**Example: To use the spherify modifier to distort a teapot:**

1. Click Create > Geometry > Standard Primitives > Teapot.
2. Create a teapot in the viewports.
3. On the Modify panel, choose Spherify from the Modifier List. The teapot should now look like a sphere.
4. Adjust the Percent setting to less than 100%.
Example: To animate spherifying a teapot:

1. Click Create >Geometry > Standard Primitives > Teapot.
2. Create a teapot in the viewports.
3. On the Modify panel, choose Spherify from the Modifier List.
4. Turn the Auto Key button on.
5. Set the Spherify Percent to 0.
6. Move the time slider ahead to frame 30.
7. Set the Spherify Percent to 100.
8. Turn the Auto Key button off.
9. Drag the time slider to play the animation, or click Play.

Interface

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Percent:</td>
</tr>
<tr>
<td>100.0</td>
</tr>
</tbody>
</table>

**Percent** Sets the percentage of spherical distortion to apply to an object.

**Spline IK Control Modifier**

Select a spline or NURBS curve > Modify panel > Modifier List > Spline IK Control

When the Spline IK Control modifier is applied to a spline, you can select and transform its vertices without having to access the vertex sub-object level. It can also place helpers at each vertex location to aid in moving vertices.

The Spline IK Control modifier works by placing knots (control points) at each vertex. The knots can then be used to control vertices, which in turn reshape the spline.
This modifier also works on NURBS curves, placing a knot at each control point or control vertex (CV).

Use the Spline IK Control modifier to prepare a spline or NURBS curve for use with the Spline IK Solver.

See also:

- Spline IK on page 3733

Interface

Control Objects When helpers are created, knot numbers and their corresponding names appear here. Knot #1 is placed at the first vertex on page 8578 on the spline, and additional knots are numbered in sequence.

Create Helpers Places a helper at each knot, and displays knot numbers and helper names in the Control Objects area. Helper display is based on selections in the Helper Display group. Helpers are linked upon creation if a linking option is selected in the Link Types group.
**Link Types group**

These options cause helpers to be linked upon creation.

**Link All in Hierarchy** Links each helper to its immediately previous helper. For example, the helper at knot #3 is linked to the helper at knot #2, while the helper at knot #2 is linked to the helper at knot #1.

**Link All to Root** Links each helper to the helper at knot #1.

**No Linking** Helpers are not linked.

**Helper Display**

When you click Create Helpers, 3ds Max can place one or more Point helper objects at each knot, making it easier to move and animate the knots. You can enable more than one type of helper.

**Center Marker** Places a small X-shaped Point helper at each knot.

**Axis Tripod** Places a small tripod-axis-shaped Point helper at each knot.

**Cross** Places a small cross-shaped Point helper at each knot.

**Box** Places a small box-shaped Point helper at each knot.

**Size** Sets the size for helpers.
**Constant Screen Size** Keeps the sizes of helpers constant regardless of the zoom extent of the viewports.

**Draw On Top** Displays the helpers on top of all other objects in the scene for improved visibility in busy scenes.

**TIP** To change the display of helpers after creation, select each helper and change selections on the Modify panel.

---

**Spline Select Modifier**

Select a shape. > Modify panel > Modifier List > Object-Space Modifiers > Spline Select

Select a shape. > Modifiers menu > Selection Modifiers > Spline Select

The Spline Select modifier passes a sub-object selection of shapes up the stack to subsequent modifiers. It provides much of the same set of selection functions available in the *Edit Spline modifier* on page 1424. You can select vertices, segments, or splines, and you can change the selection from sub-object level to object level.

This modifier is similar to the *Mesh Select* on page 1500 and *Poly Select modifiers* on page 1582, except for the type of sub-object components.

**Procedures**

**To use the Spline Select modifier:**

1. Create a multi-spline shape.
2. Apply a Spline Select modifier.
   By default, the Vertex sub-object level is active.
3. If you wish to work at a different sub-object level, use the modifier stack display to choose it.
4. In the viewports, select vertices, segments, or splines.

**TIP** You can transform the selection using an *XForm modifier* on page 2010 or *Linked XForm modifier* on page 1484.
Interface

Modifier Stack

The sub-object level you choose for the spline select modifier determines which rollout appears. (There are no parameters at the top, object level.)

**Vertex** Creates a sub-object selection of vertices.

**Segment** Creates a sub-object selection of segments.

**Spline** Creates a sub-object selection of splines.

For more information on the stack display, see Modifier Stack on page 8187.

Select Vertex rollout

**Get Segment Selection, Get Spline Selection** Select vertices based on the last Segment or Spline selection. This selection is added to the current selection. Available only when Vertex is not the current sub-object level.
Select Segment rollout

Get Vertex Selection, Get Spline Selection Select segments based on the last vertex or spline selection. The selection is added to the current selection. Available only when Segment is not the current sub-object level.

Select Spline rollout

Get Vertex Selection, Get Segment Selection Select splines based on the last vertex or segment selection. The selection is added to the current selection. Available only when Spline is not the current sub-object level.

Copy/Paste Selection controls (all rollouts)

Copy Places a named selection into the copy buffer.

Paste Pastes a named selection from the copy buffer.

You can copy a named selection from one object to another or one modifier to another. You must copy and paste in the same sub-object level.
Squeeze Modifier

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Squeeze

Make a selection. > Modifiers menu > Parametric Deformers > Squeeze

The Squeeze modifier lets you apply a squeezing effect to objects, in which the vertices closest to the object's pivot point move inward. The squeeze is applied around the Squeeze gizmo's local Z axis. You can also use Squeeze to create a bulge on the vertical axis, to accentuate the squeeze effect.

Left: Original object
Middle and Right: Varying squeeze amounts

Interface

Modifier Stack

Gizmo At this sub-object level, you can transform and animate the gizmo like any other object, altering the effect of the Squeeze modifier. Translating the gizmo translates its center an equal distance. Rotating and scaling the gizmo takes place with respect to its center.

Center At this sub-object level, you can translate and animate the center, altering the Squeeze gizmo's shape, and thus the shape of the squeezed object.

For more information on the stack display, see Modifier Stack on page 8187.
Parameters rollout

Axial Bulge group

These controls let you apply a bulge effect along the Squeeze gizmo's local Z axis, which is aligned by default with the object's local Z axis.

Amount Controls the magnitude of the bulging effect. Higher values effectively elongate the object and cause the ends to curve outward.

Curve Sets the degree of curvature on the bulging ends. You can use this to control whether the bulge is smooth or pointy.

Radial Squeeze group

These controls let you apply a squeeze effect around the Squeeze gizmo's local Z axis, which is aligned by default with the object's local Z axis.

Amount Controls the magnitude of the squeezing action. Values larger than zero tend to constrict the “waist” of the object, and values less than zero tend to bulge the waistline out, as if the object had been stepped on.
Curve  Sets the degree of curvature into the squeeze. Low values cause a sharp squeezing effect, while high values create a gradual, less pronounced squeeze.

**Limits group**

These controls let you limit the squeeze effect's extents along the local Z axis.

