel > Modify Stack display > Expand Edit Poly. > Vertex

Select an Edit Poly object. > Quad menu > Tools 1 quadrant > Vertex

Vertices are points in space: They define the structure of other sub-objects that make up the poly object. When vertices are moved or edited, the geometry they form is affected as well. Vertices can also exist independently; such isolated vertices can be used to construct other geometry but are otherwise invisible when rendering.

At the Edit Poly (Vertex) sub-object level, you can select single and multiple vertices and move them using standard methods. This topic covers the Edit Vertices and Edit Geometry rollouts; for other controls, see [Edit Poly Modifier on page 1332](#).

**Procedures**

**To weld polygon vertices:**

You can use either of two methods to combine several vertices into one, also known as welding. If the vertices are very close together, use the Weld function. You can also use Weld to combine a number of vertices to the average position of all of them.

Alternatively, to combine two vertices that are far apart, resulting in a single vertex that's in the same position as one of them, use Target Weld.

1. To use Weld:
   1. On the Selection rollout, turn on Ignore Backfacing, if necessary. This ensures that you're welding only vertices you can see.
   2. Select the vertices to weld.
   3. If the vertices are very close together, simply click Weld. If that doesn't work, proceed to the next step.

   4. Click the Settings button to the right of the Weld button. This opens the [Weld Vertices dialog on page 2359](#).
5 Increase the Weld Threshold value gradually using the spinner (click and hold on the up-down arrow buttons to the right of the numeric field and then drag upward). If you need the value to change more quickly, hold down the Ctrl key as you drag. When the threshold equals or exceeds the distance between two or more of the vertices, the weld occurs automatically, and the resulting vertex moves to their average location.

6 If not all the vertices are welded, continue increasing the Weld Threshold value until they are.

7 Click OK to exit.

2 To use Target Weld:

1 On the Selection rollout, turn on Ignore Backfacing, if necessary. This ensures that you're welding only vertices you can see.

2 Find two vertices you want to weld, and determine the ultimate location of the resulting vertex. The two vertices must be contiguous; that is, they must be connected by a single edge.

For this example, we'll call the vertices A and B, and the resulting vertex will be at vertex B's location.

3 Click the Target Weld button.

The button stays highlighted, to indicate that you're now in Target Weld mode.

4 Click vertex A and then move the mouse.

A rubber-band line connects the vertex and the mouse cursor.

5 Position the cursor over vertex B, whereupon the cursor image changes from an arrow to a crosshairs. Reminder: Only vertices connected to the first vertex by a single edge qualify for target welding.

6 Click to weld the two.

The resulting vertex remains at vertex B's position.

7 Click Target Weld again to turn it off.
Interface

Edit Poly Mode rollout

See Edit Poly Mode rollout on page 1342 for information on the Edit Poly Mode rollout settings.

Selection rollout

See Selection Rollout (Edit Poly Modifier) on page 1346 for information on the Selection rollout settings.

Soft Selection rollout

Soft Selection controls apply a smooth falloff between selected sub-objects and unselected ones. When Use Soft Selection is on, unselected sub-objects near your selection are given partial selection values. These values are shown in the viewports by means of a color gradient on the vertices, and optionally on the faces. They affect most types of sub-object deformations, such as the Move, Rotate, and Scale functions, as well as any deformation modifiers (such as Bend) applied to the object. This provides a magnet-like effect with a sphere of influence around the selection.

For more information, see Soft Selection Rollout on page 2014.

Edit Vertices rollout

This rollout includes commands specific to vertex editing.
NOTE To delete vertices, select them and press the Delete key. This can create one or more holes in the mesh. To delete vertices without creating holes, use Remove (see following).

Remove Deletes selected vertices and combines the polygons that use them. The keyboard shortcut is Backspace.

Removing one or more vertices deletes them and retriangulates the mesh to keep the surface intact. If you use Delete instead, the polygons depending on those vertices are deleted as well, creating a hole in the mesh.

WARNING Use of Remove can result in mesh shape changes and non-planar polygons.

Break Creates a new vertex for each polygon attached to selected vertices, allowing the polygon corners to be moved away from each other where they were once joined at each original vertex. If a vertex is isolated or used by only one polygon, it is unaffected.

Extrude Lets you extrude vertices manually via direct manipulation in the viewport. Click this button, and then drag vertically on any vertex to extrude it.

Extruding a vertex moves it along a normal and creates new polygons that form the sides of the extrusion, connecting the vertex to the object. The extrusion has the same number of sides as the number of polygons that originally used the extruded vertex.
Following are important aspects of vertex extrusion:

- When over a selected vertex, the mouse cursor changes to an Extrude cursor.
- Drag vertically to specify the extent of the extrusion, and horizontally to set the size of the base.
- With multiple vertices selected, dragging on any one extrudes all selected vertices equally.
- You can drag other vertices in turn to extrude them while the Extrude button is active. Click Extrude again or right-click in the active viewport to end the operation.

Chamfer box showing extruded vertex

- Extrude Settings Opens the Extrude Vertices dialog on page 2350, which lets you perform extrusion via interactive manipulation.
If you click this button after performing a manual extrusion, the same extrusion is performed on the current selection as a preview and the dialog opens with Extrusion Height set to the amount of the last manual extrusion.

**Weld** Combines contiguous, selected vertices that fall within the tolerance specified in Weld dialog on page 2359. All edges become connected to the resulting single vertex.

![Using Weld at the Vertex level](image)

Vertices farther apart than the Threshold distance are not welded.

Weld is best suited to automatically simplifying geometry that has areas with a number of vertices that are very close together. Before using Weld, set the Weld Threshold via the Weld dialog on page 2359. To weld vertices that are relatively far apart, use Target Weld on page 1366 instead.

**Weld Settings** Opens the Weld dialog on page 2359, which lets you specify the weld threshold.

**Chamfer** Click this button and then drag vertices in the active object. To chamfer vertices numerically, click the Chamfer Settings button and use the Chamfer Amount value.

If you chamfer multiple selected vertices, all of them are chamfered identically. If you drag an unselected vertex, any selected vertices are first deselected.

Each chamfered vertex is effectively replaced by a new face that connects new points on all edges leading to the original vertex. These new points are exactly <chamfer amount> distance from the original vertex along each of these edges. New chamfer faces are created with the material ID of one of the neighboring
faces (picked at random) and a smoothing group which is an intersection of all neighboring smoothing groups.

For example, if you chamfer one corner of a box, the single corner vertex is replaced by a triangular face whose vertices move along the three edges that led to the corner. Outside faces are rearranged and split to use these three new vertices, and a new triangle is created at the corner.

Alternatively, you can create open space around the chamfered vertices; for details, see Chamfer Vertices dialog on page 2344.

Top: The original vertex selection
Center: Vertices chamfered
Bottom: Vertices chamfered with Open on

Chamfer Settings Opens the Chamfer Vertices dialog on page 2344, which lets you chamfer vertices via interactive manipulation and toggle the Open option.
If you click this button after performing a manual chamfer, the same chamfer is performed on the current selection as a preview and the dialog opens with Chamfer Amount set to the amount of the last manual extrusion.

**Target Weld** Allows you to select a vertex and weld it to a neighboring target vertex. Target Weld works only with pairs of contiguous vertices; that is, vertices connected by a single edge.

In Target Weld mode, the mouse cursor, when positioned over a vertex, changes to a + cursor. Click and then move the mouse; a dashed, rubber-band line connects the vertex to the mouse cursor. Position the cursor over another, neighboring vertex and when the + cursor appears again, click the mouse. The first vertex moves to the position of the second and the two are welded. Target Weld remains active until you click the button again or right-click in the viewport.

**Connect** Creates new edges between pairs of selected vertices.

Connect does not let the new edges cross. Thus, for example, if you select all four vertices of a four-sided polygon and then click Connect, only two of the vertices will be connected. In this case, to connect all four vertices with new edges, use **Cut** on page 1417.

**Remove Isolated Vertices** Deletes all vertices that don’t belong to any polygons.

**Remove Unused Map Verts** Certain modeling operations can leave unused (isolated) map vertices that show up in the Unwrap UVW editor on page 1856, but cannot be used for mapping. You can use this button to automatically delete these map vertices.
**Edit Geometry rollout**

![Edit Geometry Rollout](image)

For detailed descriptions of these controls, see *Edit Geometry Rollout (Polymesh and Edit Poly)* on page 1409.

**Paint Deformation rollout**

Paint Deformation lets you stroke elevated and indented areas directly onto object surfaces. For more information, see *Paint Deformation Rollout (Polymesh)* on page 2333.
Edit Poly (Edge)

Select an Edit Poly object. > Modify panel > Selection rollout > Edge

Select an Edit Poly object. > Modify panel > Modifier Stack display > Expand Edit Poly. > Edge

Select an Edit Poly object. > Quad menu > Tools 1 quadrant > Edge

An edge is a line connecting two vertices that forms the side of a polygon. An edge can't be shared by more than two polygons. Also, the normals of the two polygons should be adjacent. If they aren't, you wind up with two edges that share vertices.

At the Edit Poly Edge sub-object level, you can select single and multiple edges and transform them using standard methods. This topic covers the Edit Geometry and Edit Edges rollouts; for other controls, see Edit Poly Modifier on page 1332.

Procedures

Example: To use the Cut and Turn features:

3ds Max provides a convenient function for turning edges, which, along with the Cut feature, streamlines the custom modeling process considerably. Specifically, cutting a new polygon into existing geometry minimizes the number of extra visible edges, typically adding none or one. And after using cut, the Turn function lets you adjust any diagonal with a single click.

1  In the Perspective viewport, add a Plane object. This object is available from the Create panel > Standard Primitives > Object Type rollout.
   By default, the Plane object is divided into 4 x 4 polygons. If you don't see the polygons in the Perspective viewport, press F4 to activate Edged Faces view mode.
2 Convert the Plane object to Editable Poly format. If you’re not sure how, continue in this step; otherwise, skip to the next step after converting. To convert the object, right-click once in the Perspective viewport to exit create mode. This leaves the object selected. Right-click again in the Perspective viewport, and then at the bottom of the Transform quadrant, choose Convert To > Convert To Editable Poly. Alternatively, apply the Edit Poly modifier.
The object is now an editable poly and the command panel switches to the Modify panel.

3 Cut is available at the object level as well as at every sub-object level. On the Edit Geometry rollout, find the Cut button, and then click it.

4 In the Perspective viewport, position the mouse cursor in the center of a corner polygon, such as the one closest to you, click once, and then move the mouse around the viewport.
Two or three lines appear and move as you move the mouse. One line connects the mouse cursor to the original click location, and indicates where the next cut will appear when you click the mouse button. Another connects to a corner of the polygon; this connection changes depending on the mouse position. And, if the cursor isn’t over an edge or a vertex (it changes appearance if it is, depending on which), a third line connects the mouse cursor to another vertex.

This demonstrates one aspect of the new Cut functionality; in previous versions, the first click in a Cut operation connected to two corners of the polygon.

5 Continue cutting in a rectangular pattern, clicking once at the center of a different polygon, finish by clicking once more at the starting point, and then right-click to exit Cut mode.
The result is a rectangle across four polygons, without any connecting visible edges. In previous versions, you would have had eight connecting visible edges: two in each of the original polygons. Note that all the edges you created are selected, and ready for further transformation or editing.

6 Cut a rectangle into the center of a single polygon.
   In this case you end up with a single, additional visible edge instead of seven, as in previous versions. The edge connects corner of the new polygon with a corner of the original one. This new edge is not selected, but the ones you created explicitly are.
Connecting the remaining corners are a number of diagonals on page 8551, which serve to fully triangulate the polygons. The new Turn function lets you manipulate each of these with a single click.

7 Go to the Edge sub-object level, and then, on the Edit Edges rollout, click Turn.

All diagonals, including those created from the Cut operations, appear as dashed lines.
Click a diagonal to turn it, and then click it again to return it to its original status.

In Turn mode, click a diagonal (dashed line) once to turn it.

Each diagonal has only two different available positions, given no changes in any other diagonals' or edges' positions.

Compare this with the Edit Triangulation tool, with which you must click two vertices to change a diagonal's position.

This simple demonstration shows how, when manually subdividing a polygon mesh for modeling and animation purposes, you can save a good deal of time by using the Cut and Turn tools in 3ds Max.

To create a shape from one or more edges:

1. Select the edges you want to make into shapes.
2. On the Edit Edges rollout, click Create Shape From Selection.
3. Make changes, as needed, on the Create Shape dialog that appears.
   - Enter a curve name or keep the default.
   - Choose Smooth or Linear as the shape type.
4. Click OK.

The resulting shape consists of one or more splines whose vertices are coincident with the vertices in the selected edges. The Smooth option results in vertices using smooth values, while the Linear option results in linear splines with corner vertices.

If the selected edges are not continuous, or if they branch, the resulting shape will consist of more than one spline. When the Create Shape function runs into a branching 'Y' in the edges, it makes an arbitrary decision as to which edge produces which spline. If you need to control
this, select only those edges that will result in a single spline, and perform a Create Shape operation repeatedly to make the correct number of shapes. Finally, use Attach on page 655 in the Editable Spline to combine the shapes into one.

Above: Original object

Below: Object with edges selected
Above: Selected edges removed from original object

Below: Unwanted edges removed

Interface

Edit Poly Mode rollout

See Edit Poly Mode rollout on page 1342 for information on the Edit Poly Mode rollout settings.
Selection rollout

See Selection Rollout (Edit Poly Modifier) on page 1346 for information on the Selection rollout settings.

Soft Selection rollout

Soft Selection controls apply a smooth falloff between selected sub-objects and unselected ones. When Use Soft Selection is on, unselected sub-objects near your selection are given partial selection values. These values are shown in the viewports by means of a color gradient on the vertices, and optionally on the faces. They affect most types of sub-object deformations, such as the Move, Rotate, and Scale functions, as well as any deformation modifiers (such as Bend) applied to the object. This provides a magnet-like effect with a sphere of influence around the selection.

For more information, see Soft Selection Rollout on page 2014.

Edit Edges rollout

This rollout includes commands specific to edge editing.

**NOTE** To delete edges, select them and press the Delete key. This deletes all selected edges and attached polygons, which can create one or more holes in the mesh. To delete edges without creating holes, use Remove (see following entry).

**Insert Vertex** Lets you subdivide visible edges manually.

After turning on Insert Vertex, click an edge to add a vertex at that location. You can continue subdividing polygons as long as the command is active.
To stop inserting edges, right-click in the viewport, or click Insert Vertex again to turn it off.

**Remove** Deletes selected edges and combines the polygons that use them.

Removing one edge is like making it invisible. The mesh is affected only when all or all but one of the edges depending on one vertex are removed. At that point, the vertex itself is deleted and the surface is retriangulated.

To delete the associated vertices when you remove edges, press and hold Ctrl while executing a Remove operation, either by mouse or with the Backspace key. This option, called Clean Remove, ensures that the remaining polygons are planar.

Left: The original edge selection
Center: Standard Remove operation leaves extra vertices.

Right: Clean Remove with Ctrl-Remove deletes the extra vertices.

Edges with the same polygon on both sides usually can’t be removed.

**WARNING** Use of Remove can result in mesh shape changes and non-planar polygons.

**Split** Divides the mesh along the selected edges.
This does nothing when applied to a single edge in the middle of a mesh. The vertices at the end of affected edges must be separable in order for this option to work. For example, it would work on a single edge that intersects an existing border, since the border vertex can be split in two. Additionally, two adjacent edges could be split in the middle of a grid or sphere, since the shared vertex can be split.

**Extrude** Lets you extrude edges manually via direct manipulation in the viewport. Click this button, and then drag vertically on any edge to extrude it.

![Extrusion Example](http://example.com/extrusion.png)

*When extruding a vertex or edge interactively in the viewport, you set the extrusion height by moving the mouse vertically and the base width by moving the mouse horizontally.*

Extruding an edge moves it along a normal and creates new polygons that form the sides of the extrusion, connecting the edge to the object. The extrusion has either three or four sides; three if the edge was on a border, or four if it was shared by two polygons. As you increase the length of the extrusion, the base increases in size, to the extent of the vertices adjacent to the extruded edge’s endpoints.
Following are important aspects of edge extrusion:

- When over a selected edge, the mouse cursor changes to an Extrude cursor.
- Drag vertically to specify the extent of the extrusion, and horizontally to set the size of the base.
- With multiple edges selected, dragging on any one extrudes all selected edges equally.
- You can drag other edges in turn to extrude them while the Extrude button is active. Click Extrude again or right-click in the active viewport to end the operation.

Chamfer box showing extruded edge

Extrude Settings Opens the Extrude Edges dialog on page 2350, which lets you perform extrusion via interactive manipulation. If you click this button after performing a manual extrusion, the same extrusion is performed on the current selection as a preview and the dialog opens with Extrusion Height set to the amount of the last manual extrusion.

Weld Combines selected edges that fall within the threshold specified in Weld dialog on page 2359.
You can weld only edges that have one polygon attached; that is, edges on a border. Also, you cannot perform a weld operation that would result in illegal geometry (e.g., an edge shared by more than two polygons). For example, you cannot weld opposite edges on the border of a box that has a side removed.

**Weld Settings** Opens the Weld dialog on page 2359, which lets you specify the weld threshold.

**Chamfer** Click this button and then drag edges in the active object. To chamfer edges numerically, click the Chamfer Settings button and change the Chamfer Amount value.

If you chamfer multiple selected edges, all of them are chamfered identically. If you drag an unselected edge, any selected edges are first deselected.

An edge chamfer "chops off" the selected edges, creating a new polygon connecting new points on all visible edges leading to the original vertex. The new edges are exactly \(<\text{chamfer amount}\) distance from the original edge along each of these edges. New chamfer faces are created with the material ID of one of the neighboring faces (picked at random) and a smoothing group which is an intersection of all neighboring smoothing groups.

For example, if you chamfer one edge of a box, each corner vertex is replaced by two vertices moving along the visible edges that lead to the corner. Outside faces are rearranged and split to use these new vertices, and a new polygon is created at the corner.

![Using Chamfer at the Edge level](image)

Alternatively, you can create open space around the chamfered edges; for details, see Chamfer Edges dialog on page 2344.
Chamfer Settings Opens the Chamfer Edges dialog on page 2344, which lets you chamfer edges via interactive manipulation and toggle the Open option.

If you click this button after performing a manual chamfer, the same chamfer is performed on the current selection as a preview and the dialog opens with Chamfer Amount set to the amount of the last manual chamfer.

Target Weld Allows you to select an edge and weld it to a target edge. When positioned over an edge, the cursor changes to a + cursor. Click and move the mouse and a dashed line appears from the vertex with an arrow cursor at the other end of the line. Position the cursor over another edge and when the + cursor appears again, click the mouse. The first edge is moved to the position of the second, and the two are welded.

You can weld only edges that have one polygon attached; that is, edges on a border. Also, you cannot perform a weld operation that would result in illegal geometry (e.g., an edge shared by more than two polygons). For example, you cannot weld opposite edges on the border of a box that has a side removed.

Bridge Connects border edges on an object with a polygon “bridge.” Bridge connects only border edges; that is, edges that have a polygon on only one side. This tool is particularly useful when creating edge loops or profiles.

There are two ways to use Bridge in Direct Manipulation mode (that is, without opening the Bridge Edges settings dialog):

- Select two or more border edges on the object, and then click Bridge. This immediately creates the bridge between the pair of selected borders using the current Bridge settings, and then deactivates the Bridge button.

- If no qualifying selection exists (that is, two or more selected border edges), clicking Bridge activates the button and places you in Bridge mode. First click a border edge and then move the mouse; a rubber-band line connects the mouse cursor to the clicked edge. Click a second edge on a different border to bridge the two. This creates the bridge immediately using the current Bridge settings; the Bridge button remains active for connecting more edges. To exit Bridge mode, right-click the active viewport or click the Bridge button.

The new polygons that result from a Bridge operation are automatically selected; you can see this by accessing the Polygon sub-object level.
Using Bridge at the Edge level

**NOTE** Bridge always creates a straight-line connection between edges. To make the bridge connection follow a contour, apply modeling tools as appropriate after creating the bridge. For example, bridge two edges, and then use Bend on page 1165.

**Bridge Settings** Opens the Bridge Edges dialog on page 2341, which lets you add polygons between pairs of edges via interactive manipulation.

**Connect** Creates new edges between pairs of selected edges using the current Connect Edges dialog settings. Connect is particularly useful for creating or refining edge loops.

**NOTE** You can connect only edges on the same polygon. Also, Connect will not let the new edges cross. For example, if you select all four edges of a four-sided polygon and then click Connect, only neighboring edges are connected, resulting in a diamond pattern.
Connecting two or more edges using the Settings dialog creates equally spaced edges. The number of edges is set in the dialog. When you click the Connect button, the current dialog settings are applied to the selection.

- **Connect Settings** Opens the Connect Edges dialog on page 2345, which lets you preview the Connect results, specify the number of edge segments created by the operation, and set spacing and placement for the new edges.

- **Create Shape** After selecting one or more edges, click this button to create a spline shape or shapes from the selected edges, using the current settings from the Create Shape Settings dialog (see following).
  
  The new shape's pivot is placed at the same location as that of the Edit Poly object.

- **Create Shape Settings** Lets you name the Create Shape output and set it to Smooth or Linear.
An edge selection (top); a smooth shape (center); a linear shape (bottom)

**Edit Tri[angulation]** Lets you modify how polygons are subdivided into triangles by drawing internal edges, or **diagonals** on page 8551.

In **Edit Triangulation** mode, you can see the current triangulation in the viewport, and change it by clicking two vertices on the same polygon.
To edit triangulation manually, turn on this button. The hidden edges appear. Click a polygon vertex. A rubber-band line appears, attached to the cursor. Click a non-adjacent vertex to create a new triangulation for the polygon.

**TIP** For easier editing of triangulation, use the Turn command instead (see following).

**Turn** Lets you modify how polygons are subdivided into triangles by clicking diagonals. When you activate Turn, the diagonals on page 8551 become visible as dashed lines in wireframe and edged-faces views. In Turn mode, click a diagonal to change its position. To exit Turn mode, right-click in the viewport or click the Turn button again.

Each diagonal has only two available positions at any given time, so clicking a diagonal twice in succession simply returns it to its original position. But changing the position of a nearby diagonal can make a different alternate position available to a diagonal.

For more information on how to use Turn with the enhanced Cut tool, see this procedure on page 1368.
**Edit Geometry rollout**

For detailed descriptions of these controls, see Edit Geometry Rollout (Polymesh and Edit Poly) on page 1409.

**Paint Deformation rollout**

Paint Deformation lets you stroke elevated and indented areas directly onto object surfaces. For more information, see Paint Deformation Rollout (Polymesh) on page 2333.
Edit Poly (Border)

Select an Edit Poly object. > Modify panel > Selection rollout > Border

Select an Edit Poly object. > Modify panel > Modifier Stack display > Expand Edit Poly. > Border

Select an Edit Poly object. > Quad menu > Tools 1 quadrant > Border

A border is a linear section of a mesh that can generally be described as the edge of a hole. This is usually a sequence of edges with polygons on only one side. For example, a box doesn’t have a border, but the teapot object has several: on the lid, on the body, on the spout, and two on the handle. If you create a cylinder, and then delete an end polygon, the adjacent row of edges forms a border.

At the Edit Poly Border sub-object level, you can select single and multiple borders and transform them using standard methods. This topic covers the Edit Geometry and Edit Borders rollouts; for other controls, see Edit Poly Modifier on page 1332.

Procedures

To create a polygon that closes the surface at the selected border:

1. At the Border sub-object level, select any open edge.
   This selects the entire closed loop of continuous open edges that make up the border selection.

2. Click Cap.

Interface

Edit Poly Mode rollout

See Edit Poly Mode rollout on page 1342 for information on the Edit Poly Mode rollout settings.

Selection rollout

See Selection Rollout (Edit Poly Modifier) on page 1346 for information on the Selection rollout settings.

Soft Selection rollout

Soft Selection controls apply a smooth falloff between selected sub-objects and unselected ones. When Use Soft Selection is on, unselected sub-objects near your selection are given partial selection values. These values are shown in the viewports by means of a color gradient on the vertices, and optionally on the faces. They affect most types of sub-object deformations, such as the Move, Rotate, and Scale functions, as well as any deformation modifiers (such as Bend) applied to the object. This provides a magnet-like effect with a sphere of influence around the selection.

For more information, see Soft Selection Rollout on page 2014.

Edit Borders rollout

This rollout includes commands specific to editing borders.

**NOTE** To delete a border, select it and press the Delete key. This deletes the border and all attached polygons.

**Extrude** Lets you extrude a border manually via direct manipulation in the viewport. Click this button, and then drag vertically on any border to extrude it.

Extruding a border moves it along a normal and creates new polygons that form the sides of the extrusion, connecting the border to the object. The extrusion can form a varying number of additional sides, depending on the geometry near the border. As you increase the length of the extrusion, the base increases in size, to the extent of the vertices adjacent to the extruded border's endpoints.

Following are important aspects of border extrusion:

- When the mouse cursor is over a selected border, it changes to an Extrude cursor.
To specify the extent of the extrusion, drag vertically, and to set the size of the base, drag horizontally.

With multiple borders selected, dragging on any one extrudes all selected borders equally.

While the Extrude button is active, you can extrude other borders in turn by dragging them. Click Extrude again or right-click in the active viewport to end the operation.

**Extrude Settings** Opens the Extrude Edges dialog on page 2350, which lets you perform extrusion via interactive manipulation.

If you click this button after performing a manual extrusion, the same extrusion is performed on the current selection as a preview and the dialog opens with Extrusion Height set to the amount of the last manual extrusion.

**Insert Vertex** Lets you subdivide border edges manually.

After turning on Insert Vertex, click a border edge to add a vertex at that location. You can continue subdividing border edges as long as the command is active.

To stop inserting vertices, right-click in the viewport, or click Insert Vertex again to turn it off.

**Chamfer** Click this button and then drag a border in the active object. The border need not be selected first.

If you chamfer multiple selected borders, all of them are chamfered identically. If you drag an unselected border, any selected borders are first deselected.

A border chamfer essentially “frames” the border edges, creating a new set of edges paralleling the border edges, plus new diagonal edges at any corners. These new edges are exactly <chamfer amount> distance from the original edges. New chamfer faces are created with the material ID of one of the neighboring faces (picked at random) and a smoothing group which is an intersection of all neighboring smoothing groups.

Alternatively, you can create open space around the chamfered borders, essentially cutting away at the open edges; for details, see Chamfer Edges dialog on page 2344.

**Chamfer Settings** Opens the Chamfer Edges dialog on page 2344, which lets you chamfer borders via interactive manipulation and toggle the Open option.
If you click this button after performing a manual chamfer, the same chamfer is performed on the current selection as a preview and the dialog opens with Chamfer Amount set to the amount of the last manual chamfer.

**Cap** Caps an entire border loop with a single polygon. Select the border, and then click Cap.

**Bridge** Connects pairs of borders on an object with polygon “bridges.” There are two ways to use Bridge in Direct Manipulation mode (that is, without opening the Bridge Settings dialog):

- Select an even number of borders on the object, and then click Bridge. This immediately creates the bridge between each pair of selected borders using the current Bridge settings, and then deactivates the Bridge button.

- If no qualifying selection exists (that is, two or more selected borders), clicking Bridge activates the button and places you in Bridge mode. First click a border edge and then move the mouse; a rubber-band line connects the mouse cursor to the clicked edge. Click a second edge on a different border to bridge the two. This creates the bridge immediately using the current Bridge settings; the Bridge button remains active for connecting more pairs of borders. To exit Bridge mode, right-click the active viewport or click the Bridge button.

The new polygons that result from a Bridge operation are automatically selected; you can see this by accessing the Polygon sub-object level.

![Using Bridge at the Border level.](image)
**NOTE** Bridge always creates a straight-line connection between border pairs. To make the bridge connection follow a contour, apply modeling tools as appropriate after creating the bridge. For example, bridge two borders, and then use Bend on page 1165.

- **Bridge Settings** Opens the Bridge dialog on page 2339, which lets you connect pairs of borders via interactive manipulation.

- **Connect** Creates new edges between pairs of selected border edges. The edges are connected from their midpoints.
  
  You can connect only edges on the same polygon.
  
  Connect will not let the new edges cross. Thus, for example, if you select all four edges of a four-sided polygon and then click Connect, only neighboring edges are connected, resulting in a diamond pattern.

- **Connect Settings** Lets you preview the Connect and specify the number of edge segments created by the operation. To increase the mesh resolution around the new edge, increase the Connect Edge Segments setting.

- **Create Shape** After selecting one or more borders, click this button to create a spline shape or shapes from the selected edges, using the current settings from the Create Shape Settings dialog (see following).
  
  The new shape's pivot is placed at the same location as that of the Edit Poly object.

- **Create Shape Settings** Lets you preview the Create Shape function, name the shape, and set it to Smooth or Linear.

- **Edit Triangulation** Lets you modify how polygons are subdivided into triangles by drawing internal edges, or diagonals on page 8551.
  
  To edit triangulation manually, turn on this button. The hidden edges appear. Click a polygon vertex. A rubber-band line appears, attached to the cursor. Click a non-adjacent vertex to create a new triangulation for the polygon.

**TIP** For easier editing of triangulation, use the Turn command instead (see following).

- **Turn** Lets you modify how polygons are subdivided into triangles by clicking diagonals. When you activate Turn, the diagonals on page 8551 become visible as dashed lines in wireframe and edged-faces views. In Turn mode, click a
diagonal to change its position. To exit Turn mode, right-click in the viewport or click the Turn button again.

Each diagonal has only two available positions at any given time, so clicking a diagonal twice in succession simply returns it to its original position. But changing the position of a nearby diagonal can make a different alternate position available to a diagonal.

For more information on how to use Turn with the enhanced Cut tool, see this procedure on page 1368.

**Edit Geometry rollout**

For detailed descriptions of these controls, see Edit Geometry Rollout (Polymesh and Edit Poly) on page 1409.
Paint Deformation rollout

Paint Deformation lets you stroke elevated and indented areas directly onto object surfaces. For more information, see Paint Deformation Rollout (Polymesh) on page 2333.

Edit Poly (Polygon/Element)

Select an Edit Poly object. > Modify panel > Selection rollout > Polygon/Element

Select an Edit Poly object. > Modify panel > modifier stack display > Expand Edit Poly. > Polygon/Element

Select an Edit Poly object. > Quad menu > Tools 1 quadrant > Polygon/Element

A polygon is a closed sequence of three or more edges connected by a surface. Polygons provide the renderable surface of Edit Poly objects.

At the Edit Poly (Polygon) sub-object level, you can select single and multiple polygons and transform them using standard methods. This is similar for the Element sub-object level; for the distinctions between polygon and element, see Edit Poly > Selection rollout on page 1345. This topic covers the Edit Polygons/Elements rollout and Edit Geometry rollout functions for these sub-object types. For other controls, see Edit Poly Modifier on page 1332.

NOTE Workflow enhancements in the Edit Poly user interface give you a choice of editing methods. See Edit Poly Workflow on page 1339 for more information.

Interface

Edit Poly Mode rollout

See Edit Poly Mode rollout on page 1342 for information on the Edit Poly Mode rollout settings.

Selection rollout

See Selection Rollout (Edit Poly Modifier) on page 1346 for information on the Selection rollout settings.
**Soft Selection rollout**

Soft Selection controls apply a smooth falloff between selected sub-objects and unselected ones. When Use Soft Selection is on, unselected sub-objects near your selection are given partial selection values. These values are shown in the viewports by means of a color gradient on the vertices, and optionally on the faces. They affect most types of sub-object deformations, such as the Move, Rotate, and Scale functions, as well as any deformation modifiers (such as Bend) applied to the object. This provides a magnet-like effect with a sphere of influence around the selection.

For more information, see *Soft Selection Rollout* on page 2014.

**Edit Polygons/Elements rollout**

At the Element sub-object level, this rollout includes commands that are common to both polygons and elements. At the Polygon level, it contains those as well as a number more that are unique to polygons. The commands available at both levels are Insert Vertex, Flip, Edit Triangulation, Retriangulate, and Turn.

**NOTE** To delete polygons or elements, select them and press the Delete key. If *Delete Isolated Vertices* on page 1422 is off, this can result in isolated vertices; that is, vertices with no associated face geometry.

**Insert Vertex** Lets you subdivide polygons manually. Applies to polygons, even if at the element sub-object level.

After turning on Insert Vertex, click a polygon to add a vertex at that location. You can continue subdividing polygons as long as the command is active.
To stop inserting vertices, right-click in the viewport, or click Insert Vertex again to turn it off.

**Extrude** Lets you perform manual extrusion via direct manipulation in the viewport. Click this button, and then drag vertically on any polygon to extrude it.

Extruding polygons moves them along a normal and creates new polygons that form the sides of the extrusion, connecting the selection to the object.

Following are important aspects of polygon extrusion:

- When over a selected polygon, the mouse cursor changes to an Extrude cursor.
- Drag vertically to specify the extent of the extrusion, and horizontally to set the size of the base.
- With multiple polygons selected, dragging on any one extrudes all selected polygons equally.
- You can drag other polygons in turn to extrude them while the Extrude button is active. Click Extrude again or right-click in the active viewport to end the operation.
**Extrude Settings** Opens the *Extrude Polygons* dialog on page 2349, which lets you perform extrusion via interactive manipulation.

If you click this button after performing an extrusion, the same extrusion is performed on the current selection as a preview and the dialog opens with Extrusion Height set to the amount of the last manual extrusion.

**Outline** Lets you increase or decrease the outside edge of each contiguous group of selected polygons.

Outline is often used after an extrusion or bevel to adjust the size of the extruded faces. It doesn't scale the polygons; only changes the size of the outer edge. For example, in the following illustration, note that the sizes of the inner polygons remain constant.
Extruded polygons (top), outline expanded (middle), outline reduced (bottom)
Note that inner polygons do not change size.
Outline Settings Opens the Outline Polygons dialog, which lets you perform outlining by a numeric setting.

Bevel Lets you perform manual beveling via direct manipulation in the viewport. Click this button, and then drag vertically on any polygon to extrude it. Release the mouse button and then move the mouse vertically to outline the extrusion. Click to finish.

- When over a selected polygon, the mouse cursor changes to a Bevel cursor.
- With multiple polygons selected, dragging on any one bevels all selected polygons equally.
- You can drag other polygons in turn to bevel them while the Bevel button is active. Click Bevel again or right-click to end the operation.

Polygon beveled outward (left) and inward (right)

Bevel Settings Opens the Bevel Polygons dialog on page 2337, which lets you perform beveling via interactive manipulation.

If you click this button after performing a bevel, the same bevel is performed on the current selection as a preview and the dialog opens with the same settings used for the previous bevel.
**Inset** Performs a bevel with no height; that is, within the plane of the polygon selection. Click this button, and then drag vertically on any polygon to inset it.

- When over a selected polygon, the mouse cursor changes to an Inset cursor.
- With multiple polygons selected, dragging on any one insets all selected polygons equally.
- While the Inset button is active, you can drag other polygons in turn to inset them. To end the operation, click Inset again or right-click.

Inset works on a selection of one or more polygons. As with Outline, only the outer edges are affected.

**Inset Settings** Opens the Inset Polygons dialog on page 2353, which lets you inset polygons via interactive manipulation.

If you click this button after performing a manual inset, the same inset is performed on the current selection as a preview and the dialog opens with Inset Amount set to the amount of the last manual inset.

**Bridge** Connects two polygons or polygon selections on an object with a polygon “bridge.” There are two ways to use Bridge in Direct Manipulation mode (that is, without opening the Bridge Settings dialog):

- Make two separate polygon selections on the object, and then click Bridge. This creates the bridge immediately using the current Bridge settings, and then deactivates the Bridge button.
If no qualifying selection exists (that is, two or more discrete polygon selections), clicking Bridge activates the button and places you in Bridge mode. First click a polygon and move the mouse; a rubber-band line connects the mouse cursor to the clicked polygon. Click a second polygon to bridge the two. This creates the bridge immediately using the current Bridge settings; the Bridge button remains active for connecting more pairs of polygons. To exit Bridge mode, right-click the active viewport or click the Bridge button.

**Using Bridge at the Polygon level**

**NOTE** Bridge always creates a straight-line connection between polygon pairs. To make the bridge connection follow a contour, apply modeling tools as appropriate after creating the bridge. For example, bridge two polygons, and then use Bend on page 1165.

**Bridge Settings** Opens the Bridge dialog on page 2339, which lets you connect pairs of polygon selections via interactive manipulation.

**Flip** Reverses the directions of the normals of selected polygons, hence their facing.

**Hinge From Edge** Lets you perform a manual hinge operation via direct manipulation in the viewport. Make a polygon selection, click this button, and then drag vertically on any edge to hinge the selection. The mouse cursor changes to a cross when over an edge.
The hinge edge needn’t be part of the selection. It can be any edge of the mesh. Also, the selection needn’t be contiguous.

Hinging polygons rotates them about an edge and creates new polygons that form the sides of the hinge, connecting the selection to the object. It’s essentially an extrusion with rotation, with the exception that, if the hinge edge belongs to a selected polygon, that side is not extruded. The manual version of Hinge From Edge works only with an existing polygon selection.

**TIP** To avoid inadvertently hinging about a backfacing edge, turn on Ignore Backfacing.

**Hinge Settings** Opens the Hinge From Edge dialog on page 2352, which lets you hinge polygons via interactive manipulation. If you click this button after performing a manual hinge, the dialog opens with Angle set to the extent of the last manual hinge.

**Extrude Along Spline** Extrudes the current selection along a spline.
You can extrude a single polygon (1) or a selection of contiguous (2) or non-contiguous polygons (3). Extrusion 2 uses Taper Curve and Twist (available via Settings). Extrusion 3 uses Taper Amount; each extrusion has a different curve rotation.

Make a selection, click Extrude Along/On Spline, and then select a spline in the scene. The selection is extruded along the spline, using the spline’s current orientation, but as though the spline’s start point were moved to the center of each polygon or group.

**Extrude Along Spline Settings** Opens the **Extrude Polygons Along Spline dialog** on page 2347, which lets you extrude along splines via interactive manipulation.

**Edit Triangulation** Lets you modify how polygons are subdivided into triangles by drawing internal edges.
In Edit Triangulation mode, you can see the current triangulation in the viewport, and change it by clicking two vertices on the same polygon.

To manually edit triangulation, turn on this button. The hidden edges appear. Click a polygon vertex. A rubber-band line appears, attached to the cursor. Click a non-adjacent vertex to create a new triangulation for the polygon.

**Retriangulate** Lets 3ds Max automatically do its best triangulation on the polygon or polygons currently selected.

Retriangulate attempts to optimize how selected polygons are subdivided into triangles.
Turn Lets you modify how polygons are subdivided into triangles by clicking diagonals. When you activate Turn, the diagonals on page 8551 become visible as dashed lines in wireframe and edged-faces views. In Turn mode, click a diagonal to change its position. To exit Turn mode, right-click in the viewport or click the Turn button again.

Each diagonal has only two available positions at any given time, so clicking a diagonal twice in succession simply returns it to its original position. But changing the position of a nearby diagonal can make a different alternate position available to a diagonal.

For more information on how to use Turn with the enhanced Cut tool, see this procedure on page 1368.

**Edit Geometry rollout**

![Edit Geometry rollout](image)
For detailed descriptions of these controls, see Edit Geometry Rollout (Polymesh and Edit Poly) on page 1409.

**Polygon Properties rollout**

![Polygon Properties rollout](image)

These controls let you work with material IDs and smoothing groups.

**Material group**

**Set ID** Lets you assign a particular material ID to selected sub-objects for use with multi/sub-object materials on page 6120 and other applications. Use the spinner or enter the number from the keyboard. The total number of available IDs is 65,535.

**Select ID** Selects sub-objects corresponding to the Material ID specified in the adjacent ID field. Type or use the spinner to specify an ID, then click the Select ID button.

[Select By Name] This drop-down list shows the names of sub-materials if an object has a multi/sub-object material assigned to it. Click the drop arrow and choose a sub-material from the list. This selects any sub-objects assigned that material. If an object does not have a multi/sub-object material assigned, the
name list is unavailable. Likewise, if multiple selected objects have an Edit Patch, Edit Spline, or Edit Mesh modifier applied, the name list is inactive.

**NOTE** Sub-material names are those specified in the Name column on the material’s multi/sub-object Basic Parameters rollout. By default, 3ds Max assigns the material name “No Name” followed by a sequence number in parentheses. These names don't appear in the Material Editor, but they do show up in the drop-down list.

**Clear Selection** When on, choosing a new ID or material name unselects any previously selected sub-objects. When off, selections are cumulative, so new ID or sub-material name selections add to the existing selection set of patches or elements. Default=off.

**Smoothing Groups group**

Use these controls to assign selected polygons to different smoothing groups on page 8724, and to select polygons by smoothing group.

To assign polygons to one or more smoothing groups, select the polygons, and then click the number(s) of the smoothing group(s) to assign them to.

**Select By SG (Smoothing Group)** Displays a dialog that shows the current smoothing groups. Select a group by clicking the corresponding numbered button and clicking OK. If Clear Selection is on, any previously selected polygons are first unselected. If Clear Selection is off, the new selection is added to any previous selection set.

**Clear All** Removes any smoothing group assignments from selected polygons.

**Auto Smooth** Sets smoothing groups based on the angle between polygons. Any two adjacent polygons are put in the same smoothing group if the angle between their normals is less than the threshold angle, set by the spinner to the right of this button.

**[threshold]** This numeric setting (to the right of Auto Smooth) lets you specify the maximum angle between the normals of adjacent polygons that determines whether those polygons will be put in the same smoothing group.

**Paint Deformation rollout**

Paint Deformation lets you stroke elevated and indented areas directly onto object surfaces. For more information, see **Paint Deformation Rollout** on page 2333.
Edit Geometry Rollout (Polymesh and Edit Poly)

Create or select an editable poly or Edit Poly object. > Modify panel > Edit Geometry rollout

The Edit Geometry rollout provides global controls for changing the geometry of the poly object, at either the top (Object) level or the sub-object levels. The controls are the same at all levels, except as noted in the descriptions below.

Interface

- **Repeat Last**
  - Repeats the most recently used command.
  - For example, if you extrude a polygon, and want to apply the same extrusion to several others, select the others, and then click Repeat Last.
You can apply a spline extrusion of a single polygon (left) repeatedly to other single polygons (1) or to multiple polygon selections, contiguous (2) or not (3).

**NOTE** Repeat Last does not repeat all operations. For example, it does not repeat transforms. To determine which command will be repeated when you click the button, check the tooltip for the Repeat Last button on the command panel, which gives the name of the last operation that can be repeated. If no tooltip appears, nothing will happen when you click the button.