**Limit Effect** Limits the extent of the squeeze effect as defined by the Lower and Upper Limit settings.

**Lower Limit** Sets the limit in the positive direction along the Z axis.

**Upper Limit** Sets the limit in the negative direction along the Z axis.

**Effect Balance group**

**Bias** Changes the relative amounts of bulge and squeeze while retaining a constant object volume.

**Volume** Increases or decreases the effects of both Squeeze and Bulge in parallel.

**STL Check Modifier**

Select an object. > Modify panel > Modifier List > STL Check

Select an object. > Modifiers menu > Mesh Editing > STL check

The STL Check modifier checks an object to see if it's correct for exporting to an STL (stereolithography) file format on page 7784. Stereolithography files are used by specialized machines to produce prototype physical models based on the data in the STL file.

To create a physical model, an STL file must have a complete and closed surface. Using STL Check to test your geometry before you export it can save time and money when the file is used to create the physical model.
STL Check errors.
1. Open edges
2. Double face
3. Spikes
4. Multiple edges

Procedures

To check an object for STL compatibility:

1. Select the object, then on the Modify panel, choose Mesh Editing > STL Check from the Modifier List.
2. Turn on Check.
   The message in the Status group shows if errors are found. STL Check indicates errors by selecting the problem geometry, assigning it a special material ID, or both.
Errors group

Choosing one of these options selects incorrect geometry specific to the choice, and selects it depending on the option chosen in the Selections group.
Open Edge  Checks for open edges (holes).

Double Faces  Checks for faces that share the same 3D space.

Spike  Checks for spikes, which are isolated faces that share only one edge with the object.

Multiple Edges  Checks for faces that share more than one edge.

Everything  Checks for all of the above.

**TIP** While checking Everything takes the longest amount of time, it is recommended if you plan to use the STL file for generating a physical model.

**Selections group**

These options specify the level of incorrect geometry that's selected, based on the settings in the Errors group.

**Don't Select**  When on, STL Check doesn't select any part of objects in error.

**Select Edges**  When on, STL Check marks the edges of faces in error by selecting them. The selection of erroneous edges is visible in viewports.

**Select Faces**  When on, STL Check marks the faces of any object in error by selecting them. The selection of erroneous faces is visible in viewports.

**Change Mat-ID**  When on (the default), STL Check also marks faces in error by assigning them a unique material ID. Use the spinner to choose the value of the material ID that STL Check uses.

**Check**  Turn on to perform the STL check. For complex models, expect a pause between the time you turn this on, and the time you see the reported errors in the Status group. Default=off.

**Status**  Displays the number of errors when Check is on.

**TIP** If Select Edges is turned off, you can see faces in error by applying an Edit Mesh modifier on page 1321 and selecting by material ID at the Face sub-object level. You can also assign a Multi/Sub-Object material on page 6120 to the object to help you see where the errors are.

---

**Stretch Modifier**

Select an object. > Modify panel > Modifiers List > Object–Space Modifiers > Stretch
Select an object. > Modifiers menu > Parametric Deformers > Stretch

The Stretch modifier simulates the traditional animation effect of "squash-and-stretch." Stretch applies a scale effect along a specified stretch axis and an opposite scale along the two remaining minor axes.

The amount of opposite scaling on the minor axes varies, based on distance from the center of the scale effect. The maximum amount of scaling occurs at the center and falls off toward the ends.

Applying a Stretch modifier to the object on the left creates the object on the right.

Procedures

To stretch an object:

1. Select an object.
2. Apply Stretch.
3. On the Parameters rollout > Stretch Axis group, choose X, Y, or Z.
4. On the Parameters rollout > Stretch group, enter a value in the Stretch field.
5 Adjust the Parameters rollout > Stretch group > Amplify setting to change the amount of scaling along the minor axes.

**To limit a stretch:**

1 Apply a Stretch modifier to an object and specify the stretch amounts and stretch axis.
2 On the Parameters rollout > Limits group, turn on Limit Effect.
3 Set values for the Upper and Lower Limits to define the Stretch boundaries on either side of the Stretch center.
4 In the stack display, choose the Center sub-object level, and move the center to locate the limited stretch effect.

**Interface**

**Modifier stack**

**Gizmo** At this sub-object level, you can transform and animate the gizmo like any other object, altering the effect of the Stretch modifier. Translating the gizmo translates its center an equal distance. Rotating and scaling the gizmo takes place with respect to its center.

**Center** At this sub-object level, you can translate and animate the center, altering the Stretch gizmo's shape, and thus the shape of the stretched object.
Use options in the Parameters rollout to set the following:

- Amount of stretch
- Major stretch axis
- Area affected by the stretch

**Stretch group**

The Stretch group of the Parameters rollout has two fields that control the amount of stretch scaling applied.

**Stretch** Sets the base scale factor for all three axes. The scale factor derived from the Stretch value varies according to the sign of the value.

- Positive stretch values define a scale factor equal to Stretch+1. For example, a stretch value of 1.5 yields a scale factor of 1.5+1=2.5, or 250 percent.
Negative stretch values define a scale factor equal to \(-1/(\text{Stretch}-1)\). For example, a stretch value of -1.5 yields a scale factor of \(-1/(-1.5-1)\)=0.4, or 40 percent. The calculated scale factor is applied to the selected stretch axis and the inverse scale is applied to the minor axes.

![Stretch values of 0.0, 0.5, and -0.5](image)

**Amplify** Changes the scale factor applied to the minor axes. Amplify generates a multiplier using the same technique as stretch. The multiplier is then applied to the Stretch value before the scale factor for the minor axes is calculated. Amplify values affect scaling along the minor axes in the following way:

- A value of 0 has no effect. It uses the default scale factor calculated from the Stretch amount.
- Positive values exaggerate the effect.
- Negative values reduce the effect.
Stretched objects with Amplify values of 0.0, 1.0, and -1.0.

**Stretch Axis group**

You select which of the object's local axes is the Stretch Axis using options in the Stretch Axis group of the Parameters rollout.

- The scale factor calculated from the Stretch Amount is applied to the Stretch Axis.
- The inverse scale factor is applied to the remaining minor axes.
**Limits group**

You can apply the stretch effect to the entire object, or limit it to a portion of the object, using controls in the Limits group of the Parameters rollout. The limits restrict the stretch effect along the positive and negative Stretch Axis as measured from the modifier's center.

**Limit Effect** Limits the stretch effect. When Limit Effect is turned off, values in the Upper and Lower Limit fields are ignored.

**Upper Limit** Sets the boundary of the stretch effect along the positive Stretch Axis. The Upper Limit can be 0 or any positive number.

**Lower Limit** Sets the boundary of the stretch effect along the negative Stretch Axis. The Lower Limit can be 0 or any negative number.

Limiting the effect of Stretch

Click Sub-Object and move the modifier's center to change the location of the limited stretch areas. The Upper and Lower Limit boundaries move with the modifier center to maintain their specified distances.
Effects of moving the Stretch center

**NOTE** You can also limit the stretch effect by using an Edit or Select modifier, defining a sub-object selection, and then applying Stretch. If the modifier’s Sub-Object button is active, only the selected sub-objects will be stretched.

### Subdivide Modifier (Object Space)

Select an object > Modify panel > Modifier List > Object-Space Modifiers > Subdivide

Make a selection. > Modifiers menu > Radiosity Modifiers > Subdivide

The Subdivide modifier provides an algorithm for creating meshes used for radiosity on page 6615 processing. Processing radiosity requires meshes that have elements shaped as close as possible to equilateral triangles. The density of the mesh also needs to be considered in determining the resolution of the lighting details that need to be captured. The denser the mesh is, the finer the lighting detail and accuracy will be. The trade-off is a larger memory requirement and slower rendering times. The Subdivide modifier works on a whole object and does not work on selected faces in a mesh.
Subdivide modifier breaks flat surfaces into meshes.

Although it is primarily developed for increasing the quality of radiosity solutions, the Subdivide modifier can also be used by any application that requires well-formed meshes. For example, irregular mesh elements generated for Terrain on page 730 compound objects can be improved.

The modifier has world space and object space variants. In the world space modifier the size limit is on the mesh after it is transformed into world space coordinates. The object space modifier limits the size in object space coordinates.

**NOTE** Typically, the Subdivide modifier is applied automatically to objects in the scene when a radiosity solution is processed. Meshing parameters can be set on a global basis in the radiosity control panel on page 6634 or for individual objects in the Object Properties dialog on page 283.

**TIP** When you are satisfied with the subdivision settings on one object, you can drag the modifier to other objects to propagate it.
Interface

Size Controls the size of triangles in the subdivided mesh. The length of the longest edge of any triangle will not exceed the square root of 2 times the size in the Subdivide modifier. The square root of 2 factor is used, so that a square whose edges are the size will not be subdivided.

Update group

The radio buttons in the Update group control when the meshing is done.

Automatic Updates immediately when changes are made to the controls or the mesh.

Render Updates only for rendering.

Manual Updates only when Update Now is pressed. Subdivision can be interrupted using the Esc key. If the subdivision is interrupted the Update mode is changed to Manual.

Update Now Updates the mesh when Manual is turned on.

Display Subdivision Controls whether all of the triangles are visible, or only the edges where face properties are changing. Allows you to reduce the visible triangles in the scene if it appears cluttered.
Substitute Modifier

Make a selection. > Modify panel > Modifier List > Object-Space Modifiers > Substitute

Typically, designers use two-dimensional shapes to represent objects, such as furniture, in their AutoCAD designs. However, when they link their DWG files on page 8556 into 3ds Max for visualization, they want to see how the objects will look in their design.

The Substitute modifier lets you quickly replace one or more objects with another in the viewports or at render time. The substitute object can be instanced from the current scene or can be referenced from an external file.
The Substitute modifier replaces the 2D objects with their 3D counterparts.

To get rid of the substitute object, simply remove the modifier from the stack. This frees up the memory required to store it.

**TIP** When you file link to a DWG file, the file is imported to 3ds Max as groups of VIZBlocks on page 8758. If the pivot points of the VIZBlock and the substituted geometry do not match, you may not obtain the desired results. Adjust the pivot point of the VIZBlock object using the Adjust Geometry button to align the substituted geometry correctly.

**See also:**
- XRef Objects on page 7450
- XRef Scene on page 7477

**Procedures**

To use an object from the current scene as a substitute:

1. Select an object, and then apply the Substitute modifier.
2 Click Pick Scene Object, and then in the viewport, select an object to substitute for the selection.
   Alternatively, click the ... button to the right of Pick Scene Object and select an object from the dialog that is displayed.
   The original object is replaced by an instance of the substitute object.

3 To see the original object in the viewport, turn off In Viewport. To see the original object in the final rendering, turn off In Render. To permanently disable the substitution, delete the modifier.

To use an externally referenced object as a substitute:

1 Select an object, and then apply the Substitute modifier.

2 Click Select XRef Object.

3 Use the Open File dialog to designate the file that contains the substitute object you want to use.

4 Use the XRef Merge dialog on page 7471 to designate the object to use as a substitute.
   The original object is replaced by an instance of the substitute object.
   To see the original object in the viewport, turn off Display group > In Viewport. To see the original object in the final rendering, turn off Display group > In Render. To permanently disable the substitution, delete the modifier.

Interface

Modifier Stack

Substitute Object  At this sub-object level, you can transform the substitute object without affecting the original, changing the offset distance between them. Otherwise, transforming the substitute object affects both equally.
Parameters rollout

- Display Parameters

  - Display
    - In Viewport
    - In Render

Object:

- Foliage01

Type:

Substitute Assignment

- Pick Scene Object
- Select XRef Object...

- Retain Local Rotation
- Retain Local Scale

Display group

In Viewport Replaces the original object with the substitute in the viewports.

In Render Replaces the original object with the substitute when you render the scene.

Object This editable text field displays the name of the substitute object and lets you rename it.

NOTE The name, if changed, appears only on the Modify panel at the current stack level. That is, the name is local to the current application of the Substitute modifier.

Type (label) Displays the type of object used as a substitute. If you use a scene object, the type is shown as Instance. If you use an XRef object, the type is shown as XRef Object. Appears only after you designate a substitute object.
Substitute Assignment group

Pick Scene Object Lets you choose an object from the current scene to be instanced as a substitute for the selected object. Click Pick Scene Object, and then select the object from a viewport to use as a substitute. If In Viewport is on and Retain Current Position is off (the default settings), an instance of the substitute object appears in the place of the original object. The mouse cursor changes to a plus sign (+) when over an object that can be used as a substitute. You cannot use an object to which the Substitute modifier is applied as a substitute object.

Use the button labeled "..." to the right of Pick Scene Object to choose a substitute object using the Select Substitute Object dialog, which works like the Select From Scene dialog on page 206. In the dialog’s list window, highlight the object to use as a substitute, and then click Select.

Select XRef Object Lets you specify an object to be instanced from an external scene file as the substitute. Click Select XRef Object, and then, in the Open File dialog, open the file containing the substitute object. On the XRef Merge dialog on page 7471, select the substitute object and then click OK. Objects to which the Substitute modifier is applied don't appear in the list.

NOTE Because the object used as a substitute is referenced from an external file, any changes to the object in that file apply to the substitute after reloading. For example, if you apply a Bend modifier to the substitute object in the external file, then the next time you load the file containing the object with the Substitute modifier, it appears bent.

Retain Local Rotation/Scale When on, rotates or scales the new object instance in the same place as the substitute object you select. In this case, the two objects coincide in space, and you must move one to see both. When off, 3ds Max positions the instanced substitute object in the same place as the object containing the Substitute modifier.

You must specify the Retain Local Rotation/Scale setting before designating the substitute object. Changing this setting afterward has no effect.

Surface Modifier

Select a spline object. > Modify panel > Modifier List > Object-Space Modifiers > Surface

Select a spline object. > Modifiers menu > Patch/Spline Editing > Surface

Procedures on page 1770 Interface on page 1773
The Surface modifier generates a patch surface based on the contours of a spline network. A patch is created wherever the segments of the interwoven splines form a three- or four-sided polygon. The Surface modifier and the CrossSection modifier, taken together, are referred to as Surface Tools. They allow you to create complex or organic surfaces, like the fuselage of a plane, or a three-dimensional character.

Applying the Surface modifier to create a patch surface.

The CrossSection modifier on page 1299 can be applied before the Surface modifier to connect splines representing cross-sections. Once the basic spline network is created and the Surface modifier is applied, the model can be adjusted by editing the splines using an Edit Spline modifier below the Surface modifier in the modifier stack. Since the Surface modifier creates a Patch surface, further refinements can be made to the patch model by adding an Edit Patch modifier above the Surface modifier.

The bulk of the work in using Surface tools to model lies in creating and editing splines in an Editable Spline or Edit Spline modifier. One of the benefits to modeling using splines and Surface Tools is the ease of editing the model. At almost any stage of modeling, you can add a nostril, ear, limb or body by simply adding splines. This lends itself to a free-form approach to organic modeling.
modeling: you have a mental image of what you want, then you create and edit the spline network until you are satisfied.