**Constraints** Lets you use existing geometry to constrain sub-object transformation. Choose the constraint type:

- **None**: No constraints. This is the default option.
- **Edge**: Constrains sub-object transformations to edge boundaries.
- **Face**: Constrains sub-object transformations to individual face surfaces.
- **Normal**: Constrains each sub-object's transformations to its normal, or the average of its normals. In most cases, this causes sub-objects to move perpendicular to the surface.

**NOTE** This constraint works like the Push modifier on page 1640, including the fact that it operates on unmodified base normals. Edited normals are unsupported.
When set to Edge, moving a vertex will slide it along one of the existing edges, depending on the direction of the transformation. If set to Face, the vertex moves only on the polygon’s surface.

**NOTE** You can set constraints at the Object level, but their use pertains primarily to sub-object levels. The Constraints setting persists at all sub-object levels.

**Preserve UVs** When on, you can edit sub-objects without affecting the object’s UV mapping. You can choose any of an object’s mapping channels to preserve or not; see Preserve UVs Settings, following. Default=off.

Without Preserve UVs, there is always a direct correspondence between an object’s geometry and its UV mapping. For example, if you map an object and then move vertices, the texture moves along with the sub-objects, whether you want it to or not. If you turn on Preserve UVs, you can perform minor editing tasks without changing the mapping.

**TIP** For best results with Preserve UVs at the vertex level, use it for limited vertex editing. For example, you’ll usually have no trouble moving a vertex within edge or face constraints. Also, it’s better to perform one big move than several smaller moves, as multiple small moves can begin to distort the mapping. If, however, you need to perform extensive geometry editing while preserving mapping, use the Channel Info utility on page 6486 instead.
Preserve UVs Settings Opens the Preserve Map Channels dialog on page 2355, which lets you specify which vertex color channels and/or texture channels (map channels) to preserve. By default, all vertex color channels are off (not preserved), and all texture channels are on (preserved).

Create Lets you create new geometry. How this button behaves depends on which level is active:

- **Object, Polygon, and Element levels**  
  Lets you add polygons in the active viewport. After you turn on Create, click three or more times in succession anywhere, including on existing vertices, to define the shape of the new polygon. To finish, right-click.
  
  While creating a polygon at the Polygon or Element level, you can delete the most recently added vertex by pressing Backspace. You can do this repeatedly to remove added vertices in reverse order of placement.
  
  You can start creating polygons in any viewport, but all subsequent clicks must take place in the same viewport.

  **TIP** For best results, click vertices in counterclockwise (preferred) or clockwise order. If you use clockwise order, the new polygon will face away from you.

- **Vertex level**  
  Lets you add vertices to a single selected poly object. After selecting the object and clicking Create, click anywhere in space to add free-floating (isolated) vertices to the object. The new vertices are placed on the active construction plane unless object snapping is on. For example, with face snapping on, you can create vertices on object faces.

- **Edge and Border levels**  
  Lets you create an edge between a pair of non-adjacent vertices on the same polygon. Click Create, click a vertex, and then move the mouse. A rubber-band line extends from the vertex to the mouse cursor. Click a second, non-adjacent vertex on the same polygon to connect them with an edge. Repeat, or, to exit, right-click in the viewport or click Create again.
  
  Edges you create separate the polygons. For example, by creating an edge inside a quadrilateral polygon, you turn it into two triangles.

Collapse (Vertex, Edge, Border, and Polygon levels only) Collapses groups of contiguous selected sub-objects by welding their vertices to a vertex at the selection center.
Using collapse on a vertex selection

Using collapse on a polygon selection

Attach lets you attach other objects in the scene to the selected poly object. After activating Attach, click an object to attach to the selected object. Attach remains active, so you can continue clicking objects to attach them. To exit, right-click in the active viewport or click the Attach button again.

You can attach any type of object, including splines, patch objects, and NURBS surfaces. Attaching a non-mesh object converts it to editable-poly format.

When you attach an object, the materials of the two objects are combined in the following way:

- If the object being attached does not have a material assigned, it inherits the material of the object it is being attached to.
Handle inherits material from the cup it is being attached to.

- Likewise, if the object you're attaching to doesn't have a material, it inherits the material of the object being attached.

- If both objects have materials, the resulting new material is a multi/sub-object material on page 6120 that includes the input materials. A dialog appears offering three methods of combining the objects' materials and material IDs. For more information, see Attach Options Dialog on page 2233.
  
  Attach remains active in all sub-object levels, but always applies to objects.

Attach List Lets you attach other objects in the scene to the selected mesh. Click to open the Attach List dialog, which works like Select From Scene on page 206 to let you choose multiple objects to attach.
Detach (sub-object levels only) Detaches the selected sub-objects and the polygons attached to them as a separate object or element(s).

With an Editable Poly object, when you click Detach, the software prompts you for the options specified on the Detach dialog. With an Edit Poly object, Detach on the Modify panel automatically uses those settings. To change them, click Detach Settings (see following).

Detach Settings Opens the Detach dialog on page 1423, which lets you set several options. Available only with Edit Poly objects; with Editable Poly, this dialog opens automatically when you click Detach.
Cut and Slice group

These knife-like tools let you subdivide the poly mesh along a plane (Slice) or in a specific area (Cut). Also see Full Interactivity on page 1422.

Slice Plane (sub-object levels only) Creates a gizmo for a slice plane that you can position and rotate to specify where to slice. Also enables the Slice and Reset Plane buttons; click Slice to create new edges where the plane intersects the geometry.

If you use Slice Plane from the modeling ribbon, the Slice, Split, and Reset Plane controls are available on the Slice Mode contextual panel on page 2098. If snapping is off, you see a preview of the slice as you transform the slice plane. To perform the slice, click the Slice button.

NOTE At the Polygon or Element sub-object level, Slice Plane affects only selected polygons. To slice the entire object, use Slice Plane at any other sub-object level, or at the object level.

Split When on, the QuickSlice and Cut operations create double sets of vertices at the points where the edges are divided. This lets you easily delete the new polygons to create holes, or animate the new polygons as separate elements.

Slice (sub-object levels only) Performs the slice operation at the location of the slice plane. Available only when Slice Plane is on. This tool slices the poly just like the “Operate On: Polygons” mode of the Slice modifier on page 1727.

Left: Using Slice; Right: After slicing and moving the pieces apart

Reset Plane (sub-object levels only) Returns the Slice plane to its default position and orientation. Available only when Slice Plane is on.
**QuickSlice** Lets you quickly slice the object without having to manipulate a gizmo. Make a selection, click QuickSlice, and then click once at the slice start point and again at its endpoint. You can continue slicing the selection while the command is active.

To stop slicing, right-click in the viewport, or click QuickSlice again to turn it off.

With Quickslice on, you can draw a line across your mesh in any viewport, including Perspective and Camera views. The mesh is sliced interactively as you move the line endpoint.

**NOTE** At the Object level, QuickSlice affects the entire object. To slice only specific polygons, use QuickSlice on a polygon selection at the Poly sub-object level.

**NOTE** At the Polygon or Element sub-object level, QuickSlice affects only selected polygons. To slice the entire object, use QuickSlice at any other sub-object level, or at the object level.

**Cut** Lets you create edges from one polygon to another or within polygons. Click at the start point, move the mouse and click again, and continue moving and clicking to create new connected edges. Right-click once to exit the current cut, whereupon you can start a new one, or right-click again to exit Cut mode.
While cutting, the mouse cursor icon changes to show the type of sub-object it’s over, to which the cut will be made when you click. The following illustration shows the three different cursor icons.

Top: Cutting to a vertex
Center: Cutting to an edge
Bottom: Cutting to a polygon

Cut is available at the object level and all sub-object levels.
NOTE You can use Cut with Turn for enhanced productivity. For more information, see this procedure on page 1368.

---

**MSmooth** Smoothes the object using the current settings. This command uses subdivision functionality similar to that of the MeshSmooth modifier on page 1505 with NURMS Subdivision, but unlike NURMS subdivision, it applies the smoothing instantly to the selected area of the control mesh.

![Smoothing a low-poly object with NURMS subdivision](image)

**MSmooth Settings** Opens the MeshSmooth Selection dialog on page 2354, which lets you specify how smoothing is applied.

**Tessellate** Subdivides all polygons in the object based on the Tessellation settings on page 2358.

Tessellation is useful for increasing local mesh density while modeling. You can subdivide any selection of polygons. Two tessellation methods are available: Edge and Face.

**Tessellate Settings** Opens the Tessellate Selection dialog on page 2358, which lets you specify how smoothing is applied.

**Make Planar** Forces all selected sub-objects to be coplanar. The plane's normal is the average surface normal of the selection.

At the Object level, forces all vertices in the object to become coplanar.
**TIP** One application for Make Planar is making a flat side on an object. Normally, you would use a contiguous selection set. If the selection includes vertices on various parts of the object, the vertices are still made planar, but with distorting effects on the rest of the geometry.

**X/Y/Z** Makes all selected sub-objects planar and aligns the plane with the corresponding plane in the object's local coordinate system. The plane used is the one to which the button axis is perpendicular; so, for example, clicking the X button aligns the object with the local YZ axis. At the Object level, makes all vertices in the object planar.

**View Align** Aligns all vertices in the object to the plane of the active viewport. At sub-object levels, this function affects only selected vertices or those belonging to selected sub-objects.

In orthographic viewports, aligning to the view has the same effect as aligning to the construction grid when the home grid is active. Aligning to a perspective viewport (including camera and light views), reorients the vertices to a plane that is parallel to the camera's viewing plane. This plane is perpendicular to the view direction that is closest to the vertices' average position.
Grid Align Aligns all vertices in the selected object to the plane of the current view. At sub-object levels, aligns only selected sub-objects.

This command aligns the selected vertices to the current construction plane. The current plane is specified by the active viewport in the case of the home grid. When using a grid object, the current plane is the active grid object.

Relax Applies the Relax function to the current selection, using the Relax dialog settings (see following). Relax normalizes mesh spacing by moving each vertex toward the average location of its neighbors. It works the same way as the Relax modifier on page 1643.

At the object level, Relax applies to the entire object. At sub-object levels, Relax applies only to the current selection.

Relax Settings Opens the Relax dialog on page 2357, which lets you specify how the Relax function is applied.

Hide Selected (Vertex, Polygon, and Element levels only) Hides selected sub-objects.

Unhide All (Vertex, Polygon, and Element levels only) Restores hidden sub-objects to visibility.

Hide Unselected (Vertex, Polygon, and Element levels only) Hides unselected sub-objects.
Named Selections (sub-object levels only)

Lets you copy and paste named selection sets of sub-objects between objects. Start by creating one or more named selection sets, copy one, select a different object, go to the same sub-object level, and then paste the set.

**NOTE** This function uses sub-object IDs, so if the target object’s geometry differs from that of the source object, the pasted selection will probably comprise a different set of sub-objects.

For more information, see Named Selection Sets on page 185.

**Copy** Opens a dialog that lets you specify a named selection set to place into the copy buffer.

**Paste** Pastes the named selection from the copy buffer.

________

Delete Isolated Vertices (Edge, Border, Polygon, and Element levels only) When on, deletes isolated vertices when you delete a selection of contiguous sub-objects. When off, deleting sub-objects leaves all vertices intact. Default=on.

**Full Interactivity (editable poly only)** Toggles the level of feedback for the QuickSlice and Cut tools, as well as all settings dialogs. Available with editable poly objects, but not the Edit Poly modifier.

When on (the default), the final result is always visible as you use the mouse to manipulate the tool or change a numeric setting. With Cut and QuickSlice, when Full Interactivity is turned off, only the rubber-band line is visible until you click. Similarly, with numeric settings in dialogs, the final result is visible only when you release the mouse button after changing the setting.

The state of Full Interactivity doesn't affect changing a numeric setting from the keyboard. Whether it's on or off, the setting takes effect only when you exit the field by pressing Tab or Enter, or by clicking a different control in the dialog.

**Align Geometry Dialog**

Select an Edit Poly object. > Modify panel > object level or any sub-object level > Animate mode > Edit Geometry rollout > Click View Align or Grid Align > Edit Poly Mode rollout > Settings button
This Edit Poly-specific dialog lets you change the alignment method after using the View Align or Grid Align function. Available only in Animate mode after using the View Align or Grid Align command.

Interface

Align to

- **View**  Aligns the selection with the view plane.
- **Construction Plane**  Aligns the selection with the active grid.

Update  Click this button to realign the selection with the designated entity after changing it. Typically you'd use this with the View option after rotating the view.

Detach Dialog

Select an Edit Poly object. > Modify panel > any sub-object level > Edit Geometry rollout > Detach Settings button

This dialog lets you specify how a sub-object selection is detached from an Edit Poly object.

By default, both Detach To Element and Detach As Clone are off. Thus, when you detach a sub-object selection, it's removed from the original object and becomes a new object. The dialog options let you keep the detached item as an element of the original object and/or detach it as a copy of the original selection.
NOTE When you detach a vertex or an edge, any adjacent polygons are detached as well. Also, a detached item remains in its original location.

NOTE Any Detach dialog settings you change are saved as program defaults automatically.

Interface

**Detach as** Lets you assign a name to the new object. By default, the name is "Object" followed by a sequence number.

This option is unavailable when Detach To Element is on.

**Detach To Element** The detached sub-object selection remains as part of the original object, but becomes a new element. It can then be manipulated independently at the Element sub-object level. Default=off.

**Detach As Clone** Detaches the selection as a copy of the original selection; the latter remains intact. Default=off.

**Edit Spline Modifier**

Create or select a spline > Modify panel > Object–Space Modifiers > Edit Spline

Create or select a spline > Modifiers menu > Patch/Spline Editing > Edit Spline

The Edit Spline modifier provides explicit editing tools for different levels of the selected shape: vertex, segment, or spline. The Edit Spline modifier matches all the capabilities of the base Editable Spline object, with the exceptions noted below. For a complete parameter reference, see *Editable Spline* on page 620.
The Rendering and Interpolation rollouts found in Editable Spline, which allow manipulation of the spline's creation parameters, are not available in the Edit Spline modifier. (The creation parameters are available in the modifier stack on page 8187 for a spline to which Edit Spline is applied.) In addition, the direct vertex animation capabilities of Editable Spline are not possible in Edit Spline.

When possible, it's far more efficient and reliable to perform explicit editing at the Editable Spline level rather than store those edits within the Edit Spline modifier. The Edit Spline modifier must copy the geometry passed to it, and this storage can lead to large file sizes. The Edit Spline modifier also establishes a topological dependency that can be adversely affected if earlier operations change the topology being sent to it.

There are, however, situations where using Edit Spline is the preferred method.

- You want to edit a parametric shape as a spline, but want to retain the ability to modify its creation parameters after the edit.
- You want to store your edits temporarily within Edit Spline until you are satisfied with the results, before committing them permanently to an editable spline object.
- You need to make edits across several shapes at once, but do not want to convert them to a single editable spline object.
- You have a modifier in the stack that must stay parametric, and the resulting spline must be edited after the modifier is applied.

**Extrude Modifier**

Select a shape. > Modify panel > Modifier List > Object-Space Modifiers > Extrude

Select a shape. > Modifiers menu > Mesh Editing > Extrude

The Extrude modifier adds depth to a shape and makes it a parametric object.
Above: Spline before extrusion
Below left: Extruded spline with Cap End off
Below right: Extruded spline with Cap End on
**Interface**

Amount Sets the depth of the extrusion.

Segments Specifies the number of segments that will be created in the extruded object.

**Capping group**

Cap Start Generates a flat surface over the start of the extruded object.

Cap End Generates a flat surface over the end of the extruded object.

Morph Arranges cap faces in a predictable, repeatable pattern, which is necessary for creating Morph targets on page 667. Morph capping can generate long, thin faces that don't render or deform as well as grid capping. Use morph capping primarily if you're extruding multiple morph targets.

Grid Arranges cap faces in a square grid trimmed at the shape boundaries. This method produces a surface of evenly sized faces that can be deformed easily by other modifiers. When you choose the Grid capping option, the grid lines are hidden edges rather than visible edges. This primarily affects any
objects assigned a material with the Wire option turned on, or any objects that use the Lattice modifier on page 1479.

**Output group**

**Patch** Produces an object that you can collapse to a patch object; see Editing the Stack on page 1049.

**Mesh** Produces an object that you can collapse to a mesh object; see Editing the Stack on page 1049.

**NURBS** Produces an object that you can collapse to a NURBS surface; see Editing the Stack on page 1049.

---

**Generate Mapping Coords** Applies mapping coordinates to the extruded object. Default=off.

When on, Generate Mapping Coordinates applies separate mapping coordinates to the end caps, placing a single 1 x 1 tile on each cap.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material’s Coordinates rollout on page 6201. Default=on.

**Generate Material IDs** Assigns different material IDs to the sides and the caps of the extruded object. Specifically, the sides receive ID 3, and the caps receive IDs 1 and 2.

This check box is turned on as a default when you create an extruded object, but if you load an extruded object from a MAX file, the check box is turned off, maintaining the same material ID assignment for that object as it had in R1.x.

**Use Shape IDs** Uses the material ID values assigned to segments in the spline on page 577 you extruded, or curve sub-objects in the NURBS on page 2416 curve you extruded.

**Smooth** Applies smoothing to the extruded shape.

---

**Face Extrude Modifier**

Modify panel > Select one or more faces of a mesh object. > Modifier List > Face Extrude
Modify panel > Select one or more faces of a mesh object. > Modifiers menu > Mesh Editing > Face Extrude

The Face Extrude modifier extrudes faces along their normals, creating new faces along the sides of the extrusion that connect the extruded faces to their object. As with most modifiers, this affects the current face selection passed up the stack. There are various differences between the Face Extrude modifier and the Face Extrude function in an editable mesh on page 2192, especially the fact that all parameters in the Face Extrude modifier are animatable.

Faces extruded on the top and along the edge of the object
Interface

Modifier Stack

**Extrude Center** At this sub-object level, you can select and move (or animate) the center point. This affects the geometry only if you turn on Extrude From Center.

For more information on the stack display, see Modifier Stack on page 8187.

**Parameters rollout**

**Amount** Determines the extent of the extrusion. You can adjust and readjust the Amount spinner as often as you choose. To extrude a second level, apply another Face Extrude modifier.

**Scale** Scales each cluster of selected faces independently about its center.

**NOTE** By using multiple extrude modifiers with Scale, you can achieve a bevel effect.

**Extrude From Center** Extrudes each vertex radially from the center point.
The direction in which the faces are extruded is slightly different than Face Extrude in the editable mesh. Each vertex is displaced in the direction of the average surface normal of selected faces that share that vertex. So each vertex may move in a slightly different direction. Put another way, each vertex is extruded in the direction of the surface normal at the point on the surface where that vertex lies.

**FFD (Free-Form Deformation) Modifiers**

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > FFD 2x2x2, FFD 3x3x3, or FFD 4x4x4

Make a selection. > Modifiers menu > Free Form Deformers > FFD 2x2x2, FFD 3x3x3, or FFD 4x4x4

FFD stands for Free-Form Deformation. Its effect is used in computer animation for things like dancing cars and gas tanks. You can use it as well for modeling rounded shapes such as chairs and sculptures.

The FFD modifier surrounds the selected geometry with a lattice. By adjusting the control points of the lattice, you deform the enclosed geometry.

FFD deformation creates a bulge in the snake.
There are three FFD modifiers, each providing a different lattice resolution: 2x2, 3x3, and 4x4. The 3x3 modifier, for example, provides a lattice with three control points across each of its dimensions or nine on each side of the lattice.

There are also two FFD-related modifiers that provide supersets of the original modifiers; see FFD (Box/Cyl) modifier on page 1436. With the FFD (Box/Cyl) modifiers, you can set any number of points in the lattice, which makes them more powerful than the basic FFD modifier.

**Animating FFD Control Points and the Master Point Controller**

Turn on the Auto Key button and move the lattice points to animate an FFD and any underlying geometry. When you animate FFD control points, a Master Point Controller is created automatically. In Track View the master controller allows you to move multiple animated control points in time by simply moving one master key (master keys display green in Track View).

**Procedures**

To use an FFD modifier:

1. Select the geometry. This can be the whole object, or you can use a Mesh Select modifier to select a portion of the object’s vertices.
2. Apply the FFD 2X2, FFD 3X3, or FFD 4X4 modifier, depending on the resolution of the lattice you want.
   An orange lattice gizmo surrounds the geometry.
3. In the modifier stack display, choose the Control Points sub-object level, and then move the control points of the lattice to deform the underlying geometry. To animate the deformation, turn on Auto Key.

The lattice volume defaults to the bounding box of the selected geometry. However, you can position, rotate, and/or scale the lattice box so that it modifies only a subset of vertices. Choose the Lattice sub-object level, and then use any of the transform tools to adjust the lattice volume relative to the geometry.
Interface

Modifier Stack

**Control Points** At this sub-object level, you can select and manipulate control points of the lattice, one at a time or as a group (select multiple points using standard techniques). Manipulating control points affects the shape of the underlying object. You can use standard transformation methods with the control points. If the Auto Key button is turned on when modifying the control points, the points become animated.

**Lattice** At this sub-object level, you can position, rotate, or scale the lattice box separately from the geometry. If the Auto Key button is turned on, the lattice becomes animated. When you first apply an FFD, its lattice defaults to a bounding box surrounding the geometry. Moving or scaling the lattice so that only a subset of vertices lies inside the volume makes it possible to apply a localized deformation.

**Set Volume** At this sub-object level, the deformation lattice control points turn green, and you can select and manipulate control points without affecting the modified object. This lets you fit the lattice more precisely to irregular-shaped objects, giving you finer control when deforming.

Set Volume essentially lets you set the initial state of the lattice. If you use it after you have animated a control point or when the Auto Key button is turned on, then it works the same as at the Control Points sub-object level, deforming the object as you manipulate points.

For more information on the stack display, see Modifier Stack on page 8187.

FFD (Free-Form Deformation) Modifiers | 1433
**Display group**

Affects the display of the FFD in the viewports.

**Lattice** Draws lines connecting the control points to make a grid. Although the viewports can sometimes become cluttered when these lines are drawn, it helps to visualize the lattice.

**Source Volume** Displays the control points and lattice in their unmodified state. When you're in the Lattice selection level, this helps to position the source volume.
To see which points lie in the source volume (and therefore will be deformed), temporarily deactivate the modifier by clicking to turn off the light bulb icon in the modifier stack display.

**Deform group**

**Only in Volume** Deforms vertices that lie inside the source volume. Default=on.

**All Vertices** Deforms all vertices, regardless of whether they lie inside or outside the source volume.

The deformation outside the volume is a continuous extrapolation of the deformation inside the volume. The deformation can be extreme for points far away from the source lattice.

**Control Points group**

**Reset** Returns all control points to their original positions.

**Animate All** Assigns Point3 controllers to all control points so that they're immediately visible in Track View.

By default the control points of an FFD lattice don't appear in Track View because they don't have controllers assigned to them. But when a control point is animated, a controller is assigned to it and becomes visible in Track View. With Animate All, you can add and delete keys and perform other key operations.

**Conform to Shape** Moves each FFD control point to the intersection of the modified object with a straight line extending between the object's center to the control point's original location, plus an offset distance specified by the Offset spinner.

**NOTE** Conform to Shape works best with regular shapes, such as primitives. It's less effective if the object has degenerate (long, narrow) faces or sharp corners. All the controls are unavailable with shapes, because there are no faces to intersect with.

**Inside Points** Only control points inside the object are affected by Conform to Shape.

**Outside Points** Only control points outside the object are affected by Conform to Shape.

**Offset** The distance by which control points affected by Conform to Shape are offset from the object surface.
About Displays a dialog with copyright and licensing information.

**FFD (Box/Cylinder) Modifiers**

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > FFD(box) or FFD(cyl)

Make a selection. > Modifiers menu > Free Form Deformers > FFD Box or FFD Cylinder

FFD stands for Free-Form Deformation. Its effect is used in computer animation for things like dancing cars and gas tanks. You can use it as well for modeling rounded shapes such as chairs and sculptures.

The FFD modifier surrounds the selected geometry with a lattice box. By adjusting the control points of the lattice, you deform the enclosed geometry. With the Auto Key button turned on, you can animate the lattice points, and thus the deformation of the geometry.

![FFD deformation creates a bulge in the snake.](image)

1436 | Chapter 9  Modifiers
With the FFD(box) and FFD(cyl) modifiers you can create box-shaped and cylinder-shaped lattice free-form deformation objects. Both are available as object modifiers and as space warps.

The source lattice of an FFD modifier is fitted to the geometry it's assigned in the stack. This can be a whole object, or a sub-object selection of faces or vertices.

**Interface**

**Modifier Stack**

![Modifier Stack](image)

**Control Points** At this sub-object level, you can select and manipulate control points of the lattice, one at a time or as a group (select multiple points using standard techniques). Manipulating control points affects the shape of the underlying object. You can use standard transformation methods with the control points. If the Auto Key button is turned on when modifying the control points, the points become animated.

**Lattice** At this sub-object level, you can position, rotate, or scale the lattice box separately from the geometry. If the Auto Key button is turned on, the lattice becomes animated. When you first apply an FFD, its lattice defaults to a bounding box surrounding the geometry. Moving or scaling the lattice so that only a subset of vertices lie inside the volume makes it possible to apply a localized deformation.

**Set Volume** At this sub-object level, the deformation lattice control points turn green, and you can select and manipulate control points without affecting the modified object. This lets you fit the lattice more precisely to irregular-shaped objects, giving you finer control when deforming.

Set Volume essentially lets you set the initial state of the lattice. If a control point is already animated or the Animate button is turned on, then Set Volume works the same as at the Control Points sub-object level, deforming the object as you manipulate points.

For more information on the stack display, see Modifier Stack on page 8187.
Dimensions group

Adjusts the unit dimensions of the source volume and specifies the number of control points in the lattice. Note that the point dimensions also show up beside the modifier name in the stack list.

Lattice dimensions The text displays the current number of control points in the lattice (for example 3x4x4).

Set Number of Points Displays a dialog containing three spinners labeled Length, Width, and Height, plus OK/Cancel buttons. Specify the number of control points you want in the lattice, and then click OK to make the change.

WARNING Make changes to the lattice dimensions before you adjust the positions of the lattice control points. When you change the number of control points with this dialog, you lose any adjustments you've already made to the control points. (You can undo this dialog.)

Display group

Affects the display of the FFD in the viewports.

Lattice Draws lines connecting the control points to make a grid. Although the viewports can sometimes become cluttered when these extra lines appear, they help to visualize the lattice.

Source Volume Displays the control points and lattice in their unmodified state. This is an important display when you're adjusting the source volume to affect specific vertices that lie inside or outside it.

TIP To see which points lie in the source volume (and therefore will be deformed), temporarily deactivate the modifier by clicking to turn off the light bulb icon in the modifier stack display.

Deform group

Provides controls that specify which vertices are affected by the FFD.

Only In Volume Deforms vertices that lie inside the source volume. Vertices outside the source volume are not affected.

All Vertices Deforms all vertices regardless of whether they lie inside or outside the source volume depending on the value in the Falloff spinner. The deformation outside the volume is a continuous extrapolation of the deformation inside the volume. Note that the deformation can be extreme for points far away from the source lattice.
Falloff Determines the distance from the lattice that the FFD effect will decrease to zero. Available only when you choose All Vertices. When set to 0, it's effectively turned off, and there is no falloff. All vertices are affected regardless of how far they are from the lattice. The units of the Falloff parameter are actually specified relative to the size of the lattice. A falloff of 1 means that the effect will go to 0 for points that are a lattice width/length/height away from the lattice (depending on which side they are).

Tension/Continuity Adjusts the tension and continuity of the deformation splines. Although you can't actually see the splines in an FFD, the lattice and control points represent the structure that controls the splines. As you adjust the control points, you alter the splines (which move through each of the points). The splines, in turn, deform the geometry of the object. By altering the tension and continuity of the splines, you alter their effect on the object.

Selection group

Provides additional methods of selecting the control points. You can toggle the state of any combination of the three buttons to select in one, two, or three dimensions at once.

All X, All Y, All Z Selects all control points along the specified local dimension when you select a control point. By turning on two buttons, you can select all control points in two dimensions.

Control Points group

Reset Returns all control points to their original positions.

Animate All By default, the control points of an FFD lattice don't appear in Track View because they don't have controllers assigned to them. But when you animate a control point, a controller is assigned and it becomes visible in Track View. You can also add and delete keys and perform other key operations. Animate All assigns Point3 controllers to all control points so that they're immediately visible in Track View.

Conform to Shape Moves each FFD control point to the intersection of the modified object with a straight line extending between the object's center to the control point's original location, plus an offset distance specified by the Offset spinner.
NOTE Conform to Shape works best with regular shapes, such as primitives. It’s less effective if the object has degenerate (long, narrow) faces or sharp corners. All the controls are unavailable with shapes, because there are no faces for the lattice to intersect with.

**Inside Points** Only control points inside the object are affected by Conform to Shape.

**Outside Points** Only control points outside the object are affected by Conform to Shape.

**Offset** The distance by which control points affected by Conform to Shape are offset from the object surface.

**About** Displays a dialog with copyright and licensing information.

### FFD (Free-Form Deformation) Select Modifier

Select an FFD space warp. > Modify panel > Modifier List > FFD Select

Select an FFD space warp. > Modifiers menu > Selection Modifiers > FFD Select

The FFD Select modifier works on an FFD (Box) Space Warp on page 2962 or FFD (Cyl) Space Warp on page 2969 to change the selection of its control points, and pass the selection up the stack.

The space-warp versions of the FFD modifiers provide sub-object geometry that you can manipulate in the stack. For example, you can apply a Bend modifier on page 1165 to an FFD space warp, bend its control points, and thus bend the object to which the space warp is bound. Using the FFD Select modifier, you can select a sub-object pattern of control points, and then use the subsequent modifier(s) to deform the selected points.

The FFD Select modifier is especially useful for assigning Linked XForm modifiers on page 1484 to portions of an FFD space warp.

#### Procedures

**Example: To use the Linked XForm modifier with an FFD space warp:**

1. Create an object, an FFD space warp (such as FFD (Box) on page 2962), and a couple of dummies on page 2840.
2. Bind the FFD space warp to the object you want to deform.
3. Select the FFD space warp and apply an FFD Select modifier.
4 At the Control Points sub-object level, select the control points you want to use to affect the object.

5 Apply a Linked XForm modifier, and then pick one of the dummies as a control object.

6 Apply another FFD Select modifier, and make a different selection of control points.

7 Apply another Linked XForm modifier and assign the other dummy as a control object.

8 You can now move either of the dummy objects to both translate the linked control points in the FFD space warp, and to deform the target object.

**Interface**

![FFD Select](image)

**All X/All Y/ All Z** Select the control points corresponding to the specified axis plane.
First click a selection button, and then select FFD control points in the viewports.

**Fillet/Chamfer Modifier**

Select a shape. > Modify panel > Modifier List > Object-Space Modifiers > Fillet/Chamfer
Select a shape. > Modifiers menu > Patch/Spline editing > Fillet/Chamfer
The Fillet/Chamfer modifier lets you fillet or chamfer the corners between linear segments of Shape objects on page 8720. Fillet rounds corners where segments meet, adding new control vertices. Chamfer bevels corners, adding another vertex and line segment. Note that this modifier works on the splines at the sub-object level of the shape. It does not work between two or more independent shape objects.
When you apply Fillet/Chamfer, you're placed in a Vertex sub-object selection level. You can select (and move) any vertex, but only Corner vertices and Bezier Corner vertices are valid for fillet and chamfer functions. In addition, both segments connected by a Bezier Corner vertex must be linear rather than curved.

There are two methods for applying either fillets or chamfers:

- Select one or more valid corner vertices, and then adjust either the Radius spinner to fillet the selected corners, or the Distance spinner to chamfer the corners.

- You can preset the Radius or Distance values, and then select one or more valid corner vertices, and click one of the Apply buttons to apply the specified value to the selected vertices.

**NOTE** As of version 3 of 3ds Max, Edit/Editable Spline on page 634 includes interactive fillet/chamfer functions. The only reason to use this modifier is to apply it at a specific location on the stack.

Star with selected vertices
Procedures

Example: To fillet/chamfer a star:

1. Create a Star shape on page 599.
2. Apply a Fillet/Chamfer modifier.
3. Select one or more of the star’s vertices.
4. Adjust the parameters to achieve different effects.
Interface

Fillet group

Radius Specifies the radius of the filleted corner.

Apply Applies the value specified in the Radius spinner to selected vertices. For example, before selecting any vertices, set the Radius to the desired value, then select your vertices and click Apply to fillet the selection with the specified radius.

Chamfer group

Distance Specifies the distance of the new vertices from the original corner vertex.

Apply Applies the value specified in the Distance spinner to selected vertices. For example, before selecting any vertices, set Distance to the desired value, then select your vertices and click Apply to chamfer the corners.

Flex Modifier

Select a Mesh, Patch, or NURBS object. > Modify panel > Modifier List > Object-Space Modifiers > Flex

Select a Mesh, Patch, or NURBS object. > Modifiers menu > Animation Modifiers > Flex Modifier

The Flex modifier simulates soft-body dynamics using virtual springs between an object's vertices. You can set the springs' stiffness, or how actively they
keep vertices from coming close to each other, as well as stretch, or how far apart they can move. At its simplest, this system causes vertices to lag behind an object as it moves. At a more advanced level, you can also control the sway, or how much the spring angle can change.

Flex causes the tongue to wag as the head rotates.

Flex works with NURBS, patches, meshes, shapes, FFD space warps, and any plug-in-based object types that can be deformed. You can combine Flex with space warps on page 2887 such as Gravity, Wind, Motor, Push, and PBomb to add realistic, physically based animation to an object. In addition, you can apply deflectors to soft-body objects to simulate collision.

NOTE The Flex modifier is aware of vertex/control-point motion in any animated modifier that deforms points below Flex in the modifier stack, such as the Morpher modifier on page 1518. Use this to simulate soft body motion on a morphed or otherwise deform-animated object.

TIP To change the center of the flex effect, after applying the Flex modifier to an object or sub-object selection, choose the Flex modifier's Center sub-object and use Move.
TIP  Using Flex’s advanced capabilities can significantly impede real-time playback. To improve performance in such cases, use the **Point Cache modifier** on page 1574 to record the vertex animation to disk, and then play it back using the cache.

The antennae, with the Flex modifier applied, move around like springs reacting to the motion of the character’s head.

**Surfaces Influenced by the Flex Modifier**

- On a mesh surface, the Flex modifier influences every vertex.
- On a patch surface, the Flex modifier influences both control points and tangent handles. Flex unlocks tangent handles and moves them independently.
- On a NURBS surface, Flex influences control vertices (CVs) or points.
- On a Spline (shape), the Flex modifier influences both control points and tangent handles.
- On an FFD Space Warp, the Flex modifier influences control points.
Effects

You can apply space warps to the Flex modifier. For example, you can add Wind on page 2926 to animate plants and trees, or a waving flag. In such cases, you don't need to create keyframes to see the effects; the space warp alone can animate the surface.

Character Animation

Use Flex above the Skin modifier on page 1667 to add secondary motion to a character animated with Bones, or above the Physique modifier to add secondary motion to a character animated with Biped.

Procedures

Example: To paint on weights:

1. Create a sphere on the left side of the Top viewport.
2. Turn on Auto Key and move the time slider to frame 50.
3. In the Top viewport, move the sphere to the right side of the viewport.
4. Turn off Auto Key.
5. On the Modify panel, click Modifier List, and then choose Flex. The Flex modifier is applied to the sphere.
6. Click Play. The sphere flexes around the Transform gizmo evenly.
7. Open the Flex modifier hierarchy in the stack display, and click Weights & Springs. This enables modification of the Weights & Springs sub-object settings.
8. In the Paint Weights group, turn on Paint.
9. In the Left viewport, paint on the lower part of the sphere. The vertex color changes as the vertex weight changes. Yellow vertices are more rigid, blue vertices are less rigid.
TIP  You can change Flex vertex colors through Customize menu > Customize User Interface > Colors > Elements=Geometry > Subselection Hard/Medium/Soft.

10 Click Play.
The sphere wobbles on one side more than the other.
If the Strength setting in the Paint Vertex group is a positive value, you paint rigidity. If the values are negative, you paint flexibility.
To reverse the effect, paint with negative Strength values.

Example: To use wind as a force:

1 In the Top viewport, create a sphere.

2 On the Create panel, click Space Warps, and then, if necessary, choose Forces from the drop-down list.

3 Click Wind, and then click and drag in the Front viewport to create a wind gizmo.

4 On the Wind Parameters rollout, set Strength and Turbulence to 4.

5 Select the Sphere.

6 Apply the Flex modifier.

7 On the Modify panel > Parameters rollout, set Samples to 1.

8 On Forces and Deflectors rollout > Forces group, click the Add button, and then select the Wind gizmo in the viewports.

9 Click Play.
The sphere undulates in the wind. The Advanced Parameters rollout > Reference Frame setting determines the frame where the force(s) in the list take effect.
You can also use this example to see how the Chase Springs option works.
10 Turn off Chase Springs and click Play again.

The sphere keeps moving in the direction the wind is blowing without "bouncing" back. That's because the chase springs, which attempt to return the object to its original shape, are no longer in effect.

To add custom springs:

1 Apply Flex to an object and go to the Weights & Springs sub-object level. The Flex vertices appear at object vertices in the viewports.

2 On the Advanced Springs rollout, turn on Show Springs.

3 Click the Options button and in the Spring Option dialog on page 1462, choose how you want to add springs. Exit the Spring Option dialog.

4 Select vertices according to the options. For instance, if you want to add one Hold Shape spring between two vertices, select both vertices.

5 Click Add Spring. The new spring or springs appear. Edge springs are blue and Hold Shape springs are red.

Example: To create a swinging rope:

1 Use Create menu > Space Warps to add a Drag and a Gravity space warp in the Top viewport.

2 Use Create menu > Shapes > Line to create a line with ten vertices spaced evenly in the top viewport.

3 In the Modify panel, turn on Vertex sub-object and select all the vertices except the first vertex.

4 Add the Flex modifier.

5 In the modifier stack view, open Weights and Springs sub-objects.

6 Turn off Use Chase Springs.

7 Turn off Use Weights.

8 Set the solver to Runge-Kutta4.

9 Set Samples to 5.
10 In a viewport, select all the points on the spline.
11 In the Advance Springs rollout, click the Option button.
12 In the dialog, turn on Hold Edge Length Springs and click OK.
13 Click Add Springs.
14 On the Forces and Deflectors rollout, add Gravity and Drag in the Forces group.
15 Click Play.
   The spline resembles a swinging rope.

Example: To create cloth draping on a sphere:

1 Use Create menu > Space Warps to add a Drag and a Gravity space warp in the Top viewport.
2 Use Create menu > Space Warps > Deflectors > SDeflector to create a spherical deflector. Set Bounce to 0 and Friction to 100. Place the deflector below Z=0.
3 Use Create menu > Geometry > Standard Primitives > Plane to create a 20 x 20 plane in the Top viewport. It should be above the spherical deflector.
4 Apply a Mesh Select modifier to the plane.
5 In the Top viewport, select all the vertices except for the leftmost column.
6 Apply the Flex modifier to the plane.
7 Turn off Use Chase Springs and Use Weights.
8 Set Samples to 3.
9 Click Create Simple Soft Body.
10 In the Forces and Deflectors rollout, add the Gravity and Drag forces.
11 In the Forces and Deflectors rollout, add the spherical deflector.
12 Click Play.
   The plane drapes over the spherical deflector like cloth.
Interface

Modifier Stack

These modifier sub-object levels are available in the stack display by opening the modifier hierarchy (click the + icon to the left of the modifier name).

Center Move the Transform gizmo in the viewports to set the center of the effect.

The flex effect increases as the distance between the center and a vertex increases.

Edge Vertices Select vertices in the viewports to control the falloff and direction of the flex effect.

Selected vertices flex less than unselected vertices.

Weights & Springs Use the Weights And Painting rollout controls to select and deselect vertices for subsequent operations on the Weights And Painting rollout and the Advanced Springs rollout.

You can paint weights at any sub-object level, and add and remove springs at any sub-object level (or even at the Flex modifier object level), but while a Weights & Springs selection is active, only the selected vertices are affected.
Parameters rollout

**Flex** Sets the amount of flex and bend. Range=0 to 1000; Default=1.
This value represents the amount of the flexed animation that is used; the flexed animation is determined by other factors such as motion and vertex weighting. The default setting of 1 causes the flexed animation to occur unmodified; higher settings cause unnaturally high amounts of stretching, and lower settings cause diminished stretching.

**Strength** Sets the overall spring strength of the chase springs.
A value of 100 is rigid. Range=0 to 100; Default=3.

**Sway** Sets the time for the object to come to rest for chase springs.
Lower values increase the time for the object to come to rest. Range=0 to 100; Default=7.

**Use Chase Springs** When on, enables chase springs, which force the object to return to its original shape. When off, no chase springs are used, and the amount by which vertices move depends only on their weights. Default=on.
Typically, for soft-body simulations when you want objects to be influenced by forces and deflectors, you would turn off Use Chase Springs.

**Use Weights** When on, Flex recognizes the different weights assigned to an object's vertices, applying different amounts of flexing accordingly. When off, the flex effect applies itself to the object as a monolithic whole. Default=on.
Typically, for soft-body simulations when you want objects to be influenced by forces and deflectors, you would turn off Use Weights.
**Solver Type** Choose a solver for the simulation from the drop-down list. The three choices are Euler, Midpoint, and Runge-Kutta4. Midpoint and Runge-Kutta4 require successively more computation than Euler, but are more stable and accurate. Default=Euler.

**TIP** In most cases, you can use Euler successfully, but if unexpected object deformations occur during a simulation, try using one of the more accurate solver types. Specifically, you might need to use Midpoint or Runge-Kutta4 with higher Stretch and Stiffness settings.

**Samples** The number of times per frame the Flex simulation is run at equal time intervals. The more samples you take, the more accurate and stable the simulation. When using the Midpoint or Runge-Kutta4 solver, you might not need as many samples as with Euler. Default=5.

**TIP** If your simulation produces unexpected results, such as object vertices moving to seemingly random locations, try increasing the Samples setting.

**Simple Soft Bodies rollout**

Let 3ds Max determine spring settings for the entire object automatically. Alternatively, you can use the Advanced Springs on page 1460 rollout settings to specify spring settings between each pair of vertices.

**Create Simple Soft Body** Generates spring settings for the object based on the Stretch and Stiffness settings.

**NOTE** After you use Create Simple Soft Body, you can change the Stretch and Stiffness settings without having to click the button again; the changes take effect immediately.
**Stretch** Determines how much object edges can elongate. When Advanced Springs rollout > Enable Advanced Springs is off, the Stretch setting is linked to the Advanced Springs rollout > Stretch Str. and Stretch Sway settings.