NOTE 3ds Max offers a simplified workflow for this modeling technique, using Edit/Editable Spline and the Edit Patch modifier. For details, see To create a patch object using the Cross Section and Spline Surface tools: on page 1330.

Surface Modifier Basics

1. Create a spline object.

2. Make sure that the Spline vertices form valid three-sided or four-sided, closed regions. Vertices on splines that cross one another should be coincident.
   
   To make spline vertices coincident, drag vertices over each other with 3D Snap turned on. 3D Snap must have the Vertex or End Point option turned on. With 3D Snap turned on, you can snap to vertices on existing splines as you create new splines. You can also select vertices and use the Fuse option in an Editable Spline to make vertices co-incident.

3. Use the CrossSection modifier to connect spline cross-sections, unless you plan on manually creating the splines that connect the model’s cross-sections.

4. Apply the Surface modifier, then adjust the weld threshold to generate a patch object. Ideally all spline vertices that will form a patch surface are coincident; the Threshold parameter allows patch creation even if vertices are not quite coincident.

5. Optionally, add an Edit Patch modifier to edit the patch surface.

TIP Make a reference copy of the spline object, then add the Surface modifier to the copy and edit the original. As you edit the original spline object, patches appear on the reference copy as splines form three-or four-sided shapes. This allows you to view a shaded surface as you model.

You can take this a step further and add a Mirror modifier to the reference copy. As you create splines for one side of a head or body, the reference copy displays an entire model.
Modeling with Surface Tools

There are two primary methods of using the Surface modifier to create patch models.

- Create splines that represent a model’s cross sections, add the CrossSection modifier to connect the cross sections, and apply the Surface modifier to create the patch surface. This approach works for models like the body of an airplane. Alternatively, use the editable spline Cross Section function on page 633 to connect the cross sections, and then use the editable patch Spline Surface tools on page 1331 to create the surface.

- Create a network of splines manually, and then apply the Surface modifier or editable patch Spline Surface tools to create the patch surface. This approach works for modeling a face or body of a character.

Modeling Examples
Scooter: Splines form cross sections of the body

One method of using Surface Tools is to create splines that represent a model's cross sections, then the CrossSection and Surface modifiers are applied to create the patch surface.
Two intersecting texture-mapped polygons are used as a reference to create a network of splines manually. Drawing lines on the physical sculpture is used as an added visual aid to position the splines in this case. The CrossSection modifier is not necessary if you create the spline network manually.

As the spline network is edited, the patch surface of the reference copy is updated dynamically. This allows you to view a shaded patch model as you manipulate the spline network, any surface anomalies can be spotted and corrected.
Sequence of images showing the spline network, the patches created by the Surface modifier, and a shaded view of an alien character.

**Additional Details**

- Splines are initially created using the tools in Create panel > Shapes > Splines > Object Type rollout, such as Line on page 584, Circle on page 590, Arc on page 592, and Section on page 607. Splines can also be created using the Create Line command in an Editable Spline or and Edit Spline modifier.
Splines are edited by applying an Edit Spline modifier to the selected spline object or editing parameters in an Editable Spline. Editing splines changes the patch surface created by the Surface modifier.

To add splines to a spline object, use the Attach command in the Edit Spline modifier.

Within a spline object, splines need not be continuous. A spline object may consist of ten splines, for example. As long as the spline vertices are coincident, or close enough for the Threshold parameter in the Surface modifier to weld them together, a surface will be generated.

**Procedures**

**Example: Understanding valid splines:**

1. In the Top viewport, use Create panel > Shape > NGon to create three NGons: a three-sided, four-sided, and five-sided NGon, each about 100 units wide.

2. Make sure that all the splines form one object. Do this by applying an Edit Spline modifier to one of the NGons and using Attach to add the remaining NGon objects.
3 Choose Modifiers menu > Patch/Spline Editing > Surface from the Modifier List.

Notice that the three- and four-sided splines formed patches but the five-sided NGon did not. The five-sided spline does not form a three- or four-sided closed region. To make it a valid spline, a line must bisect the NGon to form a three- and four-sided region.

4 In the stack display, choose the Edit Spline modifier again. Turn on Create Line on the Geometry rollout, and create a line that bisects the five-sided NGon.

The start and end points of the line should overlap the vertices on the NGon. Being exact is not critical; the Threshold parameter fuses spline vertices based on their proximity.
In the stack display, choose the Surface modifier again. Now the five-sided NGon is a patch object, consisting of a quad patch and a tri patch.

NOTE If the spline object did not turn into a patch, increase the Surface modifier's Threshold parameter until the patches appear.

Example continued: Adjusting the shape of the spline:

1. In the stack display, expand the Edit Spline modifier's hierarchy, and choose the Vertex sub-object level.

2. In the Top viewport, select the top vertex of the five-sided NGon. Two vector handles are displayed. These handles can be moved on any axis.

3. Turn on Select and Move on the toolbar, then drag the handles around in the Top viewport. The shape of the spline changes.

4. Below the stack display, turn on the Show End Result On/Off Toggle button. The patch changes shape to fit the spline.
Interface

Parameters

- Spline Options
  - Threshold: 1.0
  - Flip Normals
  - Remove interior patches
  - Use only selected segs.

- Patch Topology
  - Steps: 5
Spline Options group

**Threshold** Determines the overall distance that is used to weld the vertices of the spline object. All vertices/vectors within the threshold of each other are treated as one. Threshold uses units set in the [Units Setup dialog](page 8366) on page 8366.

**NOTE** Spline control handles are also treated as vertices, so setting high Threshold levels can produce unexpected results.

**Flip Normals** Flips the normal direction of the patch surface.

**Remove Interior Patches** Removes interior faces of an object that you would not normally see. These are the faces created within the caps or other interior patches of the same type of a closed polygon.

**Use only selected segs** Only segments selected in the Edit Spline modifier will be used by the Surface modifier to create patches.

**NOTE** Segment Sub-Object does not have to be left on in the Edit Spline modifier.

Patch Topology group

**Steps** The steps field spinner determines how many steps are used between each vertex. The higher the step count, the smoother the curve you will get between vertices.

SurfDeform Modifier (Object Space)

Select an object. > Modify panel > Modifiers List > Object–Space Modifiers > SurfDeform

Select an object. > Modify panel > Modifiers List > World–Space Modifiers > SurfDeform

Select an object. > Modifiers menu > Animation Modifiers > SurfDeform

Select an object. > Modifiers menu > Animation Modifiers > SurfDeform (WSM)

The SurfDeform modifier works the same way as the PatchDeform modifier on page 1567, except that it uses a NURBS Point or CV surface instead of a patch surface to apply surface deformation.
SurfDeform shapes how the snake rests.

Procedures

To use the SurfDeform modifier:

1. Select an object.

2. From the Modify panel > Modifier List, choose Object-Space Modifiers > SurfDeform.

3. On the Parameters rollout, click Pick Surface.

4. Select a NURBS Point or CV surface.

5. Deform the object by adjusting the controls in the Surface Deform group.
Interface

See PatchDeform modifier on page 1567 for a description of the user interface.

### Sweep Modifier

Modify panel > Select a 2D shape. > Modifier List > Sweep
Select a 2D shape. > Modifiers menu > Patch/Spline Editing > Sweep

The Sweep modifier is used to extrude a cross-section along an underlying spline or NURBS curve path. It is similar to the Loft compound object but is a more efficient method. The Sweep modifier allows you to work with a series of pre-made cross-sections such as angles, channels and wide flanges. You can also use your own splines or NURBS curves as custom sections that you create in 3ds Max or import from other MAX files.