**Stiffness** Determines how rigid the object is. When Advanced Springs rollout > Enable Advanced Springs is off, the Stretch setting is linked to the Advanced Springs rollout > Shape Str. and Shape Sway settings.

The differences between Stretch and Stiffness are subtle, and understanding them is further complicated by the fact the two affect each other. In addition, how they work depends on object topology. For example, say you create a box, add a Flex modifier, apply Create Simple Soft Body, and then set a high Stretch value and a low Stiffness value. If you use the box in a Flex-based dynamics simulation, such as dropping it onto a surface (deflector) with gravity, you might expect the box to fall over and flatten out. But instead, because of the box’s topology, which causes Create Simple Soft Body to apply a relatively small number of shape springs, you’d actually get better results with a low Stretch value and a high Stiffness value. However, if you use a sphere of eight segments instead, you’ll get the collapsing behavior with the default Stretch and Stiffness settings, and as expected, increasing rigidity with higher Stiffness settings.

In soft-body simulations, such as the above-cited example of dropping an object onto a surface, particularly with dense meshes, you might get better results by applying the mesh to an FFD space warp that’s bound to the object. If the object’s shape isn’t suitable for use with the space warp, you might have to instead use the **Advanced Springs** on page 1460 rollout settings to apply springs manually. In such cases, you should create shape springs between opposite vertices rather than adjacent ones.

Cloth-like animation usually works best with a high Stretch setting and a low Stiffness setting. For soft bodies, you would usually use high settings for both Stretch and Stiffness, depending on how "squishy" you want the object to be.
Weights and Painting rollout

When you first apply Flex to an object, the modifier automatically sets a weight for each vertex based on its distance from the modifier’s center. The higher a vertex weight, the less prone it is to being affected by Flex effects. The modifier applies the highest weights to vertices closest to its center, and the lowest weights to vertices farthest from the center. So, for example, with a cylinder whose pivot point is at the base, you’ll get the greatest amount of flexing at the top. But with a sphere, all of whose vertices are equidistant from the pivot point (center), all vertices have, by default, equal weight values.

The Paint Weights controls let you use a spherical brush with adjustable radius and falloff to change vertex weights in the viewports, thus controlling the amount of lag. The Vertex Weights controls let you apply absolute or relative weighting to single vertices or groups of vertices.

Paint Weights group

Paint At any sub-object level, click Paint, and then drag the cursor over the mesh in the viewports to "paint" vertex weights using the current Strength and Feather settings. Vertex colors changes to reflect the new vertex weight. Painting changes vertex weights relative to their current values; it does not apply an absolute weight. Longer strokes over an area of the mesh will increase or decrease vertex weights more than short strokes, and repeated strokes over the same area will cause incremental changes in weight values unless they’re already at their extremes.
The vertex coloring shown at any Flex sub-object level provides an approximate indication of weighting. The colors are determined by the settings in Customize menu > Customize User Interface > Colors tab > Elements: Geometry. In this list are three color entries: Subselection Hard, used to display vertices with the highest Weight values; Subselection Medium, used to display vertices with medium Weight values; and Subselection Soft, used to display vertices with low Weight values.

**Strength** Sets the amount by which painting changes weight values. Higher values change weighting more quickly. At Strength=0, painting does not change weight values. Range=–1 to 1; Default=0.1. Negative values allow you to remove weight.

**TIP** When painting, you can use the Alt key to invert the strength.

**Radius** Sets the size of the brush in world units. Range=0.001 to 99999; Default=36.

**NOTE** If you position the mouse cursor over the object before painting, you can see a wireframe representation of the spherical “brush” that depicts the Radius setting.

**Feather** Sets the falloff in strength from the center of the brush to its edge. Default=0.7. Range=0.001 to 1. Vertices at the center of the brush are always changed by the full amount of the Strength setting, but the higher the Feather setting, the less vertices closer to the edge change. At the lowest setting, all vertices inside the radius are changed equally.

**Vertex Weights group**

Sets vertex weighting manually. At the Weights & Springs sub-object level, select vertices in the viewports, and then change the value of the Vertex Weight parameter. Alternatively, turn on Absolute Weight, set the desired Vertex Weight, and then select vertices to set; changes are immediate.

**Absolute Weight** Turn on to assign absolute weights to the selected vertices. Turn off to add or remove weight based on the Vertex Weight setting.

**Vertex Weight** Assigns weight to selected vertices.
Depending on the state of the Absolute Weight parameter, weight assignment is either absolute or relative.
NOTE  The Vertex Weight range is -100 to 100. With Absolute Weight on, the negative Vertex Weight settings have no effect; the effective range is 0 to 100. With Absolute Weight off, changing the Vertex Weight setting adds the amount to the current weights of selected vertices, and then the setting is reset to 0.

Forces and Deflectors rollout

Forces group

Use these controls to add space warps in the Forces category to the Flex modifier. Supported space warps are:

- Displace on page 2930
- Drag on page 2908
- Gravity on page 2923
- Motor on page 2898
List Window Displays particle space warps applied to the Flex modifier.

Add Click this, and then select a particle space warp in the viewports to add the effect to Flex. The added space warp displays in the list window.

Remove Select a space warp in the list and click Remove to remove the effect from Flex.

Deflectors group

Using deflectors with Flex lets object movement be impeded by surfaces. This lets you simulate collisions with soft-body objects. For best results with collisions, in the deflector settings use a low value for Bounce and a high value for Friction.

Supported deflectors are:
- POmniFlect on page 2935
- SOmniFlect on page 2946
- UOmniFlect on page 2948
- UDeflector on page 2956
- SDeflector on page 2953
- Deflector on page 2959

List Window Displays deflectors applied to the Flex modifier.

Add Click this, and then select a deflector in the viewports to add the effect to Flex. The added deflector displays in the list window.

Remove Select a deflector in the list and click Remove to remove the effect from Flex.
Advanced Parameters rollout

Reference Frame Sets the first frame at which Flex begins its simulation.

End Frame When on, sets the last frame at which Flex is to take effect. After this frame, the object snaps back to its shape as currently defined by the stack. For instance, if you animate a Bend modifier in the stack under Flex, then when Flex stops, the object’s shape is altered only by the Bend modifier settings as of that frame.

Affect All Points Forces Flex to ignore any sub-object selection in the stack and apply itself to the entire object.

Set Reference Updates the viewports.

After moving the effect center, click Set Reference to update the viewports.

Reset Resets vertex weighting to the defaults.

Advanced Springs rollout

Use these settings when you need a more precise springs setup than is provided by the Simple Soft Body feature. Flex uses two types of spring: edge springs, which create springs only along existing edges, and shape springs, which can exist between any two vertices in the object that are not connected by an edge. In general, add edge springs along existing edges and shape springs between vertices that don’t share an edge.

NOTE Before using these controls, go to the Weights & Springs sub-object level.

TIP Additional spring types are available using MAXScript. See the MAXScript Help for details.
Enable Advanced Springs  Makes the numeric controls available for editing, and disconnects the Strength and Sway settings from the Simple Soft Bodies controls. Default=off.

The four numeric Stretch and Sway settings in this rollout are available only when Enable Advanced Springs is on.

Add Spring  Adds one or more springs to the object based on the vertex selection at the Weights & Springs sub-object level and the Spring Option dialog on page 1462 settings.

NOTE  You cannot undo this action. To delete existing springs, select the endpoints and click Remove Spring.

Options  Opens the Spring Option dialog on page 1462 for determining how springs are added with the Add Spring function.

Remove Spring  Deletes any springs that have both vertices selected at the Weights & Springs sub-object level.

Stretch Str.  Determines the strength of the edge springs; the higher the strength, the less the distance between them can vary.
**Stretch Sway** Determines the sway of the edge springs; the higher the strength, the less the angle between them can vary.

**Shape Str.** Determines the strength of the shape springs; the higher the strength, the less the distance between them can vary.

**Shape Sway** Determines the sway of the shape springs; the higher the strength, the less the angle between them can vary.

**Spring Count** Displays the number of edge springs, followed by the number of shape springs in parentheses.

**Hold Length** Maintains the length of edge springs within the specified percentage.

**NOTE** This setting, which is applied after the Flex simulation, can affect the object shape, and thus cause collision detection to fail.

**Show Springs** Displays edge springs as blue lines and shape springs as red lines. Springs are visible only when a Flex sub-object mode is active.

You can change the spring colors using MAXScript.

### Spring Option Dialog

Select a Mesh, Patch, or NURBS object. > Modify panel > Modifier List > Animation Modifiers > Flex > Advanced Springs rollout > Options button

Use the Spring Option dialog to determine how springs are added in the Flex modifier when you click the Advanced Springs rollout > Add Spring button.
Interface

Single Edge Spring Creates one edge spring between two selected vertices. If any number of vertices is selected other than two, no springs are created.

Hold Edge Length Springs Creates edge springs along the edges of the objects between any vertex selection and neighboring vertices.

Hold Edge Length Springs Apply Only To Selected Creates edge springs along the edges of the objects between all selected vertices.

Hold Shape Springs Creates shape springs from the selected vertex or vertices to all other vertices within the Hold Shape Radius.

Hold Shape Springs Apply Only To Selected Creates shape springs between all selected vertices within the Hold Shape Radius.

Hold Shape Radius The radius within which shape springs are created. No shape springs are created between vertices farther apart than this distance.

At the bottom of the dialog is an informational display showing the object's average edge length, maximum edge length, and minimum edge length. This information can help in determining an appropriate Hold Shape Radius setting.
HSDS Modifier

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > HSDS Modifier

Select an object. > Modifiers menu > Subdivision Surfaces > HSDS Modifier

The HSDS modifier implements Hierarchical SubDivision Surfaces. It is intended primarily as a *finishing* tool rather than as a modeling tool. For best results, perform most of your modeling using low-polygon methods, and then use HSDS to add detail and adaptively refine the model.

The modifier’s primary features are:

- Local refinement
- Hierarchical modeling
- Adaptive tessellation

With local refinement, you subdivide part of a polygon mesh and edit the mesh in the subdivided area. This is done indirectly by manipulating sub-objects in a *control grid*. Use this feature when you need to increase mesh resolution in specific areas of a model rather than uniformly over the entire object, as with the *Tessellate modifier* on page 1812. An example of usage would be a human hand. Once you’ve modeled the basic shape, you might use the HSDS modifier to add bumps for the knuckles.

The HSDS modifier supports multiple levels of detail, hence its hierarchical nature. The Subdivision Stack lets you visually navigate the levels of detail at any time while using the modifier. Thus, you can edit the same part of a mesh at different mesh resolutions. If you work at a level of detail lower than the highest available, the higher-detail areas are still in effect, but you control them indirectly by means of the more widespread sub-objects at the lower level.

Sub-object animation is supported only at the lowest level of detail: Base Level. This is accomplished by animating the mesh below the HSDS modifier. To apply deformation animation after HSDS modeling, first convert the object to an editable mesh by right-clicking the modifier stack and choosing Collapse All.

The adaptive tessellation automatically subdivides polygons as needed to maintain a smoothly curved surface when transforming mesh sub-objects. You can use a preset or provide custom settings.
IMPORTANT  HSDS models are not passed up the modifier stack. The HSDS modifier takes a polygon mesh as input, and outputs a triangle-based mesh.

Also, The HSDS modifier does not handle changes to the modified object's topology, such as altering a sphere's Segments setting. Topology changes to the input mesh results in the loss of all edits made in the HSDS modifier.

Procedures

To use the HSDS modifier:

1  Apply the HSDS modifier to an object.
   By default, the HSDS modifier doesn't convert non-quadrilateral polygons to quads. Because the modifier works best with four-sided polygons, it's recommended you perform the conversion if necessary.

2  If the object contains any non-quadrilateral polygons, in the HSDS Parameters dialog, turn on Force Quads. Click Yes in the Force Quads? dialog that appears.

   NOTE  Upon conversion to quads, the modifier automatically performs one level of subdivision with smoothing (like MeshSmooth on page 1505 with one iteration) on the object to which it's applied. Thus, for best results, use it with relatively low-polygon objects. For example, if you usually work with the Sphere object at the default 32 segments, use a 16-segment sphere with HSDS.

   If the object is made up of quads only, Force Quads isn't available because no conversion is necessary.

3  Choose a sub-object mode at which to subdivide.
   The object is covered with a gold control grid (or, in Vertex sub-object mode, a white grid with blue vertices), indicating that the entire mesh is available for subdivision and/or sub-object transformation at base level.

4  Select one or more sub-objects.

5  Click the Subdivide button.
   The modifier again subdivides and smooths the selected sub-objects as well as all surrounding polygons. The resultant sub-objects reside at a higher level of detail, as indicated by the addition of a level in the Subdivision Stack. Now the control grid shows only polygons at the new level.
level. With sub-objects other than Element, this typically covers only part of the object’s surface.

In wireframe views, you can still see polygons at lower levels of detail, but you can select only sub-objects resulting from the subdivision, as indicated by the control grid. You can subdivide sub-objects further, transform them, hide and delete them, and change material IDs.

**NOTE** When you transform an HSDS sub-object, the control grid tends to expand by adding segments at its edges, in order to maintain surface smoothness.

6 To subdivide a different part of the object, choose a lower level in the Subdivision Stack, and then repeat steps 2–4.

Each time you subdivide a sub-object that has been subdivided, a higher level in the Subdivision Stack is highlighted, indicating a finer mesh.
resolution. You can then work at that level, or any lower level by selecting the level.

**NOTE** If you transform a sub-object at a level lower than the highest level in which the subject exists, the mesh uses the resolution imparted by the detail in the higher levels.

Interface

**HSDS Parameters rollout**

The sub-objects available in the HSDS modifier belong to the control grid rather than the mesh object itself. Transforming the grid sub-objects also transforms the underlying mesh, but the mesh doesn’t always move to the full extent of the control grid. This is particularly true in cases where you transform a sub-object at a level lower than the highest level in which the sub-object resides.

For example, if you subdivide a vertex at the Base Level, it then resides in the Base Level and Level 1. If you then move the vertex in the base level, the mesh doesn’t, by default, move as far as the vertex. This is roughly analogous to the way free-form deformation works, but with HSDS, the control grid conforms much more closely to the shape of the mesh object.

With vertices, you can control the degree to which the mesh follows the control-grid vertex with the settings on the **Vertex Interpolation** on page 1470 group.
**Vertex**

Turns on Vertex sub-object mode, which lets you select a vertex beneath the cursor; region selection selects vertices within the region.
**Edge** Turns on Edge sub-object mode, which lets you select a face or polygon edge beneath the cursor; region selection selects multiple edges within the region.

**Polygon** Turns on Polygon sub-object mode, which lets you select a single face or polygon. A polygon is the area you see within the visible wire edges. Region selection selects multiple polygons within the region.

**Element** Turns on Element sub-object mode, which lets you select all contiguous polygons beneath the cursor in the current level of detail.

**Ignore Backfacing** When on, you can select only those sub-objects whose normals are visible in the viewport. When off (the default), selection includes all sub-objects, regardless of the direction of their normals. Default=off.

**Only Current Level** Displays only polygons at the current level of detail, with highlights, but without smoothing. Use this option to speed up the display when working with complex objects. Default=off.

**Subdivision Stack** Shows the current level of the subdivision hierarchy. Automatically increments when you subdivide a sub-object selection. To edit at a different level of detail, select the level in the stack. The current level is outlined in red.

Visibility is controlled by the box icon to the right of the level label. Turning on the visibility at one level activates the visibility from that level down to the base level. Visibility above that level will be turned off.
Subdivide

Performs subdivision and smoothing on the current selection, and adds a level to the Subdivision Stack. When the subdivision results in a control grid and other subdivisions have been performed at the same level of detail, the control grids may become interconnected.

**Vertex Interpolation group**

Determines how selected vertices are treated during subdivision. Available only in Vertex sub-object mode.

For best results, use when moving control grid vertices at a level of detail lower than the highest in which the vertex resides.

**Standard/Conic/Cusp/Corner** Determines how closely mesh vertices follow the movement of control grid vertices. Standard provides the least amount of relative movement, while Cusp and Corner provide the most. Corner also keeps edges adjacent to subdivided vertices from being rounded off during subdivision. Default=Standard.

**NOTE** Corner is available only when the selected vertex or vertices aren't surrounded by polygons, such as the vertices on the edge of a plane object.

**Edge Crease group**

Determines the extent to which selected edges are treated as creases during subdivision. Available only in Edge sub-object mode.
For best results, use with control grid edges at a level of detail lower than the highest in which the edge resides. Also, for creasing to be visible, the edge should be offset from the surrounding surface by a significant amount.

Left: Crease=1.0
Center: The eyebrow edges selected at LOD 0
Right: Crease=0.0

Crease Specifies how much creasing is performed on the selected edge or edges. At low settings, the edge is relatively smooth. At higher settings, the crease becomes increasingly visible. At 1.0, the highest setting, the edge is not smoothed at all. Default=0.0. Range=0.0 to 1.0.

Advanced Options rollout

Force Quads When on, the modifier converts all non-quadrilateral faces or polygons to four-sided polygons. When off, converts all polygons to triangles. Available only when the object contains any non-quadrilateral faces or polygons. Default=off.
When you change the status of Force Quads, any edits made in the HSDS modifier are lost. A message appears warning you of this, and asking you to confirm the change.
Because the modifier works best with four-sided polygons, it's recommended you confirm the conversion if an object contains non-quadrilateral faces or polygons. The sphere primitive is an example of such an object; the uppermost and lowermost faces are three-sided.

Smooth Result When turned on, all faces on the object will be in smoothing group 1, but if Smooth Result is turned off, each face will inherit smoothing groups from the input MNMesh.
Material ID  Displays the material ID assigned to the current selection. Available only in Polygon and Element sub-object modes. If multiple sub-objects are selected and they don't share an ID, this field is blank. You can change the material ID assigned to selected sub-objects at the current and higher levels of detail by changing this setting. Material IDs are used primarily with Multi/Sub-Object material on page 6120.

Hide  Hides the current polygon selection. Available only at the Polygon and Element sub-object levels. Use Unhide All to reveal hidden polygons.

TIP  Use Hide to isolate part of an object you want to work on. The Select Invert command on the Edit menu is useful in this case. Select the faces you want to focus on, choose Edit > Select Invert, then click the Hide button.

Unhide All  Reveals hidden polygons.

Delete Polygon  Deletes the current polygon selection, creating a hole or holes in the surface. Available only in Polygon sub-object mode.

NOTE  When the current level of detail does not encompass the entire object surface, you cannot delete polygons at the border of the control grid; that is, polygons that do not share all edges with other polygons in the grid.

Adaptive Subdivision  Opens the Adaptive Subdivision dialog on page 1472. This option is best used for smoothing subdivided and edited portions of the mesh when you're finished using the HSDS functionality.

Soft Selection rollout

These controls let you set a gradual falloff of influence between selected and unselected vertices. See Soft Selection Rollout (Edit/Editable Mesh) on page 2014.

Adaptive Subdivision Dialog

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > HSDS Modifier > Advanced Options rollout > Adaptive Subdivision button

Select an object. > Modifiers menu > Subdivision Surfaces > HSDS Modifier > Advanced Options rollout > Adaptive Subdivision button

Use adaptive subdivision for smoothing subdivided and edited portions of the mesh when you're finished using the HSDS modifier on page 1464.
Alternatively, you can use adaptive subdivision to remove a level of detail from the object.

**Procedures**

**To use adaptive subdivision:**

1. Edit an object with the HSDS modifier.
2. Choose Add Detail or Remove Detail, depending which operation you want to perform.
3. Set the desired amount of detail with one of the presets or by specifying custom Length and Angle settings.
4. Click OK to perform the specified operation.
   The detail addition or removal is performed, and you're returned to the HSDS modifier. Depending on whether you removed or added detail, the highest level of detail is decremented or incremented by 1.

**Interface**

**Detail group**

*Add/Remove* Determines whether clicking the OK button increases or decreases detail.
**Parameters group**

These settings determine the extent to which detail is added or removed. The Length and Angle settings are available for editing only when the Custom option is chosen. However, they show the default settings for the Low, Medium, and High options.

**Low/Medium/High/Custom** Choose one of the presets, or choose Custom to set your own Length and Angle values.

**Max. LOD** Specifies the highest number of levels of detail that 3ds Max can add when increasing detail. Not available when removing detail.

**Length** The maximum permissible length of any edge after adding or removing detail. The smaller the length, the higher the amount of tessellation that is allowed.

**Angle** The maximum permissible angle between two opposite edges emanating from a vertex. The smaller the angle, the higher the amount of tessellation that is allowed.

**OK** Performs the subdivision or removal of detail and closes the dialog.

**Cancel** Closes the dialog without changing the mesh.

---

**Lathe Modifier**

Select a shape. > Modify panel > Modifier List > Lathe

Select a shape. > Modifiers menu > Patch/Spline Editing > Lathe

Lathe creates a 3D object by rotating a shape or NURBS curve about an axis.
Object resulting from 360-degree lathe

Interface

**Modifier Stack**

```
<table>
<thead>
<tr>
<th>Light Lathe</th>
<th>Axis</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ellipse</td>
<td></td>
</tr>
</tbody>
</table>
```

**Axis** At this sub-object level, you can transform and animate the axis of revolution.

For more information on the stack display, see [Modifier Stack](#) on page 8187.
Parameters rollout

Degrees  Determines the number of degrees that the object is spun around the axis of revolution (0 to 360, default=360). You can set keyframes for Degrees to animate the circular growth of a lathed object. The Lathe axis auto-sizes itself to the height of the shape being lathed.
Object resulting from 270-degree lathe

**Weld Core** Simplifies the mesh by welding together vertices that lie on the axis of revolution. Keep it turned off if you intend to create morph targets.

**Flip Normals** Depending on the direction of the vertices on your shape, and the direction of rotation, the lathed object might be inside out. Toggle the Flip Normals check box to fix this.

**Segments** Determines how many interpolated segments are created in the surface between the start and endpoint. This parameter is also animatable. Default=16

**NOTE** You can create up to 10,000 segments using the segments spinner. Try not to create geometry that is more complex than you need. Often you can get satisfactory results by using smoothing groups or smoothing modifiers, rather than increasing segmentation.

**Capping group**

Controls whether or not caps are created for the interior of the lathed object if Degrees is set to less than 360.
Cap Start Caps the start of the lathed object with Degrees set to less than 360 and a closed shape.

Cap End Caps the end of the lathed object with Degrees set to less than 360 and a closed shape.

Morph Arranges cap faces in a predictable, repeatable pattern necessary for creating morph targets. Morph capping can generate long, thin faces that don't render or deform as well as grid capping. Use morph capping primarily if you are lathing multiple morph targets.

Grid Arranges cap faces in a square grid trimmed at the shape boundaries. This method produces a surface of evenly sized faces that can easily be deformed by other modifiers.

**Direction group**

Sets up the direction of the axis of revolution, relative to the pivot point of the object.

X/Y/Z Set the direction of the axis of revolution relative to the pivot point of the object.

**Align group**

Min/Center/Max Align the axis of revolution to the minimum, center, or maximum extents of the shape.

**Output group**

Patch Produces an object that you can collapse to a patch object (see Editing the Stack on page 1049).

Mesh Produces an object that you can collapse to a mesh object (see Editing the Stack on page 1049).

NURBS Produces an object that can be collapsed to a NURBS surface (see Editing the Stack on page 1049).

Generate Mapping Coordinates Applies mapping coordinates to the lathed object. When Degrees is less than 360, and Generate Mapping Coordinates is turned on, additional mapping coordinates are applied to the end caps, placing a 1 x 1 tile on each cap.

Real-World Map Size Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by
the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=on.

Generate Material IDs Assigns different material IDs to the sides and the caps of the lathed object. Specifically, the sides receive ID 3, and the caps (when Degrees is less than 360 and the lathed shape is closed) receive IDs 1 and 2. Default=on.

Use Shape IDs Uses the material ID values assigned to segments in the spline on page 577 you lathed, or curve sub-objects in the NURBS on page 2416 curve you lathed. Use Shape IDs is available only when Generate Material IDs is turned on.

Smooth Applies smoothing to the lathed shape.

### Lattice Modifier

Select an object or a shape. > Modify panel > Modifier List > Object-Space Modifiers > Lattice

Select an object or a shape. > Modifiers menu > Parametric Deformers > Lattice

The Lattice modifier converts the segments or edges of a shape or object into cylindrical struts with optional joint polyhedra at the vertices. Use this either to create renderable structural geometry based on the mesh topology, or as an alternate method to achieve a rendered wireframe effect.
Top: Joints only
Middle: Struts only
Bottom: Both (joints and struts)

**NOTE** This modifier can act on the whole object or on sub-object selections in the stack.
You can combine the Scatter compound object on page 674 with the Lattice modifier to place any object you want as a joint, rather than the provided polyhedra. To do this, create your mesh distribution object and your source object (for example, a box). Use Scatter to scatter the box at the vertices of the distribution object. (Be sure to use the Copy option rather than Instance.) In the Scatter Display parameters, hide the distribution object. Select the original object that was used as a distribution object, apply Lattice to it, and turn off the joints. You’ll have two coincident objects: one providing the lattice struts, and the other positioning the boxes.
Interface

Parameters

Geometry
- Apply to Entire Object
- Joints Only from Vertices
- Struts Only from Edges
- Both

Struts
- Radius: 2.0
- Segments: 1
- Sides: 4
- Material ID: 1

- Ignore Hidden Edges
- End Caps
- Smooth

Joints
- Geodesic Base Type
  - Tetra
  - Octa
  - Icosa
- Radius: 5.0
- Segments: 1
- Material ID: 2

- Smooth

Mapping Coordinates
- None
- Reuse Existing
- New
Geometry group

Specifies whether to use the whole object or selected sub-objects, and which of the two components (struts and joints) is displayed.

Apply To Entire Object Applies Lattice to all edges or segments in the object. When turned off, applies Lattice only to selected sub-objects passed up the stack. Default=on.

**NOTE** When Apply To Entire Object is turned off, unselected sub-objects render normally. For example, if you convert a box to an editable mesh, select one polygon, and then apply Lattice with Apply To Entire Object turned off, the face does not render, while the edges and vertices that form that face are converted to struts and joints, and the remaining faces render normally. However, if you select the four edges surrounding the polygon and turn off Ignore Hidden Edges, the struts and joints are added to the object while all faces render as normal. If you turn on Struts group > Ignore Hidden Edges, one of the polygon's faces renders, while the other doesn't.

Joints Only From Vertices Displays only the joints (polyhedra) generated by the vertices of the original mesh.

Struts Only From Edges Displays only the struts (cylinders) generated by the segments of the original mesh.

Both Displays both struts and joints.

Struts group

Provides controls that affect the geometry of the struts.

Radius Specifies the radius of the struts.

Segments Specifies the number of segments along the struts. Increase this value when you need to deform or distort the struts with subsequent modifiers.

Sides Specifies the number of sides around the perimeter of the struts.

Material ID Specifies the material ID to be used for the struts. The struts and the joints can have different material IDs, making it easy to assign them different materials. The struts default to ID #1.

Ignore Hidden Edges Generates struts only for visible edges. When turned off, generates struts for all edges, including the invisible edges. Default=on.

End Caps Applies end caps to the struts.

Smooth Applies smoothing to the struts.
Joints group

Provides controls that affect the geometry of the joints.

Geodesic Base Type Specifies the type of polyhedron used for the joints.

Tetra Uses a tetrahedron.

Octa Uses an octahedron.

Icosa Uses an icosahedron.

Radius Specifies the radius of the joints.

Segments Specifies the number of segments in the joints. The more segments, the more spherical the joints' shape.

Material ID Specifies the material ID to be used for the joints. Defaults to ID #2.

Smooth Applies smoothing to the joints.

Mapping Coordinates group

Determines the type of mapping assigned to the object.

None Assigns no mapping.

Reuse Existing Uses the mapping currently assigned to the object. This might be the mapping assigned by Generate Mapping Coords., in the creation parameters, or by a previously assigned mapping modifier. When using this option, each joint inherits the mapping of the vertex it surrounds.

New Uses mapping designed for the Lattice modifier. Applies cylindrical mapping to each strut, and spherical mapping to each joint.

Linked XForm Modifier

Modify panel > Select objects or sub-objects. > Modifier List > Object-Space Modifiers > Linked XForm

Select an object or sub-objects. > Modifiers menu > Animation Modifiers > Linked XForm

The Linked XForm modifier links the transforms for any object or sub-object selection to another object, called the control object. The control object’s
motion, rotation, and/or scale transforms are passed onto the object or
sub-object selection.

**Using Linked XForm**

Linked XForm connects any geometry it receives from the stack to another
object, which is called the control object. Its single control simply picks the
control object. To use this modifier, you must have at least two objects in
your scene.

**See also:**
- XForm Modifier on page 2010

**Procedures**

**To apply a Linked XForm modifier:**

1. Choose a location in an object's stack and apply a Linked XForm from
   the Modifier List.
2. On the Parameter's rollout, click Pick Control Object. When animating,
   do this at frame 0.
3. Select the object you want to be the control object.
   This completes the link. The name of the control object appears on the
   Parameters rollout.

**To apply a Linked XForm modifier at a Sub-Object level:**

1. Choose an Editable Mesh or an object to which a Mesh Select modifier
   has been applied.
2. Turn on the Vertex sub-object level and select some vertices on the object.
3. Apply a Linked XForm modifier.
4. On the Parameter's rollout, click Pick Control Object. When animating,
   do this at frame 0.
5. Select another object that you want to control the sub-object selection.
   This completes the link. The name of the control object appears on the
   Parameters rollout.
6. Move the control object and see how the vertices are affected.
Interface

Control Object  Object that the vertices are linked to. When transformed, the vertices follow.

Pick Control Object  Click this button, and then select the object that you want to be the control object.

Back Transform  Allows an object with a Linked XForm modifier to be linked to a Control Object. Normally, moving the Control Object causes the linked object to move twice as much as it should, once with the Control Object and once with the link. When the switch is turned on, any transforms to the Control Object are only applied to the linked object once. This switch is similar to the 'Back Transform Vertices' switch of the Skin on page 1667 modifier.

LS Mesh Modifier

Select a Lightscape mesh object. > Modify panel > Modifier List > LS Mesh

The LS Mesh modifier refines a Lightscape mesh object.

When you import a Lightscape scene into 3ds Max, the mesh produced by Lightscape doesn't contain the refinements that Lightscape introduced to improve the lighting. This information is kept and used by the Lightscape material while rendering. This modifier will add these refinements to the Lightscape mesh. In conjunction with the LS Colors modifier on page 1145, this modifier can be used to produce meshes suitable for game engines.

The refinement stored in a Lightscape mesh is hierarchical. When a polygon is refined, it is broken into four smaller polygons. These polygons can then be refined further. A polygon in the refinement has a depth from the original polygon, which is the number of refinements needed to get from the original polygon to the polygon in question.
The modifier allows you to reduce the number of polygons in the result by limiting the depth to which the modifier will descend, or by limiting the size of polygons that will be refined.

You can apply the LS Mesh modifier to a Face sub-object selection of a Lightscape mesh object. In this case, only the selected faces will be refined.

See also:
- Lightscape Files (LP, LS, and Other Formats) on page 7756

Interface

Limit subdivision depth When the toggle is on, the value sets the maximum depth of refinement. When the toggle is off, then the mesh modifier will descend to the bottom of the refinement. Default=on, 0.

Limit subdivision size When the toggle is on, the value limits the size of polygons that are refined. When the toggle is off, then the mesh modifier will refine polygons to any size. The size is a length in the current view units. Polygons smaller than that size squared will not be refined by the modifier. Default=off, 19.685 units or 0.5 meters.

MapScaler Modifier (Object Space)

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > MapScaler

The MapScaler (OSM) modifier works in object space to maintain the scale of a map applied to an object. This lets you resize the object via its creation parameters without altering the scale of the map. Typically, you might use this to maintain the size of a map regardless of how the geometry is scaled, if you change the object size by adjusting its creation parameters. However, if
you use a Select And Scale tool to change the object size, the map scales along with the object.

To maintain the scale of the map regardless of how the object is resized, use the **MapScaler (WSM)** modifier on page 1147.

For example, if you scale a brick wall with the MapScaler (WSM) modifier applied, the bricks will all remain the same size as you increase the size of the wall. However, if you scale the same wall with the MapScaler (OSM) modifier applied, the size of the bricks will grow in proportion with the scale of the wall.

The MapScaler (OSM) modifier has two primary benefits compared to the WSM version:

- As an object-space modifier, it can reside anywhere in the stack and be collapsed with the stack, rather than being restricted to the top of the stack, as with world-space modifiers. This lets other object-space modifiers take effect after the map-scaling operation.

- When instanced among multiple objects, the object-space version appears in the modifier stack display when any number of objects is selected. This differs from the world-space version, which, when instanced among multiple objects, appears in the stack display only when a single object is selected.

**TIP** MapScaler also works at the sub-object level. If the object you’re working on requires different scaling of the texture map on each surface, you can do so by creating a modifier stack with multiple occurrences of the MapScaler modifier.

**Procedures**

**Example: To use the MapScaler at a sub-object level:**

1. Create a Box and apply a brick or other patterned material to the object.

2. Open the Modify panel and choose Mesh Select from the Modifier List.

3. On the Parameters rollout, click the Polygon button and select one of the sides of the box.

4. Open the Modifier List and apply either MapScaler modifier.
5  Change the Scale value.

Notice that the texture map only on the selected set of polygons is changed.

To change the scale of the texture on another part of the same object, add another Mesh Select modifier and make a new sub-object selection. Add the next MapScaler modifier to the new selection set and change the scale as you did in step 5.

Interface

Scale Represents the size of one repetition of the texture pattern. Size is measured in current scene units. Repetitions occur across the object in the U and V directions. Default=1.0.

NOTE When the Use Real-World Texture Coordinates switch is active in the General Preferences dialog on page 8299, the scale setting defaults to 1.0. If Use Real-World Texture Coordinates is turned off, scale defaults to 100.0.

U/V Offset Specify horizontal and vertical offsets respectively. Available only when Wrap Texture is off.

Wrap Texture When on, Map Scaler attempts to wrap the texture evenly around the object. This option requires more computing, but usually produces the most satisfactory results. Default=on.

Wrap Using Smoothing Groups When turned on, textures are wrapped around corners when they share the same smoothing groups. Curved walls
will map smoothly while sharp corners get a new texture origin. This switch is only available when the Wrap Textures switch is turned on. Default=off.

**Channel** Specifies the map channel on page 8627. Default=1.

---

**Material Modifier**

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Material  
Select an object. > Modifiers menu > Surface > Material  
Select an object. > Modifiers tab > Material Modifier

The Material modifier allows you to animate, or simply change, the assignment of material IDs on page 8633 on an object. If the material ID is animated, the change to a new material ID is abrupt, from one frame to the next.

Object mapped using a multi/sub-object material:

Material ID 1 for the housing of the monitor  
Material ID 2 for the image on the screen
TIP  If you want a gradual blend from one material to another, try animating the Mix parameter on a Blend on page 6107 material.

Use this modifier in conjunction with the multi/sub-object on page 6120 material type, to assign different materials to objects or faces at different frames of an animation, or to quickly change the material ID of an object.

See also:

■  Editable Mesh Surface on page 2192

Patches

This modifier does not convert a patch object below it in the modifier stack to a mesh. A patch object input to the Material modifier retains its patch identity.

Procedures

Example: To change the material ID of a sub-object selection:

1  In the Top viewport, create a sphere.

2  In the Material Editor, create a multi/sub-object material. Make the colors of material ID 1 and 2 different.

3  Assign the multi/sub-object material to the sphere.

4  On the Modify panel, choose Mesh Select from the Modifier List.

5  On the Mesh Select Parameters rollout, click Polygon.

6  In the Front viewport, region-select the lower half of the sphere. The selected polygons turn red.

7  While Polygon is still the active sub-object level (in the stack display, a square polygon icon appears to the right of Mesh Select), choose Material from the Modifier List.
On the Material modifier Parameters rollout, set the value of the Material ID to 1 and 2 to toggle the color on and off.

In the shaded viewport, the lower half of the sphere changes to the color of the selected material ID.

**Interface**

![Parameters](image)

**Material ID** Sets the material ID to be assigned; this can be animated. If the input object is in face sub-selection, then the ID is only applied to selected faces; otherwise, it is applied to the entire object. The ID number refers to one of the materials in a multi/sub-object material.

**MaterialByElement Modifier**

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > MaterialByElement

Make a selection. > Modifiers menu > Surface > Material By Element

The MaterialByElement modifier lets you apply different material IDs to objects containing multiple elements, at random or according to a formula. When animated, this effect is useful for such applications as an office building at night with window illumination turning on and off at random.
Various materials randomly applied to the leaves of the plant

Procedures

Example: To assign colors randomly in a group of spheres:

1. Create six spheres.

   **TIP** One method is to add a sphere on page 396 primitive, then use Shift+Move on page 914 with the Copy option, and enter 5 in the Number Of Copies field.

2. Combine the spheres into a single editable mesh object.
   
   Right-click a selected sphere and from the Transform (lower-right) quadrant of the quad menu, choose Convert To: > Convert to Editable Mesh. Then click Modify panel > Edit Geometry rollout > Attach List. In the Attach List dialog, click All, and then Attach.

3. Create a **multi/sub-object material** on page 6120 with six materials, and specify a different color for each material. Assign the material to the object with multiple spheres.
Because sphere primitives are assigned material ID 2 by default, all the spheres now have the color assigned to material number 2 in the multi/sub-object material.

4 Assign the MaterialByElement modifier to the object.

5 From the Parameters rollout, turn on Random Distribution.
   Because the default ID Count setting is 2, some of the spheres are assigned sub-material #1, and the rest are assigned #2.

6 Use the spinner to increase the ID Count setting to 3. Also change the Uniqueness group > Seed value.
   Now the first three materials are assigned to the spheres at random, although with some Seed settings, you may see only two different colors.

7 Keep increasing the ID Count setting until you see all six colors in the multi/sub-object material. As the assignments are random, it may take awhile.
Interface

Material ID By Element group

The two choices in this group let you either create a truly random distribution of material IDs or divide the assignments among up to eight materials according to percentages you set.

Random Distribution Assigns the materials at random to different elements in the object.
ID Count Determines the minimum number of material IDs to assign. Because material ID assignment is random, setting it to the number of materials in the multi/sub-object material or higher doesn’t guarantee that all materials get used.

List Frequency Determines an approximate relative weight (percentage) for each of up to eight material IDs, as set by the Mat'l ID #1-8 spinners. The modifier assigns material IDs until the weights total 100.

For example, if you set Mat'l ID #1 to 40, #2 to 35, and #3 to 60, approximately 40 percent of the elements will be assigned material ID 1, 30 percent will be assigned material ID 2, and 25 percent ($100 - [40 + 35]$) will be assigned material ID 3. Any remaining percentages (as set in Mat'l IDs 4-8) are ignored.

NOTE These percentages are approximate. The more elements the object contains, the closer the assigned percentage comes to the set percentage.

Uniqueness group

Seed Sets the seed value for the (pseudo-)randomization of material ID assignments. Not animatable.

Melt Modifier

Modify panel > Make a selection. > Modifier List > Melt

Make a selection. > Modifiers menu > Animation Modifiers > Melt

The Melt modifier lets you apply a realistic melting effect to all types of objects, including editable patches and NURBS objects, as well as to sub-object selections passed up the stack. Options include sagging of edges, spreading while melting, and a customizable set of substances ranging from a firm plastic surface to a jelly type that collapses in on itself.
Increasing the Melt amount progressively melts the cake

**Procedures**

**Example: To animate a jelly-like melting sphere:**

1. In the Top viewport, create a Sphere primitive with a radius of about 50 units.
2. Apply the Melt modifier.
3. Turn on the Auto Key button and go to frame 100.
4. In the Melt group box, set Amount to 70.
5. In the Solidity group box, choose Jelly.
6. Turn off the Auto Key button.
7. Drag the time slider to see the sphere melt.
Interface

Modifier Stack

Gizmo At this sub-object level, you can transform and animate the gizmo like any other object, altering the effect of the Melt modifier. Translating the gizmo translates its center an equal distance. Rotating and scaling the gizmo takes place with respect to its center.

Center At this sub-object level, you can translate and animate the center, altering the Melt gizmo’s shape, and thus the shape of the melted object.

For more information on the stack display, see Modifier Stack on page 8187.
Parameters rollout

Melt group

Amount  Specifies the extent of the "decay," or melting effect applied to the gizmo, thus affecting the object. Range=0.0 to 1000.0.

Spread group

% of Melt  Specifies how much the object and melt will spread as the Amount value increases. It's basically a "bulge" along a flat plane.

Solidity group

Determines the relative height of the center of the melted object. Less-solid substances like jelly tend to settle more in the center as they melt. This group provides several presets for different types of substances, as well as a Custom spinner for setting your own solidity.

Ice  The default Solidity setting.
Glass Uses a high Solidity setting to simulate glass.

Jelly Causes a significant drooping effect in the center.

Plastic Relatively solid, but droops slightly in the center as it melts.

Custom Sets any solidity between 0.2 and 30.0.

**Axis to Melt group**

X/Y/Z Choose the axis (local to the object) on which the melt will occur. Note that this axis is local to the Melt gizmo and not related to the selected entity. By default, the Melt gizmo's axes are lined up with the object's local coordinates, but you can change this by rotating the gizmo.

Flip Axis Normally, the melt occurs from the positive direction toward the negative along a given axis. Turn on Flip Axis to reverse this direction.

**Mesh Select Modifier**

Create or select and object > Modify panel > Modifier List > Mesh Select

Make a selection. > Modifiers menu > Selection Modifiers > Mesh Select

The Mesh Select modifier lets you pass a sub-object selection up the stack to subsequent modifiers. It provides a superset of the selection functions available in the Edit Mesh modifier on page 1321. You can select vertices, edges, faces, polygons or elements, and you can change the selection from sub-object level to object level.

Note the following:

- When you apply the Mesh Select modifier and then go to any sub-object level, the select-and-transform buttons in the toolbar are unavailable, and the Select Object button is automatically activated.

- The Mesh Select modifier automatically turns off the Show End Result button, which becomes "spring loaded" while you're in the modifier.

For more information on the stack display, see Modifier Stack on page 8187.
Using XForm Modifiers to Animate a Mesh Selection

When you apply a Mesh Select modifier, there are no animation controllers assigned to the sub-object selection. This means that the selection has no way to "carry" the transform information needed for animation.

To animate a sub-object selection using Mesh Select, apply either an XForm or Linked XForm modifier to the selection. These modifiers provide the necessary controllers for animating the effects of transforms. In a sense, they give "whole-object status" to the sub-object selection.

- **XForm** on page 2010
  Animates transforms directly on a sub-object selection. Creates a gizmo and center for the sub-object selection. You can animate both, with the center acting as a pivot point for the selection.

- **Linked XForm** on page 1484
  Lets you choose another object to control the animation. The sub-object selection is linked to the "control object." When you transform the control object, the sub-object selection follows accordingly.

Procedures

To use the Mesh Select modifier:

1. Create a mesh object.
2. Select a mesh object.
3. Apply a Mesh Select modifier.
4. Select vertices, edges, faces, polygons or elements.
5. Add another modifier to affect only the selection from step 3.

Interface

**Modifier Stack controls**

- **Show End Result** Normally, if you apply a modifier such as Twist to an editable-mesh object and then return to the Editable Mesh stack entry, you cannot see the effect of the modifier on the object's geometry. But if you turn on Show End Result, you can see the final object as a white mesh, and the original editable mesh as an orange mesh.
Mesh Select Parameters rollout

Provides buttons for turning different sub-object modes on and off, working with named selections and handles, display settings, and information about selected entities.

The icons at the top of the Selection rollout let you specify the method of sub-object selection.

Clicking a button here is the same as selecting a sub-object level in the modifier stack. Click the button again to turn it off and return to the object selection level.

Vertex Selects a vertex beneath the cursor; region selection selects vertices within the region.
**Edge** Selects a face or polygon edge beneath the cursor; region selection selects multiple edges within the region.

**Face** Selects a triangular face beneath the cursor; region selection selects multiple triangular faces within the region.

**Polygon** Selects all coplanar faces (defined by the value in the Planar Threshold spinner) beneath the cursor. Usually, a polygon is the area you see within the visible wire edges. Region selection selects multiple polygons within the region.

**Element** Selects all contiguous faces in an object. Region selection selects the same.

**By Vertex** Selects any sub-objects at the current level that use a vertex you click. Applies to all sub-object levels except Vertex. Also works with Region Select.

**Ignore Backfaces** Selects only those sub-objects whose normals make them visible in the viewport. When turned off (the default), selection includes all sub-objects, regardless of the direction of their normals.

**NOTE** The state of the Backface Cull setting in the Display panel doesn't affect sub-object selection. Thus, if Ignore Backfacing is turned off, you can select sub-objects even if you can't see them.

**NOTE** The state of the Ignore Backfaces check box also affects edge selection at the Edge sub-object selection level.

**Ignore Visible Edges** When turned off (the default), and you click a face, the selection won't go beyond the visible edges no matter what the setting of the Planar Thresh spinner. When turned on, face selection ignores the visible edges, using the Planar Thresh setting as a guide. Enabled when the Polygon face selection method is chosen.

Generally, if you want to select a "facet" (a coplanar collection of faces), you set the Planar Threshold to 1.0. On the other hand, if you're trying to select a curved surface, increase the value depending on the amount of curvature.
**Planar Thresh (Planar Threshold)** Specifies the threshold value that determines which faces are coplanar for Polygon face selection.

**Get from Other Levels group**

Applies selections from one sub-object level to another.

**Get Vertex Selection** Selects faces based on the last vertex selection. Selects all faces shared by any selected vertex. The selection is added to the current selection. Available only when Vertex is not the current sub-object level.

**Get Face Selection** Selects vertices based on the last face/polygon/element selection. This selection is added to the current selection. Available only when Face/Polygon/Element is not the current sub-object level.

**Get Edge Selection** Selects faces based on the last edge selection. Selects those faces that contain the edge. Available only when Edge is not the current sub-object level.

**Select by Material ID group**

Selects faces based on their material ID.

**ID** Set the spinner to the ID number you want to select, and then click the Select button. Press Ctrl while clicking to add to the current selection, or press Alt to remove from the current selection.

**Named Selection Sets group**

These functions are primarily for copying named selection sets on page 185 of sub-objects between similar objects, and between comparable modifiers and editable objects. For example, you can apply a mesh select modifier to a sphere, create a named selection set of edges, and then copy the selection to a different sphere that's been converted to an editable mesh object. You can even copy the selection set to a different type of object, because the selection is identified by the entities' ID numbers.

The standard procedure is to create a selection set, name it, and then use Copy to duplicate it into the copy buffer. Next, select a different object and/or modifier, go to the same sub-object level as you were in when you copied the set, and click Paste.

**NOTE** Because sub-object ID numbers vary from object to object, the results of copying named selection sets between different objects can be unexpected. For example, if the buffered set contains only entities numbered higher than any that exist in the target object, no entities will be selected when the set is pasted.
Copy Places a named selection into the copy buffer.

Paste Pastes a named selection from the copy buffer.

Select Open Edges Selects all edges with only one face. In most objects, this will show you where missing faces exist. Available only at the Edge sub-object level.

Selection Information

At the bottom of the Mesh Select Parameters rollout is a text display giving you information about the current selection. If 0 or more than one sub-object is selected, the text gives the number and type selected. If one sub-object is selected, the text gives the ID number and type of the selected item.

NOTE When the current sub-object type is Polygon or Element, selection information is given in faces.

Soft Selection rollout

These controls let you set a gradual falloff of influence between selected and unselected vertices. See Soft Selection Rollout (Edit/Editable Mesh) on page 2014.

MeshSmooth Modifier

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > MeshSmooth

Make a selection. > Modifiers menu > Subdivision Surfaces > MeshSmooth

The MeshSmooth modifier smoothes geometry in your scene by means of several different methods. It lets you subdivide the geometry while interpolating the angles of new faces at corners and edges, and apply a single smoothing group to all faces in the object. The effect of MeshSmooth is to round over corners and edges as if they had been filed or planed smooth. Use MeshSmooth parameters to control the size and number of new faces, and how they affect the surface of the object.
Angular model (shown on the right) changed to a smooth model with MeshSmooth

You can use MeshSmooth to produce a Non-Uniform Rational MeshSmooth object (NURMS for short). A NURMS object is similar to a NURBS object in that you can set different weights for each control vertex. You can further control the object's shape by changing edge weights.

MeshSmooth's effect is most dramatic on sharp corners and least visible on rounded surfaces. Use MeshSmooth on boxes and geometry with crisp angles. Avoid using it on spheres and similar objects.

**TIP** To better understand MeshSmooth, create a sphere and a cube and apply MeshSmooth to both. The cube's sharp corners become rounded, while the sphere's geometry becomes more complex without changing shape significantly.

**NOTE** Having an animated deformer placed before a meshsmoothed object that has had control level editing can result in the meshsmoothed object becoming distorted. It's recommended that deforming modifiers be placed after the MeshSmooth modifier in the stack if you're using the deformers for animation.

**See also:**
- Quadify Mesh Modifier on page 1641
Procedures

To apply MeshSmooth to an object:
1. Select an angular object.
2. Apply the MeshSmooth modifier.

To apply MeshSmooth to sub-objects:
1. Select an object.
2. Apply a Mesh Select modifier.
3. Select a group of vertices or faces.
4. Apply MeshSmooth.
5. In the Subdivision Method rollout, turn off Apply To Whole Mesh. This lets MeshSmooth work only on the sub-object selection.

Interface

Modifier Stack

- **Vertex** At this sub-object level you can transform or edit vertices in the smoothed mesh.
- **Edge** At this sub-object level you can transform or edit face edges in the smoothed mesh.

See Local Control rollout on page 1511.
For more information on the stack display, see Modifier Stack on page 8187.
Subdivision Method rollout

Subdivision Method list Choose one of the following to determine the output of the MeshSmooth operation:

- **NURMS**  Produces Non-Uniform Rational MeshSmooth object (NURMS for short). The Strength and Relax smoothing parameters are unavailable with the NURMS type.
  
  A NURMS object is similar to a NURBS object in that you can set different weights for each control vertex. You can further control the object’s shape by changing edge weights. See Display/Weighting group, following, for further information on changing weights.

- **Classic**  Produces three- and four-sided facets. (This is the same as applying MeshSmooth in version 2.x without turning on Quad Output.)

- **Quad Output**  Produces only four-sided facets (assuming you don’t look at the hidden edges, since the object is still made up of triangular faces). If you apply this with default parameters to a whole object, like a box, it’s topologically exactly the same as Tessellate on page 1812, edge-style. However, rather than using tension to project face and edge vertices out of the mesh, use the MeshSmooth Strength to relax the original vertices and the new edge vertices into the mesh.

**Apply To Whole Mesh** When turned on, any sub-object selection passed up the stack is ignored and MeshSmooth is applied to the entire object. Note that the sub-object selection is still passed up the stack to any subsequent modifiers.

**Old Style Mapping** Use the 3ds Max version 3 algorithm to apply MeshSmooth to the mapping coordinates. This technique tends to distort the underlying mapping coordinates as it creates new faces and as texture coordinates shift.
Effect of MeshSmooth with two iterations on a cube and different iteration method:

A. NURMS
B. Quad
C. Classic
D. Original object with no MeshSmooth

**Subdivision Amount rollout**

Sets how many times to apply MeshSmooth.
**Iterations** Sets the number of times the mesh is subdivided. When you increase this value, each new iteration subdivides the mesh by creating smoothly interpolated vertices for every vertex, edge, and face from the iteration before. The modifier then subdivides the faces to use these new vertices. Default=0. Range=0 to 10.

The default value of 0 iterations allows you to modify any setting or parameter, such as the type of MeshSmooth or the update options, before 3ds Max starts subdividing the mesh.

**NOTE** Be cautious when increasing the number of iterations. The number of vertices and faces in an object (and thus the calculation time) can increase as much as four times for each iteration. Applying four iterations to even a moderately complex object can take a long time to calculate. You can press Esc to stop calculation; this also automatically sets Update Options to Manually. Reduce the Iterations value before setting Update Options back to Always.

**Smoothness** Determines how sharp a corner must be before faces are added to smooth it. Smoothness is calculated as the average angle of all edges connected to a vertex. A value of 0.0 prevents the creation of any faces. A value of 1.0 adds faces to all vertices even if they lie on a plane.

**TIP** To subdivide only sharp edges and corners, use a Smoothness value of less than 1.0. To see the subdivisions in Wireframe/Edged Faces viewports, turn off Isoline Display on page 1512.

**Render Values** These let you apply a different number of smoothing iterations and a different Smoothness value to the object at render time. Typically you would use a low number of iterations and a lower Smoothness value for modeling, and higher values for rendering. This lets you work quickly with a low-resolution object in the viewports, while producing a smoother object for rendering.

**Iterations** Lets you choose a different number of smoothing iterations on page 1510 to be applied to the object at render time. Turn on Iterations, and then use the spinner to its right to set the number of iterations.

**Smoothness** Lets you choose a different Smoothness value to be applied to the object at render time. Turn on Smoothness, then use the spinner to its right to set the smoothness value.
From right to left, effect of increasing the number of iterations

Local Control rollout

MeshSmooth Modifier | 1511
Sub-object Level  Turns Edge or Vertex level on or off. When both levels are off, you're working at the object level. Information about the selected edges or vertices is displayed in the message area under the Ignore Backfacing check box.

Ignore Backfacing  When on, selection of sub-objects selects only those sub-objects whose normals make them visible in the viewport. When off (the default), selection includes all sub-objects, regardless of the direction of their normals.

Control Level  Allows you to see the control mesh after one or more iterations and to edit sub-object points and edges at that level. Transform controls and the Weight setting are available for all sub-objects at all levels. The Crease setting is available only at the Edge sub-object level.

Crease  Creates a discontinuity on a surface so you get a hard edge, such as a wrinkle or lip. You select one or more edge sub-objects and adjust the Crease setting; the crease appears in the surfaces associated with the selected edges. Available only at the Edge sub-object level.

Weight  Sets the weight of selected vertices or edges. Increasing a vertex weight "pulls" the smoothed result toward that vertex. Edge weights are more complex and behave in an opposite manner in some respects. They aren't really "weights" as such, but "knot intervals," in NURBS terminology. Consequently, increasing an edge weight tends to push the smoothed result away. Kinks will form in the result if weights of 0 are used.

Isoline Display  When on, 3ds Max displays only isolines: the object's original edges, before smoothing. The benefit of using this option is a less cluttered display. When off, 3ds Max displays all faces added by MeshSmooth; thus, higher Iterations settings (see Subdivision Amount Rollout on page 1509) result in a greater number of lines. Default=on.

Show Cage  Toggles the display of a two-color wireframe that shows the modified object before subdivision. The cage colors are shown as swatches to the right of the check box. The first color represents unselected edges at the Vertex sub-object level, and the second color represents unselected edges at the Edge sub-object level. Change a color by clicking its swatch.

Soft Selection rollout

Soft Selection controls affect the action of sub-object Move, Rotate, and Scale functions. When these are on, 3ds Max applies a spline curve deformation to unselected vertices surrounding the transformed selected sub-object. This provides a magnet-like effect with a sphere of influence around the transformation.
For more information, see Soft Selection Rollout on page 2014.

Parameters rollout

These settings are available only when MeshSmooth Type is set to Classic or Quad Output. Also, Project To Limit Surface is available only in Classic mode.

Strength

Sets the size of the added faces using a range from 0.0 to 1.0.

- Values near 0.0 create small faces that are very thin and close to the original vertices and edges.
- Values near 0.5 size faces evenly between edges.
- Values near 1.0 create large new faces and make the original faces very small.

Relax

Applies a positive relax effect to smooth all vertices.

Project to Limit Surface

Places all points on the "limit surface" of the MeshSmooth result, which is the surface that would be produced after an infinite number of iterations. The topology is still controlled by the number of iterations.

Parameters rollout > Surface Parameters group

Applies smoothing groups to the object and restrict the MeshSmooth effect by surface properties.
Smooth Result Applies the same smoothing group to all faces.

Separate by Materials Prevents the creation of new faces for edges between faces that do not share Material IDs.

Separate by Smoothing Groups Prevents the creation of new faces at edges between faces that don't share at least one smoothing group.

Settings rollout

Settings rollout > Input Conversion group

Operate On Faces/Polygons Operate On Faces treats every triangle as a face and smooths across all edges, even invisible edges. Operate On Polygons ignores invisible edges, treating polygons (like the quads making up a box or the cap on a cylinder) as a single face.

Keep Faces Convex (Available only with Operate On Polygons mode.) Keeps all input polygons convex. Selecting this option causes non-convex polygons to be handled as a minimum number of separate faces, each of which is convex. (Turn on Display/Weighting group > Display Control Mesh to see what's happening here.)

"Convex" means that you can connect any two points in the polygon with a line that doesn't go outside the polygon. Most letters aren't convex. In the capital letter "T," for example, you can't connect the upper-left corner to the bottom with a straight line without going outside the shape. Circles, rectangles, and regular polygons are all convex.

Problems that can occur with non-convex faces include the fact that changes in the geometry of the input object can result in a different topology for the MeshSmooth result. For instance, in a box, if you drag one of the top corners
across the middle of the top face, the box becomes non-convex. MeshSmooth would then see this as two triangles instead of one quad, and the number of points in the result would change.

If you need to make sure your output topology is stable, turn this off. If you have a lot of letters or other non-convex faces in your mesh, however, you'll probably want it on.

**Settings rollout > Update Options group**

Sets manual or render-time update options, for situations where the complexity of the smoothed object is too high for automatic updates. Note that you can also set a greater degree of smoothing to be applied only at render time, on the Subdivision Amount rollout.

**Always** Updates the object automatically whenever you change any MeshSmooth settings.

**When Rendering** Updates the viewport display of the object only at render time.

**Manually** Turns on manual updating. When manual updating is selected, any settings you change don't take effect until you click the Update button.

**Update** Updates the object in the viewport to match the current MeshSmooth settings. Works only when you choose When Rendering or Manually.

**Resets rollout**

This rollout allows you to go back to default or initial settings on any changes you made such as sub-object transforms (geometric edits), and changes to edge creases, vertex weights, and edge weights.

You can reset changes for all control levels or to the current control level. Turn on the reset option for the sub-object level you want, and then click the appropriate button.
Reset All Levels Returns to the default or initial settings for geometric edits, creases, and weights for all sub-object levels.

Reset This Level Returns to the default or initial settings for geometric edits, creases, and weights for the current sub-object level.

Reset Geometric Edits Returns to the default or initial settings for any transforms made to vertices or edges.

Reset Edge Creases Returns to the default or initial setting for edge creases.

Reset Vertex Weights Returns to the default or initial setting for vertex weights.

Reset Edge Weights Returns to the default or initial setting for edge weights.

Reset Everything Returns to the default or initial setting for everything.

**Mirror Modifier**

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Mirror

Make a selection. > Modifiers menu > Parametric Deformers > Mirror

The Mirror modifier provides a parametric method of mirroring an object or a sub-object selection. You can apply the Mirror modifier to any type of geometry, and you can animate the mirror effect by animating the modifier's gizmo.
Mirroring a bench

Procedures

To apply the Mirror modifier:

1. Apply the Mirror modifier to a selection.
2. Set the axis or axis pair on which to mirror the object.
3. To create a mirrored pair, specify an Offset amount and turn on Copy.

Interface

Modifier Stack
Mirror Center Represents the axis of the mirror effect. You can move, rotate or scale the gizmo to affect the mirroring. You can animate the gizmo transforms, which you can't do with the toolbar Mirror on page 940 tool. For more information on the stack display, see Modifier Stack on page 8187.

Parameters rollout

![Parameters rollout]

Mirror Axis group

X, Y, Z, XY, YZ, ZX Specify the axis or axes about which the mirroring takes place. You can usually see the effect in the viewport as you select the option.

Options group

Offset Specifies the offset, in units, from the mirror axis. This is an animatable parameter.

Copy Copies the geometry rather than simply mirroring it.

NOTE The Copy option affects only geometry with triangular meshes.

Morpher Modifier

Select a mesh, patch, or NURBS object. > Modify panel > Modifier List > Morpher

Select a mesh, patch, or NURBS object. > Modifiers menu > Animation Modifiers > Morpher
Use the Morpher modifier to change the shape of a mesh, patch, or NURBS model. You can also morph shapes (splines), and World Space FFDs. As well as morphing from one shape to another, the Morpher modifier also supports material morphing.

On this patch model, morph targets are created by moving control vertices and tangent handles in an Editable Patch.

Morphing is commonly used for lip sync and facial expression on a 3D character, but can be used to change the shape of any 3D model. There are 100 channels available for morph targets and materials. Channel percentages can be mixed, and the result of the mix can be used to create a new target.

On a mesh object, vertex count on the base object and targets must be the same. On a patch or NURBS object, the Morpher modifier works on control points only. This means that the resolution of patches or NURBS surfaces can be increased on the base object to increase detail at render time.

A Flex modifier above the Morpher modifier is aware of vertex/control point motion in the Morpher modifier. If, for example, a jaw is morphed to slam shut, then the Flex modifier placed above the Morpher modifier in the modifier stack can be used to make the lips quiver to simulate soft tissue.
See also:
- Morpher Material on page 6116

Lip Sync and Facial Animation

For lip sync and facial animation, create a character's head in an "at rest" pose. The head can be a mesh, patch, or NURBS model. Copy and modify the original head to create the lip-sync and facial-expression targets. Select the original or "at rest" head and apply the Morpher modifier. Assign each lip-sync and facial-expression target to a channel in the Morpher modifier. Load an audio file in the Track View sound track, turn on the Auto Key button, scrub the time slider, and view the audio waveform in Track View to locate frames for lip sync. Then set the channel spinners on the Morpher modifier to create key frames for lip position and facial expression.

Teeth can either be a part of the model or animated separately. If the teeth and head are two different objects, model the teeth in an open position, and then apply the Morpher modifier, and create one target with the teeth closed. Eyes and head motion can be animated after the morph keys are created.

Morph Targets for Speech

Nine mouth shape targets are commonly used for speech. If your character speaks an alien dialect, don't hesitate to create extra morph targets to cover these mouth shapes.

Include cheek, nostril, and chin-jaw movement when creating mouth position targets. Examine your own face in a mirror or put a finger on your face while mouthing the phonemes, if necessary, to establish the direction and extent of cheek motion.

Set lip-sync keys by viewing the audio waveform as well as listening to the sound as you scrub the time slider. Many mouth-position keys benefit from being set a frame early. Often the mouth must assume a shape before the appropriate sound is uttered. For the word "kilo", the "K" mouth shape precedes the actual sound, for example.
A, I

E

E, V

C, D, G, J, K, N, S, T, Y, Z
Chapter 9  Modifiers
M,B,P (This target can be the same shape as the "at rest" base object)

**Morph Targets for Expression**

Create as many expression targets as necessary for the character. Joy, sadness, surprise, evil can all have their own targets. Depending on the personality of the character, certain targets, like a terror target, may not be necessary. Targets like nostril flare, jaw-muscle bunching, temple twitching can be effective to give a character an edge. Each morph channel can contain a material as well: as you morph the brows up, a bump map can crease the forehead, for example.

Save time and create targets as the need arises; if the audio file or scene you are working on requires a look of surprise, create the "surprise" target while the mood of the scene is with you.

If the character has teeth, copy the teeth and the base head to create a new target. The teeth act as a guide to shape and position the lips.
Procedures

Example: To add the morpher modifier to an object and assign a morph target to a channel:

1. On the Create panel, click Geometry.
2. On the drop-down list, choose Patch Grids.
3. On the Object Type rollout, click Quad Patch.
4. In the Top viewport, click and drag to create a patch grid.
5. On the Modify panel, on the modifier stack display, right-click Quad Patch and choose Convert To: Editable Patch from the right-click menu.
   The base object is now an Editable Patch.
6. In the Top viewport, use Shift+Move to create a copy of the patch object.
7 On the Modify panel, on the Selection rollout, click Vertex.

8 In the Front viewport, move patch vertices to deform the patch surface.

9 In the stack display, choose Editable Patch to go to the object (top) level. (The highlight should change from yellow to gray, and the Vertex sub-object icon is no longer displayed at the right of the stack.)

10 Select the first patch object.

11 On the Modify panel, choose Morpher from the Modifier List. The Morpher modifier is added to the modifier stack.

12 On the Morpher modifier, on the Channel List rollout, right-click the first channel (over the word "empty"). A right-click menu displays.

13 Choose Pick from Scene on the right-click menu, and click the deformed patch grid in the viewports. QuadPatch02 is listed in the channel as a morph target.

14 Drag the Channel spinner, to the right of QuadPatch02, up and down. The flat patch grid "morphs" to the shape of the target.

To use progressive morphing:

1 Create starting and ending morph targets, and one or more intermediate targets.

2 Apply the Morpher modifier to the starting morph target, and click Load Multiple Targets to load the starting and ending morph targets.

3 In the Channel List rollout, select the channel you want to be influenced by an intermediate target.

4 In the Channel Parameters rollout, click Pick Object from Scene, and select the intermediate target.
5 In the Progressive Morph group Target List, set the Target % to determine the degree to which each target affects the channel.

6 Use the down arrow button to move the original channel target to the bottom of the Target List.

**Interface**

Whatever is assigned as the default float controller in 3ds Max will be assigned as the float controller on the morph channels as well. Float controllers handle the interpolation between keys; Bezier is the default float controller. You can assign the TCB float controller to the morph channels in Track View, if you prefer.

For morphing, the Bezier controller allows you to use function curves with vector handles on the keys for smoothing and easing control of interpolation in Track View. Default parameters of the TCB controller, however, handles morph interpolation with less overshoot. Try using both controllers, to decide which one you prefer.

![Channel Color Legend]

**Gray** The channel is empty, and has not been edited.

**Orange** The channel has been changed in some way but contains no morph data.

An artist may wish to name a channel and set up its parameters before actually assigning a morph target.

**Green** The channel is live. The channel contains morph data and the target object still exists in scene (the target is available for refresh).
Blue The channel contains morph data but the target has been deleted from the scene.

Dark Gray The channel is disabled.

- There is a problem with the morph, the topology of the base object, or targets, have changed and are no longer valid; for example, the vertex count might have changed. The channel cannot be used.

- The channel is not active. This is controlled by the Channel is Active toggle in the Channel Parameters rollout.

- Disabled channels are not included in the morph result.

**Global Parameters rollout**

![Global Parameters rollout](image)

**Global Settings group**

**Use Limits** Use the minimum and maximum limits for all channels. You can turn off limits to double purpose a target. The target for a smile can be used to turn the corners of the mouth down using negative values for example.
Minimum Sets the minimum limit.

Maximum Sets the maximum limit.

Use Vertex Selection Turn on to limit morphing to vertices selected in a modifier below the Morpher modifier in the modifier stack.

If your are using Character Studio Physique, limit morph animation on the base object to just the head and exclude the neck, for example. Place the Physique modifier above the Morpher modifier and assign the head vertices as rigid (green) in the Physique modifier.

Channel Activation group

Set All Click to activate all channels.

Set None Click to deactivate all channels.

Morph Material group

Assign New Material Click to assign the Morpher material to the base object (the object to which the Morpher modifier is applied).

Open the Material Editor to view and edit the Morpher material. There is a direct correlation between the Channel Material Maps and the Channel list in the Morpher modifier (100 channels and 100 maps). For example, if channel 1 contains a brows up target and the Morpher material has a material assigned to map 1, then, as the brows are morphed so is the material.

In the Morpher material, if a material is assigned to a map or channel that has no morph target in the Morpher modifier, then the channel spinner in the Morpher modifier can be used to simply morph the material on a static object. See Morpher Material on page 6116.
Channel List rollout

The upper section of the Channel List rollout contains controls for managing markers, which designate different locations in the list of morph targets. For example, channels 15 through 24 might contain all the emotion targets. Rather than scrolling to display these tracks, you can choose a marker from the list to display those channels.

[marker drop-down list] Choose a previously saved marker in the list, or enter a new name in the text field and click Save Marker to create a new marker.
For example, channel 15 through 24 might contain all the emotion targets. Rather than scrolling to display these tracks, you can choose a marker from the list to display these channels in the list.

Save Marker Move the scroll bar to frame a particular set of 10 channels, enter a name in the text field, and then click Save Marker to store the channel selection.

Delete Marker Choose a marker name to delete from the drop-down list, and then click Delete Marker to delete it.

---

Channel List The Morpher modifier provides up to 100 morph channels. Scroll through the channels using the slider. Once you've assigned a morph target to a channel, the target's name appears in the channel list. Each channel has a percentage value field and a spinner to change the value.

You can change channel names and order in the Channel Parameters on page 1531 rollout.

Right-click a morph channel to display a right-click menu:

- **Pick from Scene** Choose this command and select an object in the viewports to assign a morph target to the channel.

- **Delete Channel** Deletes the morph data, name and parameters from the channel. Displays only if the channel has data.

- **Reload Target** Retrieves morph data from the target. Use this after editing a target.
List Range Displays the range of visible channels in the channel list.

Load Multiple Targets Load multiple morph targets into empty channels by selecting object names in the selection dialog and clicking Load.
If there are more targets than empty channels, a warning displays and the channels are not assigned.

Reload All Morph Targets Reloads all the morph targets.
If the targets have been edited, the channels are updated to reflect the changes.
If a morph target has been deleted from the scene, then the morpher updates using the stored data in the channel, functions using the last stored morph data.

Zero Active Channel Values Click to create keys with a value of 0 for all active morph channels, if the Auto Key is on.
This is handy to prevent key interpolation from distorting the model. First click Zero Active Channel Values, and then set a particular channel to the value you want; only the altered channel affect the model.

Automatically reload targets Turn this on to allow animated targets to be updated dynamically by the Morpher modifier. There is a performance penalty when using this option.

Channel Parameters rollout

The channel number button and channel name field at the top of this rollout reflect the current active channel in the channel list.
Click the number next to the channel name to display a menu. Use commands on the menu to group and organize channels, or to locate a channel.
Move To Displays the Channel Operations dialog. To move the current channel to the selected channel, choose a channel from the list, and click Move To.

Swap With Displays the Channel Operations dialog. To swap the current channel with the selected channel, choose a channel from the list, and click Swap With.

Used Channels Displays a list of active channels. Choose a channel to place it at the top of the channel list display in the Channel List rollout.

Channel Name Displays the name of the current target. Change the name of the target in the text field if necessary. Parameter changes in the Channel Parameters rollout affect the current target.

Channel is Active Toggles a channel on and off. Inactive channels do not affect the morph result. Use this control to turn off certain channels to focus on animating other channels.

Create Morph Target group

Pick Object from Scene Turn on and click an object in the viewports to assign a morph target to the current channel. Picking an object adds it to the Progressive Morph list.

Capture Current State Choose an empty channel to activate this function. Click to create a target using the current channel values. The captured channel is always blue because there is morph data but no specific geometry. Use Extract to create a mesh copy of the captured state.

Delete Deletes the target assignment for the current channel.

Extract Choose a blue channel and click this option to create an object from the morph data. If you have used Capture Current State to take a snapshot of a group of channel values, but then want to edit it, use Extract to make a new object, pick it as the channel's target, and then start editing.
Channel Settings group

Use Limits  Turn on to use limits on the current channel if Use Limits is turned off in the Global Parameters rollout.

Minimum  Sets the lower limit.

Maximum  Sets the upper limit.

Use Vertex Selection  Morphs only selected vertices on the current channel.

Progressive Morph group

Progressive morphing performs a tension-based interpolation, similar to the TCB animation controller, that creates smooth interpolation through each intermediary targets. This provides the artist with an unprecedented amount of control over the morph transformation.

Morphed object using multiple, intermediary targets
When morphing from one target to another, the object can sometimes pass through intermediary stages that are not desirable. For example, morphing a straight cylinder directly to a bent cylinder causes the cylinder to squash at intermediate stages.

You could get a better result by creating several intermediate morph targets for the object, and using them as channels. However, an easier solution is to create fewer intermediate targets, and use progressive morphing. With progressive morphing, you do not use the intermediate targets as channels; you use them to influence the end targets.

**Target List** Lists all intermediary morph targets associated with the current channel. To add morph targets to the list, click Pick Object from Scene.

**Move Up** Moves the selected intermediary morph target up in the list.

**Move Down** Moves the selected intermediary morph target down in the list.

**TIP** For best results, move the original morph target (the one in the channel) to the bottom of the list.
**Target %** Specifies how much the selected intermediate morph target contributes to the overall morph solution.

**Tension** Specifies the overall linearity of the vertex transformation between intermediary morph targets. A value of 1.0 creates a “loose” transition, causing the interpolation to overshoot each target slightly. A value of 0.0 creates a direct, linear transformation between each intermediary target.

**Delete Target** Deletes the selected intermediary morph target from the target list.

**Reload Morph Target** Reloads data from the current target into the channel. Reload a target if it has been adjusted or edited.

If the active morph target entry in the channel list is empty, this button is unavailable, and displays the text “No Target to Reload.”

**Advanced Parameters rollout**

**Spinner Increments** Specify fine or coarse spinner increments. 5.0 is coarse and 0.1 is fine. Default=1.0

**Compact Channel List** Compact the channel list by filling in any empty channels in between assigned channels. The status window displays how many channels were moved.

**Approximate Memory Usage** Displays an approximation of the current memory usage.
MultiRes Modifier

Select an object. > Modify panel > Modifiers List > Object-Space Modifiers > MultiRes

Make a selection. > Modifiers menu > Mesh Editing > MultiRes

The MultiRes modifier reduces the memory overhead needed to render models by decreasing the number of vertices and polygons. This is useful not only within 3ds Max, but for content creators who export models for use outside of 3ds Max, such as in Web-based 3D applications. MultiRes offers several advantages over the Optimize modifier, including faster operation and the ability to specify reduction as an exact percentage or vertex count.

NOTE

The MultiRes modifier supports the preservation of map channels when face count is increased or reduced.

Left: Original model
Center and right: Model progressively simplified by the MultiRes modifier
Modeling Tips for MultiRes

The MultiRes multi-resolution mesh algorithms are designed to be general-purpose, and yield high-quality meshes on a wide variety of model types. However, careful modeling can improve the results of the algorithm. The following are suggestions to yield high-quality multi-resolution meshes:

- Avoid using complex model hierarchies with MultiRes. For such models you should generate an individual multi-resolution mesh for each model component, or collapse the entire model into a single mesh. In general, single-skin meshes work best with animation engines like Physique in character studio. MultiRes works especially well with single-skin meshes.

- Avoid duplicating vertices. The presence of extra vertices is an often-overlooked artifact of some modeling techniques. The Weld function in the Edit Mesh modifier on page 1321 and Editable Poly on page 2240 is useful for cleaning these up.

- Be conservative with texture and normal discontinuities. For example, an artist might associate multiple texture coordinates with a single vertex. MultiRes will seek to preserve this discontinuity and the border between the two texture mappings, but it might do so at the expense of model shape.

- Create high-resolution models. High-resolution models provide MultiRes with more faces and vertices that describe the shape of the model. The more initial information MultiRes has about the shape of the model, the better the decisions it makes in generating a final multi-resolution mesh.

Procedures

To use the MultiRes modifier:

1. Select a model and apply the MultiRes modifier.

2. In the Generation Parameters group in the MultiRes Parameters rollout, click the Generate button to initialize the modifier.

3. In the Resolution group, use the keyboard or spinner controls to decrease the Vert Percent or Vert Count value.

As the vertex and polygon counts decrease, the mesh updates in real time in the viewports.
To maintain part of a mesh at full resolution while reducing the rest:

1. Select a model and apply the MultiRes modifier.
2. In the modifier stack display, click the + icon next to the MultiRes modifier to open the sub-object hierarchy.
3. Click the Vertex label to access the Vertex sub-object level.
4. Select the vertices in areas whose resolution you want to maintain.
5. In the Generation Parameters group, turn on Maintain Base Vertices.
6. Click the Generate button to initialize or re-initialize the mesh.
   Notice that the selected vertices look like asterisks instead of standard ticks.
7. Reduce the resolution as in the first procedure.
   The selected vertices are the last to be removed during vertex reduction.

**NOTE** You can change the base vertices at any time by selecting a different group of vertices and regenerating the mesh.

To merge vertices:

If there are gaps between vertices that you want to close as vertex resolution decreases, use the Vertex Merging feature of the MultiRes modifier. With vertex merging, vertices within a given threshold distance eventually collapse during vertex reduction.

You can estimate the gap length by activating the Select Object tool on page 172, moving the mouse cursor over the extents of the gap in the active viewport (it might help to access the Vertex sub-object level), and comparing the values displayed in the X/Y/Z readouts in the status bar, or use the Tape helper on page 2855 object to get an exact measurement. Enter the estimated gap length value in the Threshold field.

1. Select a model and apply the MultiRes modifier.
2. Turn on Vertex Merging. This makes the Merge Threshold and Within Mesh controls available.
3 Set the appropriate parameters:

- To define the maximum distance over which vertices are merged, enter a value in Merge Threshold.
- To merge boundaries of adjacent elements and vertices within elements, turn on Within Mesh.

4 Click the Generate button.
The effect of the change is displayed in the object.
After the Generate button is clicked, a busy cursor will display. If the merge threshold is too large relative to the dimensions of the model, the busy cursor may display for a long time. To cancel the generation process at any time, press the Esc key.

Interface
Resolution group

Use these controls to change the vertex count and overall topology of the modified object.

Vert Percent The modified object's vertex count as a percentage of the overall number of vertices in the original mesh. Adjusting this setting alters the Vert Count value as well.

NOTE After you enter a specific percentage, such as 30, you might find that 3ds Max changes the value to a slightly lower one, such as 29.971. This is due to the relationship between the overall number of vertices in the model and the percentage calculation. It is not a bug, but simply the closest solution to your request.

Vert Count The total number of vertices in the modified object. Use this control to set the maximum number of vertices in the output mesh. Adjusting this setting alters the Vert Percent value as well.

Max Vertex Displays the vertex count from the original mesh that you applied MultiRes to. You cannot enter values larger than this in the Vert Count field.

Face Count Displays the current face count. As you adjust the Vert Percent/Vert Count settings, the value for the face count will update on the fly.

Max Face Displays the maximum face count.

Generation Parameters group

Vertex Merging When on, lets MultiRes merge vertices between discrete elements on page 8559 in a model.

For example, if you apply MultiRes to a teapot, which comprises four separate elements, and turn on Vertex Merging, as you adjust the vertex resolution, the separate components will meld together into one contiguous lower-resolution object.

To control Vertex Merging, you can set a Merge Threshold. This value determines the unit distance within which vertices will merge at a higher rate.

Threshold Sets the maximum distance in 3ds Max units between vertices in order for those vertices to be considered for merging. Within this distance, the vertices between elements are welded together at a higher rate as the mesh is reduced in complexity. Available only when Vertex Merging is on.

NOTE To eliminate only coincident vertices, set Threshold to 0.0. This is similar to the Weld Vertex function.
**Within Mesh** When on, MultiRes merges the boundaries of adjacent elements and vertices within elements. Many objects can contain multiple groups of vertices that don't share connectivity. A simple example of this is the Teapot object on page 416. It comprises four different elements: the body, the handle, the spout, and the lid. Normally, MultiRes optimizes each discrete element in a mesh on its own.

The default behavior of the Vertex Merging option is to merge vertices between elements. Turning on Within Mesh causes vertices within elements to be merged as well.

**Boundary Metric** When on, MultiRes preserves materials assigned to the selected model. The material boundaries defined by Material IDs are retained as long as possible, and are the last to be eliminated at low vertex counts. Default=off.

**Maintain Base Vertices** When on, overrides the MultiRes optimization algorithms and preserves any vertices selected at the MultiRes Vertex sub-object level as “critical” ones. Use this feature to retain critical features of an object or character such as its fingers or claws, or other geometry that might become unrecognizable if reduced too severely.

To select vertices for use with this option, use the MultiRes Vertex sub-object level. To access this level, first go to the modifier stack display and click the plus-sign icon next to the MultiRes modifier. This opens its hierarchy, which consists of the single Vertex sub-object level. Next, click the Vertex entry. The MultiRes vertices appear on the mesh as blue dots. You can select these using any standard interactive method, but you cannot transform them.

**IMPORTANT** After selecting MultiRes sub-object vertices with Maintain Base Vertices turned on, regenerate the mesh before changing the vertex resolution.

In the following illustration, the clown started out as a high-resolution mesh. All of the MultiRes vertices in the right half were selected, Maintain Base Vertices was turned on, and then the vertices were reduced.
Clown model with left half reduced, right half at original resolution

**Multiple Vertex Normals** When on, lets MultiRes assign multiple normals for each vertex. By default, MultiRes generates a single normal per vertex. If multiple normals are generated, they are applied as the vertex resolution is decreased and increased.

When the Multiple Vertex Normals option is on, the MultiRes modifier generates normal updates when the geometry surrounding a vertex changes.
You must specify a *crease angle* in degrees (0.0 - 180.0). The crease angle is the angle between the face normals. It is used to decide when a normal should be shared across an edge between two faces.

For example, in a plane defined as a mesh grid of 10 x 10 faces, any two adjacent faces have a crease angle of zero. In a cube, adjacent faces have a crease angle of 90 degrees. In general, crease angles approaching 0 yield smoother shading. Crease angles approaching 180 yield more visible corners.

**Crease Angle** The value of the crease necessary in order to generate multiple normals. Available only when Multiple Normals Per Vertex is on.

The optimal crease angle depends on the model; set it interactively and check the viewport and rendered images for shading effects. While use of Multiple Vertex Normals enables more accurate shading, it can require more internal data.

**Generate** Applies the current MultiRes settings to the modified object. When you first apply MultiRes to an object, you must use Generate to initialize the mesh-optimizing algorithm before you can change the vertex count.

**Reset** Sets all Generation Parameters rollout settings to their values as of the last time you used Generate. Available only when one or more of these settings has changed.

Use Reset to review the generation parameters as of the last time you generated the mesh.

---

**Noise Modifier**

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Noise

Make a selection. > Modifiers menu > Parametric Deformers > Noise

The Noise modifier modulates the position of an object's vertices along any combination of three axes. This important animation tool simulates random variations in an object's shape.

Using a fractal setting, you can achieve random, rippling patterns, like a flag in the wind. With fractal settings, you can also create mountainous terrain from flat geometry.

You can apply the Noise modifier to any kind of object. The Noise gizmo changes shape to help you visualize the effects of changing parameter settings. The results of the Noise modifier are most noticeable on objects that have greater numbers of faces.
Most of the Noise parameters have an animation controller. The only keys set by default are for Phase.
Adding texture to the plane creates a calm sea.
Plane with fractal noise applied
Procedures

To apply noise to an object:

1. Select an object and apply the Noise modifier. To animate, move to a nonzero frame and turn on the Auto Key button.

2. In the Parameters rollout > Strength group, increase Strength values along one or more of the three axes. You begin to see noise effects as the strength goes up.

3. In the Noise group, adjust Scale. Lower values increase the dynamics of the Strength settings, making the effect more obvious. See Noise group, below, for other options. If you’ve animated this procedure, you can change parameters as the animation runs to see the effects.

For another source of noise effects, go to the sub-object level of the Noise modifier and transform the gizmo and center of the modifier.
To create terrain effects:

When set for Fractal, the Noise modifier produces a random fractal noise that creates a variety of topological and terrain effects. You can animate these effects or use them to model static landscapes and other complex forms.

The following steps assume you begin with a broad object like a multi-segment box lying on the XY plane.

1. Apply the Noise modifier to the object.
2. In the Parameters rollout > Noise group, turn on Fractal.
   Roughness and Iterations settings are now available.
3. Increase Strength on the Z axis and adjust other parameters.
   Once you have a base terrain, you can select sub-objects with Edit Mesh and apply Noise to grow mountains in a smaller region. You can also apply a second Noise modifier to amplify the first one.

Interface

Modifier Stack

Gizmo/Center You can move, rotate, or scale the gizmo and center sub-objects to affect the noise. You can also animate the sub-object transforms.

For more information on the stack display, see Modifier Stack on page 8187.
Parameters rollout

`Noise group`

Controls the appearance of the noise, and thus its effect on the physical deformations of the object. By default, the controls are inactive until you change the settings.

- **Seed** Generates a random start point from the number you set. Especially useful in creating terrain, because each setting can produce a different configuration.

- **Scale** Sets the size of the noise effect (not strength). Larger values produce smoother noise, lower values more jagged noise. Default=100.

- **Fractal** Produces a fractal effect based on current settings. Default=off.

If you turn on Fractal, the following options are available:
Roughness Determines the extent of fractal variation. Lower values are less rough than higher values. Range=0 to 1.0. Default=0.

Iterations Controls the number of iterations (or octaves) used by the fractal function. Fewer iterations use less fractal energy and generate a smoother effect. An iteration of 1.0 is the same as turning Fractal off. Range=1.0 to 10.0. Default=6.0.