**NOTE** This modifier is similar to the Extrude modifier in that once the Sweep is applied to a spline, the end result is a 3D mesh object. Both sections and paths can contain multiple splines or multiple NURBS curves.

This modifier is very useful for creating structural steel details, molding details, or in any situation where you need to extrude a section along a spline.
Examples of extrusions created with the Sweep modifier

Procedures

To apply the Sweep modifier to a line:

1. Create a line in the perspective viewport.
2. Apply the Sweep modifier to the line.
   The line takes on the shape of an angled extrusion.
3. Open the Built-In Section list and choose a different section.
   The line now has the new section swept along its length.

To use a custom section with the Sweep modifier:

1. Create a line and a six sided N-Gon in the perspective viewport.
2. Apply the Sweep modifier to the line.
   The line takes on the shape of an angled extrusion.
3. Click the Use Custom Section radio button.
The line displays as a line again.

4 Click the Pick button in the Custom Section Types group and choose the NGon in the viewport.
The hexagonal shape is swept along the line's length.

**NOTE** If you find that you need to rescale the Custom Section shape, the effects of using a transform like Select and Squash or Non-Uniform Scale will not be reflected when swept. You need to apply an XForm modifier on page 2010 to the section and then rescale the XForm modifier’s gizmo.

---

**Interface**

**Section Type rollout**

![Section Type rollout](image)

**Use Built-In Section** Choose this to use one of the included stock sections.
Built-In Section group

Built-In Section list Clicking the arrow button for this list displays common structural sections.

- **Angle section** Sweeps a structural angle section along the spline. Default section=Angle.
- **Bar section** Sweeps a 2D rectangular section along the spline.
- **Channel section** Sweeps a structural channel section along the spline.
- **Cylinder section** Sweeps a solid 2D circle section along the spline.
- **Half Round section** This section produces a half round extrusion along the spline.
- **Pipe section** Sweeps a circular hollow tube section along the spline.
- **Quarter Round section** Useful for molding details; this section produces a quarter round extrusion along the spline.
- **Tee section** Sweeps a structural tee section along the spline.
Tube section  Based on a square, this sweeps a hollow tube section along the spline. Similar to the Pipe section.

Wide Flange section  Sweeps a structural wide flange section along the spline.

Use Custom Section  Choose this if you've created your own section or there is another shape in the current scene or in another MAX file that you'd like to use as your section.

NOTE  Using a 2D shape as the Sweep modifier's custom section will yield the most predictable results. If using a 3D shape as the custom section, for the most predictable results the base object should be a straight line or smooth path like a circle or an arc. The same applies to custom sections made up of multiple splines. You'll get the best results attained by insuring that all vertices in all the shapes are coplanar.

Custom Section Types group

Section  Displays the name of the custom shape you've selected. This area is blank until you select a custom shape.

NOTE  You can switch from a custom section to a built-in section and back without having to pick the custom-section shape again from the viewports.

Pick  If the custom shape you want to use is visible in the viewport, click the Pick button and then pick the shape directly from the scene.

Pick Shape  Click the Pick Shape button to open the Pick Shape dialog on page 1796. This dialog shows only valid shapes that are currently in the scene.

Extract  Lets you create a new shape in the scene that is either a copy, instance, or reference of the current custom section. Opens the Extract Shape dialog on page 1798.

Merge From File  Lets you choose a section that is stored in another MAX file. Opens the Merge File dialog on page 1799.

NOTE  When you use the Merge from File option, you will not be able to Undo your work.

Move  Sweeps the custom section along the specified spline. Unlike the Instance, Copy and Reference switches, the selected section is moved to the
spline. Editing the original shape in the viewports has no effect on the Sweep mesh.

**Copy** Sweeps a copy of the selected section along the specified spline.

**Instance** Sweeps an instance on page 8611 of the selected section to the specified spline.

**Reference** Sweeps a reference on page 8699 of the selected section along the specified spline.

**NOTE** When using Instance or Reference, adding modifiers to or editing the original section in the viewports will change the Sweep mesh.

**Interpolation rollout (Sweep modifier)**

The controls in the Interpolation rollout of the Sweep modifier work exactly as they do for any other spline. However, the controls affect only the built-in section you've chosen, not the spline that the section is swept along.

**NOTE** If you want to change the interpolation settings of the underlying spline path, you need to select the path object in the modifier stack.

In general, all spline curves are divided into small straight lines that approximate a true curve. The number of divisions between each vertex on the spline are called steps. The more steps used, the smoother the curve appears.

**NOTE** The Interpolation rollout is only active when built-in sections are used.
Left: The quarter-round section is set to zero steps.
Right: The same section on the right is set to four steps.

**Steps** Sets the number of divisions, or steps, 3ds Max uses between each built-in section’s vertices. Splines with tight curves require many steps to look smooth while gentle curves require fewer steps. Range=0 to 100.

Splines steps can be either adaptive or manually specified. The method used is set by the state of the Adaptive switch. The main use for manual interpolation is to create splines for morphing or other operations where you must have exact control over the number of vertices created.

**Optimize** When on, removes unneeded steps from straight segments in the spline. Default=on.

**NOTE** Optimize is not available when Adaptive is on.

Left: Optimize is on for the left-hand sweep.
Right: Optimize is off for the right-hand sweep.
**Adaptive** When on, automatically sets the number of steps for each spline to produce a smooth curve. Straight segments always receive 0 steps. When off, enables manual interpolation control using Optimize and Steps. Default=off.

**Parameters rollout**

The Parameters rollout is context-sensitive and displays different settings depending upon the built-in section you've chosen to sweep along a spline. For example, more complex sections such as the Angle have seven settings that you can change whereas the Quarter-Round has only one setting.

**Parameters rollout: Angle**

![Parameters rollout: Angle](image)

**Length** Controls the height of the vertical leg of the angle section. Default=6.0.

**Width** Controls the width of the horizontal leg of the angle section. Default=4.0.

**Thickness** Controls the thickness of both legs of the angle. Default=0.5.

**Sync Corner Fillets** When turned on, Corner Radius 1 controls the radius of both the interior and exterior corners between the vertical and horizontal legs. It also maintains the thickness of the section. Default=off.

**Corner Radius 1** Controls the exterior radius between the vertical and horizontal legs of the angle section. Default=0.0.

**Corner Radius 2** Controls the interior radius between the vertical and horizontal legs of the angle section. Default=0.5.
**Edge Radii** Controls the interior radius at the outermost edges of the vertical and horizontal legs. Default=0.0.

**NOTE** Be cautious when adjusting these settings. There are no constraining relationships between them. Therefore, it's possible to set an inside radius (Corner Radius 2) that is greater than the length or width of the legs of the angle.

### Parameters rollout: Bar

![Bar parameters rollout]

**Length** Controls the height of the bar section. Default=6.0.

**Width** Controls the width of the bar section. Default=6.0.

**Corner Radius** Controls the radius of all four corners of the section. Default=0.0.

### Parameters rollout: Channel

![Channel parameters rollout]

**Length** Controls the height of the bar section. Default=12.0.

**Width** Controls the width of the bar section. Default=4.0.

**Thickness** Controls the thickness of the channel. Default=0.5.

**Sync Corner Fillets** Synchronizes the corner fillets.

**Corner Radius 1** Controls the radius of the first corner. Default=0.0.

**Corner Radius 2** Controls the radius of the second corner. Default=0.5.
**Length** Controls the height of the vertical web of the channel section. Default=12.0.