Strength group

Controls the magnitude of the noise effect. No noise effect occurs until some strength is applied.

X, Y, Z Set the strength of the noise effect along each of three axes. Enter a value for at least one of these axes to produce a noise effect. Default=0.0,0.0,0.0.

Animation group

Controls the shape of the noise effect by overlaying a sine wave for the noise pattern to follow. This keeps the noise within bounds, dampening random extremes. When Animate Noise is turned on, these parameters influence the overall noise effect. However, you can animate Noise and Strength parameters independently; these do not require Animate Noise to be on during animation or playback.

Animate Noise Regulates the combined effect of Noise and Strength parameters. The following parameters adjust the underlying wave.

Frequency Sets the periodicity of the sine wave. Regulates the speed of the noise effect. Higher frequencies make the noise quiver faster. Lower frequencies produce a smoother and more gentle noise.

Phase Shifts the start and end points of the underlying wave. By default, animation keys are set at either end of the active frame range. You can see the effect of Phase more clearly by editing these positions in Track View. Select Animate Noise to enable animation playback.

Normal Modifier

Select an object. > Modify panel > Modifier List > Normal
Select an object. > Modifiers menu > Mesh Editing > Normal Modifier
The Normal modifier allows you to unify or flip the normals of an object without applying an Edit Mesh modifier.
For example, if you wanted to fly inside of a procedural object, such as a sphere or a cylinder, and wanted to retain control over the radius and number of segments, you couldn’t collapse the object to an Editable Mesh and maintain the procedural nature of the primitive.

Flipping the normals of a sphere creates a sky dome over a city.

**TIP** If you are animating the creation of a complex object such as a nested Boolean or a loft, and you think the operation might result in inconsistent faces, apply Normal to the result and turn on Unify.

**TIP** The Lathe modifier sometimes creates an object with normals pointing inward. Use the Normal modifier with both Unify and Flip turned on to fix “inside-out” lathe objects. The Normal modifier allows whole-object manipulations of normals to be performed quickly without using an Edit Mesh modifier.
Patches

Patch objects coming up the modifier stack are not converted to a mesh by this modifier. A patch object input to the Material modifier retains its patch definition. Files that contain patch objects with the Material modifier from previous versions of 3ds Max will be converted to meshes to maintain backward compatibility.

Procedures

To use the normal modifier:

1. Select an object, then on the Modify panel, choose Object-Space Modifiers > Normal from the Modifier List. The object appears to turn inside-out, since Flip Normals is on by default.

2. If the object has some faces pointing inward and others outward, turn on Unify Normals to make all the faces point similarly.

   **TIP** To flip or unify normals on portions of objects, convert to Editable Mesh and select Faces or Polygons. On the Surface Properties rollout in the Normals group, use the Flip and Unify buttons.

Interface

![Parameters](image)

**Unify Normals** Unifies the normals of an object by flipping the normals so that they all point in the same direction, usually outward. This is useful for restoring an object's faces to their original orientations. Sometimes normals of scenes that have come into 3ds Max as part of a DWG or DXF file are irregular, depending on the methods used to create the scene. Use this option of the modifier to correct them.
**NOTE** Unify Normals does not work on *editable poly* on page 2240 objects; before applying the Normal modifier, convert the model to editable mesh format or apply a *Mesh Select* on page 1500 or *Turn To Mesh* on page 1825 modifier.

*Flip Normals* Reverses the direction of all the surface normals of the faces of the selected object or objects. Default=on.

**Normalize Spline Modifier**

Select a spline object. > Modify panel > Modifier List > Normalize Spl. Select a spline object. > Modifiers menu > Patch/Spline Editing > Normalize Spline

The Normalize Spline modifier adds new control points in the spline at regular intervals. Use Normalize Spline to produce splines for motion paths that require constant velocity.

The spline on the left has been normalized.

**NOTE** This feature is not animatable.
Interface

Seg Length  Sets the length of the spline's segments, in 3ds Max units. The positions of the original vertices are discarded, and vertices are set to regular intervals. Segment length determines how many control points are added: shorter segments result in more control points, longer segments result in fewer. Default=20.0 units.

NSurf Sel Modifier

Select a NURBS curve or surface object. > Modify panel > Modifier List > NSurf Sel
Select a NURBS curve or surface object. > Modifiers menu > Selection Modifiers > NURBS Surface Select
Select a NURBS curve or surface object. > Modifiers menu > NURBS Editing > Surface Select

The NSurf Sel (NURBS Surface Selection) modifier lets you place a NURBS on page 2416 sub-object selection on the modifier stack. This lets you modify only the selected sub-objects. Also, selected curve sub-objects are shape objects that you can use as paths and motion trajectories.

If a NURBS surface object is nonrelational on page 2484, NSurf Sel can't select the sub-object levels Curve, Curve CV, or Point. NURBS surfaces are nonrelational by default. You can make the surface relational by turning on Relational Stack on the object's General rollout.

NSurf Sel can select any kind of NURBS sub-objects except imports. Each sub-object selection is of one particular sub-object level only.

NOTE  The NSurf Sel modifier doesn't support copying and pasting selections as Mesh Select on page 1500 does. Copying and pasting mesh selections is based on vertex indexes. NURBS selections are based on object IDs, which are unique to each model.
Procedures

To use the NSurf Sel (NURBS Surface Selection) modifier:

1. With a NURBS object selected in the Modify command panel, apply NSurf Sel.
   This modifier has no controls at the top level.

2. In the stack display, choose a sub-object level from the list.

   NSurf Sel has the same selection controls you see for NURBS surfaces, except that selecting connected curves or surfaces is not available.

   For more information on the stack display, see Modifier Stack on page 8187.
While applying the modifier, you can also select NURBS sub-objects by name. Turn on the Keyboard Shortcut Override toggle on page 8420 and then press the **H** key. This displays a version of the Selection Floater on page 209 that lists only sub-objects at the current level. Choose one or more objects in the list, and then click Select.

3 Use the selection controls to create a selection set of the chosen sub-object type.

   With NSurf Sel, the selection can be of surface CV or surface sub-objects. If you turn on Relational Stack for the NURBS object, you can also select point, curve, and curve CV sub-objects.

4 At the Surface CV sub-object level, adjust Soft Selection controls as you wish. These controls are the same as those in the Soft Selection rollout on page 2541 for NURBS curves and surfaces, except that the Same Type Only toggle is absent.

Once you've used the modifier to create the selection, you can apply other modifiers to it.

**Optimize Modifier**

Select an object. > Modify panel > Modifier List > Optimize
Select an object. > Modifiers menu > Mesh Editing > Optimize

The Optimize modifier lets you reduce the number of faces and vertices in an object. This simplifies the geometry and speeds up rendering while maintaining an acceptable image. A Before/After readout gives you exact feedback on the reduction as you make each change.
Optimize simplifies a smooth model with a high number of faces without greatly changing the model’s appearance.

**TIP** Because Optimize makes decisions based on angles between faces, it's sometimes best to apply it to selected face sub-objects rather than to an entire object. Avoid applying Optimize to areas where you want to preserve geometric detail.

**Applying Optimize**

When you first apply Optimize, you might not see any change in the viewports. Adjust the Face Threshold setting to obtain the best optimization. In the Last Optimize Status group, you can see how the object or faces were optimized. Watch these values while you adjust the Optimize parameters, until you have the best possible result.

**Setting Level of Detail**

Optimize lets you maintain two levels of optimization detail. You might set a lower optimization level, with fewer faces, to speed up your viewport work, and a higher level for final output in the renderer. However, you can render
at either level. You can also switch to the higher level in a viewport to get an idea of what the rendered image will look like.

**Procedures**

**To optimize manually:**

1. Set up two viewports: one wireframe, one smooth shaded.
2. Select an object and apply the Optimize modifier. The Parameters rollout for this modifier appears.
3. Turn off Manual Update and then adjust the Face Thresh value. Observe the result in the viewports. You can also choose to view the results of the Optimize operation manually by leaving the Manual Update check box turned on and clicking the Update button every time you wish to view a result.
4. In the Parameters rollout > Last Optimize Status group, notice the Before/After count for vertices and faces.
5. In the Optimize group, vary parameters to continue reducing geometry. Compare the result in the two viewports against the Before/After count.

**To set the level of detail:**

1. In the Parameters rollout > Level of Detail group, choose Viewports L1.
2. Adjust parameters in the Optimize and Preserve groups. This sets the L1 level of optimization for both the viewport and the renderer.
3. Repeat steps 1 and 2 for Viewports L2, adjusting parameters for a different optimization.

**To use level of detail:**

- Switch between L1 and L2 for either Viewports or Renderer. You see the effect immediately in a smooth shaded viewport. Do a test rendering to see the effect on the renderer.

The following parameters are stored for each level: Face Threshold, Edge Threshold, Bias, Max Edge Len, Material Boundaries, and Smooth Boundaries.
Interface

Level of Detail group

**Renderer L1, L2** Set the level of display for the default scanline renderer. Use Viewports L1 and L2 to change the stored optimization level. Default=L1.

**Viewports L1, L2** Set the optimization level for both viewport and renderer. Also toggles the level of display for the viewport. Default=L1.
Optimize group

Adjusts the degree of optimization.

**Face Thresh** Sets the threshold angle used to determine which faces are collapsed. Low values produce less optimization but better approximations of the original shape. Higher values improve optimization, but are more likely to result in faces that render poorly (see Bias). Default=4.0.

**Edge Thresh** Sets a different threshold angle for open edges (those that bound only one face). A low value preserves open edges. At the same time you can apply a high face threshold to get good optimization. Default=1.0.

**Bias** Helps eliminate the skinny or degenerate triangles that occur during optimization, which can cause rendering artifacts. Higher values keep triangles from becoming degenerate. The default of 0.1 is enough to eliminate the skinniest triangles. Range=0.0 to 1.0 (a 0 value turns Bias off).

**Max Edge Len** Specifies the maximum length, beyond which an edge cannot be stretched when optimized. When Max Edge Len is 0, it has no effect. Any value greater than 0 specifies the maximum length of the edges. Default=0.0.

Along with Bias, this control helps you avoid creating long skinny faces while optimizing.

**Auto Edge** Turns edges on and off following optimization. Turns on any open edges. Turns off any edges between faces whose normals are within the face threshold; such edges beyond the threshold are not turned on. Default=off.

Preserve group

Maintains clean separation at the face level between material and smoothness boundaries.

**Material Boundaries** Prevents face collapse across material boundaries. Default=off.

**Smooth Boundaries** Optimizes an object and maintain its smoothing. When turned on, allows only faces that share at least one smoothing group to collapse. Default=off.

Update group

**Update** Updates the viewports with the current optimization settings. Available only when Manual Update is turned on.

**Manual Update** Enables the Update button. When turned off, Optimize works as it does by default, updating the viewport display dynamically.
NOTE When using Manual Update, if you make any changes that cause the reevaluation of the stack, the existing optimization display disappears. Click the Update button again to restore it.

The Renderer ignores the optimization display in the viewport, using the Optimize settings, regardless of the state of the Manual Update.

**Last Optimize Status group**

Displays numerical results of optimization with exact before-and-after counts for vertices and faces.

**Patch Select Modifier**

Make a selection. > Modify panel > Modifier List > Patch Select

Make a selection. > Modifiers menu > Selection Modifiers > Patch Select

The Patch Select modifier lets you pass a sub-object selection up the stack to subsequent modifiers. It provides a superset of the selection functions available in the Edit Patch modifier on page 1329. You can select vertices, edges, patches, and elements. You can also change the selection from sub-object level to object level.

NOTE When you apply the Patch Select modifier and then go to any sub-object level, the select-and-transform buttons in the toolbar are unavailable, and the Select Object button is automatically activated.

**Using XForm Modifiers to Animate a Patch Selection**

When you apply a Patch Select modifier, there are no animation controllers assigned to the sub-object selection. This means that the selection has no way to "carry" the transform information needed for animation.

To animate a sub-object selection using Patch Select, apply either an XForm or Linked XForm modifier to the selection. These modifiers provide the necessary controllers for animating the effects of transforms. In a sense, they give "whole-object status" to the sub-object selection.

■ XForm on page 2010

    Animates transforms directly on a sub-object selection. Creates a gizmo and center for the sub-object selection. You can animate both, with the center acting as a pivot point for the selection.
Linked XForm on page 1484

Lets you choose another object to control the animation. The sub-object selection is linked to the "control object." When you transform the control object, the sub-object selection follows accordingly.

Procedures

To use the patch select modifier:

1 Create or select a patch object.

2 Go to the Modify panel and choose Patch Select from the modifier list.

3 Select vertices, handles, edges, patches, or elements.

4 Add another modifier to affect only the selection from step 3.

Interface

Modifier Stack

- Vertex Selects vertices.
- Handle Selects handles.
- Edge Selects edges.
- Patch Selects patches.
- Element Selects elements.

For more information on the stack display, see Modifier Stack on page 8187.
Parameters rollout

Provides buttons for turning different sub-object modes on and off, working with named selections and handles, display settings, and information about selected entities.

The icons at the top of the Selection rollout let you specify the method of face selection. Clicking a button here is the same as selecting a sub-object type in the modifier stack. Click the button again to turn it off and return to the object selection level.

- **Vertex** Selects a vertex beneath the cursor; region selection selects vertices within the region.

- **Handle** Selects a handle beneath the cursor; region selection selects multiple handles within the region.
Edge Selects an edge beneath the cursor; region selection selects multiple edges within the region.

Patch Selects a patch beneath the cursor; region selection selects multiple patches within the region.

Element Selects all contiguous faces in an object; region selection selects the same.

Select By Vertex Selects any sub-objects at the current level that use a vertex you click. Applies to all sub-object levels except Vertex. Also works with Region Select.

Ignore Backfaces Selects only those edges, patches, or elements whose normals make them visible in the viewport. When turned off (the default), selection includes all sub-objects, regardless of the direction of their normals.

NOTE The state of the Backface Cull setting in the Display panel doesn't affect sub-object selection. Thus, if Ignore Backfacing is turned off, you can select sub-objects even if you can't see them.

NOTE The state of the Ignore Backfaces check box also affects edge selection at the Edge sub-object selection level.

Get from Other Levels group

Applies selections from one sub-object level to another.

Get Vertex Selection Selects edges, patches, or elements based on the last vertex selection. The selection is added to the current selection. Available only when Vertex is not the current sub-object level.

Get Edge Selection Selects vertices, patches, or elements based on the last edge selection. Selects those vertices, patches, or elements that contain the edge. Available only when Edge is not the current sub-object level.

Get Patch Selection Selects vertices, edges, or elements based on the last patch selection. This selection is added to the current selection. Available only when Patch is not the current sub-object level.
Select by Material ID group

Selects faces based on their material ID.

ID Set the spinner to the ID number you want to select, and then click the Select button. Press Ctrl while clicking to add to the current selection, or press Alt to remove from the current selection.

Named Selection Sets group

These functions are primarily for copying named selection sets on page 217 of sub-objects between similar objects, and between comparable modifiers and editable objects. For example, you can apply a patch select modifier to a sphere, create a named selection set of edges, and then copy the selection to a different sphere that's been converted to an editable patch object. You can even copy the selection set to a different type of object, because the selection is identified by the entities' ID numbers.

The standard procedure is to create a selection set, name it, and then use Copy to duplicate it into the copy buffer. Next, select a different object and/or modifier, go to the same sub-object level as you were in when you copied the set, and click Paste.

NOTE Because sub-object ID numbers vary from object to object, the results of copying named selection sets between different objects can be unexpected. For example, if the buffered set contains only entities numbered higher than any that exist in the target object, no entities will be selected when the set is pasted.

Copy Places a named selection into the copy buffer.

Paste Pastes a named selection from the copy buffer.

Select Open Edges Selects all edges with only one face. In most objects, this will show you where missing patches exist. Available only at the Edge sub-object level.

Selection Info

At the bottom of the Patch Select Parameters rollout is a text display giving you information about the current selection. If 0 or more than one sub-object is selected, the text gives the number and type selected. If one sub-object is selected, the text gives the ID number and type of the selected item.

NOTE When the current sub-object type is Patch or Element, selection information is given in Patches.
Soft Selection rollout

PatchDeform Modifier (Object Space)

Select an object. > Modify panel > Modifiers List > Object-Space Modifiers > PatchDeform
Select an object. > Modifiers menu > Animation Modifiers > Patch Deform

The PatchDeform modifier deforms an object based on the contours of a patch object. This modifier works similarly to the PathDeform modifier on page 1569, but uses a quad-based patch object instead of a spline shape or NURBS curve path.

To use the PatchDeform modifier, apply it to the object you want to deform, click the Pick Patch button, and then select a patch object. Deform the object by manipulating the patch object or adjusting the various controls in the Patch Deform panel.

Not all objects can be used with PatchDeform. Objects that are valid PatchDeform targets include: Plane, Cylinder, Cone and Torus.

This modifier is also similar to the SurfDeform modifier on page 1774, except that it uses a patch surface instead of a NURBS Point or CV surface.

There’s also a world-space version of the PatchDeform modifier. See PatchDeform (WSM) on page 1150. Generally, the PatchDeform object-space modifier leaves the object in place while moving the patch to the object, while the PatchDeform world-space modifier leaves the patch in place while moving the object to the patch. Also, the WSM version has a Move to Patch button, while the object-space version does not.

Procedures

To use the PatchDeform modifier:

1. Select an object.
2. Apply PatchDeform.
3. On the Parameters rollout, click Pick Patch.
4. Select a patch object.
Deform the object by adjusting the controls in the Patch Deform panel and by manipulating the patch object.

**Interface**

**Modifier Stack**

**Gizmo** At this sub-object level, you can transform and animate the gizmo like any other object, altering the effect of the modifier. The PatchDeform gizmo is a representation of the deforming patch object, so transforming it determines which part of the patch affects the modified object.

**Parameters rollout**

![Parameters rollout image]

**Patch Deform group**

Provides controls that let you pick the patch and adjust the object's position and deformation along the gizmo copy of the patch.

**Patch** Displays the name of the selected patch object.

**Pick Patch** Click this button, and then select the patch object you want to use for the deformation. A gizmo is created for the object that matches the
patch. Once you assign the patch gizmo, you can adjust the deformation using the remaining controls in this rollout.

NOTE Patch Deform can be used only with a rectangular quad patch form. 3ds Max makes no distinction between quad-style patches and certain primitive meshes. Examples of suitable patches are the primitive quad patch object on page 2410, the primitive cylinder on page 403, and the primitive torus on page 409. (The cylinder actually has tri-patches at each end, but since they are at the end of the list of patches, PatchDeform just ignores these extra faces.)

U Percent Moves the object along the U (horizontal) axis of the gizmo patch, based on a percentage of the U distance. This spinner defaults to a setting of 50 percent, which places the object at the center of the gizmo patch. A setting of 0 percent places the object at the left edge of the gizmo patch, as seen from the viewport where the patch was created.

U Stretch Scales the object along the U (horizontal) axis of the gizmo patch.

V Percent Moves the object along the V (vertical) axis of the gizmo patch, based on a percentage of the V distance. A setting of 0 percent places the object at the bottom of the gizmo patch.

V Stretch Scales the object along the V (vertical) axis of the gizmo patch.

Rotation Rotates the modified object with respect to the gizmo patch.

Move To Patch Clicking this button moves the object from its original position to the patch object you are using for deformation. This button is only available with the PatchDeform (WSM).

Patch Deform Plane group

XY/YZ/ZX Choose a two-axis plane of the object to make parallel with the XY plane of the gizmo patch.

Flip Reverses the gizmo direction.

PathDeform Modifier (Object Space)

Select an object. > Modify panel > Modifier List > Object–Space Modifiers > PathDeform

Select an object. > Modifiers menu > Animation Modifiers > Path Deform
The PathDeform modifier deforms an object using a spline or NURBS curve as a path. You can move and stretch the object along the path, and rotate and twist it about the path. There's also a world-space modifier version. See PathDeform (WSM) on page 1150.

PathDeform creates a wiggle for the snake.

**Using a Path to Deform an Object**

Generally, you use the PathDeform modifier when you want to keep an object in place while deforming to a path. Use the PathDeform world-space modifier when you want to move an object to a path while keeping the path in the same world space.

To use the PathDeform modifier, you apply it, then click the Pick Path button and select a shape or curve consisting of a single open or closed spline. Once the object is assigned to the path, you can adjust the parameters to deform or animate the object along a gizmo copy of the path.
Procedures

To use the PathDeform modifier:

1. Select an object.
2. Apply PathDeform.
3. On the Parameters rollout, click Pick Path.
4. Select a spline or NURBS curve.
   Deform the object by adjusting the various controls in the Path Deform
   panel and by editing the path object.

Example: To use the PathDeform modifier to curve text:

1. In the Top viewport, create a circle with a radius of 100 units.
2. In the Front viewport, create a text shape with six or seven letters, and a
   size of 25. (You can use the default "MAX Text").
3. Apply an Extrude modifier on page 1425 to the text shape and set Amount
   to -5.0.
4. On the main toolbar, set the Reference Coordinate System to Local.
   Looking at the axis tripod for the extruded text object, you can see that
   its Z axis runs from back to front, relative to world space.
5. Apply a PathDeform object-space modifier to the text object, click the
   Pick Path button, and then select the circle.
   A circular gizmo is displayed. The circle runs through the local Z axis of
   the text object. Because of its orientation, its effect is minimal, but you
   can see a slight wedge-shaped deformation from the top view.
6 In the Path Deform Axis group, choose the Y option, and then the X option. The circle gizmo rotates to run through the specified axes, deforming the text object differently with each change.

7 Adjust the Percent spinner to view its effect, and then set it to 0. Try the same with Stretch, Rotation, and Twist, and then restore them to their original values. (Tip: Use the Ctrl key with Twist to amplify the effect.)

8 Turn Flip on and off to switch the direction of the path.

9 In the stack display, choose the Gizmo sub-object level, and move the gizmo path around. The text object is further deformed by its relative position to the gizmo.

10 In the stack display, turn off sub-object selection by selecting the original circle shape.

11 Adjust the circle's radius. The deformation of the text object changes because its gizmo is an instance of the shape object.

**Interface**

**Modifier Stack**

**Gizmo** At this sub-object level, you can transform and animate the gizmo like any other object, altering the effect of the modifier. The PathDeform gizmo is a representation of the deforming path object, so transforming it determines which part of the path affects the modified object.
Parameters rollout

![Path Deform Modifier (Object Space)](image)

### Path Deform group

Provides controls that let you pick a path and adjust an object's position and deformation along the path.

**Path** Displays the name of the selected path object.

**Pick Path** Click this button and then select a spline or NURBS curve to use as the path. The gizmo that appears is shaped like the path and is aligned with the local Z axis of the object. Once you assign the path, you can adjust the deformation of the object using the remaining controls in this rollout. The path you pick should contain a single, open or closed curve. If you use a path object consisting of multiple curves, only the first one is used.

**Percent** Moves the object along the gizmo path based on a percentage of the path length.

**Stretch** Scales the object along the gizmo path, using the object's pivot point as the base of the scale.

**Rotation** Rotates the object about the gizmo path.

**Twist** Twists the object about the path. The twist angle is based on the rotation of one end of the overall length of the path. Typically, the deformed object takes up only a portion of the path, so the effect can be subtle.
Path Deform Axis group

X/Y/Z Choose one to rotate the gizmo path to align with a specified local axis of the object.

Flip Reverses the gizmo path 180 degrees about the specified axis.

Point Cache Modifier (Object Space)

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Point Cache
Select an object. > Modifiers menu > Cache Tools > Point Cache

The Point Cache modifier lets you store modifier and sub-object animation to a disk file that records only changes in vertex positions, and then play back the animation using the information in the disk file instead of the modifier keyframes.

Point Cache is useful when the computation required for vertex animation becomes so excessive that it causes animation playback to run slowly or drop frames. Another use for this modifier is to apply the same animation to a number of objects, varying the Start Time and Strength settings for each so they don't all move identically.

NOTE Point Cache can be useful with Cloth animations on page 1204. If your Cloth animation includes cloth that tears (see Tearing Cloth on page 1207), the Welder modifier on page 2004 can help smooth joins and seams before tearing occurs.

The Point Cache modifier is also available in a world-space version on page 1156, for which usage is the same.

Special Point Cache Features

Special features in the Point Cache modifier include:

■ You can save animation files in XML and MCB formats for greater compatibility with other applications, such as Autodesk Maya, as well as the legacy PC2 format.

■ When recording to XML, you can save each animation frame in a separate file. Cache files for large meshes and long animations can be very large. Saving as a file per frame lets you manage data more easily and replace single frames if you find errors.
Compatibility with Autodesk Maya

Following is a suggested workflow for using Point Cache for working on an animation project in both 3ds Max and Autodesk Maya:

1. Create a deforming mesh (Skin, Cloth, etc.).
2. Apply the Point Cache modifier.
3. Save the cache in XML format with referenced MC files.
4. Save the mesh in FBX format.
5. Bring the mesh into Maya.
6. In Maya, load the cache data onto the mesh using the XML file to load the referenced MC files.
7. Modify the animation in Maya and save it, overwriting the XML and MC files.
   In 3ds Max, use the Point Cache > Reload command; this updates the animation to that saved from Maya.

Special Features in Point Cache

Both versions of the Point Cache modifier provide enhanced animation capabilities, including:

- Adjustable playback ranges and a playback graph, to animate which cache frame is played back. This lets you load a cache and then animate it, slowing down, stopping, reversing, etc.
- Nth-frame sampling, so you can sample every few frames to save disk space if sampling every frame is unnecessary, or record multiple samples per frame for improved motion blurring.
- The "strength" is adjustable in Absolute mode, so you can easily blend the cache with what is below in the stack.
- Improved cache file management.
- Pre-loaded caches to speed up playback.
Procedures

To use the Point Cache modifier:

1. Use one or more modifiers to animate an object. For example, you might apply a Bend modifier on page 1165, and then set keyframes for the Angle parameter to make the object bend back and forth.

2. Click Play Animation.
   If the animation is a good candidate for caching, the playback will drop many frames with Real Time Playback turned on, and will run slowly with Real Time Playback turned off.

3. From the Modify panel > Modifier List, choose Object-Space Modifiers > Point Cache.

4. On the Parameters rollout > Record group, set values for Start Time and End Time.

5. If you plan to render the cached animation using motion blur, decrease the Sample Rate setting.

6. Click the Record button, and use the Save Cache dialog to specify a cache file. To export the animation to another program, such as Autodesk Maya, use the XML file format; otherwise, use the PC2 file format.
   3ds Max records the animation to the cache file. When finished, the cache file name appears in the Cache File group.

7. In the Record group, click Disable Modifiers Below.
   This turns off all the object's modifiers below Point Cache so that only the cached vertex animation will appear when you play back the animation.

8. Click Play Animation again.
   This time the animation plays back quickly and smoothly.
Interface

Parameters rollout
**Cache File group**

Contains settings for recording vertex animation.

[file name] After you specify or load a cache file, its name appears in this field.

**New** Creates a new, empty cache file. After setting a new file, use Record to create the cache data.

You can save the file in either of two formats:

- **XML**: Saves the basic cache information in an XML file, and the animation data in one or more MC files (The XML file includes references to the MC files). The modifier uses multiple MC files if you set the Record group option to One File Per Frame. When recording multiple MC files, the modifier gives them the name [file name]Frame[frame number].mc; for example, Cylinder01Frame10.mc. If you set a non-integer value for Sample Rate, the modifier appends the sub-frame cache file names with Tick[tick number].

- **PC2**: Saves all cache information and data in a single PC2 file. When you use this format, the One File Per Frame option is unavailable.

**Load** Loads a vertex animation from a cache file on disk into the Point Cache modifier. If the number of vertices in the cache does not match the number of vertices in the object, the Cache Info group reports an error, and the animation doesn’t take effect.

Load supports these file formats: XML, PC2, PTS.

**Unload** Temporarily frees the current cache file, so it can be edited or deleted externally.

**Reload** Reopens the current cache file, if previously unloaded.

**Cache Info group**

Displays cache statistics in read-only format, including the number of files, point count, evaluations (number of samples), sample rate, start and end frames, and errors, if any.

**Record group**

Contains settings for recording cached animation.
One File/One File Per Frame Choose whether to save the cache in a single file, or in a separate file for each frame of recorded animation. The latter option is available only when using the XML file format.

Start Frame Sets the first frame for recording the vertex animation. Default=first frame of the active time segment.

End Frame Sets the last frame for recording the vertex animation. Default=last frame of the active time segment.

Sample Rate Sets the number of frames between each recorded sample. When rendering with motion blur, which uses sub-frame sampling, decrease this value. Default=1.0.

At the default value of 1.0, Point Cache records one sample per frame. Increasing the value causes a sample to be recorded every Nth frame. For example, a value of 10.0 records every tenth frame. Decreasing the value causes multiple samples to be recorded for each frame. For example, if you set Sample Rate to 0.1, Point Cache records 10 samples per frame at evenly spaced intervals.

Record Stores the vertex animation to a disk file. If no cache file is specified, or the specified file doesn’t exist, activates the Save Points dialog, which lets you specify a path and file name for the cache file. Click Save to record the file, and then load it into the Point Cache modifier, ready for playback.

TIP To change the path or file name, use Cache File group > New and specify a different cache file.

Enable Modifiers Below Turns on all stack modifiers below the Point Cache modifier. Use this when you want to change modifier settings.

Disable Modifiers Below Turns off all the object’s stack modifiers below Point Cache so that only the cached vertex animation appears when you play back the animation.

Load Type group

These options apply only to PC2 and PTS files; when the cache file type is XML they are unavailable.
Local  The method the modifier uses to load the cache file. The options are:
■ Stream  Keeps the cache file open for fast access, but loads only a single frame at a time to conserve memory. This is the default mode.
■ Per-Sample  Opens the cache file, reads a single frame, and then immediately closes the file. This is slower than the Stream method, but is useful if many users are reading/writing the same set of cache files since the cache files won't be locked open as you read from them.
■ Pre-Load  Loads the entire cache file into memory for fast access, and then closes the file. This is particularly useful in networked situations, or when a few cache files are used by many objects in one scene. In the latter case, using this option prevents each object from thrashing the disk on playback.
Be conservative in using this, as it can consume a great deal of memory. However, if one cache file is used by several objects, the cache is loaded into memory only once.

Slave  These options apply if 3ds Max is running as a network-rendering client; see the preceding for details. In this situation, only Per-Sample and Pre-Load are available, and the default option is Per-Sample, so the clients don't lock files.

[label]  This read-only field displays the size of the pre-loaded data when Local is set to Pre-Load.

Playback Options group

Strength  Affects the motion relative to the original animation. Applies only when Relative Offset is on. Default=1.0. Range=-10.0 to 10.0.
At 1.0, the animation plays back the same as recorded. With strengths between 0.0 and 1.0, the animation is relatively restrained. At strengths greater than 1, the animation is exaggerated. With negative Strength settings, the motion is reversed.

Relative Offset  Enables offsetting the animated vertex positions relative to their positions as recorded, based on the Strength setting. Default=off.

NOTE  When you turn on Relative Offset and play back a cached animation with the modifiers turned on, the cached vertex positions are calculated relative to their positions as calculated by the modifiers. For example, if you record a Bend animation to a cache file, and then play it back with both Relative Offset and the Bend modifier on and Strength=1.0, all vertex positions are doubled, resulting in exaggerated motion.
Apply To Whole Object  When off, only the active vertex selection is animated. In this case, for the cache animation to be visible, the selection must include at least some of the originally animated vertices.

Playback Type group

Playback Type  Specifies how playback occurs:

- **Original Range**  Plays back the cache over the range it was originally recorded, so the animation will always be the same as the original.

- **Custom Start**  Plays back the cache from a custom start time, set by Start Frame, but the animation length and playback speed will be the same as the original animation.

- **Custom Range**  Lets you set start and end frames within which the current cache plays back. Using a range that is smaller than the original record range plays the cache back faster, while specifying a larger range plays the cache back slower.

- **Playback Graph**  Lets you animate which cache frame is played at any given time.
  For example, if you record a cache from frames 0 to 100 and then want it to play back twice as fast forward and then in reverse, choose this option, turn on Auto Key, set the Frame parameter to 0.0 at frame 0, 100.0 at frame 50, and then back to 0.0 at frame 100. The function curve of this parameter in Track View shows how the cache is played back. Animating the Frame value lets you achieve unusual effects such as slowing a cache down over time, creating a ping-pong effect during playback, etc.

Start Frame  The frame number at which the cached animation starts playing back. Using decimal fractions lets you start at a sub-frame setting when using a Frame:Ticks time display. Available only when Playback Type is set to Custom Start or Custom Range. Default=0.0.

End Frame  The frame number at which the cached animation starts playing back. Using decimal fractions lets you start at a sub-frame setting when using a Frame:Ticks time display. Available only when Playback Type is set to Custom Range. Default=0.0.

Frame  Lets you animate playback of the cache; for details, see Playback Graph, above.

Clamp Graph  Controls what gets loaded when the Playback Graph frame is out of the original recorded range.
Take an example in which the playback frame is set to 105, but the original cache was recorded over frames 0-100. With Clamp Graph on, the loaded frame will be 100. If it's off (the default), the cache will "wrap around" and load frame 5.

This lets you loop caches more easily. In the above example, you could simply have a two-key playback graph. The first key would be at frame 0 with a value of 0.0, and the second would be at frame 100 with a value of 100.0. You would then set the out-of-range type on page 3961 for the Frame parameter (Playback Frame in Track View) to Linear, and the cache would loop back smoothly to the beginning at frame 101.

### Poly Select Modifier

Make a selection. > Modify panel > Modifier List > Poly Select

Make a selection. > Modifiers menu > Selection Modifiers > Poly Select

The Poly Select modifier lets you pass a sub-object selection up the stack to subsequent modifiers. It provides a superset of the selection functions available in Editable Poly on page 2240. You can select vertices, edges, borders, polygons, and elements. You can change the selection from sub-object level to object level.

When you apply the Poly Select modifier and then go to any sub-object level, the select-and-transform buttons in the toolbar are unavailable, and the Select Object button is automatically activated.

#### Using XForm Modifiers to Animate a Poly Selection

When you apply a Poly Select modifier, there are no animation controllers assigned to the sub-object selection. This means that the selection has no way to "carry" the transform information needed for animation.

To animate a sub-object selection using Poly Select, apply either an XForm or Linked XForm modifier to the selection. These modifiers provide the necessary controllers for animating the effects of transforms. In a sense, they give "whole-object status" to the sub-object selection.

- **XForm on page 2010**
  Animates transforms directly on a sub-object selection. Creates a gizmo and center for the sub-object selection. You can animate both, with the center acting as a pivot point for the selection.

- **Linked XForm on page 1484**
Lets you choose another object to control the animation. The sub-object selection is linked to the "control object." When you transform the control object, the sub-object selection follows accordingly.

Procedures

To use the Poly Select modifier:

1 Create or select an object.

   NOTE Applying a Poly Select modifier to an object other than a polymesh type will convert the object to a polymesh object. If you want more control over the conversion, add a Turn To Poly modifier on page 1830 before applying the Poly Select modifier. The Turn To Poly modifier provides conversion options that aren't available with the Poly Select modifier.

2 Apply the Poly Select modifier.

3 Select vertices, faces, or polygons.

4 Add another modifier to affect only the selection from step 3.

Interface

Modifier Stack

Vertex Selects vertices.
**Edge** Selects edges.

**Border** Selects borders.

**Polygon** Selects polygons.

**Element** Selects elements.

For more information on the stack display, see *Modifier Stack* on page 8187.

**Parameters rollout**

![Parameters rollout diagram]

Provides buttons for accessing different sub-object levels, working with named selections and handles, display settings, and information about selected entities.

The icons at the top of the Selection rollout let you specify the method of face selection.
Clicking a button here is the same as choosing a sub-object type in the modifier stack. Click the button again to turn it off and return to the Object selection level.

**NOTE** You can convert sub-object selections in two different ways with the use of the Ctrl and Shift keys:

- Clicking a sub-object button in the Selection rollout with Ctrl held down converts the current selection to the new level, selecting all sub-objects in the new level that touch the previous selection. For example, if you select a vertex, and then Ctrl+click the Polygon button, all polygons that use that vertex are selected.

- To convert the selection to only sub-objects all of whose source components are originally selected, hold down both Ctrl and Shift as you change the level. For example, if you convert a vertex selection to a polygon selection with Ctrl+Shift+click, the resultant selection includes only those polygons all of whose vertices were originally selected.

**Vertex** Selects a vertex beneath the cursor; region selection selects vertices within the region.

**Edge** Selects a polygon edge beneath the cursor; region selection selects multiple edges within the region.

**Border** Turns on Border sub-object mode, which lets you select an area on a mesh that can generally be described as a hole. Areas like this are usually sequences of edges with faces on only one side. For example, a box doesn’t have a border, but the Teapot object has several of them: on the lid, on the body, on the spout, and two on the handle. If you create a cylinder, then delete the top face, the top row of edges forms a border.

When the Border sub-object level is active, you can’t select edges that aren’t on borders. Clicking a single edge on a border selects that whole border. Borders can be capped (either in editable poly or by applying the cap holes modifier). They can also be connected to another object (compound object connect).
**Polygon** Selects all coplanar polygons beneath the cursor. Usually, a polygon is the area you see within the visible wire edges. Region selection selects multiple polygons within the region.

**Element** Selects all contiguous polygons in an object; region selection selects the same.

**By Vertex** Selects any sub-objects at the current level that use a vertex you click. Applies to all sub-object levels except Vertex. Also works with Region Select.

**Ignore Backfaces** Selecting sub-objects selects only those whose normals make them visible in the viewport. When turned off (the default), selection includes all sub-objects, regardless of the direction of their normals.

**NOTE** The state of the Display properties on page 164 > Backface Cull setting doesn’t affect sub-object selection. Thus, if Ignore Backfacing is turned off, you can select sub-objects even if you can’t see them.

**NOTE** The state of the Ignore Backfaces check box also affects edge selection at the Edge sub-object selection level.

**Shrink** Reduces the sub-object selection area by deselecting the outermost sub-objects. If the selection size can no longer be reduced, the remaining sub-objects are deselected.

**Grow** Expands the selection area outward in all available directions. For this function, a border is considered to be an edge selection.
With Shrink and Grow, you can add or remove neighboring elements from the edges of your current selection. This works at any sub-object level.

**Ring** Expands an edge selection by selecting all edges parallel to the selected edges. Ring applies only to edge and border selections.

Ring selection adds to the selection all the edges that are parallel to the ones selected originally.
**Loop** Expands the selection as far as possible, in alignment with selected edges.

Loop applies only to edge and border selections, and propagates only through four-way junctions.

Loop selection extends your current edge selection by adding all the edges aligned to the ones selected originally.

**Get from Other Levels group**

Applies selections from one sub-object level to another.

**Get Vertex Selection** Selects faces based on the last vertex selection. Selects all faces shared by any selected vertex. The selection is added to the current selection. Available only when the current sub-object level is not Vertex.

**Get Poly Selection** Selects vertices based on the last polygon/element selection. This selection is added to the current selection. Available only when the current sub-object level is not Polygon or Element.
**Get Edge Selection** Selects faces based on the last edge selection. Selects those faces that contain the edge. Available only when the current sub-object level is not Edge or Border.

**Select by Material ID group**

Selects faces based on their material ID.

**ID** Set the spinner to the ID number you want to select, and then click the Select button. Press Ctrl while clicking to add to the current selection, or press Alt to remove from the current selection.

**Named Selection Sets group**

These functions are primarily for copying named selection sets on page 217 of sub-objects between similar objects, and between comparable modifiers and editable objects. For example, you can apply a Poly Select modifier to a sphere, create a named selection set of edges, and then copy the selection to a different sphere that's been converted to an editable mesh object. You can even copy the selection set to a different type of object, because the selection is identified by the entities' ID numbers.

The standard procedure is to create a selection set, name it, and then use Copy to duplicate it into the copy buffer. Next, select a different object and/or modifier, go to the same sub-object level as you were in when you copied the set, and click Paste.

**NOTE** Because sub-object ID numbers vary from object to object, the results of copying named selection sets between different objects can be unexpected. For example, if the buffered set contains only entities numbered higher than any that exist in the target object, no entities will be selected when the set is pasted.

**Copy** Places a named selection into the copy buffer.

**Paste** Pastes a named selection from the copy buffer.

**Select Open Edges** Selects all edges with only one face. In most objects, this will show you where missing faces exist. Available only at the Edge or Border sub-object level.

**Selection Info**

At the bottom of the Parameters rollout for Mesh Select is a text display giving you information about the current selection. If 0 or more than one sub-object
is selected, the text gives the number and type selected. If one sub-object is selected, the text gives the ID number and type of the selected item.

NOTE When the current sub-object type is Element, selection information is given in polygons When the current sub-object type is Border, selection information is given in edges.

Soft Selection rollout

Soft Selection controls affect the action of sub-object Move, Rotate, and Scale functions. When these are on, 3ds Max applies a spline curve deformation to unselected vertices surrounding the transformed selected sub-object. This provides a magnet-like effect with a sphere of influence around the transformation.

For more information, see Soft Selection Rollout on page 2014.

Preserve Modifier

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Preserve

Make a selection. > Modifiers menu > Parametric Deformers > Preserve

The Preserve modifier lets you retain, as much as possible, the edge lengths, face angles, and volume of an edited and deformed mesh object using an unmodified copy of the object before it was deformed. When you push and pull vertices at the sub-object level, the process typically stretches the edges and often alters the face angles, resulting in irregular topology. You can use the Preserve modifier to generate more regular edge lengths, and a “cleaner” mesh.

Procedures

Using the Preserve modifier:

1. Create an object. Before you edit it, create a copy.
2. Edit the copy at the sub-object level, pushing and pulling vertices, faces, and so on.
3. Apply the Preserve modifier to the copy, click the Pick Original button, and then select the original, unmodified object.
4. Adjust controls in the Preserve modifier to fine-tune the mesh.
Example: Use the Preserve modifier on a geosphere:

1. Create a GeoSphere on page 401 and use Shift+Move to make a copy of it.

   **TIP** If you want to see the effect of Preserve on mapping, apply a checker-mapped material to the sphere and display it in the viewports before making the copy.

2. Convert the copy to an editable mesh on page 2192.

3. At the Vertex sub-object level, select a third of the vertices at the top of the sphere, and move them upward (as seen from the front) about one radius in distance. Notice the stretched edges between the moved vertices and the remaining vertices.

4. While still at the Vertex sub-object level, apply the Preserve modifier.

5. Click the Pick Original button, and then select the original (unedited) sphere. The selected vertices move back toward the sphere in an attempt to maintain the original volume and edge lengths.