**Width** Controls the width of the top and bottom horizontal legs of the channel section. Default=4.0.

**Thickness** Controls the thickness of both legs of the channel. Default=0.5.

**Sync Corner Fillets** When on, Corner Radius 1 controls the radius of both the interior and exterior corners between the vertical web and horizontal legs. It also maintains the thickness of the section. Default=off.

**Corner Radius 1** Controls the exterior radius between the vertical web and horizontal legs of the channel. Default=0.0.

**Corner Radius 2** Controls the interior radius between the vertical web and horizontal legs of the channel. Default=0.5.

**NOTE** Be cautious when adjusting these settings. There are no constraining relationships between them. Therefore, it's possible to set an inside radius (Corner Radius 2) that is greater than the length of the web or width of the legs.

### Parameters rollout: Cylinder

![Parameters rollout: Cylinder]

**Radius** Controls the radius of the cylinder section. Default=3.0.

### Parameters rollout: Half-Round

![Parameters rollout: Half-Round]

**Radius** Controls the radius of the half round section. Default=3.0.
**Parameters rollout: Pipe**

Radius  Controls the exterior radius of the pipe section. Default=3.0.
Thickness  Controls the thickness of the wall of the pipe. Default=0.5.

**Parameters rollout: Quarter-Round**

Radius  Controls the radius of the quarter round section. Default=3.0.

**Parameters rollout: Tee**

Length  Controls the height of the vertical web of the tee section. Default=12.0.
Width  Controls the width of the flange crossing the tee section. Default=6.0.
Thickness  Controls the thickness of the web and flange. Default=0.5.
Corner Radius  Controls the radius of the two interior corners between the vertical web and horizontal flange of the section. Default=0.5.
NOTE Be cautious when adjusting these settings. There are no constraining relationships between them. Therefore, it's possible to set a radius (Corner Radius) that is greater than the length of the web or width of the flange.

Parameters rollout: Tube

**Length** Controls the height of the tube section. Default=6.0.

**Width** Controls the width of the tube section. Default=6.0.

**Thickness** Controls the thickness of the walls of the tube. Default=0.5.

**Sync Corner Fillets** When turned on, Corner Radius 1 controls the radius of both the interior and exterior corners of the tube. It also maintains the thickness of the section. Default=on.

**Corner Radius 1** Controls the radius of all four interior and exterior corners of the section. Default=0.8.

If Sync Corner Fillets is turned off, Corner Radius 1 controls the radius of the four exterior corners of the tube.

**Corner Radius 2** Controls the radius of the four interior corners of the tube. Default=0.0.

Corner Radius 2 is only available when Sync Corner Fillets is turned off.

NOTE Take care when adjusting these settings. There are no constraining relationships between them. Therefore, it's possible to set an inside radius (Corner Radius 2) that is greater than the length and width of the sides.
Parameters rollout: Wide Flange

**Length** Controls the height of the vertical web of the wide flange section. Default=14.0.

**Width** Controls the width of the horizontal flanges crossing the section. Default=8.0.

**Thickness** Controls the thickness of the web and flanges. Default=0.5.

**Corner Radius** Controls the radius of the four interior corners between the vertical web and horizontal flanges. Default=0.5.

**NOTE** Be cautious when adjusting these settings. There are no constraining relationships between them. Therefore, it's possible to set a radius (Corner Radius) that is greater than the length of the web or width of the flanges.
Mirror On XZ Plane When turned on, the section is flipped vertically in relation to the spline to which the Sweep modifier is applied. Default=off.
Mirror On XY Plane  When turned on, the section is flipped horizontally in relation to the spline to which the Sweep modifier is applied. Default=off.

X Offset  Lets you shift the horizontal position of the section relative to the underlying spline.
Left: The section is in the default position.

Right: The section is offset –10 relative to the underlying spline path (red).

**Y Offset** Lets you shift the vertical position of the section relative to the underlying spline.

---

**NOTE** The X and Y Offsets let you fine tune the section position while the Pivot Alignment settings allow for a quick initial adjustment.

**Angle** Allows you to rotate the section relative to the plane on which the underlying spline is located.
Left: The section is in the default position.

Right: The section is rotated 30 degrees.

**Smooth Section** Provides a smooth surface around the perimeter of the section that is swept along the underlying spline. Default=on.

**Smooth Path** Provides a smooth surface along the length of the underlying spline. This type of smoothing is useful when for curved paths. Default=off.
Left: Smoothing the path

Right: Smoothing the section

Rear: Smoothing both path and section

**Pivot Alignment** This is 2D grid that helps you align the section to the underlying spline path. Selecting one of the nine buttons shifts the section's pivot around the spline path.

**NOTE** When none of the Pivot Alignment buttons is depressed the pivot point of the section is used as the alignment point.

**Align Pivot** When turned on, a 3D representation of the Pivot Alignment grid appears in the viewport. You only see the 3x3 alignment grid, the section and the underlying spline path. Once you're satisfied with the alignment, turn off the Align Pivot button or right-click to see the sweep.
Align Pivot grid showing control points (in orange) superimposed over a duplicate sweep.

**Banking** When on, sections rotate about the spline path whenever the path bends and changes height in the path's local Z axis. Banking is ignored if the spline path is 2D. When off, shapes do not rotate about their Z axis as they traverse a 3D path. Default=on.

**Union Intersections** If working with multiple intersecting splines, like a grid, turn this switch on to produce cleaner intersections with fewer artifacts.

**NOTE** Union Intersections takes additional time to compute the intersections, so leave this switch off if you don’t have intersecting splines. Furthermore, this setting will only calculate intersections of separate splines contained in one shape object. So a figure X (separate, intersecting splines) will be properly intersected, but a figure 8 (a single, self-intersecting spline) will not.

**Gen. Mapping Coords** Applies mapping coordinates to the extruded object. Default=off.
**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=on.

**Generate Mapping IDs** Assigns different material IDs to the sides and the caps of the sweep. Specifically, if both Use Section IDs and Use Path IDs are both turned off the sides receive ID 3, the front cap receives ID 1, and the rear cap receives ID 2. Default=on.

**Use Section IDs** Uses the material ID values assigned to segments of the section that is swept along the underlying spline on page 577 or NURBS on page 2416 curve. Default=on.

By applying an Edit Spline modifier on page 1424 to a Custom Section, different material IDs can be assigned to each segment that makes up the section.

**NOTE** Built-in sections do not benefit from the Use Section IDs switch.

**Use Path IDs** Uses the material ID values assigned to segments of the underlying spline or curve sub-objects in the underlying curve.

By applying an Edit Spline modifier to the underlying spline, each segment can be assigned its own material ID.

**NOTE** Use Section IDs and Use Path IDs does not control the material IDs of the front and rear caps of the sweep.

![Image](image_url)

Left: Materials set by path IDs
Pick Shape Dialog (Sweep Modifier)

Select a shape that already has a Sweep modifier applied. > Modify Panel > Section Type rollout > Turn on Use Custom Section > Click Pick Shape.

The Pick Shape dialog is displayed when you select a custom shape in the scene. This shape can be any of the splines, extended splines or NURBS curves.

Procedures

To pick a custom section using the Pick Shape dialog:

1. In the viewport, pick a shape you want to use as the underlying path of the sweep.
2. From the Modifiers menu, open the Patch/Spline Editing menu and choose Sweep.
3. On the Modify panel, turn on Use Custom Section in the Section Types rollout.
4. Click the Pick Shape button.
   The Pick Shape dialog is displayed.
5. Select a shape in the list and click the Pick button.
If the scene contains multiple shapes, you can choose only one shape to be swept along the underlying spline in your scene.

**All/None/Invert** These buttons are unavailable in the Pick Shape dialog.

**Display Subtree** Displays the shapes in the list in an indented format. Turn this switch off to activate the Sort group options.

**Select Subtree** Unavailable in the Pick Shape dialog.

**Case Sensitive** When on, distinguishes between upper case and lower case for item names.
**Sort group**

Options allow you to sort the list on the left. When Display Subtree is on, these options are not available.

**Alphabetical** Sorts from A at the top to Z at the bottom.

**By Type** While this switch is available, it has no effect because only shapes are listed in the Pick Shape dialog.

**By Color** Sorts by object wireframe color. The sorting order is arbitrary; shapes of the same color are grouped together.

**By Size** This switch is available but has no effect on sorting.

**List Types group**

Because this dialog is specifically designed to work with the Sweep modifier, the List Type group is locked to only display Shapes. Shapes is the only switch in this group that affects what is displayed.

**All/None/Invert** These buttons alter the pattern of activation of the List Types options.

**Selection Sets group**

The Selection Sets group is unavailable in the Pick Shape dialog.

**Extract Shape Dialog (Sweep Modifier)**

Select a shape that already has a Sweep modifier using a Custom Section applied. > Modify Panel > Section Type rollout > Click Extract.

The Extract functionality allows you to recover custom cross-sections that may have been deleted from the scene. As long as you have a sweep in the scene that uses the deleted shape as a custom cross-section, Extract can be used to restore it to the scene.

In a large scene that has many objects and shapes, you can also use Extract if you want to quickly duplicate a section used by the sweep instead of searching for the original shape you used as the section.
Procedures

To extract a section from a sweep:

1. In the viewport, pick a swept shape.

2. Open the Modify panel and click the Extract button from the Custom Section Types group of the Section Types rollout. The Extract Shapes dialog is displayed.

3. Enter a new name for the extracted section if you want.

4. Specify the type of cloned shape you want extracted; a copy, an instance or a reference.

5. Click OK.

Interface

Name
This field shows the default name that will be given to the extracted section. By default, it always has the naming convention of Sweep_ShapeName01, Sweep_ShapeName02, etc.

For example, if your missing section was named Roman-Ogee, the extracted shape will be named Sweep_Roman-Ogee01.

Copy
Places a copy of the extracted section at the global origin (0,0,0).

Instance
Places an instance of the extracted section at the global origin.

Reference
Places a reference of the extracted section at the global origin.

Merge File (Sweep Modifier)

Select a shape that already has a Sweep modifier using a Custom Section applied. > Modify Panel > Section Type rollout > Click Merge From File.
The Merge File dialog for the Sweep modifier appears when you click the Merge From File button. Merge From File allows you to bring shapes or section profiles from other scene files into the current scene.

**Automatic Unit Conversion**

When Respect System Units in Files is turned on in the Units Setup dialog on page 8366 in the System Unit Scale group, merged objects from a file with a different scene-unit scale are scaled to maintain their correct size in the new scene.

**NOTE** If Respect System Units is off (which is not recommended), a 10-foot square tube that was created in a 1 unit = 1 foot scene becomes a 10-inch square tube in a 1 unit = 1 inch scene.

**Resolving Conflicts When Merged Shapes Have the Same Name**

When an incoming shape has the same name as a shape in the scene, an alert gives you the following options:

- **Merge** Merges the incoming shape using the name in the field at the right. To avoid having two shapes with the same name, type a new name before proceeding.

- **Skip** This button is unavailable when Merge From File is used in the Sweep modifier.

- **Delete Old** This button is unavailable when Merge From File is used in the Sweep modifier.

- **Auto Rename** The merged shape's name is left intact except it is given a numeric suffix that is one number higher than any duplicates found in the scene.

- **Cancel** Cancels the merge operation.

**Interface**

In the standard file selector dialog, select the scene file to merge. You can only merge MAX files.
This dialog has the same functionality as the Merge File dialog on page 7572 that appears when you choose Application menu on page 7989 > Import > Merge with one minor exception.

If you choose a MAX file that does not include a valid 2D shape that can be used as a custom section, you will receive a warning.

Once the scene file is selected, you can choose the shape or section profile that you want the Sweep modifier to use.
If the scene file you selected contains multiple shapes, keep in mind that you can only choose one shape to be swept along the spline in your current scene.

**All/None/Invert** These buttons are unavailable when Merge From File is used in the Sweep modifier.

**Display Subtree** Displays the shapes in the list in an indented format. Turn off this option to activate the Sort group options.

**Select Subtree** This switch is unavailable when Merge From File is used in the Sweep modifier.

**Case Sensitive** Distinguishes between uppercase and lowercase for item names.
Sort group

Options allow you to sort the list on the left. If the Display Subtree switch is on, these options are not available.

Alphabetical  Sorts from A at the top to Z at the bottom.

By Type  This switch is unavailable when Merge From File is used in the Sweep modifier.

By Color  Sorts by object wireframe color.

List Types group

Because this dialog is specifically designed to work with the Sweep modifier, the List Type group is locked to display only Shapes. None of the switches or buttons in this group can be activated.

Symmetry Modifier

Modify panel > Make a selection. > Modifier List > Symmetry

Make a selection. > Modifiers menu > Mesh Editing > Symmetry

The Symmetry modifier is especially useful when modeling characters or building ships or aircraft

This modifier is unique in that it allows you to perform three common modeling tasks:

- Mirror a mesh about the X, Y, or Z plane.
- Slice a mesh, removing parts if necessary.
- Automatically weld vertices along a common seam.
Examples of using Symmetry with different mirror axes or by moving the mirror gizmo

You can apply the Symmetry modifier to any geometry, and you can animate the mirror or slicing effect by animating the modifier’s gizmo.

When the Symmetry modifier is applied to a mesh, any edits you make to the original half of the mesh below the Symmetry modifier in the stack also occur interactively to the other half. For an example, see the second procedure, below.

NOTE The Symmetry modifier converts patch and NURBS objects to mesh format in the modifier stack; editable poly and editable mesh objects remain in their original format.

Procedures

Example: To apply the Symmetry modifier to an object:

1. Create a teapot in the Perspective viewport.
2. Apply the Symmetry modifier.
   The teapot appears to have two spouts.
3 In the modifier stack, click the + button to see the Mirror gizmo, and then select Mirror.
   The mirror gizmo acts as a slice plane when it is within the boundaries of the object.

4 With Mirror Axis set to X, click and drag the mirror gizmo along the X axis.
   Dragging right slices more of the teapot until there is nothing visible. Dragging left causes a second teapot to appear. When the mirror gizmo is moved beyond the boundaries of the original mesh, it acts as a mirror plane showing you two complete teapots.