6. Turn on Invert Selection. The selected vertices return to their moved position, and the unselected vertices (the inverted selection) move up toward the selected vertices.

7. Turn off Invert Selection and slowly reduce the Iterations to 0. The object now looks as it did before you applied Preserve.

8. Increase Iterations to the default 25, and then increase it to approximately 75. The object is now almost completely spherical again.

9. Set Iterations back to 25, and then try different Edge Lengths, Face Angles, and Volume settings. (You can restore the defaults by setting Edge Lengths to 1.0, and Face Angles and Volume to 0.3.)
Steps in applying the Preserve modifier to a geosphere

Example: Animating a preserved object:

You can animate the Preserve parameters, but the following procedure shows you how to use Morph and Preserve together.

1. Remove the Preserve modifier from the copied sphere, and go to object level (instead of sub-object level).

2. With the copied (and deformed) sphere still selected, choose Create panel > Compound Objects > Morph to make it into a Morph object.
3 Make sure Instance is chosen in the Pick Targets rollout.
4 At frame 0, click Pick Target, and then select the original sphere.
5 In the Modify panel, go to frame 100, select sphere02 in the Morph Targets list, and click Create Morph Key.
The object now morphs from a sphere to a deformed sphere.
6 Apply Preserve to the morph object.
7 Click Pick Original, and select the original sphere.
The object now morphs from the sphere to a preserved and deformed sphere. Note that because the object selection is passed up the stack, the Preserve effect is applied to the entire sphere.
8 Choose Selected Verts Only in the Selection group.
Now, only the selected vertices are affected by Preserve. The morph still works, however.

Example: Using the Selection check boxes:
1 Reset 3ds Max, create a box, and convert it to an editable mesh.
2 Use Shift+Move to make a copy.
3 Use the Modify panel to select the top four vertices in the second box. Move them upward in Z, making the copied box taller than the original.
4 Apply Preserve, and pick the first box as the original.
The selected vertices move down to match the original edge lengths.
5 Set Iterations to 0 to move the vertices back up, then turn on Invert Selection, and set iterations back up to 25.
The selected vertices stay in their original locations, but the unselected vertices move upward to restore the original edge lengths.
6 Turn Iterations back down to 0. Turn on Apply To Whole Mesh (Invert Selection becomes unavailable), and then turn Iterations back up to 25. Preserve is now applied to the whole mesh. Since all vertices are affected, the top and bottom of the box approach each other.
7 Turn off Apply To Whole Mesh.
All vertices are translated, but maintain the same positions relative to each other.

8  Turn off Invert Selection and turn on Selected Verts Only.
    You're back to the original effect. You can move the Iterations spinner up and down to see that you're affecting only the selected vertices.

Example: Simulating cloth:

1  Reset 3ds Max, create a Quad Patch Grid, and convert it to an editable mesh.

2  Make a copy, and then make a reference of the copy.
    You should have a total of three objects in the scene.

3  Apply Preserve to the third patch, using the first as the original.

4  Select Selected Verts Only and Invert Selection.

5  Set Iterations to 100.

6  Select the second patch and go to the Sub-Object > Vertex level.

7  Select a single vertex in the middle of the patch and move it upward in Z.
    The third patch becomes a floating handkerchief.

8  Undo the vertex move.

9  Select the far two corner vertices of the second patch, and drag them upward in Z.
    Now, you've got the beginnings of a sheet hanging on the line.
Interface

**Original** Displays the name of the selected original object. (Note that the so-called "original" object doesn't actually have to be the original. It's simply a copy of the object that represents its unmodified topology.)

**Pick Original** Click this, and then select an unmodified copy of the current object. You should pick an object with the same topology as the current object, which has the same number of vertices. While you can select a completely different object with equal vertices, the results are unpredictable.

**Iterations** Specifies the number of calculations toward the solution. The higher this number, the closer the object comes to matching the original object and the slower the process. When this is set to zero, the original object has no effect, as if the Preserve modifier were never applied.

**Preservation Weights group**

**Edge Lengths, Face Angles, Volumes** Adjusts the relative importance of the three components you're attempting to preserve: edge lengths, face angles, and volume. In most cases, you'd leave these at their default settings, but you can achieve some interesting effects by altering them. Higher face angles, for example, produce stiffer meshes.
Selection group

Provides options that let you specify which selection level to take from previous selection modifiers in the stack. The Preserve modifier acts on the specified selection.

Apply to Whole Mesh Applies Preserve to the entire object, regardless of the selection passed from previous levels of the stack. Disables the other two check boxes.

Selected Verts Only Uses previous sub-object vertex selections. Note that it doesn't matter if the Vertex sub-object level is active in a previous stack item. As long as vertices have been selected, Preserve will use that selection.

Invert Selection Inverts the selection passed up the stack.

NOTE If all of the check boxes are turned off, Preserve uses whatever active selection is passed up the stack. Thus, if a Mesh Select modifier is set to the Vertex level, then that vertex selection is used. If the same Mesh Select modifier is set to the top (object) level, then the entire object is affected.

Projection Modifier

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Projection

The Projection modifier is used primarily to manage objects for producing normal bump maps on page 6856. You apply it to the low-resolution object, and then pick a high-resolution object as the source for the projected normals. When you use the Render To Texture dialog on page 6869 to set up projection, Render To Texture applies the Projection modifier to the low-resolution object automatically. You can also explicitly apply the Projection modifier to set up the projection before you use Render To Texture.

NOTE The low-resolution object requires UV coordinates, but the high-resolution source object does not need to have them. When the normals map is rendered, you can choose to have Render To Texture apply an “Automatic Flatten UVs” (Unwrap UVW) modifier on page 1837 to the top of the low-res object's stack; or you can use existing mapping, if such exists.

You can apply more than one instance of the Projection modifier to the same object, and you can instance it across multiple objects.
The Projection modifier is a topology-dependent modifier on page 8744, so when you select an item in the stack that is lower than the Projection modifier, you see a warning dialog that asks if you want to proceed. (The same is true of the Automatic Flatten UVs modifier.)

**Projection and Sub-Object Selections**

You can match geometry to sub-object selections. There are two ways to do so: matching material IDs, or matching named selections of sub-object geometry.

**Matching Material IDs**

Here is a sample workflow for using material IDs to match portions of the low-res object to different high-res objects:

1. At the level of the low-res object itself, assign differing material IDs to different face selections.
   - To do so, the low-res object must be a surface model; that is, an editable mesh, editable poly, editable patch, or NURBS surface. Use the Surface Properties rollout to change the material ID of sub-object selections.

2. For the high-res target objects, assign corresponding material IDs. An easy way to do this is to apply the Material modifier on page 1490.

3. In the Resolve Hit group of the Projection Options dialog on page 6888, turn on Hit Only Matching Material ID.

4. Render to texture.
   - The texture for faces of the low-res object receive texture element information only from the source object that had the corresponding material ID.

**Matching Selected Geometry**

Here is a sample workflow for using sub-object selections to match portions of the low-res object to different high-res objects.

1. In the Projection modifier, go to the Face or Element sub-object level.
   - See Selection Rollout (Projection Modifier) on page 1598.

2. Make a sub-object selection, then on the Reference Geometry rollout on page 1601, enter a descriptive name in the Name field.
3 Click the Add button or press Enter.
   The name of the sub-object selection set is added to the list.

4 Click in the list to highlight the selection-set name, click Pick or Pick List, and then select the high-res source object to associate with the sub-object selection.

5 Repeat steps 2 through 4 to associate different sub-object selections with different source objects.

6 Choose Rendering > Render To Texture.
   The Render To Texture dialog appears.

7 In the Projection group of the Objects To Bake rollout on page 6872, turn off Object Level and turn on Sub-Object Levels.

8 Click Render.
   Render To Texture renders a separate texture for each of the named sub-object selections contained in the Projection modifier.

See also:
- Soft Selection Rollout on page 2014

**Selection Rollout (Projection Modifier)**

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Projection > Selection rollout

The Projection modifier's Selection rollout is for managing sub-object selections.
Interface

- **Cage** Click to turn on the Cage sub-object level.

The Cage is the surface from which normals are projected. At the Cage sub-object level, you can adjust the cage manually by transforming sub-object selections of cage vertices.

- **Face** Click to turn on the Face sub-object level.

The Face sub-object level lets you assign different source geometry to different portions of a surface.

- **Element** Click to turn on the Element sub-object level.

The element sub-object level lets you assign different source geometry to individual elements. (An element is a group of contiguous faces.)

**Shrink** Reduces the sub-object selection area by deselecting the outermost sub-objects. If the selection size can no longer be reduced, the remaining sub-objects are deselected.

**Grow** Expands the selection area outward in all available directions.
With Shrink and Grow, you can add or remove neighboring elements from the edges of your current selection. Shrink and Grow work at any sub-object level.

**Ignore Backfacing** When on, selection of sub-objects affects only those facing you. When off, you can select any sub-objects under the mouse cursor, regardless of visibility or facing. If multiple sub-objects lie under the cursor, repeated clicking cycles through them. Likewise, with Ignore Backfacing off, region selection includes all sub-objects, regardless of the direction they face. Default=off.

**Get Stack Selections** Click to collect sub-object selections from modifiers that are below the Projection modifier on the stack.

**Select SG** To select by smoothing group value, use the spinner to set the number of the smoothing group, and then click Select SG.

**Select MatID** To select by material ID, use the spinner to set the ID number, and then click Select MatID.

- **Sub-material drop-down list** When a multi/sub-object material is applied to the low-res object, this list shows the names and numbers of sub-materials that are assigned to faces or elements of the object. When you have selected by material ID, the corresponding sub-material appears in the field above the list.

**Clear Selection** When on, each stack, smoothing group, or material ID selection you make replaces the previous selection. When off, each new selection is added to the previous selection set. Default=on.
Reference Geometry Rollout (Projection Modifier)

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Projection > Reference Geometry rollout

On the Reference geometry rollout, you can create named sub-object selection sets, and associate them with high-resolution geometry.

Interface

Name Lets you enter a name for the current set of selected sub-objects.

Delete Click to delete the sub-object selection set whose name is highlighted in the list.

Add Click to add the named sub-object selection set to the list.
Keyboard shortcut: Enter.

Select Click to select the sub-objects in the selection set whose name is highlighted in the list.

Delete All Click to delete all named sub-object selection sets in the list.

Reference geometry window This window shows a list of named sub-object selection sets, and the high-resolution source geometry with which they’re associated. If you have picked a high-res object at the object level, it also shows “Object Level” followed by the name of the source object.

Proportion Multiplier When Proportional is chosen for sub-object normal bump mapping in the Projection Mapping group of the Objects To Bake rollout on page 6872 for Render To Texture, this value multiplies the default size of the normal bump map. Range=0.0 to 2.0. Default=1.0.

For example, if Proportional rendering of a sub-object were to render a sub-object selection at 16 x 16 pixels, changing Proportion Multiplier to 2.0 would change the size of the normal bump map to 32 x 32 pixels.

This control is unavailable unless a sub-object selection is active.

Pick To associate high-res geometry with the current selection, click Pick to turn it on, then click a source object in a viewport.

Pick List To associate high-res geometry with the current selection, click Pick List, then use the Add Objects dialog, which works like the Select From Scene dialog on page 206, to choose a source object.

Display Toggle group

The Display Toggle group is useful when you want to compare the hi—res to your low-res geometry. You can quickly toggle between your low-res geometry and your hi-res geometry to compare versions. You can show selected or all hi-res geometry.

Enable When on, makes it possible to show or hide reference geometries. Default=off.

Hide Reference Geometry/Hide Working Geometry When Enabled is on, click Hide Reference Geometry to hide your hi-res geometry. Conversely, click Hide Working Geometry to hide your low-res geometry. You can also selectively
show and hide high-res geometries in your Pick List. Click Off to hide a geometry. Click Hide to show a geometry.

**Cage Rollout (Projection Modifier)**

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Projection > Cage rollout

These settings adjust the cage and its display. The cage is the nonrenderable geometry that the Projection modifier uses as the surface from which it ray-traces normals.

---

**NOTE** Special export/import functionality available on this rollout lets you convert the cage into standard geometry of the same type and topology as the cage and modified object, which you can edit using standard methods and then use to define a new shape for the cage. This provides access to the full range of mesh-editing tools available in 3ds Max for shaping the cage to your precise requirements. For example, with editable poly, you can take advantage of tools such as Loop, Ring, Grow, and Shrink, and quickly switch among sub-object levels such as Face and Vertex.

---

**Procedures**

**To use Export and Import with a cage:**

1. Create a cage:
   1. Create low-resolution and high-resolution objects. In most cases, for best results they should be arranged concentrically.
   2. Apply the Projection modifier to the low-resolution object. This creates the cage with the same shape and position as the low-resolution object.
   3. Use the Reference Geometry rollout controls to specify one or more high-resolution objects.
   4. On the Cage rollout, click Update. This reshapes the cage, roughly enveloping the high-resolution object(s).

2. On the Cage rollout, click Export.
This creates a separate geometrical object in the same shape as the cage, with the same type and topology as the low-resolution object. We'll call this the cage object.

For example, if the low-resolution object is an editable poly, or has an Edit Poly modifier at the top of the modifier stack, the resultant cage object is of editable poly type.

3 Use standard object-editing tools to modify the cage object's shape. Do not alter its topology by adding or removing vertices, edges, etc., because that would invalidate its usage for reshaping the cage. Also, for best results, do not move the cage object. If you wish, you can temporarily hide any overlapping objects.

4 Select the low-resolution object.

5 On the Cage rollout, click Import and then select the cage object. If the cage object type and topology are the same as the low-resolution object, 3ds Max reshapes the cage to match the cage object's shape. Alternatively, if the cage object can be converted to the same type as the low-resolution object without a change in topology, it is also accepted. If not, a warning appears and no reshaping takes place.

**IMPORTANT** The resultant cage matches the imported cage object's shape, position, orientation, and size exactly.

If the import is successful, the cage object can be deleted, or retained for possible future cage modification.
## Interface

### Display group

**Cage** When on, the cage is displayed. When off, the cage is hidden except at the Cage sub-object level. Default=on.

The cage is always displayed at the Cage sub-object level, regardless of this toggle's setting. See [Selection Rollout (Projection Modifier)] on page 1598.

- **Shaded** When on, the cage is shaded with a transparent gray. When off, the cage is displayed as a blue lattice. Default=off.

  The Shaded option can be useful when you need to tell whether or not high-resolution source geometry is within the cage, and when you need to expand the cage to include more geometry.

- **Point to Point** When on, additional lines connect vertices in the cage to points on the target object, showing how the projection will be done. Default=off.
Push group

These controls let you adjust the size of the cage as a whole, or on a sub-object selection if one is currently chosen (see Reference Geometry Rollout (Projection Modifier) on page 1601).

Amount Change to adjust the size of the cage in 3ds Max units. Positive values increase the size of the cage; negative values decrease the size. Default=0.0.

Percent Change to adjust the size of the cage as a percentage. Positive values increase the size of the cage; negative values decrease the size. Default=0.0.

Auto-Wrap group

By default, the Projection modifier does not automatically create a cage that wraps around the geometry. To change the cage, use the settings in this group or the Push group, or adjust cage vertices manually at the Cage sub-object level.

Tolerance The distance in 3ds Max units, between the cage and the target geometry. Positive values are outside the high-res source geometry; negative values are inside the source geometry. Default=varies, depending on the geometry.

Always Update When on, the cage automatically expands around high-res geometry as it is added to the list (see Reference Geometry Rollout (Projection Modifier) on page 1601). When off, the initial cage is not updated automatically. Default=off.

Update Click to update the cage. Use this when Always Update is off.

Import Lets you specify a mesh object to define the cage shape. This is typically an object that was created with Export (see following) and then modified using standard mesh-editing methods. After clicking Import, select the object to import. After importing the object, the cage conforms to its shape. You can then delete the imported object if you wish.

IMPORTANT The imported object should be of the same type (for example, editable mesh) as the projection object (that is, the object with the Projection modifier), or be convertible to that type without topology change, and must have the identical topology. If it doesn't meet either or both of those criteria, an alert appears requesting that you select an object of the same type and identical topology.
Export  Creates a geometry object from the cage, with the same type and
topology as the modified object. Clicking Export causes the Export Cage dialog
to open. Accept the default “Export as” object name or enter a new one, and
then click OK.

For a detailed description of the export/import process, see To use Export and
Import with a cage: on page 1603.

Reset  Click to reset the cage to a wrapping that is the same size as the
low-resolution target geometry.

Selection Check Rollout (Projection Modifier)

Select an object. > Modify panel > Modifier List > Object-Space Modifiers >
Projection > Selection Check rollout

This rollout lets you check selections to see if any are overlapping; that is, if
a material ID or a face or element is assigned to more than one selection.

Interface

Check group

- Material IDs  Checks for material IDs being assigned to more than one
selection.
- **Geometry**  Checks for faces or elements being assigned to more than one selection.

- **Both** (The default.) Checks for both material ID and sub-object overlap.

---

**Check**  Click to run the check.

**Select Faces**  When on, if running the selection check detects “bad” selections, the “bad” faces are selected by the Projection modifier automatically. When off, “bad” selections are not selected automatically. Default=on.

**Results group**

After you click Check, the fields in this group display the results. The first field is for material IDs, and the second is for sub-object selections. If there is no conflict, the first field says “No conflicting Mat IDs detected,” and the second says “No conflicting face selections detected.” If there is a conflict, the results say something such as, “6 Mat IDs are assigned to more than one selection.”

**Projection Rollout (Projection Modifier)**

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Projection > Projection rollout

The Projection rollout has controls for projecting data from the object with the Projection modifier to a different object. This data flow is the reverse of what it is when you project normals from a high-resolution object to a low-resolution object.
Interface

**Projector list** Shows the active projector plug-ins.

**Projector plug-in drop-down list** Lets you choose a projector plug-in. Only one projector, Project Mapping, is provided with 3ds Max. See Project Mapping Rollout (Projection Modifier) on page 1610. Additional projectors might be available from third-party sources.

**NOTE** Multiple instances of the Project Mapping plug-in can be active.

**Add** Adds a projector of the type chosen in the drop-down list.

**Remove** Removes the projector that is currently highlighted in the projector list.

**Project to** Shows the name of the geometry to which you're projecting. To choose this geometry, use the Reference Geometry rollout on page 1601.

**Show Alignment** Click to display the faces of the geometry selection that will project to the selected faces of the object that has the Projection modifier. This shows which hi-res faces will be projected to the selected low-res faces. This works only for selected faces, not selected vertices: you can lock a face selection and then make adjustments to the cage, then click Show Alignment to see the effects of the cage modification. This button is unavailable if no selection has been made in the Reference Geometry rollout.
Clear Click to turn off the Show Alignment display.

Project Click to perform the projection.

Project All Click to perform all projections that are in the projector list.

**Project Mapping Rollout (Projection Modifier)**

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Projection > Projection rollout > Choose Project Mapping in the plug-in drop-down list (this is the only available choice unless third-party plug-ins have been installed). > Click Add > Project Mapping rollout.

The Project Mapping rollout contains controls for the Project Mapping projector plug-in. This rollout is visible when a Project Mapping instance is highlighted in the Projector list on the **Projection rollout** on page 1608. Use Project Mapping to project a map channel value, material IDs, or vertex attributes from the object that has the Projection modifier applied, onto other geometry.
Interface

- Project Mapping
  - Project Mapping 1
    - Projection Holder
      - Projection Holder 1
        - Create New Holder
        - Same Topology
        - Always Update
  - Source Channel
    - Map Channel
    - Vertex Color
    - Vertex Illum
    - Vertex Alpha
    - Vertex Position
  - Target Channel
    - Same as Source
    - Map Channel
    - Vertex Color
    - Vertex Illum
    - Vertex Alpha
    - Vertex Position
  - Project Material IDs
    - Projection Mapping Quality
      - Ignore Backfaces
      - Test Seams
      - Check Edge Ratios
        - Threshold: 0.1
      - Weld UVs
        - Threshold: 5.0
**Projector name field** Shows the name of the Project Mapping projector. If you edit this field, the change is reflected on the Projection rollout on page 1608.

**Projection Holder group**

**Projection Holder name field** Shows the name of the Projection Holder modifier. If you edit this field, the change is reflected in the target object’s stack, but not until you click Project on the Projection rollout.

**Create New Holder** When you click the Project button in the Project rollout, a Projection Holder modifier is added to the geometry selection. When Create New Holder is on, 3ds Max creates and adds a new modifier each time you click Project. When Create New Holder is off, clicking Project simply updates the data in the existing Projection Holder; it creates a new Projection Holder modifier only if none was present, before. Default=off.

**Same Topology** When on, the source object’s topology is transferred to the target object. Default=off.

**IMPORTANT** You need to turn on Same Topology when you project to the target object’s Vertex Position.

**Always Update** When on, changing the object with the Projection modifier automatically re-projects and updates the Projection Holder modifiers on the geometry selections. When off, projection is recalculated only when you click Project. Default=off.

This toggle is available only when Create New Holder is off and Same Topology is on.

When Always Update is on, changes to the geometry with the Projection modifier can manipulate UVW channels or animate vertex colors of the objects with the Projection Holder modifiers.

**Source Channel group**

- **Map Channel** (The default.) Projects a map channel on page 8627 value. Use the spinner to set the channel value.

- **Vertex Color** Projects vertex color values.

- **Vertex Illum** Projects vertex illumination (grayscale) values.

- **Vertex Alpha** Projects vertex alpha values.

- **Vertex Position** Projects vertex positions.
Target Channel group

**Same as Source** When on, the radio buttons in this group are disabled, and the Project Mapping projector projects to the same channel that is chosen in the Source Channel group. When off, the radio buttons in this group are enabled. Default=on.

The radio buttons are the same as the ones in the Source Channel group.

When Same As Source is off, the chosen map channel or vertex data of the target geometry derives its value from the channel or vertex data chosen in the Source Channel group.

The projection does not take place until you click Project or Project All on the Projection rollout.

---

**Project Material IDs** When on, projects values. Default=off.

The projection does not take place until you click Project or Project All on the Projection rollout.

Projection Mapping Quality group

Use these settings to improve the quality of the mapping when projecting texture mapping from one object to another.

**Ignore Backfaces** When on, does not take backfaces into account when calculating the projection. In the case of overlapping faces, this can prevent projection, resulting in undesirable erroneous faces. In almost all cases this should remain off.

**Test Seams** Tests for seams by walking around the neighboring faces and then will try to fix the faces.

**Check Edge Ratios** Attempts to correct UVW faces that look abnormal; that is, that are not similar to their geometry faces. This compares edge ratio lengths and angle ratio. It typically finds the sliver faces generated by projections across seams. The larger the Threshold value, the more likely a face is to be tagged as abnormal and fixed.

**Weld UVs** Welds all the UVs at the end of the projection and combines them into groups, based on the Threshold value. The Threshold value is based on edges, so it welds UVs based on the the closest N edges. In most cases this should be on.
Projection Holder Modifier

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Projection modifier > Geometry rollout > Choose target geometry > Projection rollout > Click Add. > Click Project. > Projection Holder is applied to the target geometry.

The Projection Holder modifier appears for objects being used by the Projection modifier's Project Mapping feature on page 1608. It contains the data generated by the Project Mapping operation, much as UVW Mapping Add or UVW Mapping Clear do for Channel Info manipulations.

Interface

The Projection Holder modifier has no parameters.

ProOptimizer Modifier

Create or import an object. > Modify panel > Modifier List > ProOptimizer modifier

Select an object or objects. > Modify panel > Modifier List > ProOptimizer modifier

The ProOptimizer modifier lets you select objects and interactively optimize them.

The ProOptimizer feature is an optimization tool that helps you reduce the number of vertices (and so the number of faces) in an object while preserving the object's appearance. Options let you maintain material, mapping, and vertex color information in the optimized model.

Optimizing objects can reduce a scene's memory requirements, simplify modeling because objects have fewer faces, and improve the speed of viewport display and rendering time.

There are two ways to use ProOptimizer:

- The ProOptimizer modifier, described here, lets you select objects and interactively optimize them.

- The Batch ProOptimizer utility on page 2768 lets you optimize multiple scene files (MAX or OBJ files) at the same time.
TIP With the Batch ProOptimizer, you can optimize meshes before you import them. This can save time. The Batch ProOptimizer is also a good choice if the original meshes are extremely dense.

Original model
Vertices: 47226
Faces: 93792

Optimized model, Vertex % = 10.0
Vertices: 4722
Faces: 9323
Optimized model, Vertex % = 5.0
Vertices: 2361
Faces: 4660

Optimization Level Rollout

Create or import an object. > Modify panel > Modifier List > ProOptimizer modifier > Optimization Level rollout

The main ProOptimizer modifier controls are on the Optimization Level rollout.

To initialize ProOptimizer, click Calculate. You can then adjust the optimization level interactively. You choose the level of optimization either by setting the percent of vertices to preserve (Vertex %), or by setting an explicit count of vertices to preserve (Vertex Count).
Additional rollouts contain options that let you control how the model is optimized, and what kind of information to retain or discard. These options are not interactive. If you adjust their settings after an initial optimization, you must click Calculate once again to see the effects.

**ProOptimizer Workflow**

To use the ProOptimizer modifier, follow these steps for most situations:

1. Select the object or objects you want to optimize.

2. Go to the Modify Panel and apply the ProOptimizer modifier.

   **NOTE** The ProOptimizer modifier is available for 3ds Max geometric objects, but not for nongeometric objects such as lights, cameras, or helpers.

3. In the Optimization Level rollout, click Calculate. This initializes ProOptimizer and lets you interactively adjust the optimization level.

4. Adjust the Vertex % or Vertex Count value until you have the level of optimization you want to achieve.

5. If you want to change the optional settings, do so now, and then click Calculate once again.

   **TIP** Once you are familiar with ProOptimizer, you can also change these settings before the first time you click Calculate.
When you have obtained the level of optimization and detail that you want, right-click the stack and choose Collapse All from the pop-up menu. This creates an Editable Mesh object with an optimized number of faces.

**Interface**

**Optimization Level rollout**

- **Vertex %** Sets the number of vertices in the optimized object as a percentage of the vertices in the original object. Default=100.0 percent.
  
  This control is unavailable before you click Calculate. After you click Calculate, you can adjust the Vertex % value interactively.

- **Vertex Count** Directly sets the number of vertices in the optimized object.
  
  This control is unavailable before you click Calculate. After you click Calculate, this value is set to the number of vertices in the original object (because Vertex % defaults to 100). Once this control is available, you can adjust the Vertex Count value interactively.

- **Calculate** Click to apply the optimization.
  
  If optimization takes some time, you can cancel the operation by pressing Esc.

**Status window** This text window shows the ProOptimizer status. Before you click Calculate, it displays “Modifier Ready.” After you click Calculate and adjust the optimization level, it displays statistics that describe the effect of the operation: “before” and “after” vertex and face counts.
If, after a calculation, you change a setting in the one of the Options rollouts, the text changes to “Optimization Invalid.” You must click Calculate again to see the results of changing the options.

The optimization can also become invalid if you move the ProOptimizer modifier location on the stack, or change topology on the stack below the ProOptimizer modifier.

If you press Esc to cancel an optimization, this window displays “Optimization Cancelled.”

**Options rollouts**

The options rollouts contain various settings that control ProOptimizer. They are described in the the topics that follow.

**Optimization Options Rollout**

Create or import an object. > Modify panel > Modifier List > ProOptimizer modifier > Optimization Options rollout

The Optimization Options rollout lets you control how ProOptimizer treats such features as object borders, materials and mapping, vertex colors, and sub-object selections.

**IMPORTANT** The controls on this rollout are *not* interactive. If you change a setting, the Status window on the Optimization Level rollout displays “Optimization Invalid,” and you must click Calculate once again to see the result of changing the option value.
**Optimization Mode Group**

Create or import an object. > Modify panel > Modifier List > ProOptimizer modifier > Optimization Options rollout > Optimization Mode group

Controls how ProOptimizer treats object borders.

An edge is considered to be on the “border” of an object, when it is shared by no other face. Preserving borders can be important to preserving the appearance of a model.

*Original model*

*Vertices: 557*
Interface

**Crunch Borders** ProOptimizer optimizes the object without considering whether edges and faces lie on borders or not.

Crunch Borders active

Vertex % = 50.0

Vertices = 278

Faces are reduced but object borders are not preserved
Protect Borders (The default.) ProOptimizer protects faces with edges that are on the border of the object. However, a high optimization level can still cause border faces to be removed. If you are optimizing multiple connected objects, gaps might appear between them.

Protect Borders active

Vertex % = 50.0

Vertices: 557

Borders are preserved
Protect Borders active

Vertex % = 1.0

Vertices: 5

Decreasing Vertex % or Vertex Count can cause borders to become distorted.

**Exclude Borders** ProOptimizer never removes faces with border edges. This reduces the number of faces you are able to remove from the model, but it ensures that gaps don’t appear when you optimize multiple connected objects.
Exclude Borders active
Vertex % = 10.0
Vertices: 65
At low Vertex % values, Exclude Borders can interfere with optimization.

**Materials and UVs Group**

Create or import an object. > Modify panel > Modifier List > ProOptimizer modifier > Optimization Options rollout > Materials and UVs group

Controls how ProOptimizer treats objects with materials or texture mapping.
Interface

Keep Material Boundaries When on, ProOptimizer preserves boundaries between materials. Points that belong to faces that have different materials are frozen, and not removed during optimization. Default=on.

When off, ProOptimizer can remove faces along the boundary between materials.
Original object with red points showing the boundaries between materials

Optimized object with Keep Material Boundaries active (red points show the boundaries)
Keep Textures When on, ProOptimizer preserves texture mapping coordinates. When off, ProOptimizer removes texture coordinates. Default=off. This option is disabled if the object doesn’t have texture coordinates.

NOTE If Keep Textures is off when you optimize a mapped object, 3ds Max will display a Missing Map Coordinates dialog when you attempt to render that object.

Keep UV Boundaries This control is available only when Keep Textures is turned on. When on, ProOptimizer preserves boundaries between UV mapping channels. When off, ProOptimizer disregards UV mapping boundaries. Default=off.

- Tolerance This is available only when Keep UV Boundaries is turned on. The Tolerance value controls how UV boundaries are treated. A value of 0.0 (the default), preserves all faces that have UV mapping channels that differ from neighboring faces. A value of 1.0 allows any face to be removed, even if its neighbor has a different UV channel.

TIP Setting Tolerance to 0.1 preserves most mapping boundaries, but also allows a reasonable amount of optimization.
**Vertex Colors Group**

Create or import an object. > Modify panel > Modifier List > ProOptimizer modifier > Optimization Options rollout > Vertex Colors group

Controls how ProOptimizer treats objects that have vertex colors assigned to them.

**Interface**

![Vertex Colors Group Interface](image)

**Keep Vertex Colors** When on, ProOptimizer preserves vertex color data. When off, ProOptimizer discards vertex colors. Default=Off

This control is unavailable if the object has no vertex color data.

**Keep VC Boundaries** This control is available only when Keep Vertex Colors is turned on. When on, ProOptimizer preserves boundaries between vertex colors. When off, ProOptimizer disregards vertex color boundaries. Default=off.

- **Tolerance** This is available only when Keep VC Boundaries is turned on.
The Tolerance value controls how vertex color boundaries are treated. A value of 0 (the default), preserves all vertices that have a color that differs from a neighboring vertex. A value of 255 allows any vertex to be removed, even if its neighbor has a different vertex color.

**TIP** A tolerance of 20 preserves most color boundaries, but also allows a reasonable amount of optimization.
Keep Vertex Colors turned off

ProOptimizer shows the object’s two materials, but vertex color is lost.
Keep Vertex Color turned on

Tolerance = 0

Frozen points are shown in red. Almost all faces are frozen and not optimized, because each point has a color that differs from its neighbor.

Keep Vertex Color turned on

Tolerance = 35
Frozen points are shown in red. Only the center, which has important color variations, is frozen.

Keep Vertex Color turned on

Tolerance = 90

Frozen points are shown in red. Only the frontier between the two materials is frozen.

**Normals Group**

Create or import an object. > Modify panel > Modifier List > Edit Normals modifier > Modifier List > ProOptimizer modifier > Optimization Options rollout > Normals group

The Normals group lets you manage the face normals on page 8654 of the geometry you are optimizing.

In general, turning on Keep Normals can improve the appearance of the optimized model, but also can reduce the number of faces that are removed during optimization.
Interface

Keep Normals When on, applies the normal controls to geometry. When off, normals are not taken into account during optimization, and all explicit normals are removed after optimization. Default=off.

This toggle is unavailable unless you have applied an Edit Normals modifier on page 1322 to the geometry. The ProOptimizer Keep Normals toggle is also available if you collapse the stack after applying Edit Normals.

- Crunch Normals When chosen, normals are ignored while optimizing, but explicit normals are kept after optimization.

- Protect Normals (The default) When chosen, ProOptimizer protects normals using the value of Threshold Angle: when the angle between the normals of two faces is greater than the Threshold Angle, the faces are preserved as long as possible. Explicit normals are kept after optimization.

- Exclude Normals Normals are excluded from the optimization using the value of Threshold Angle: when the angle between the normals of two faces is greater than the threshold angle, the faces are always preserved. Explicit normals are kept after optimization.

Threshold Angle Sets an angle value used in optimizing normals. Default=10.0.

When Crunch Normals is chosen, this value is ignored.

When Protect Normals is chosen, two faces are protected from optimization if the angle between their normals exceeds this value.

When Exclude Normals is chosen, two faces are excluded from the optimization if the angle between their normals exceeds this value.
Merge Tools Group

Create or import an object. > Modify panel > Modifier List > ProOptimizer modifier > Optimization Options rollout > Merge Tools group

Each of the Merge tools adds a preprocessing step to the optimization process. These can help correct specific problems in a model.

- **“Dirty” objects** If a model has faces that are disconnected, but should not be, the Merge Vertices tool can correct the discontinuities and improve the optimization.

- **Coplanar faces** If the model has surfaces that are subdivided into many coplanar (or nearly coplanar) faces, the Merge Faces tool can simplify these planes, leading to better optimization.

### Interface

![Merge Tools Interface](image)

**Merge Vertices** When on, merges vertices before performing the optimization. Default=off.

**Threshold** Sets the distance within which vertices are merged. This distance is based on a percentage of the size of the object’s bounding box. At the Threshold value of 0.0, the distance is about 0.0001 percent of the bounding-box size. At the Threshold value of 100.0, the distance is about 5 percent of the bounding-box size. Range=0.0 to 100.0. Default=0.0.

**Merge Faces** When on, merges coplanar (or nearly coplanar) faces before performing the optimization. Default=off.

**WARNING** If the planar surface has holes in it, Merge Faces might not give correct results. Also, if the planar surface has repeated (tiled) UV mapping, the tiling information will be lost.

**Threshold Angle** Sets the angle between face normals within which faces are merged. Range=0.0 to 10.0. Default=0.0.
Original model
Vertices: 557
Merge Faces turned off
Vertex % = 25.0
Vertices: 139
Faces: 214
Merge Faces turned on

Vertex % = 25.0

Vertices: 23

Faces: 21

When a model has coplanar faces, Merge Faces can greatly improve optimization.

Sub-Object Selection Group

Create or import an object. > Modify panel > Modifier List > ProOptimizer modifier > Optimization Options rollout > Sub-Object Selection group
These options control how ProOptimizer treats vertex sub-object selections. You can’t create a sub-object selection in ProOptimizer, but it can acquire a vertex selection from an object or modifier below it on the stack.

**Interface**

![Sub-Object Selection](image)

**Preserve Vertices** When on, ProOptimizer does not optimize vertex selections passed up from the stack. When off, ProOptimizer disregards vertex sub-object selections. Default=off.

**Invert** When on, ProOptimizer optimizes the vertex selection and disregards the rest of the object. Default=off. This control is unavailable unless Preserve Vertices is turned on.

**Symmetry Options Rollout**

Create or import an object. > Modify panel > Modifier List > ProOptimizer modifier > Symmetry Options rollout

The Symmetry options preserve an object’s symmetry around a plane that you specify.

When one of the Symmetry options is active, ProOptimizer looks for symmetrical pairs of edges. When it finds a symmetrical pair, it applies the same optimization on either side of the plane.

These options work best if the object is truly symmetrical; for example, if it was originally created by mirroring. If ProOptimizer cannot detect symmetry about the plane you specify, it optimizes the object as it normally does.

Points that lie on the plane itself are frozen (not optimized), because they are symmetrical by definition.

Some 3ds Max objects appear to be symmetrical but are not; for example, a surface of revolution created by the Lathe modifier. In this case, although the overall geometry is symmetrical, edges all have the same orientation in the direction of revolution, so when bisected by a plane, opposite edges face in
opposite directions. In this case, ProOptimizer cannot detect symmetry, and optimizes according to the usual method.

**IMPORTANT** The controls on this rollout are not interactive. If you change a setting, the Status window on the Optimization Level rollout displays “Optimization Invalid,” and you must click Calculate once again to see the result of changing the option value.

**Interface**

![Symmetry Options](image)

No Symmetry (The default.) ProOptimizer does not attempt to make symmetrical optimizations.

XY Symmetry ProOptimizer attempts to make optimizations symmetrical about the XY plane.

YZ Symmetry ProOptimizer attempts to make optimizations symmetrical about the YZ plane.

XZ Symmetry ProOptimizer attempts to make optimizations symmetrical about the XZ plane.

Tolerance Specifies a tolerance value for detecting symmetrical edges. In some models, the position of symmetrical edges might not be precise; for example, roundoff error might have caused small discrepancies in position values. Increasing the Tolerance value can correct this problem. Default=0.0.

**Advanced Options Rollout**

Create or import an object. > Modify panel > Modifier List > ProOptimizer modifier > Advanced Options rollout
This rollout provides two options: Favor Compact Faces, and Prevent Flipped Normals.

The options in this rollout are on by default, because in most cases they give the best optimization results.

**IMPORTANT** The controls on this rollout are *not interactive*. If you change a setting, the Status window on the Optimization Level rollout displays “Optimization Invalid,” and you must click Calculate once again to see the result of changing the option value.

**Interface**

<table>
<thead>
<tr>
<th>Advanced Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>□ Favor Compact Faces</td>
</tr>
<tr>
<td>□ Prevent Flipped Normals</td>
</tr>
</tbody>
</table>

**Favor Compact Faces** A face is “compact” when the triangle it forms is equilateral, or nearly so. When Favor Compact Faces is on, ProOptimizer verifies that removing a face does not create sharpened faces. The optimized model is more uniform than it would be without this test. Default=on.

**Prevent Flipped Normals** When on, ProOptimizer verifies that moving a vertex does not cause a face normal to flip. When off, ProOptimizer does not perform this test; the resulting mesh might appear to have holes when viewed with 1-sided viewport shading or rendered with a 1-sided material. Default=on.

**Push Modifier**

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Push

Make a selection. > Modifiers menu > Parametric Deformers > Push

The Push modifier lets you "push" object vertices outward or inward along the average vertex normals. This produces an "inflation" effect that you can't otherwise obtain.
Positive and negative amounts of push applied to an object.

**Interface**

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Push Value: 0.0</td>
</tr>
</tbody>
</table>

**Push Value** Sets the distance in world units by which vertices are moved with respect to the object center. Use a positive value to move vertices outward, or a negative value to move vertices inward.

**Quadify Mesh Modifier**

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Quadify Mesh

Make a selection. > Modifiers menu > Mesh Editing > Quadify Mesh
The Quadify Mesh modifier converts the object structure to quadrilateral polygons whose relative size you specify. This capability helps to produce rounded edges when combined with MeshSmooth on page 1505.

Left: Original object; Right: After applying Quadify Mesh and MeshSmooth modifiers

See also:

- Quad Meshing and Smoothing on page 831

Interface

Quad Size % The approximate size of each quadrilateral relative to the size of the object. The smaller this value, the more quads will result.
Relax Modifier

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Relax

Make a selection. > Modifiers menu > Parametric Deformers > Relax

The Relax modifier changes the apparent surface tension in a mesh by moving vertices closer to, or away from, their neighbors. The typical result is that the object gets smoother and a little smaller as the vertices move toward an averaged center point. You can see the most pronounced effects on objects with sharp corners and edges.
Relax moves the bowl away from its original contours.

When you apply Relax, each vertex is moved toward the average position of its neighboring vertices. A neighboring vertex is one that shares a visible edge with the current vertex.
Patches

As of version 4, a patch object coming up the modifier stack is not converted to a mesh by this modifier. A patch object input to the Relax modifier retains its patch definition. If a file created by a previous version of 3ds Max contains a patch object applied with the Relax modifier, it will be converted to a mesh to maintain backward compatibility.

Interface

Relax Value Controls how far a vertex moves for each iteration. The value specifies a percentage of the distance from the original location of a vertex to the average location of its neighbors. Range=-1.0 to 1.0. Default=0.5.

- Positive Relax values move each vertex in closer to its neighbors. The object becomes smoother and smaller.
- When the Relax value=0.0, vertices do not move and Relax has no affect on the object.
- Negative Relax values move each vertex away from its neighbors. The object becomes more irregular and larger.

Relax Values=1.0, 0.0, -1.0

Iterations=1 (default)
**Iterations** Sets how many times to repeat the Relax process. For each iteration, average locations are recalculated and the Relax Value is reapplied to every vertex. Default=1.

- For 0 iterations, no relaxation is applied.
- Increasing iterations for positive Relax Value settings smooths and shrinks an object. With very large iteration values, the object shrinks to a point.
- Increasing iterations for negative Relax Value settings exaggerates and expands an object. With relatively few iterations, the object becomes jumbled and almost unusable.

Iterations=0, 10, 50

Relax Value=0.5 (default)

Keep Boundary Pts Fixed Controls whether vertices at the edges of open meshes are moved. Default=on.

When Keep Boundary Pts Fixed is on, boundary vertices do not move while the rest of the object is relaxed. This option is particularly useful when working with multiple objects, or multiple elements within a single object, that share open edges.

When this check box is off, all vertices of the object are relaxed.
Keep Boundary Pts Fixed=on
Iterations=0, 10, 50

Keep Boundary Pts Fixed=off
Iterations=0, 10, 50

Save Outer Corners Preserves the original positions of vertices farthest away from the object center.

Renderable Spline Modifier

Select a shape. > Modify panel > Modifier List > Renderable Spline

The Renderable Spline modifier lets you set the renderable properties of a spline object, without collapsing the spline to an editable spline. This is particularly useful with splines you have linked to from AutoCAD. It also lets you apply the same rendering properties to multiple splines at once.

NOTE This modifier cannot be applied to NURBS curves.
Interface

Enable In Renderer
When on, the shape is rendered as a 3D mesh using the Radial or Rectangular parameters set for Renderer.

Enable In Viewport
When on, the shape is displayed in the viewport as a 3D mesh using the Radial or Rectangular parameters set for Renderer.

Use Viewport Settings
Lets you set different parameters for viewport display and rendering, and displays the mesh generated by the Viewport settings in the viewports. Available only when Enable in Viewport is turned on.

Generate Mapping Coords
Turn this on to apply mapping coordinates. Default=off.
3ds Max generates the mapping coordinates in the U and V dimensions. The U coordinate wraps once around the spline; the V coordinate is mapped once along its length. Tiling is achieved using the Tiling parameters in the applied material. For more information, see Mapping Coordinates on page 5636.
**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=on.

**Viewport** Choose this to specify Radial or Rectangular parameters for the shape as it will display in the viewport when Enable In Viewport is on. Available only when Use Viewport Settings is on

**Renderer** Choose this to specify Radial or Rectangular parameters for the shape as it will display when rendered or displayed in the viewport when Enable in Viewport is turned on.

**Radial** Displays the spline as a 3D object with a circular cross-section.

- **Thickness** Specifies the cross-section diameter. Default=1.0. Range=0.0 to 100,000,000.0.

- **Sides** Sets the number of sides for the spline mesh in the viewports or renderer. For example, a value of 4 produces a square cross-section.

- **Angle** Adjust the rotational position of the cross section in the viewports or renderer. For example, if you have a square cross section you can use Angle to position a “flat” side down.

**Rectangular** Displays the spline as a 3D object with a rectangular cross-section.

- **Length** Specifies the size of the cross-section along the local Y axis.

- **Width** Specifies the size of the cross-section along the local X axis.

- **Angle** Adjusts the rotational position of the cross-section in the viewport or renderer. For example, if you have a square cross-section you can use Angle to position a "flat" side down.

- **Aspect** Sets the aspect ratio for rectangular cross-sections. The Lock check box lets you lock the aspect ratio. When Lock is turned on, Width is locked to Depth that results in a constant ratio of Width to Depth.

**Auto Smooth** When on, the spline is auto-smoothed using the smoothing angle specified by the Threshold setting. Auto Smooth sets the smoothing based on the angle between spline segments. Any two adjacent segments are put in the same smoothing group if the angle between them is less than the threshold angle.
**NOTE** Turning Auto Smooth on for every situation does not always give you the best smoothing quality. Altering the Threshold angle may be necessary or turning Auto Smooth off may produce the best results.

**Threshold** Specifies the threshold angle in degrees. Any two adjacent spline segments are placed in the same smoothing group if the angle between them is less than the threshold angle.

## Ripple Modifier

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Ripple

Make a selection. > Modifiers menu > Parametric Deformers > Ripple

The Ripple modifier lets you produce a concentric rippling effect in an object's geometry. You can set either of two ripples or a combination of both. Ripple uses a standard gizmo and center, which you can transform to increase the possible ripple effects.

The **Ripple** on page 2983 space warp has similar features. It is useful for applying effects to a large number of objects.
An object with the Ripple modifier applied.
Top (from left to right): Amplitude 1 only, Amplitude 2 only and both amplitudes.
Bottom: Both amplitudes with the Decay effect.

See also:
■ Wave Modifier on page 2000

Procedures

Example: To use the Ripple modifier:

1 Start with an empty scene, and add a Plane object on page 419 in the Perspective viewport. Set Length and Width both to 100.0, and set Length Segs and Width Segs both to 10.
   The Plane object is useful as the basis for the surface of a body of water in which ripples form.

2 Go to the Modify panel, click Modifier List, and, from the Object-Space Modifiers list, choose Ripple.
This applies the modifier to the Plane object.

3 On the Parameters rollout, set Amplitude 1 to 10.0. A large ripple forms in the Plane object.
   You can change the horizontal scale by adjusting the wave length.

4 Set Wave Length to 20.0. The waves become smaller, but now it's apparent that the Plane object needs greater geometric resolution to properly display the number of waves.

5 In the modifier stack, click the Plane item, and then set Length Segs and Width Segs both to 30.
   The smaller waves become more apparent. The Ripple modifier needs a relatively high number of subdivisions in the geometry it's applied to in order to work properly.
   You can use the Amplitude 2 parameter to add complexity to the wave forms created by Ripple.

6 Return to the Ripple level of the modifier stack, and then click and hold on the Amplitude 2 and drag downward.
   As you drag, a new set of wave forms are combined with the existing ones. The farther you drag, the more dominant the second set becomes.
   Using a negative value for Amplitude 2 (or a positive one if Amplitude 1 is negative) produces more of an interference effect between the two sets of waves.
   You can animate the waves with the Phase control.

7 Drag slowly upward or downward on the Phase spinner.
   Increasing the Phase value moves the waves inward, and decreasing it moves the outward. To animate the waves, create keyframes on page 8090 for the Phase value.
   To simulate an object dropping in liquid, use the Decay setting.

8 Drag slowly upward on the Decay spinner.
   The farther you drag, the more the wave sizes decrease with the distance from the center of the effect. This is the effect you get when an object perturbs the water surface, and the waves lose energy as they move away from the point of impact.
Interface

Modifier Stack

Gizmo At this sub-object level, you can transform and animate the gizmo like any other object, altering the effect of the Ripple modifier. Translating the gizmo translates its center an equal distance. Rotating and scaling the gizmo takes place with respect to its center.

Center At this sub-object level, you can translate and animate the center of the ripple effect, and thus the shape and positions of the ripples.

For more information on the stack display, see Modifier Stack on page 8187.

Parameters rollout

Amplitude 1/ Amplitude 2 Amplitude 1 produces a ripple across the object in one direction, while Amplitude 2 creates a similar ripple at right angles to the first (that is, rotated 90 degrees about the vertical axis).

Wave Length Specifies the distance between the peaks of the wave. The greater the length, the smoother and more shallow the ripple for a given amplitude. Default=50.0.
**Phase** Shifts the ripple pattern over the object. Positive numbers move the pattern inward, while negative numbers move it outward. This effect becomes especially clear when animated.

**Decay** Limits the effect of the wave generated from its center. The default value of 0.0 means that the wave will generate infinitely from its center. Increasing the Decay value causes the wave amplitudes to decrease with distance from the center, thus limiting the distance over which the waves are generated.

---

**Select By Channel Modifier**

Select an object. > Modify panel > Modifier List > Select By Channel

The Select By Channel modifier works in conjunction with the Channel Info utility on page 6486. After you store a vertex selection into a subcomponent with Channel Info, use Select By Channel to quickly access the selection.

**Procedures**

To use Select By Channel:

1. Use Channel Info to store one or more vertex selections in a map channel subcomponent.
2. Apply the Select By Channel modifier to the object with the stored vertex selection(s).
3. Choose the selection type.
4. Choose the selection channel.
5. To “bake” the new selection into the object, collapse the stack.
Interface

Selection Type Lets you choose how to combine the stored vertex selection with an existing vertex selection.
- **Replace** Replaces the existing selection with the stored selection.
- **Add** Adds the stored selection to the existing selection.
- **Subtract** Subtracts the stored selection from the existing selection. Has no effect if there's no overlap between the stored selection and the existing selection.

Selection Channel Lets you choose which stored, named vertex-selection channel to apply to the modified object. Click the arrow to the right of the name field to open the drop-down list, and then click a channel in the list.

Shell Modifier

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Shell

Make a selection. > Modifiers menu > Parametric Deformers > Shell

The Shell modifier “solidifies” or gives thickness to an object by adding an extra set of faces facing the opposite direction of existing faces, plus edges connecting the inner and outer surfaces wherever faces are missing in the original object. You can specify offset distances for the inner and outer surfaces, characteristics for edges, material IDs, and mapping types for the edges.

Also, because the Shell modifier doesn’t have sub-objects, you can use the Select options on page 1663 to specify a face selection for passing up the stack to other modifiers. Please note that the Shell modifier doesn’t recognize existing sub-object selections, nor does it pass such selections up the stack.
You'd typically use Shell on an object with part of its surface removed, such as a sphere with several deleted vertices or faces, as illustrated above. For best results, the original polygons should face outward. If an object has no faces with at least one free edge, Shell will not create any edges.

Watch a movie about Shell Modifier.

Examples of Shell Usage

Following are some examples of modeling tasks for which the Shell modifier would be appropriate:

- An artist is modeling a vehicle such as a car, a tank, or, in this case, a helicopter. The artist builds a solid external shell as the body of the copter. When done, the modeler breaks up his model: he selects window areas and detaches them as new objects, followed by the area for the doors (also detached as new objects). The modeler now has open objects representing the body, windows, and doors. The modeler applies Shell to the body, and sets it to extrude both outward and inward, with the inward extrusion amount greater than the outward. Next, Shell is applied to the windows, with inward extrusion only. The modeler then copies the Shell modifier from the body to the doors, and reduces the doors' outward extrusion amount. The result is a solid body with an interior that can accept
additional modeling, inset windows, and doors that are slightly less thick than the shell of the helicopter.

A designer is modeling a manufactured object that will need to be shown in an exploded view. It might be a cell phone, an engine, a mouse, shaped glass, or something similar; this example will use part of a cell phone. When working on the phone keypad area, if the modeler builds with detail in mind, she might accurately model the shell with a moderately dense mesh, using ShapeMerge on page 709 to create the shapes for the holes where the keys will poke through, and then deleting those faces. When satisfied, the modeler applies the Shell modifier, sets Segments to 2, and then turns on the Bevel Edges option to use a curve for the profile of the holes' edges. She then applies a MeshSmooth modifier on top. The extra segment helps control the curve of the edges where the outer surface curves down to the keypad holes. The modeler then goes back to the cage portion of the stack and refines the base mesh details to her liking.

A modeler is creating a suit of futuristic armor for a character. The modeler copies a selection of polygons from the character mesh to a new object; for example, the polygons that make up the arm. The modeler deletes some faces from the copied arm, and perhaps cuts some holes from it. He then applies the Shell modifier, followed by a MeshSmooth modifier, resulting in form-fitting armor.

Procedures

To solidify an object:

1. Create an object to solidify. The object should have some holes in its surface. For example, start with a primitive sphere, convert it to Editable Poly, and delete some vertices or polygons.

2. Optionally create an open spline to serve as the profile for the edges connecting the inner and outer surfaces. For example, go to Create panel > Shapes and click Line. Then, in the Top viewport, draw the spline from top to bottom. Where the spline protrudes to the right, the edge surface will be convex, and where it protrudes to the left, the surface will be concave.

3. Apply the Shell modifier to the object from step 1.

4. To use custom edges, turn on Bevel Edges, click the Bevel Spline button, and then select the spline from step 2.
5 By default, Shell keeps the material IDs of the new surfaces consistent with those of the original object. To change these, turn on the different Override options, specify appropriate material IDs, and apply a Multi/Sub-Object material on page 6120.

6 Likewise, Shell keeps the texture coordinates of the new surfaces consistent with those of the original object. To change these on the new edges, change the Edge Mapping choice, and with the Strip and Interpolate choices, optionally change the TV Offset setting.
**Inner/Outer Amount** Distance in 3ds Max generic units by which the inner surface is moved inward and the outer surface is moved outward from their original positions. Defaults=0.0 / 1.0.

The sum of the two Amount settings determines the thickness of the object's shell, as well as the default width of the edges. If you set both to 0, the resultant shell has no thickness, and resembles an object set to display as 2-sided.

**Segments** The number of subdivisions across each edge. Default=1.
Change this setting if you need greater resolution on the edge for use by subsequent modeling or modifiers.

**NOTE** When you use a Bevel Spline, the spline's properties override this setting.

**Bevel Edges** When on, and you specify a Bevel Spline, 3ds Max uses the spline to define the edges' profile and resolution. Default=off.
After you define a Bevel Spline, use Bevel Edges to switch between a flat edge whose resolution is defined by the Segments setting and a custom profile defined by the Bevel Spline.

**Bevel Spline** Click this button and then select an open spline to define the edge shape and resolution. Closed shapes such as Circle or Star will not work.
The original spline is instanced to the Bevel Spline, so changing the spline's shape and properties are reflected in the Bevel Spline. With non-corner vertices, you can change the edge resolution with the spline's Interpolation rollout settings.
A bevel spline as viewed from the top (inset) and the resulting bevel

**TIP** For best results, create the spline in the Top viewport, and draw it from top to bottom. The top point on the spline is applied to the outside edge, and the bottom point to the inside edge. Displacements to the right will create outward protrusions on the edge profile, and displacements to the left create inward protrusions.

**Override Inner Mat ID** Turn on to specify a material ID for all of the inner surface polygons using the Inner Mat ID parameter. Default=off.
If you don't specify a material ID, the surface uses the same material ID or IDs as the original faces.

**Inner Mat ID** Specifies the material ID for inner faces. Available only when Override Inner Mat ID is on.

**Override Outer Mat ID** Turn on to specify a material ID for all of the outer surface polygons using the Outer Mat ID parameter. Default=off.
If you don't specify a material ID, the surface uses the same material ID or IDs as the original faces.

**Outer Mat ID** Specifies the material ID for outer faces. Available only when Override Outer Mat ID is on.
Override Edge Mat ID  Turn on to specify a material ID for all of the new edge polygons using the Edge Mat ID parameter. Default=off.
If you don’t specify a material ID, the surface uses the same material ID or IDs as the original faces from which the edges are derived.

Edge Mat ID Specifies the material ID for edge faces. Available only when Override Edge Mat ID is on.

Auto Smooth Edge Applies automatic, angle-based smoothing across the edge faces using the Angle parameter. When off, no smoothing is applied. Default=on.
This doesn’t apply smoothing across the junction between the edge faces and the outer/inner surface faces.

Angle Specifies the maximum angle between edge faces that will be smoothed by Auto Smooth Edge. Available only when Auto Smooth Edge is on. Default=45.0.
Faces that meet at an angle greater than this value will not be smoothed.

Override Smooth Group Lets you specify a smoothing group on page 8724 for the new edge polygons using the Smooth Grp setting. Available only when Auto Smooth Edge is off. Default=off.

Smooth Grp Sets the smoothing group for the edge polygons. Available only when Override Smooth Group is on. Default=0.
When Smooth Grp is set to the default value of 0, no smoothing group is assigned to the edge polygons. To specify a smoothing group, change the value to a number between 1 and 32.

NOTE When Auto Smooth Edge and Override Smooth Group are both off, 3ds Max assigns smoothing group 31 to the edge polygons.

Edge Mapping Specifies the type of texture mapping that is applied to the new edges. Choose a mapping type from the drop-down list:

- **Copy** Each edge face uses the same UVW coordinates as the original face from which it's derived.
- **None** Each edge face is assigned a U value of 0 and a V value of 1. Thus, if a map is assigned, the edges will take the color of the upper-left pixel.
- **Strip** The edges are mapped in a continuous strip.
- **Interpolate** The edge mapping is interpolated from the mapping of the adjacent inner and outer surface polygons.
**TV Offset** Determines the spacing of the texture vertices across the edges. Available only with the Edge Mapping choices Strip and Interpolate. Default=0.05.

Increasing this value increases the repetition of the texture map across the edge polygons.

**Select Edges** Selects the edge faces. This selection is passed up the stack to other modifiers. Default=off.

**Select Inner Faces** Selects the inner faces. This selection is passed up the stack to other modifiers. Default=off.

**Select Outer Faces** Selects the outer faces. This selection is passed up the stack to other modifiers. Default=off.

**Straighten Corners** Adjusts corner vertices to maintain straight-line edges.

If you apply Shell to a subdivided object with straight edges, such as a box set to 3x3x3 segments, you might find that the corner vertices don't stay in a straight line with the other edge vertices. This gives the edges a bulging look. To resolve this, turn on Straighten Corners.
Skew Modifier

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Skew

Make a selection. > Modifiers menu > Parametric Deformers > Skew

The Skew modifier lets you produce a uniform offset in an object's geometry. You can control the amount and direction of the skew on any of three axes. You can also limit the skew to a section of the geometry.
Procedures

To skew an object:

1. Select an object, go to the Modify panel, and choose Skew from modifier list.

2. On the Parameters rollout, set the axis of the skew to X, Y, or Z. This is the axis of the Skew gizmo, not the axis of the selected object. You can change the axis at any time, but only one axis setting is carried with the modifier.

3. Set the amount of the skew. The amount is an offset in current units parallel with the axis. The object skews to this amount beginning at the lower limit, by default the location of the modifier's center.

4. Set the direction of the skew. The object swivels around the axis. You can reverse the amount and direction by changing a positive value to a negative value.

To limit the skew:

1. Turn on Limits group > Limit Effect.

2. Set values for the upper and lower limits. These are distances in current units above and below the modifier's center, which is at zero on the gizmo's Z axis. The upper limit can be zero or positive, the lower limit zero or negative. If the limits are equal, the result is the same as turning off Limit Effect. The skew offset is applied between these limits. The surrounding geometry, while unaffected by the skew itself, is moved to keep the object intact.

3. At the sub-object level, you can select and move the modifier's center. The limit settings remain on either side of the center as you move it. This lets you relocate the skew area to another part of the object.
Interface

Modifier Stack

Gizmo At this sub-object level, you can transform and animate the gizmo like any other object, altering the effect of the Skew modifier. Translating the gizmo translates its center an equal distance. Rotating and scaling the gizmo take place with respect to its center.

Center At this sub-object level, you can translate and animate the center of the Skew effect.

For more information on the stack display, see Modifier Stack on page 8187.

Parameters rollout

Skew group

Amount Sets the angle to skew from the vertical plane.
**Direction** Sets the direction of the skew relative to the horizontal plane.

**Skew Axis group**

X/Y/Z Specify the axis that will be skewed. Note that this axis is local to the Skew gizmo and not related to the selected entity. Default=Z.

**Limits group**

**Limit Effect** Applies limit constraints to the Skew modifier.

**Upper Limit** Sets the upper limit boundaries in world units from the skew center point, beyond which the skew no longer affects the geometry. Default=0.

**Lower Limit** Sets the lower limit boundaries in world units from the skew center point, beyond which the skew no longer affects the geometry. Default=0.

---

**Skin Modifier**

Select a mesh, patch, or NURBS object. > Modify panel > Modifier List > Object-Space Modifiers > Skin

Select a mesh, patch, or NURBS object. > Modifiers menu > Animation Modifiers > Skin

The Skin modifier is a skeletal deformation tool that lets you deform one object with another object. Mesh, patch, or NURBS objects can be deformed by bones, splines, and other objects.

Applying the Skin modifier and then assigning bones gives each bone a capsule-shaped "envelope." Vertices of the modified object within these envelopes move with the bones. Where envelopes overlap, vertex motion is a blend between the envelopes.

By default, each vertex that's affected by a single bone is given a weight value of 1.0, which means it's affected by that bone only. Vertices within the intersection of two bones' envelopes have two weight values: one for each bone. And you can use Skin modifier toolsets such as the Weight Tool dialog on page 1697 to arbitrarily assign vertices to any number of bones. The ratio of a vertex's weight values, which always total 1.0, determine the relative extent to which each bone's motion affects the vertex. For example, if a vertex's weight with respect to bone 1 is 0.8 and its weight with respect to bone 2 is 0.2, then the motion of bone 1 will have four times greater influence on the vertex than will the motion of bone 2.
The initial envelope shape and position depends on the type of bone object. Bones create a linear envelope that extends along the longest axis of the bone geometry. Spline objects create envelopes that follow the curve of the spline. Primitive objects create an envelope that follows the longest axis of the object.

You can also deform the mesh based on the angle of the bones. Three deformers let you shape the mesh based on bone angles:

- The Joint and Bulge Angle deformer use a lattice similar to an FFD lattice on page 1431 to shape the mesh at a specific angle.

- The Morph Angle Deformer morphs the mesh at specified angles. Morph targets are created by using modifiers above the Skin modifier in the stack, or by using the Snapshot tool on page 950 to create a copy of the mesh and deforming the mesh using standard tools.

You can apply the Skin modifier to several objects at the same time.

In 3ds Max you can mirror envelope and vertex assignments from one side of the mesh to the other with commands on the Mirror Parameters rollout.
Procedures

To use the Skin modifier:

1. Prepare the skin (mesh or patch object) and skeleton (bones or other objects). Carefully place the skeleton inside the mesh or patch object so that its elements are able to influence polygons or patches in their immediate vicinity.

2. Select the mesh or patch object and apply the Skin modifier.

3. In the Parameters rollout, click Add and choose the skeleton objects.

4. Click Edit Envelopes and select an envelope to modify the volume in which each bone can influence the surrounding geometry.

To weight vertices manually:

1. On the Parameters rollout, turn on Vertices.

2. On the mesh, select the vertices you would like to weight manually. Each selected vertex is surrounded by a small white rectangle.

3. Highlight the name of the bone for which you want to change the vertex weights.

4. In the Weight Properties group, change the Abs. Effect parameter to the new vertex weight.

To mirror envelope or vertex weight settings:

1. Adjust envelopes and vertex weights on one side of the mesh.

2. On the Mirror Parameters rollout, click Mirror Mode.

3. If the mirror plane is not at the center of the mesh, change the Mirror Offset parameter to move the plane to the center.

4. If some vertices in the left or right side of the mesh are red rather than blue or green, increase the Mirror Thresh value until all vertices are blue or green.

5. On the Mirror Parameters rollout, click the appropriate Paste button to paste green or blue envelopes or vertex weights to the other side of the mesh.
To adjust the skin and/or bones without affecting the envelopes:

1. Save the scene.
   This is a potentially destructive operation, so it's best not to take any chances with your data.

2. Select the object to which the Skin modifier is applied.

3. In the Advanced Parameters rollout, turn off Always Deform.

4. Apply any necessary transforms to the mesh/patch object or bones objects.

5. Turn Always Deform back on.
   To adjust the bones only, you can also use skin pose on page 280.

Example: To apply the Skin modifier to a cylinder with a bones skeleton:

1. On the Create panel, under Standard Primitives, click Cylinder.

2. In the middle of the Top viewport, click and drag 20 units to create the base of the cylinder.

3. Release the mouse button and drag up 130 units to establish the height of the cylinder.

4. On the parameters rollout, set Height Segments to 20.
   This provides mesh detail for a smooth surface deformation.

5. On the Create panel, under Systems, click Bones.
   Make sure an IK Solver is chosen in the IK Solver list. Turn on Assign To Children. (This should turn on Assign To Root as well.)

6. In the Front viewport, click successively three times: below the cylinder, in the middle of the cylinder, and above the top of the cylinder.

7. Right-click to end Bones creation.
   Three bones display. Two of them are within the middle of the cylinder.

8. Select the cylinder.
9  On the Modify panel, choose Skin from the Modifier List.

10 On the Skin modifier’s Parameters rollout, click Add, and use the Select Bones dialog to select the three bones.
   The names of the bones are now displayed in the list.

11 In the Front viewport, select the bone end effector (IK Chain01) and move it around.
   The cylinder deforms to follow the bones. To adjust envelopes to refine the surface deformation, choose the Skin modifier’s Envelope sub-object level, and use the Edit Envelopes controls to resize envelopes and change vertex weights.

**Example: To use a morph angle deformer:**

Create the cylinder and bones from the preceding procedure before you continue with this procedure.

1  At frame 50, animate bone 2 so that bones 1 and 2 represent a 90-degree angle.

2  At frame 0, the bones should be straight at about a 180-degree angle.

3  Move to frame 0.

4  Turn on Edit Envelopes in the Parameters rollout.

5  Select the child bone (bone 2) in the modifier’s list of bones.

6  In the Select group, turn on Vertices.
   This allows you to select vertices.

7  In the viewports, region-window select a good portion of the vertices that are controlled by both bones.

8  In the Gizmos rollout, select the Morph Angle Deformer in the drop-down list, and then click Add Gizmo.
   The Deformer Parameters rollout displays. A base morph target is the first and only target in the list.

   **TIP** if the Deformer doesn’t assign, make sure that bone 2 and not bone 1 is selected in the list.

9  Scrub the Time Slider to frame 50.
10 Add an Edit Mesh modifier above the Skin modifier in the modifier stack.

11 Turn on Vertex and Soft Selection in the Edit Mesh modifier.

12 Edit the mesh to the shape you want.

13 Go back down in the stack to the Skin modifier. If the topology warning dialog appears, click Yes.

14 In the Deformer Parameters rollout, click Add From Stack. A new morph target is added at about 90 degrees.

15 Delete the Edit Mesh modifier from the stack. There is a doubling effect of the morph if you don’t delete or deactivate the Edit Mesh modifier.

16 Scrub the time slider. The mesh morphs as the bone angle changes.

Interface

The Skin Modifier interface includes the following rollouts:

- Parameters rollout on page 1673
- Mirror Parameters rollout on page 1680
- Display rollout on page 1682
- Advanced Parameters rollout on page 1684
- Gizmos rollout on page 1687
- Deformer Parameters rollout on page 1690
- Joint Angle and Bulge Angle parameters on page 1692

Some of the Skin modifier commands are also available from the quad menu on page 8052.

Modifier Stack

Envelope Turn on this sub-object level to work on envelopes and vertex weights.

TIP You can use the quad menu to choose this sub-object level.
Parameters rollout
**Edit Envelopes** Use this sub-object level to work on envelopes and vertex weights.

**Select group**

The following filtering options are grouped together to help you work on a particular task, by preventing you from accidentally selecting the wrong item in the viewports.

**Vertices** Turn on for vertex selection.

You can rotate around selected vertices using Orbit SubObject on page 8152 from the Orbit flyout on page 8151. You can also rotate around a selected envelope as long as no vertices are selected, as they have precedence.

**NOTE** You must choose Use Selection Center on page 933 from the User Center flyout on page 930 to center on your selection. If you choose Use Pivot Point Center on page 931, Orbit centers on the selected bone/cross section.

You can zoom on selected vertices using Zoom Extents Selected on page 8144 from the Zoom Extents flyout. You can also zoom on an envelope if no vertices are selected.

- **Shrink** Modifies the current vertex selection by progressively subtracting the outermost vertices from the selected object. Has no effect if all the vertices from an object are selected.

- **Grow** Modifies the current vertex selection by progressively adding neighborhood vertices of the selected object. You must start with at least one vertex to be able to grow your selection.

- **Ring** Expands the current vertex selection to include all vertices part of parallel edges.

**NOTE** You must select at least two vertices to use the Ring selection.

- **Loop** Expands the current vertex selection to include all vertices part of continuing edges.

**NOTE** You must select at least two vertices to use the Ring selection.

- **Select Element** When on, selects all vertices of the element you select, as long as you select at least one vertex from that element.
TIP You can edit your selection by holding Ctrl or Alt, and then select vertices. This adds or removes, respectively, vertices to or from your selection.

- **Backface Cull Vertices** When on, you cannot select vertices pointing away from the current view (on the other side of the geometry).

**Envelopes** Turn on for envelope selection.

**Cross Sections** Turn on for cross-section selection.

The first step, after applying the Skin modifier to an object, is to determine which bones participate in the object’s weighting. Every bone you choose influences the weighted object with its envelope, which you can configure in the Envelope Properties group on page 1676.

**Add** Click to add one or more bones from the Select Bones dialog.

**Remove** Choose a bone in the list, and then click Remove to remove it.

**List window** Lists all bones in the system. Highlighting a bone in the list displays that bone's envelope and the vertices influenced by the envelope. An horizontal scroll bar appears if a bone's name is longer than the window's width.

**NOTE** If an older scene containing long bone names is loaded in 3ds Max, its name is truncated to fit in the window. You can overwrite this by setting the MAXScript `shortenBoneNames` property of your Skin modifier to false.

Example: `$'Sphere01'.modifiers[#Skin].shortenBoneNames = false`

For detailed information about the MAXScript utility, open the MAXScript Help, available from Help menu > MAXScript Help.

**Bone name type-in field** Enter a bone name to highlight it in the bone list above. The highlighting goes to the first matching bone.

Use these methods for finding bone names faster:

- Narrow the list by typing the first few characters in the name of the bone you want to highlight.

- Use the wildcard (*) key. For example, you can find *Robot R Index Finger* by typing * R In
Cross Sections group

By default, each envelope has two round, lateral cross sections, one at each end of the envelope. These options add and remove cross sections from envelopes.

Add Choose a bone in the list, click Add, and click a position on the bone in a viewport to add a cross section.

Remove Select an envelope cross section and click Remove to delete it.

Before you can select a cross section, the Cross Sections option in the Select group must be on.

You can delete only extra cross sections that you have added; not the default cross sections.

Envelope Properties group

Radius Select an envelope cross section, and use Radius to resize it. In order to select a cross section, the Cross Sections option in the Select group must be checked.

You can also click and drag a cross section control point in a viewport to resize it.

Squash A squash multiplier for bones that stretch. This is a single value that reduces or increases the amount of squash applied to a bone when it is stretched with Freeze Length off, and Squash on.

NOTE You can set Freeze Length and Squash in the Bone Tools dialog on page 877.

Absolute/Relative This toggle determines how vertex weights are calculated for vertices between inner and outer envelopes.

Absolute A vertex must merely fall inside the brown outer envelope to have 100% assignment weight to that particular bone. A vertex falling inside more than one outer envelope will be assigned multiple weights summing to 100% based on where it falls in the gradients of each envelope.
Relative  A vertex falling only within an outer envelope will not receive 100% weighting. A vertex must either fall inside two or more outer envelopes whose gradients sum to 100% or greater or the vertex must fall within a red inner envelope to have 100% weight. Any points within a red inner envelope will be 100% locked to that bone. Vertices falling within multiple inner envelopes will receive weighting distributed over those bones.

Envelope Visibility Determines the visibility of unselected envelopes. Choose a bone in the list and click Envelope Visibility, then choose another bone in the list. The first bone selected remains visible. Use this to work on two or three envelopes.

Falloff Flyouts Choose a falloff curve for the displayed envelopes.

Weight falls off in the area between the inner and outer envelope boundaries if envelopes overlap and Absolute is turned on. This setting lets you specify how the falloff is handled:

- **Falloff Fast Out**  Weight falls off quickly.
- **Falloff Slow Out**  Weight falls off slowly.
- **Falloff Linear**  Weight falls off in a linear way.
- **Falloff Sinual**  Weight falls off in a sinusoidal way.

Copy Copies the currently selected envelope size and shape to memory. Turn on sub-object Envelopes, choose one bone in the list, click Copy, then choose another bone in the list and click Paste to copy an envelope from one bone to another.
Paste commands are on a flyout with the following options:

- **Paste**  Pastes the copy buffer to the current selected bone.

- **Paste to All Bones**  Pastes the copy buffer to all bones in the modifier.

- **Paste to Multiple Bones**  Pastes the copy buffer to selected bones. A dialog allows you to choose the bones to paste to.

**Weight Properties group**

Abs. Effect  Enter an absolute weight for the selected bone to selected vertices. Choose the Envelope sub-object level, turn on Vertices in the Parameters rollout > Select group, select a vertex or vertices, and then use the Abs. Effect spinner to assign weight. Selected vertices move in the viewports as their weight changes.

Rigid  Causes selected vertices to be influenced only by one bone, the one with the most influence.

Rigid Handles  Causes the handles of selected patch vertices to be influenced by only one bone, the one with the most influence.

Normalize  Forces the total weights of each selected vertex to add up to 1.0.
Exclude Selected Verts Adds the currently selected vertices to the exclusion list for the current bone. Any vertices in this exclusion list will not be affected by this bone.

Include Selected Verts Takes the selected vertices out of the exclusion list for the selected bone. The bone can then affect these vertices.

Select Excluded Verts Selects all vertices excluded from the current bone (see Exclude Selected Verts, preceding).

Bake Selected Verts Click to bake the current vertex weights. Baked weights are not affected by envelope changes, only by changes to Abs. Effect on page 1678 or weights in the Weight Table on page 1704.

Weight Tool Displays the Weight Tool dialog on page 1697, which offers control tools to help you assign and blend weights on selected vertices.

Weight Table Displays a table for viewing and changing weights for all bones in the skeletal structure. See Weight Table on page 1704.

Paint Weights Click and drag the cursor over vertices in the viewports to brush on weights for the selected bone.

TIP Streamline the painting process by using the Brush Presets tools on page 8044.

Painter Options [ellipsis] Opens the Painter Options dialog on page 1989, where you can set parameters for weight painting.

Paint Blend Weights When on, blends painted values by averaging the weights of neighboring vertices and then applying the average weight based on the brush strength. Default=on.
Mirror Parameters rollout

**Mirror Mode** Activates Mirror mode, which lets you mirror the envelopes and vertex assignments from one side of the mesh to the other. This mode is available only at the Envelope sub-object level.

Mirror mode uses the Mirror Plane setting to determine the “left side” and “right side” of the mesh. When you turn on Mirror Mode, the vertices on the left side of the mirror plane turn blue, while the vertices on the right turn green. Vertices that are neither left nor right turn red, including vertices at the mirror plane. If vertices don’t change color appropriately, you might have to increase the Mirror Thresh value to expand the range used to determine the left and right sides.

If you select vertices or bones, the selected vertices or bones turn yellow, and the corresponding match on the other side of the mesh turns a brighter blue or green. This can help you check for matches.

**Mirror Paste** Pastes selected envelope and vertex assignments to the opposite side of the body.

**Paste Green to Blue Bones** Pastes the envelope settings from green bones to blue.
Paste Blue to Green Bones  Pastes the envelope settings from blue bones to green.

Paste Green to Blue Verts  Pastes the individual vertex assignments from all green vertices to the corresponding blue vertices.

Paste Blue to Green Verts  Pastes the individual vertex assignments from all blue vertices to the corresponding green vertices.

Mirror Plane  Determines the plane that will be used to determine the left and right sides. The plane appears in the viewport at the mesh’s pivot point when you turn on Mirror mode. The selected mesh’s local axes are used as the basis for the plane. If several objects are selected, one object’s local axes are used. Default=X.

TIP  For the easiest workflow with mirroring tools for the Skin modifier, set the pivot points for character meshes to align with the World before applying Skin.

Mirror Offset  Shifts the mirror plane along the Mirror Plane axis.

Mirror Thresh  Sets the relative distance the mirroring tools will look when setting vertices as left or right. If some vertices in the mesh (other than those at the mirror plane) are not colored blue or green when you turn on Mirror mode, increase the Mirror Thresh value to include a larger area of the character. You can also increase this value to compensate for lack of symmetry in asymmetrical models.

Display Projection  When Display Projection is set to Default Display, selecting vertices on one side of the mirror plane automatically projects the selection to the opposite side. The Positive and Negative options allow selection of vertices on one side of the character only. The None option does not project selected vertices to either side. Default=Default Display.

TIP  You can use the Positive and Negative options to temporarily project the display of one side’s vertices to the other side so you can see how the vertices align. This can be helpful when determining the correct Mirror Plane settings for an asymmetrical mesh.

Manual Update  When on, you can update the display manually rather than automatically after each mouse-up.

Update  When Manual Update is on, use this button to update the display with your new settings.
Display rollout

- **Show Colored Vertices** Colors vertices in viewports according to their weights.
- **Show Colored Faces** Colors faces in viewports according to their weights.
- **Color All Weights** Assigns a color to every bone in the envelope. The vertex weighting blends the colors together.

**TIP** You can toggle this feature to get a global view of all weight regions across your model at once.

**TIP** You can also assign a color to unweighted vertices: Open the Customize User Interface dialog and, on the Colors panel, choose Skin Colors from the Elements drop-down list.

- **Show All Envelopes** Displays all envelopes at the same time.
- **Show All Vertices** Draws a small tick at every vertex. On a patch surface, it will also draw all the handles.
- **Show All Gizmos** Displays all the gizmos in addition to the currently selected gizmo.
Show No Envelopes Causes no envelopes to be displayed even when an envelope is selected.

Show Hidden Vertices When on, hidden vertices are visible. Otherwise, they remain hidden until you enable the option or go into the object's modifier (Editable Mesh on page 2192 or Editable Poly on page 2258), and then click Unhide All on the Selection rollout or Edit Geometry rollout, respectively. Default=off.

Draw On Top group

These options determine which elements will be drawn on top of all other objects in viewports.

Cross Sections Forces cross sections to be drawn on top.

Envelopes Forces envelopes to be drawn on top.
Advanced Parameters rollout

Always Deform  A toggle useful for editing the transformation relationship between bones and the controlled points. This relationship is initially set when Skin is applied. To change the relationship the user can deactivate Always Deform, move the object or the bones and reactivate. The new transformation relationship is now used.

Ref. Frame  Sets the frame where the bones and the mesh are in a reference position.

Normally this is frame 0. Start your animation at frame 1 or later if frame 0 is the reference frame. If bones need to be adjusted relative to the mesh, move
the time slider to frame 0; turn off Always Deform, move the bones into the correct position and turn on Always Deform.

**Back Transform Vertices** Allows you to link the mesh to the bone structure. Ordinarily, when you do this, any movement of the bones causes the mesh to move twice as far as it should, because it moves once with the bones and once with the link. Checking this option prevents the mesh from moving twice under these circumstances.

**Rigid Vertices (All)** Causes vertices to have assignments to only one bone as if weighted 100% to the bone whose envelope has the most influence. Vertices will not have weight distributed over more than one bone and the deformation of the skinned object is rigid. This is mainly used for games that do not support weighted point transformation.

**Rigid Patch Handles (All)** On a patch model, forces patch handle weights to equal the knots weights.

**Bone Affect Limit** Limits the number of bones that can affect one vertex.

### Reset group

**Reset Selected Verts** Resets the weight of selected vertices to the envelope defaults. After manually changing vertex weight, use this to reset weights if necessary.

**Reset Selected Bone** Resets associated vertex weights back to the original weights calculated for the selected bone's envelope.

**Reset All Bones** Resets all vertex weights back to the original weights calculated for all bone's envelopes.

**Save/Load** Allows you to save and load the envelope position and shape, as well as the vertex weights. If you load a saved file onto a different system of
bones, you can use the Load Envelopes dialog on page 1693 to match the incoming bones to the current bones.

**Update on mouse up** When on and the mouse button is pressed down, no updates take place. When the mouse button is released, updates occur. This option helps keep workflow moving quickly by avoiding unnecessary updates.

**Fast Updates** Turns off viewport display of weighted deformation and gizmos and uses rigid deformation when not rendering.

**Ignore Bone Scale** Turn this option on to leave a skinned mesh unaffected by a scaled bone. Default=off.

**NOTE** To scale a bone’s length, you first need to turn off its Freeze Length option on the Object Properties rollout on page 877 of the Bone Tools floater dialog on page 871.

**Animatable Envelopes** Toggles the possibility of creating keys on all animatable envelope parameters while Auto Key is active. Default=off.

**NOTE** This does not affect keyable track settings.

**Weight All Vertices** When on, forces all vertices that are not under the control of an envelope to be weighted to the bone closest to them. Has no effect on vertices that are manually weighted. Default=on.

**TIP** If you want to revert vertices to their original weight value, click Reset Selected Verts (in the Reset group) or open the Weight Table on page 1704, and change the Modified weight status (M) of your selected vertices.

**Remove Zero Weights** Strips a vertex from its weight if it is less than the Remove Zero Limit value. This helps making your skinned model lighter (in games for instance) because less unnecessary data is stored in the geometry. Also accessible from the Weight Table.

**Remove Zero Limit** Sets the weight threshold that determines if a vertex is stripped of its weight when you click Remove Zero Weights. Default=0.0.
Gizmos rollout

Controls in the Gizmos rollout allow you to deform the mesh according to the angle of the joint, and to add gizmos to selected points on the object. The rollout consists of a list box containing all the gizmos for this modifier, a drop-down list of the current types of gizmos, and four buttons (Add, Remove, Copy and Paste).

The workflow for adding a gizmo is to select the vertices that you want to affect, select the bones that will drive the deformation, and then click the Add button.

There are three deformers available:

- The Joint Angle deformer has a lattice that can deform vertices on the parent and child bones.
- The Bulge Angle deformer has a lattice that only works on vertices on the parent bone.
- The Morph Angle deformer works on vertices of the parent and child bones. Keep these distinctions in mind when you select vertices to deform. For example, if you want to use the Joint Angle deformer, then select vertices close to the joint that will drive the deformation. If you want the parent bone vertices to deform like a biceps muscle, then select vertices that are only assigned to the parent bone before adding the Bulge Angle deformer. If all the vertices of the parent and child bone must deform, then select all of the vertices and add the Morph Angle deformer.
Bending the arm without the Morph Angle deformer causes the sleeve to crumple.
Using the Morph Angle deformer creates a smooth bend in the sleeve.

**Gizmo List Window** Lists the current Angle Deformers. The Deformer Parameters rollout changes depending on the type of gizmo selected.

**Deformer drop-down list** Lists the available deformers.

**Add Gizmo** Adds the current Gizmo to the selected vertices. To add a gizmo, you must first select the child bone for the joint you want to deform. Then you must select the vertices that you want to deform. You can then add a gizmo. After a gizmo is added, a Deformer Parameters rollout displays that contains gizmo parameters that you can adjust.

**Remove Gizmo** Remove the selected gizmo from the list.
Copy Gizmo Copy the selected gizmo.

Paste Gizmo Paste the gizmo.

The Paste button pastes the current copy buffer into the currently selected gizmo. You can only paste to like gizmos. For instance, you can't paste from a bulge gizmo to a joint gizmo.

Deformer Parameters rollout

The following parameters are for the Morph Angle deformer. One way to create morph targets, after the morph gizmo is added, is to add an Edit Mesh modifier to the stack above the Skin modifier. Use the vertex controls in the Edit Mesh
modifier to shape the geometry. Then go back in the stack to the Skin modifier and click Add From Stack. You can then delete the Edit Mesh modifier. Add From Stack looks at the last modifier in the stack to get the morph target. Note that when you go back down to the Skin modifier, the morph effect is doubled; you can rectify this by deleting or deactivating the Edit Mesh modifier.

**Joint Field** Displays the type of Deformer and the associated bone.

**List Window** Contains the current morph targets and associated bone angles.

**Naming Field** Select a morph target and rename it in this field.

**Add from stack** Uses the current state of the stack to get the morph target. Ideally, you have put an Edit Mesh modifier on top of the stack and done your edits before you click Add From Stack.

**Add from node** Uses another object as your morph target for this angle. This is like a regular morph target, but instead of being driven by a field, it is driven by the joint angle.

**TIP** You can use Snap Shot on the main toolbar to create a new target for morphing.

**Delete** Deletes the currently selected morph target from the list.

**Enable gizmo** Toggles the effect of the gizmo.
Joint Angle and Bulge Angle parameters

The following parameters are for the Joint Angle and Bulge Angle deformers. These two deformers are almost identical in the way they operate. The difference is that the Bulge Angle deformer only works on vertices of the parent bone, while the Joint Angle deformer works on vertices on both the child and parent bone.

To apply either of these deformers, first select the child link, then select vertices on the mesh, and then apply the deformer. Remember to turn on Vertices in the Parameters rollout > Select group before region-selecting vertices in the viewports.

Once the deformer is applied, turn on Edit Lattice and move the lattice control points in the viewports to deform the mesh at different bone angles.

**Name Field** Allows you to change the name of the deformer.

**Twist** Allows you to spin the gizmo around the mesh to place control points appropriately.

**Use Bounding Volume** Turn this on if you plan to change the geometry, like increasing segments on a cylinder. If the geometry changes, the mesh will still deform inside the lattice if this is turned on.
Enable Gizmo Toggles the effect of the gizmo on and off.

Edit Lattice Allows you to move the lattice control points in the viewports.

Edit Angle Keys Curves Brings up a curve editor that lets you manipulate the shape of the lattice at a particular angle. This curve is position vs. angle. It will show you the curves of the current selected points. The red curves are X, green curves are Y, and blue curves are Z.

Load Envelopes Dialog (Skin Modifier)

Select a mesh, patch, or NURBS object. > Apply Skin modifier. > Advance Parameters rollout > Load button

The Load Envelopes dialog associated with the Skin modifier on page 1667 allows you to load saved envelopes on page 1685 to specific bones. This resizable dialog shows the current envelopes in your scene and the incoming envelopes. Use the controls to manipulate the incoming envelopes so they align with the current envelopes.

**Move Up/Down** Move the current selection in the incoming list up or down.

**Create Blank** Creates space in the Incoming list.

Use this when loading data onto a skeleton that is not identical as the one from which the data was saved. For example, if your original skeleton had three fingers and the new one has only two fingers, you might need to add spaces in the list to line up the fingers correctly.

**Delete** Removes the current selected incoming envelopes.

**Match by Name** Resorts the Incoming list and matches any bones that have the same name in the list of current envelopes.

**Remove Incoming Prefix** Removes any prefixes on the names of the incoming envelopes.

**Remove Current Prefix** Removes any prefixes on the names of the current envelopes.

**Load End Points** Loads the envelope end point positions.

**Load Cross Sections** Loads the envelope cross sections.

**Load Vertex Data** When on, loads weights at the vertex level. Normally only the envelope data is loaded so any manual adjustments to the vertex data are lost. This option lets you load those manual edits.

**Load Exclusion Lists** Lets you also load user-generated exclusion-list data, which specifies that certain vertices should not be affected by certain bones. See **Exclude Selected Verts** on page 1679 and **Show Exclusions** on page 1705.

**Load Vertices By Index** Lets you load vertices by index rather than vertex position. You would typically use this option with identical meshes that have not undergone any type of topology change. This should be off if you’ve changed the topology, by, for instance, deleting or adding vertices or changing their order.

**Current Incoming Vertex Set**

When Load Vertex Data is on, use these controls to match vertex sets in cases where the Skin modifier is instanced. In such cases you might need to set up several vertex sets.
The Move Up/Create Blank/Move Down buttons have the same functions as in the Envelopes lists.

**Weight Tool Dialog (Skin Modifier)**

Select an object that has the Skin modifier applied to it. > Modify panel > Skin modifier > Parameters rollout > Weight Properties group > Weight Tool button

This dialog is launched from the Skin modifier on page 1667 and provides tools to select vertices and assign them weights. You can also copy, paste, and blend weights between vertices. Each vertex you select displays the objects contributing to its weighting in the dialog list.

To use these tools, Parameters rollout > Edit Envelopes must be on, Parameters rollout > Select group > Vertices must be on, and at least one vertex must be selected.

**IMPORTANT**  The controls on this dialog adjust vertex weighting with respect to the active bone; that is, the object highlighted in the Bones list on the Parameters rollout. When you select a vertex and then change its weighting, if the active bone does not already influence the vertex, the bone is added to the list of bones influencing the vertex. You can ensure that bone assignments don’t change by highlighting the bone in the Weight Tool dialog list after selecting the vertex and before changing weighting.

Also, the total weighting for all bones influencing a vertex is always 1.0, so if multiple bones influence a vertex and you change the weight value for one bone, the weight values for the others change as well.

**Procedures**

**Example: To Set and Blend Weights on Selected Vertices:**

1. Prepare a cylinder skinned to a bone chain.
2 On Parameters rollout of the Modify panel, turn on Edit Envelopes.

3 Turn on Vertices in the Select group.

4 In the Weight Properties group, click Weight Tool.
   The Weight Tool dialog opens.

5 Select a few vertices and then click the .25 weight button.
   The selected vertices are weighted at 0.250 for the active bone (highlighted in the Parameters rollout list), coloring them yellow.

**NOTE** The active bone is added to the list of bones influencing each of the selected vertices, if necessary.
NOTE

You might need to toggle the vertex weighting to Relative in the Envelope Properties group on page 1667.

6. Click the + button directly under the .9 weight button repeatedly until the vertices are red (that is, the weight is 1.0).
   As you increase the vertices' weight, they gradually change color.

7. Select a few other vertices, and assign them a weight of 0.250.
The left vertices are weighted 1.0 and the right vertices are weighted 0.25.

8 Select all weighted vertices and repeatedly click Blend. Every time you click Blend, each vertex’s weight is adjusted to blend with other selected neighborhood weights. This creates a smooth weighting transition among all selected vertices.
The two separate colors blend into a smooth gradient.
**Interface**

**Shrink**  Modifies the current vertex selection by progressively subtracting the outermost vertices from the selection. Has no effect if all vertices in an object are selected.

**Grow**  Modifies the current vertex selection by progressively adding neighborhood vertices of the selected object. You must start with at least one vertex to be able to grow your selection.

**Ring**  Expands the current vertex selection to include all vertices in parallel edges.

**NOTE**  You must select at least two vertices to use the Ring selection.

**Loop**  Expands the current vertex selection to include all vertices in continuing edges.
NOTE You must select at least two vertices to use the Loop selection.

<table>
<thead>
<tr>
<th>Weight Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

**[specific weight values]** Assigns an absolute weight value between 0 and 1 for the active bone to the selected vertices.

NOTE When you click one of these buttons, the active bone is added to the list of bones influencing each of the selected vertices, if necessary.

**Set Weight** Sets an absolute weight based on the field value. Default=0.5.

NOTE The spinner increments the field value by steps of 0.05.

+/- Increases/decreases each selected vertex's weight by 0.05.

**Scale Weight** Multiplies each selected vertex's weight value by the field value, resulting in a relative weight change. Default=0.95.

NOTE The spinner increments the field value in steps of 0.05.

+/- Increases/decreases each selected vertex's weight by five percent.

**Copy** Stores the current weight value(s) in the copy buffer.

**Paste** Retrieves the weight values from the copy buffer and assigns them to the selected vertices.

**Paste-Pos** Assigns the weight values currently in the copy buffer to the selected vertices based on the distance between them and the copied vertices, which is determined by the Paste-Pos Tolerance value. This is useful when you need to match weights between two juxtaposed skinned meshes sharing the a common bone.

**Blend** Modifies the selected weight values to smooth out the transition between them and their surrounding vertices.

**Paste-Pos Tolerance** Determines the radius influence of the Paste-Pos. Default=0.1.

**Vertex information**

Below the Paste-Pos Tolerance field is a text display displaying information on the amount of copied and selected vertices.

**[First Vertex Weight list]** Displays the selected vertex weight along with the bone envelopes contributing to its weighting. You can select individual
envelopes in the current viewport by highlighting the respective bone in the list.

**NOTE** If you select multiple vertices, the list only displays the weighting of the first selected vertex.

### Weight Table (Skin Modifier)

Select an object that has the Skin modifier applied to it. > Modify panel > Skin modifier > Weight Properties group > Weight Table

The weight table for the Skin modifier is used to change vertex weights for several vertices and bones at a time. This table appears when you click the Weight Table button.

</table>

Vertex numbers appear down the left column, while bone names appear across the top. Vertex weights for each bone are displayed in the chart. You can change vertex weights in a number of ways:

- Click and drag a vertex weight to the left or right.
- Highlight a weight and type in a new weight.
- Select vertices by dragging over vertex IDs, then click and drag one weight to change all selected weights for the bone.
- Right-click to enter a value of 0.
- Ctrl+right-click to enter a value of 1.0.

**Menu options:**

**Edit menu** Copy/paste vertex weights, and choose vertices to edit.
- **Copy:** Copies weights for highlighted vertices.
- **Paste:** Pastes the copied weights.
- **Remove Zero Weights:** All vertices with a weight less than the *Remove Zero Limit* on page 1686 field value are stripped from their weight. Also available on the *Advanced Parameters rollout* on page 1684.

- **Select All/None/Invert:** Changes the selection of vertices.

**Vertex Sets menu** Select vertices in the left column by holding down Ctrl while clicking vertices. Create a named selection set, which can then be picked from the drop-down menu at the lower left of the dialog.

**Options menu** Customizes the weight table display.
- **Flip UI:** Flips the UI to show vertex IDs across the top and bone names down the left side.
- **Update On Mouse Up:** When the mouse button is pressed down, no updates will take place. When the mouse button is released, updates will occur. This option helps keep workflow moving quickly by avoiding unnecessary updates.
- **Show Affected Bones:** Displays only bones that affect the displayed vertices.
- **Show Attributes:** Toggles display of the S/M/N/R/H attributes.
- **Show Exclusions:** Toggles display of small check box areas in each vertex weight field. Clicking the check box toggles exclusion of the vertex from the bone (a red X appears in the check box when the exclusion is in effect).
- **Show Global:** Shows values for all displayed vertices.
Show Set Sets UI: Displays info about vertex sets.

Dialog options

Vertex ID Vertices are displayed by number down the left column of the weight table. Double-click a vertex number to cause the vertex to display in pink in viewports. To display only selected vertices, choose Selected Vertices from the drop-down menu at the bottom left of the dialog.

S Indicates vertex is selected.

M Indicates vertex weight has been modified.

N Indicates vertex weights are normalized (total of all vertex weights is always 1.0).

R Indicates vertex is rigid (affected only by one bone, the one with the most influence).

H Indicates patch handles are rigid (affected only by one bone, the one with the most influence).

Vertex selection drop-down Choose to display all vertices, selected vertices or only vertices affected by the selected bone.

Copy Copies weights for highlighted vertices.

Paste Pastes copied weights.

Skin Morph Modifier

The Skin Morph modifier lets you use a bone's rotation to drive a morph; that is, a deformation of the object mesh. Skin Morph is intended for use with Skin or a comparable modifier such as Physique: add the Skin Morph modifier after the skin-type modifier. You create the morph at the frame in which the effect should be greatest, and then Skin Morph automatically animates the affected vertices into and out of the morph, based on the rotation of the bone that drives the morph.

Skin Morph lets you fine-tune mesh deformation at any frame, using a bone to drive the morph that is fixing a problem area. Often, when you animate a character with bones, you have to create extra bones to handle problem areas such as armpits and the groin. With Skin Morph, instead of adding extra bones, you can simply create a morph and then transform vertices into the
exact shape you want. Skin Morph provides an easy way to create muscle bulges and many other effects.

NOTE When working with Skin Morph, it’s important to be familiar with the concept of delta. The frame at which you apply the modifier determines the base position for each vertex that’s used in a morphing animation controlled by Skin Morph. After applying the modifier, go to a frame at which the bone driving the morph is rotated an amount that will cause the greatest deformation, and then transform vertices to produce the morph. The amount by which you transform the vertices is called the delta: the difference between the base pose and the morphed position.

Procedures

To use Skin Morph (basic usage):

1. Create an animated character with bones and a skinned body mesh, using a modifier such as Skin on page 1667 or Physique on page 4470.

2. Go to the “pose frame” and apply the Skin Morph modifier.
   The pose frame contains the initial pose; typically a standing character with arms outstretched and legs apart. This is often frame 0, but it can be any frame, even a negative-numbered one. This is the frame from which the modifier measures delta: the change in the vertex position between this pose and the morph.

3. Determine which bones are driving deformations that you want to modify with Skin Morph.
   For example, bending an arm might cause the inside of the elbow to indent too far, or you might want to add a bulging bicep. In this case, the forearm bone is driving the deformation.

4. Use Add to bind the deformation-driving bones to the modifier.
   The modifier overlays an orange line along the length of each bone you add.

5. Go to the frame where you wish to create the morph. Using the arm-bending example, this might be the frame where the forearm is at a 90-degree angle to the upper arm.

6. In the list box, click one of the bones.
   In the viewport, the orange line representing the bone becomes a thicker yellow line to indicate that this bone will drive the morph.
7 On the Local Properties rollout, click Create Morph. The modifier adds a morph to the highlighted bone and sets the morph to 100% at this frame, as reflected by the number next to the morph's name in the list.

8 On the Local Properties rollout, click Edit. This temporarily freezes the skin deformation at the current frame.

9 Move vertices to where they should be at the current frame.

10 Click Edit again to exit this mode, and then test the animation.

Interface

Skin Morph modifier stack

Points sub-object level At the Points sub-object level, you can view and select vertices on the skin mesh. However, you can transform these vertices only when Edit mode on page 1713 is on. The ability to select points when not in Edit mode lets you make the selection when the points are more easily accessible, and then go to the pose to transform them in Edit mode.
Parameters rollout

[list window] Lists all attached bones and their morphs in a hierarchical view. You can expand or contract a bone's morph listing by clicking the + or - box next to its name in the list. The number in parentheses next to the morph name shows its relative influence as a percentage at the current frame.

Highlighting a bone in the list highlights the bone in the viewports as a yellow line, and lets you create a morph for it. Alternatively, you can select the bone in the viewport while the modifier's Points sub-object level is active by clicking the orange line through its center.

Highlighting a morph in the list lets you edit the morph. To change the morph's name, edit the Local Properties rollout > Morph Name field.

**Add Bone** Click to add one or more bones from the Select Bones dialog.
**TIP** To keep things simple, add only bones that will drive morphs. There's no point in adding any other bones.

**Pick Bone** Lets you add bones by selecting them in a viewport.

Click Pick Bone, and then select bones in any viewport. While Pick Bone is active, the cursor resembles a cross with the words ADD BONE attached. To exit Pick Bone mode, right-click the active viewport or click Pick Bone again.

**Remove Bone** Removes a bone and its morphs from the list. Click a bone name in the list, and then click Remove.

If a morph name is highlighted when you click Remove, its bone is removed. To remove the morph only, highlight it and then click Local Properties rollout > Delete Morph.

**Selection rollout**

Use **Soft Selection** Enables soft selection for editing vertices.

Soft Selection in Skin Morph works much like **Soft Selection** on page 2014 in other parts of 3ds Max, except that instead of Pinch and Bubble settings you
can adjust the graph shape directly, and it uses a Radius setting instead of Falloff to determine the extent of the soft-selection area.

**Radius** Determines the extent of the soft-selection area in system units.

**Edge Limit** When on, Skin Morph uses the Edge Limit numeric setting to determine the extent of the soft-selection area in terms of the number of edges from the selected vertex or vertices.

**Reset Graph** Sets the soft-selection graph to default values. Use this if a vertex or handle is no longer visible and thus cannot be manipulated.

[graph] Skin Morph provides a small, full-functioned curve graph for editing soft-selection characteristics globally; it works much like other such graphs in 3ds Max, such as Curve Editor Introduction on page 3804. The toolbar above the graph offers functions for moving and scaling points on the graph, as well as inserting new ones. The same functions are available by right-clicking the graph: If you right-click a graph point, you can set it to Corner or one of two different Bezier types. If you select a Bezier point, you can reshape the curve by moving its handles.

**Ring** Expands a vertex selection by first converting the selection to an edge selection, selecting all edges parallel to the selected edges, and then converting the new edge selection back to a vertex selection. Use of Ring requires that a qualifying vertex selection exist; that is, at least two vertices on the same edge.

**Loop** Expands a vertex selection by first converting the selection to an edge selection, selecting all aligned edges, and then converting the new edge selection back to a vertex selection. Use of Loop requires that a qualifying vertex selection exist; that is, at least two vertices on the same edge.

**Shrink** Reduces the vertex selection area by deselecting the outermost vertices. If the selection size can no longer be reduced, the remaining vertices are deselected.

**Grow** Expands the vertex selection area outward in all available directions.
Local Properties rollout

This rollout contains functions for creating and editing individual morphs. The settings, such as Morph Name and Influence Angle, are specific to each morph.

Create Morph Sets a morph at the current frame for the highlighted bone. Also sets the “pose” for this morph, using the bone's current orientation, and sets the bone to 100%, as shown in the list window hierarchical view. When you edit the morph, the skinned object returns to and stays at this orientation. When you create a morph, the modifier displays, in orange, all vertices that are part of the current pose (that is, they're offset from the initial pose). Also, the modifier creates a default name for the morph and adds it as a child to the highlighted bone in the list window.
**TIP** By default, the Show Edges switch is on, which might make it difficult to see the vertices themselves. To see only the vertices, turn off Options rollout > Show Edges.

**TIP** To help keep track of morphs, use the Local Properties rollout to rename each morph as you create it.

**Delete Morph** Deletes the highlighted morph, removing it from its parent bone in the list window. Available only when a morph is highlighted.

**Edit** Lets you shape the current morph by transforming vertices. To exit Edit mode, click the Edit button again.

Transforming a vertex in Edit mode creates a morph target. Each transformed vertex moves into the morph target position (or orientation or scale) as the morph value increases to 100.0, and then out of it as the morph value decreases, based on the angle of the bone driving the morph.

Transforming a vertex in Edit mode also changes its color from orange to yellow. This lets you easily see which vertices are part of the current morph.

Choosing Edit places the skinned object at the 100% “pose” orientation for this morph (see Create Morph, above). It also activates the Points sub-object level so you can transform vertices using the standard 3ds Max transform tools.

**Clear Vents** Keeps selected vertices in the morph, but resets their deltas (changes from the initial pose) to 0.

**Reset Orientation** Sets the morph orientation to current orientation of the bone that controls the morph.

This lets you change the angle at which the morph has its greatest effect. For example, if you create a bulging bicep at frame 120, and later decide that the muscle should be largest at frame 150 instead, go to frame 150, choose the morph in the list box, and then click Reset Orientation.

**Remove Verts** Removes selected vertices from the current morph, which deletes any animation applied as part of the morph.

Use this command to save memory by removing vertices not part of the morph animation.

**Enabled** When on, the morph is active; when off, the morph doesn't appear in the animation, and is indicated in the list box with the text “Disabled.” Default=on.

The ability to enable and disable each morph individually lets you isolate the effect of each or test them in combination.
Morph Name Displays and lets you change the name of the current morph.

Influence Angle The angle around the bone's current orientation within which the morph takes place. Default=90.0.

This is an important parameter. Think of the influence angle as a cone around the bone at its orientation when you create the morph. Consider an example in which Influence Angle is set to the default value of 90.0 degrees. If the bone starts its rotation beyond 45 degrees away from the orientation at which the morph was created, the morph has no effect at that time. As the bone moves from 45 degrees away to the morph orientation, the morph increases to its full value. As the bone then rotates away, the morph gradually decreases until, at 45 degrees or more away from the morph orientation, the morph no longer appears.

Tips Influence Angle is useful for isolating morphs; that is, to prevent overlapping of different morphs on the same bone. Reduce the value until one morph's contribution percent value (shown in the list box) falls off to 0.0 before the next one begins.

Falloff Determines the rate of change of the morph as the bone moves within the influence angle. Use the drop-down list to choose one of four different falloff types: Linear, Sinual, Fast, or Slow. If you choose Custom Falloff, you can then click the G (for Graph) button and edit the falloff using standard curve-graph controls.

Tips The default graph, displayed when you first access the falloff graph, shows the Sinual falloff type.

Joint Type Determines how the modifier tracks the angular motion of the bone. This is a per-bone setting, not per-morph. Default=Ball Joint.

- Ball Joint Tracks all rotation of the bone. Use this setting in most cases.
- Planar Joint Tracks rotation of the bone only in the plane of its parent bone.

External Mesh Lets you use a different mesh as a morph target. Click the button (default label=-none-) and then select the target object. The target object should have the same mesh structure as the Skin Morph object. After specifying an external mesh, its name appears on the button.

Using an external mesh makes it easier to set up morph targets in a target mesh that uses a reference pose, rather than the skinned, animated mesh of which sections might be interpenetrating, making it difficult to select the
specific vertices to be morphed. In this situation, it's probably best to turn Reload Only Selected Verts.

**NOTE** The external-mesh connection is not live; if you edit vertices in the external mesh, Skin Morph doesn't automatically recognize the changes. To update the vertex positions after editing the external mesh, use Reload Target (see following).

**Reload Target** Updates the Skin Morph object with edited vertex positions from the external mesh.

**Reload only selected verts** When on, Reload Target copies only the positions of vertices selected in the Skin Morph mesh from the target mesh. When off, Reload Target copies the positions of all vertices. Default=off.

**Copy and Paste rollout**

These functions let you copy all morph targets for a specific bone from one side of the object to the other. Indicate the morphs to copy by highlighting the bone or any of its morphs in the Parameters rollout > list box.

**Paste Mirror** Copies the morphs from the highlighted bone to the target on the other side of the mirror gizmo. A qualified target bone must exist and be present in the list box.

**NOTE** This copies the morph data only; the rotation of the target bone must be comparable to that of the source bone for the morphing to appear in the animation.
**Show Mirror Plane** Displays the mirror plane as a red, rectangular gizmo in the viewports. The target bone must be on the opposite side of the mirror plane from the highlighted bone, and must be present in the Parameters rollout > list box.

**Preview Bone** Highlights the target bone in red in the viewports.

**Preview Vertices** Displays the morphing-qualified vertices in red in the viewports, as well as any animation present in the source vertices.

**Mirror Plane** The axis for the mirror plane. The plane is perpendicular to the indicated axis. Default=X.

**Mirror Offset** The position for the mirror plane on the Mirror Plane axis. Default=0.0.

**Mirror Threshold** The radius, in system units, within which Skin Morph looks for a qualifying target bone on the other side of the mirror plane. Default=1.0.

**Options rollout**

<table>
<thead>
<tr>
<th>- Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Beginner Mode</td>
</tr>
<tr>
<td>Show Driver Bone Matrix</td>
</tr>
<tr>
<td>Show Morph Bone Matrix</td>
</tr>
<tr>
<td>Show Current Angle</td>
</tr>
<tr>
<td>Show Edges</td>
</tr>
</tbody>
</table>

**Beginner Mode** When on, you must use the Create Morph button to create a morph and the Edit button to edit a morph.

When off, you can create and edit morphs on the fly. In this mode, when you select and move vertices at the Points sub-object level, 3ds Max first determines whether a morph exists for the selected bone at 100%; if so, all edits will go
to that morph. Otherwise, 3ds Max creates a new morph automatically and applies the edits to that morph.

**Show Driver Bone Matrix** Shows the matrix tripod of the current bone.

**Show Morph Bone Matrix** Shows the tripod of the orientation of the active morph.

**Show Current Angle** Shows pie wedges depicting the angles between the driver bone matrix and the morph bone matrix. These are color coded: red for the angle about the X axis; blue for the angle about the Y axis; and green for the angle about the Z axis.

**Show Edges** Highlights the edges connected to morphable vertices in orange. This is useful when a tessellating modifier such as MeshSmooth is applied to the skinned mesh above the Skin Morph modifier, to see the actual mesh being affected by Skin Morph.

**Matrix Size** The size of each tripod.

**Bone Size** The size of the bone display.

## Skin Wrap Modifier

Make a selection. > Modify panel > Modifier List > Object-Space Modifiers > Skin Wrap

The Skin Wrap modifier allows one or more objects to deform another. While Skin Wrap is flexible enough to serve a variety of needs, it's primarily intended for animating a high-resolution object, such as a character mesh, with a low-resolution one.

The low-resolution object doing the deforming is called a **control object**, and the high-resolution object it's affecting (that is, the one with the Skin Wrap modifier) is the **base object**. A base object can be any type of deformable object. Also, in this topic, **control vertex** refers to a vertex on the control object, and **point** refers to a vertex on the base object.

With Skin Wrap, you can modify the structure and topology of the high-resolution object after setting up the animation. The animation remains intact because it is actually contained in the control object.

In most cases, when using Skin Wrap, the control object is positioned near the modified base object, and then bound to the latter using the modifier's Add function. By default, moving a vertex in the control object affects nearby vertices in the base object. Additional options allow faces in the control object
to affect the nearest points in the base object instead (Blend To Base Object). Conversely, points in the control object can affect faces in the base object (Face Deformation).

Skin Wrap offers a great deal of control in that you can set a different strength value for each control vertex, as well as the shape of its volume of influence. You can also convert the Skin Wrap effect to a Skin modifier applied to the high-res model, suitable for use with game engines. And the ability to animate with multiple control objects lets a technical director assign animation of different parts of a complex character mesh to various artists.

**TIP** If you use a control object to which non-uniform scaling has been applied, its vertices will have non-spherical volumes of influence, which can lead to unexpected results. In such a case, before adding the control object to the modifier, apply Reset XForm on page 912 and then collapse the stack.

See also:
- Skin Wrap Patch Modifier on page 1726

**Procedures**

To use Skin Wrap (basic method):

1. Create a high-resolution base object and one or more low-resolution control objects, which will deform the base object. In general, each control object should have an overall shape similar to the part of the base object that it will deform, and be positioned near that part of the base object.

2. Apply Skin Wrap to the high-resolution base object. The modifier transfers animation or modeling from the control object to the base object.

3. On the Skin Wrap > Parameters rollout, use Add to assign the control object(s).

4. Choose a deformation engine: Vertex or Face.

5. Set global parameters as desired. These parameters affect all control vertices, and include Deformation Engine, Falloff, Distance Influence, and Face Limit.

6. To set local parameters, including strength and influence distances, access the Control Vertices sub-object level of the Skin Wrap. Select one or more control vertices, and then change the settings as necessary.
7 Edit or animate the control object with modifiers and/or sub-object transforms; the high-resolution (base) object deforms accordingly.

8 Repeat steps 5, 6, and 7 as necessary. Occasionally you might need to reset the modifier as well, by clicking the Reset button. Before doing so, always return to a non-deformed point (or “skin pose”) in the animation; typically, frame 0.

Interface

Skin Wrap modifier stack

Control Vertices sub-object level At the Control Vertices sub-object level, you can view and select vertices on the control object(s), and set local parameters on page 1722 for any selected vertices. By default, each selected vertex is surrounded by loops on page 1725 that depict its volume of influence. This sub-object level also uses color coding on affected points in the base object to show each selected vertex's relative effect on points within the volume of influence. Colors range from orange for the strongest influence to blue for the weakest influence. Red is for vertices that are within its range of influence but that it's not influencing.

By default, at this level, control vertices appear as small orange squares. To prevent this, turn off Display Parameters rollout > Display Control Vertices.
Parameters rollout

Deformation Engine
- Vertex Deformation

- Falloff: 1.0
- Distance Infl.: 1.2
- Face Limit: 3.0

- Blend To Base Mesh
- Blend Distance: 5.0

- Local Str.: 1.0
- Local Scale Mult.: 1.0
- Local X: 1.76
- Local Y: 1.76
- Local Z: 1.76

- Reset

- Threshold: 5.0

- Weight All Points
- Convert To Skin
[control object list] Lists object(s) that deform the modified object. Use the Add and Remove functions to edit the list contents.

Add Adds control objects to the list. Click Add, and then click each control object in turn. To stop adding, right-click in the viewport or click Add again. You can use as a control object anything that can be converted to a triangle mesh, such as a mesh, patch, or a NURBS object. However, avoid using objects that change topology, such as a deforming NURBS object with adaptive tessellation.

Remove Removes control objects from the list. Click an object in the list, and then click Remove.

Deformation Engine Determines which engine drives the deformation. Default=Vertex Deformation.

- The Vertex Deformation engine is a weighted engine; it uses vertex proximity to drive the deformation. That is, each vertex in the control object affects nearby points in the high-resolution (base) mesh.

- With the Face Deformation engine, each control vertex is tied to the closest face in the base object. Face deformation can use falloff, or be a rigid deformation by setting Falloff to 0.001, the lowest possible value.

Falloff Determines the extent to which the control vertices affect nearby points in the base object. This is a global setting. Default=1.0. Range=0.001 to 10.0.

Higher values pull nearby points closer to the control vertex. In Face Deformation mode, setting Falloff to the lowest value, 0.001, causes rigid deformation so that there’s no falloff; the control vertex either affects the base-object face or it doesn’t. For best results, use Falloff values between 1.0 and 2.0, or with Face Deformation, 0.001 for rigid mode.

Distance Influence Determines the distance of influence, in system units, of control vertices in the control object. This is a global setting, and is available only in Vertex Deformation mode. Default=1.2. Range=0.001 to 10.0.

Distance Influence is a multiplier. It looks at the length of each edge that touches each control vertex. For each vertex, it averages all the lengths and then multiplies the average by the Distance Influence value. This lets vertices that are touching only small faces to affect a small area, and vice-versa. The higher the influence value, the smoother the deformation, but the less individual control each vertex has. For best results, keep this value between 1.0 and 2.0.
**Face Limit** Determines the extent of influence, in control-object faces, of control vertices in the control object. This is a global setting, and is available only in Vertex Deformation mode. Default=3. Range=0 to 30.0. Beyond this limit, no base-object points can be influenced by the control vertex, even if they're within the Distance Influence radius. Face Limit is useful for preventing the control-object influence from bridging gaps in the mesh; for example, between fingers in a character mesh.

**Blend To Base Mesh** Causes the modifier to base deformation on the distance from each affected point to the closest face in the control object. Turning on this option makes the Blend Distance setting available.

**Blend Distance** Determines the relative distance between control-object faces and vertices in the base object for deformation to take effect. Available only when Blend To Base Mesh is on. Default=5.0. Increasing this setting effectively causes a stronger deformation effect and broadens the area on the control that affects the base object.

**[local parameters]**

The Local parameters are available only at the Control Vertices sub-object level (see Skin Wrap modifier stack on page 1719), and affect only selected points. If you select a single point, the numeric fields reflect its current parameter values. If you select multiple points, 3ds Max displays only those values common to all selected points; parameters with differing values are blank. With multiple points selected, changing a value sets all selected points to that value.

**Local Str(ength)** Determines the power and direction by which the control-object vertex affects points under its influence in the base object. A positive value pulls the points toward the vertex; a negative value pushes them away. Default=1.0.

**Local Scale Multiplier** Scales each selected control-object vertex's volume of influence uniformly. Default=1.0. Use the scale settings to increase or decrease the area of the base object that the selected control vertex affects.

**Local X/Y/Z** Scales each selected control-object vertex's volume of influence along the indicated axis. Default=1.0. Change these parameters to produce a non-spherical volume of influence.
**Reset** Resets all control-object vertices' local values to 1.0 and resamples the mesh. It recalculates the control vertices' influence on the base object using the current modifier settings.

Use Reset if you alter a parameter but don’t see any change in the deformation. For example, always use Reset after changing the Threshold value. Or, if you want the control object to affect a different part of the base object, move the former, and then use Reset so the modifier accounts for the change in positional relationship between the two. You might also need to reset after changing the topology of the base object or a control object.

**IMPORTANT** Use Reset at a point in the animation where no deformation is in effect; typically, frame 0.

**Threshold** Determines the distance in system units that 3ds Max uses to find the closest face to a control vertex. The greater the distances by which the control object's and base object's surfaces deviate, the higher the Threshold value needs to be. Default=5.0.

**NOTE** Threshold is recomputed only when you add a base mesh or click Reset.

**WARNING** Be careful about increasing this setting. High values can result in excessive computation times, especially with complex base objects.

**Weight All Points** Forces all base-object points to have weights. Each weight is calculated from a combination of three factors: control vertex scale, control vertex strength, and base-object point position.

By default, not all base-object points are necessarily influenced by the control object. Turning on Weight All Vertices causes all points to be influenced by one or more control vertices. If a large number of base-object points are unassigned, this can take a long time to calculate.

**Convert To Skin** Applies a new Skin modifier on page 1667 to the base object that replicates the animation in the Skin Wrap modifier. Using this function requires that a Skin modifier already be applied to each control object.

Basically, Convert To Skin intelligently “bakes” the animation from skinned low-res control objects to the high-res base object. The Skin modifier that it creates contains all the bone assignments from the original Skin modifier, but with completely rebuilt weight settings based on the base-object weights created by the Skin Wrap modifier.

This function is useful in game-development settings where the game engine recognizes the Skin modifier settings but not the Skin Wrap modifier.
Advanced Parameters rollout

The Mirror tools in Skin Wrap let you apply local settings (Strength and Scale) from control vertices on one side of a control object to the other, mirroring them across a plane aligned with the X, Y, or Z axis. This is useful for setting up character meshes.

**NOTE** Mirror copies only Skin Wrap settings from control vertices; it doesn't copy animation data. Thus, when using Skin Wrap with a character model, first make local settings for control vertices on one side of the control object, select the vertices to copy, mirror them, and then animate the control object.

The Bake/Retrieve Control Vertices functions let you store control-vertex settings into the base object and then retrieve them. This is useful for sharing data among artists working on the same project.

**Show Mirror Data** Turns on display of the mirror plane gizmo as well as a small circle showing the projected location for each selected control vertex. Move the gizmo and the projected locations with the Mirror Offset control (see following).

**NOTE** For mirror data to be visible, the Skin Wrap > Control Vertices sub-object level must be active.

**Mirror Plane** Choose the X, Y, or Z axis for mirroring.
**Mirror Offset** Moves the mirror plane as well as all mirrored vertices.

**Mirror Threshold** Sets the distance, in system units, that Skin Wrap uses to find a control vertex near a projected vertex. Increase this if vertex locations are not the same on either side of the mirror plane.

**Mirror Selected** Copies the local settings from each selected control vertex to any control vertices within the threshold distance of its projected location on the other side of the mirror plane.

**Bake Control Verts** Stores the Local Strength/Scale and the global Falloff, Distance Infl., and Face Limit settings on the control objects for later retrieval with Retrieve Control Vertices.

**NOTE** This data is static; any changes to the base-object topology invalidates it.

**Retrieve Control Verts** Takes any control-vertex data stored on the control objects with Bake Control Vertices and copies them into the modifier.

**Display Parameters rollout**

These settings determine whether or not 3ds Max displays different elements in the Skin Wrap modifier.

**Display Loops** Displays volumes of influence for selected control vertices as red loops. Default=on.

**Display Axis** Displays the axis tripods for selected control vertices. Default=on.

**Display Face Limit** Shows all base-object points that the selected control vertex or vertices can affect. This is a visualization of the Face Limit setting on page 1722. Default=on.
Display Unassigned Points  Draws a red circle around each base-object point that the system did not find a closest face for and draws a red box around each point that has a closest face but is not weighted by any control vertex. Default=off.

Unassigned points: The circled points (bottom) have no closest face, while the points with red boxes (center) have a closest face but aren't weighted by control vertices.

This is an important debugging tool because any vertex that is not assigned a closest face will never be weighted. To do so, you need to increase the Threshold value and click Reset, or turn on Weight All Points. Any points that are not weighted to a control vertex can be fixed by increasing the Local Scale of a control vertex near that point.

Display Control Verts  Toggles display of all control vertices. Default=on.

Skin Wrap Patch Modifier

Make a selection. > Modify panel > Modifier List > Object-Space Modifiers > Skin Wrap Patch
Skin Wrap Patch is a simple modifier that allows a patch object to deform a mesh object. It's very easy to use: just assign the modifier to a mesh object, and then use the modifier to specify a deforming patch object. Each point on the patch object influences a surrounding volume of points on the mesh object.

See also:

- Skin Wrap Modifier on page 1717

Interface

Pick Patch Click this button, labeled “None” by default, and then select a patch object to deform the mesh object. After picking the patch object, its name appears on the button.

Sample Rate Determines the accuracy with which the modifier samples the patch object. The higher the rate, the more accurate the resulting animation will be, but the longer it will take to calculate.

Resample Forces the system to resample the date. This should be done at a point in the animation at which no deformation takes place; typically, frame 0.

Slice Modifier

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Slice
Select an object. > Modifiers menu > Parametric Deformers > Slice
The Slice modifier lets you create a cutting plane that slices through a mesh, creating new vertices, edges and faces based on the location of the slice plane gizmo. The vertices can either refine or split the mesh according to the selected options.

The Slice modifier slices through groups, selected objects or sub-object selections of faces. It works similarly to the Editable mesh > Edge > Slice function but does not require the objects to be editable meshes.

The Slice cuts through the cake.

You can animate the cutting plane, changing its position and rotation over time. You can also use the Remove Top and Remove Bottom options to create the appearance and disappearance of objects by animating the Slice Plane gizmo.
Multiple Slices

To create multiple slices in an object you need to apply multiple Slice modifiers. If the geometry doesn't need to remain parametric, you can collapse it into an editable mesh and use the Slice tool available under Editable Mesh (Edge) on page 2209. This tool is easier to use when you need to make multiple slices in an object, but it does not stay parametric.

Warning: Slice and Sub-Object Selections

You can use Slice on sub-object selection sets by slicing or removing only the selected faces. However, because selected faces are sliced and unselected adjacent faces are not, there may be "holes" in the mesh on the edge where the slice occurs. These holes can be problematic, creating discontinuities in smoothing and rendering. Holes are created only when Operate On Faces is on.
Procedures

Example: To animate the appearance of a teapot using the Slice modifier:

1. Create a teapot on page 416 primitive. Set the viewport to wireframe.
2. Apply a Slice modifier.
   The Slice Plane gizmo appears at the base of the teapot.
3. On the stack display, choose the Slice Plane gizmo.
4. Turn on the Auto Key button, and move the time slider to frame 100.
5. Move the Slice Plane gizmo above the top of the teapot. Play the animation to verify that the slice plane is animated.
6. Change the Slice type from Refine Mesh (the default) to Remove Top. Play the animation again.
7. Make a copy of the teapot in the same position (choose Edit menu > Clone and click OK to accept the default settings).
8. Put a Wireframe material on the clone and change the Slice type on the clone to Remove Bottom.
9. Play the animation.
   The wireframe teapot magically becomes a fully shaded one.

Example: To slice vertically through an object:

1. Create a teapot on page 416 primitive.
2. Apply a Slice modifier.
The Slice Plane gizmo appears at the base of the teapot.

3 On the stack display, open the Slice modifier and choose the Slice Plane gizmo.

4 Move the Slice Plane gizmo so it intersects the middle of the teapot.

5 Rotate the Slice Plane gizmo so it is vertical.

6 Turn on Remove Top.
   The back of the teapot is sliced away.

7 Turn on Remove Bottom.
   The front half of the teapot is sliced away.

Interface

Modifier Stack

Slice Plane At this sub-object level, you can transform and animate the gizmo like any other object to determine where the slice occurs. Scaling the gizmo has no effect, because its extents are effectively infinite. If you need to limit the extent of the slice, use it on a sub-object selection set of faces, rather than on the entire object.

For more information on the stack display, see Modifier Stack on page 8187.
Slice Parameters rollout

Slice Type Defines how the slice plane will affect the geometry to which it has been applied.

- **Refine Mesh**  Adds new vertices and edges along the intersection of the geometry with the slicing plane. Faces cut by the plane are subdivided into new faces.

- **Split Mesh**  Adds a double set of vertices and edges along the plane boundary producing two separate meshes (one on either side of the slice plane), which you can modify differently if desired. Use this to break a mesh in two.

- **Remove Top**  Deletes all the faces and vertices above the Slice Plane.

- **Remove Bottom**  Deletes all the faces and vertices below the Slice Plane.

Operate On Choose one of these buttons to specify how the slice handles quads and other polygons.

- **Faces**  Treats the selection set as a set of triangular faces, slicing each one in turn. Outputs a mesh-type object on page 2192.

- **Polygons**  Converts the object to a polygon mesh based on visible edges, eliminating hidden edges. Outputs a polymesh-type object on page 2240.
Smooth Modifier

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Smooth

Select an object. > Modifiers menu > Mesh Editing > Smooth

The Smooth modifier provides auto-smoothing based on the angle of adjacent faces. You can apply new smoothing groups to objects.

Smoothing eliminates the facets on geometry by grouping faces into smoothing groups. At render time, faces in the same smoothing group appear as a smooth surface.
1. No smoothing applied
2. Smoothing threshold=15
3. Smoothing threshold=30

**Patches**

As of 3ds Max 4, patch objects coming up the modifier stack are not converted to a mesh by this modifier. A patch object input to the Material modifier retains its patch definition. Files that contain patch objects with the Material modifier from previous versions of 3ds Max will be converted to meshes to maintain backward compatibility.
Procedures

To smooth an object:

1. Select the object to be smoothed.

2. On the Modifiers menu, choose Mesh Editing > Smooth.

3. On the Modify panel, choose Object-Space Modifiers > Smooth from the Modifier List.

4. Turn on Auto Smooth and adjust the Threshold for the desired smoothing effect.

To apply smoothing groups manually:

1. Select an object.

2. Use a Mesh Select modifier on page 1500 to select the faces to be smoothed.

3. Click a numbered button to apply the corresponding smoothing group to the selected faces.

Interface

Parameters rollout

```
- Parameters

- Auto Smooth
- Prevent Indirect Smoothing

Threshold: 30.0

Smoothing Groups:

1  2  3  4  5  6  7  8
9 10 11 12 13 14 15 16
17 18 19 20 21 22 23 24
25 26 27 28 29 30 31 32
```
**Auto Smooth** If Auto Smooth is selected, the object is auto-smoothed using the (animatable) threshold specified by the Threshold setting below it. Auto Smooth sets the smoothing groups based on the angle between faces. Any two adjacent faces are put in the same smoothing group if the angle between their normals is less than the threshold angle.

**Prevent Indirect Smoothing** Turn on to prevent smoothing "leaks" when using Auto Smooth. If you apply Auto Smooth to an object, and portions of that object that should not be smoothed become smoothed, then turn on Prevent Indirect Smoothing to see if it corrects the problem.

**Threshold** Specifies the threshold angle in degrees. Any two adjacent faces are put in the same smoothing group if the angle between their normals is less than the threshold angle.

**Smoothing Groups group**

The grid of 32 buttons shows which smoothing groups are used by the selected faces, and are used to assign smoothing groups manually to selected faces.

**Spherify Modifier**

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Spherify

Select an object. > Modifiers menu > Parametric Deformers > Spherify

The Spherify modifier distorts an object into a spherical shape. This modifier has only one parameter: a Percent spinner that deforms the object, as much as possible, into a spherical shape.
Spherify shapes the dog inside the snake.

The success of the operation depends on the topology of the geometry to which it's applied. For example, a cylinder with no height segments will result in little change. Adding height segments will result in a barrel at 100 percent. Adding cap segments will produce a sphere.

Try this on a teapot on page 416.

**Procedures**