Example: To perform box modeling with the Symmetry modifier:

1 Create a box primitive in the Perspective viewport, and then convert it to Editable Poly or apply the Edit Poly modifier.
2 If necessary, press F4 to activate Edged Faces display mode in the Perspective viewport.
3 Apply the Symmetry modifier.
   Other than the new edge loop created by the modifier, the box's appearance doesn't change, because it's already symmetrical.
4 In the modifier stack, click the + button to see the Mirror gizmo, and then click Mirror.
5 In the Front viewport, with Mirror Axis set to X, drag the Mirror gizmo in either direction on the X axis.
   Only the left-hand box moves; this is the copy created by the Symmetry modifier.
6 Position the Mirror near the left side of the original box, so the two copies are merged.
7 In the modifier stack, go to the Edit/Editable Poly level and access the Vertex sub-object level.
   If you no longer see the Symmetry copy of the box, turn on Show End Result.
   With Show End Result on, you might see an orange wireframe “cage” that shows the edges of original object. This is on by default for editable poly objects, but off by default for the Edit Poly modifier. The Show Cage
toggle for editable poly objects is on the Subdivision Surface rollout, and for Edit Poly it's on the Edit Poly Mode rollout.

You can also see that only the vertices of the original object are visible; the vertices of the symmetry object can't be transformed directly.

8 Move one of the visible vertices on the right side of the box.
As you do so, its counterpart on the symmetry object moves symmetrically in real time.
As you can see, the Symmetry modifier not only creates a mirror image of an object for you, but also lets you manipulate both sides in tandem in an intuitive way.

9 Now move one of the vertices on the left side of the box, where it overlaps the symmetry box.
Because you're also moving its counterpart vertex, which is invisible, the apparent result is motion of the corresponding point on the plane of symmetry. This isn't as intuitive as moving a non-overlapping point, so for best results, position the Mirror gizmo so as to cause as little overlap as possible; that way you can edit the center vertices directly on the plane of symmetry.

Interface

Modifier Stack

Mirror The placement of the mirror gizmo delegates how the object will be affected by symmetry. You can move or rotate, as well as animate the gizmo.
For more information on the stack display, see Modifier Stack on page 8187.
Parameters rollout

Mirror Axis group

X, Y, Z Specify the axis about which the symmetry takes place. You can see the effect in the viewport as you select the axis.

Flip Turn on Flip if you want to flip the direction of the symmetry effect. Default=off.

Slice Along Mirror Turning on Slice Along Mirror causes the mirror gizmo to act as a slice plane when it is located inside the boundaries of a mesh. When the gizmo is outside the boundaries of a mesh, the symmetrical reflection is still treated as part of the originating mesh. If Slice Along Mirror is turned off, the symmetrical reflection is treated as a separate element of the originating mesh. Default=on.

Weld Seam Turning on Weld Seam assures that the vertices along the mirror axis will be automatically welded if they are within the Threshold. Default=on.

Threshold The value of the Threshold setting delegates how close vertices can be before being automatically welded together. Default=0.1.

NOTE Setting the Threshold value too high may result in some distortion of the mesh, especially when the mirror gizmo is outside the boundaries of the originating mesh.

Taper Modifier

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Taper
Make a selection. > Modifiers menu > Parametric Deformers > Taper

The Taper modifier produces a tapered contour by scaling both ends of an object’s geometry; one end is scaled up, and the other is scaled down. You can control the amount and curve of the taper on two sets of axes. You can also limit the taper to a section of the geometry.

Examples of default tapers

Interface

Modifier Stack

Gizmo At this sub-object level, you can transform and animate the gizmo like any other object, altering the effect of the Taper modifier. Translating the
gizmo translates its center an equal distance. Rotating and scaling the gizmo takes place with respect to its center.

**Center** At this sub-object level, you can translate and animate the center, altering the Taper gizmo's shape, and thus the shape of the tapered object. For more information on the stack display, see [Modifier Stack](#) on page 8187.

Moving the modifier's center changes the gizmo shape.
Parameters rollout

The Taper modifier provides two sets of axes and a symmetry setting in the Taper Axis group box of the Parameters rollout. As with other modifiers, these axes refer to the Taper gizmo, not the object itself.

**Taper group**

*Amount*  The extent to which the ends are scaled. Amount is a relative value with a maximum of 10.

*Curve*  Applies a curvature to the sides of the Taper gizmo, thus affecting the shape of the tapered object. Positive values produce an outward curve along the tapered sides, negative values an inward curve. At 0, the sides are unchanged. Default=0.

**Taper Axis group**

*Primary*  The central axis or spine of the taper: X, Y, or Z. Default=Z.

*Effect*  The axis, or pair of axes, indicating the direction of the taper from the primary axis. The available choices are determined by the choice of primary axis. The effect axis can be either of the two remaining axes, or their
combination. If the primary axis is X, the effect axis can be Y, Z, or YZ. Default=XY.

**Symmetry** Produces a symmetrical taper around the primary axis. A taper is always symmetrical around the effect axis. Default=off.

Changing the effect axis changes the effects of the modifier.

**Limits group**

The taper offset is applied between the upper and lower limits. The surrounding geometry, while unaffected by the taper itself, is moved to keep the object intact.

**Limit Effect** Enables upper and lower limits for the taper effect.

**Upper Limit** Sets the upper limit boundaries in world units from the taper center point, beyond which the taper no longer affects the geometry.

**Lower Limit** Sets the lower limit boundaries in world units from the taper center point, beyond which the taper no longer affects the geometry.
Left: Limiting the effect of the taper.
Right: Using symmetry.

**Tessellate Modifier**

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Tessellate

Make a selection. > Modifiers menu > Mesh Editing > Tessellate

The Tessellate modifier subdivides faces in the current selection. It’s particularly useful for smoothing curved surfaces for rendering, and creating additional mesh resolution for other modifiers to act on. If no sub-object selection has been passed up the stack, then the entire object is tessellated.

This modifier lets you tessellate polygonal faces; the tessellation available in an editable mesh on page 2216 does not (it works on faces, even at the Polygon selection level).
Top: Original mesh object
Lower left: Tessellation applied to polygonal facets
Lower right: Tessellation applied to triangular faces

**WARNING** Tessellating an object retains any UVW mapping that exists in the stack before the Tessellate modifier. However, in some cases, the mapping might be altered, depending on the type of mapping and the tessellation settings. Typically, this happens when the applied mapping uses extreme compound angles.
Interface

Parameters rollout

Operate On: Specifies whether to perform the tessellation on the triangular faces or on the polygonal facets (the areas bound by visible edges).

Faces Treats the selection as a set of triangular faces.

Polygons Divides the polygonal facets. For example, using the polygonal method on the side of a box results in cross-shaped edges using the Edge method, and X-shaped edges using the Face-Center method.

Edge Divides the face or polygon from its center to the middle of each edge. When applied to a triangular face, it also divides unselected faces that share edges with the selected faces.

Face-Center Select this to divide the face from the center to the vertex corners.

Tension Determines if the new faces are flat, concave, or convex after Edge tessellation. A positive value rounds faces by pushing vertices outward. A negative value creates concave faces by pulling vertices inward. A setting of 0 keeps the faces flat. Also works with the Edge/Polygon method. Default=25.
**Iterations group**

**Iterations** Specifies how many times the tessellation is applied. For example, setting Iterations to 2 is similar to clicking the Tessellation button twice in an editable mesh, except that you can easily back out at any time while using the Tessellate modifier. If you want more than four iterations, apply another Tessellate modifier.

**Update Options group**

**Always** Tessellation is updated whenever the base geometry changes.

**When Rendering** Tessellation is updated only when the object is rendered.

**Manually** Tessellation is updated only when the user clicks Update.

**Update** Click to update tessellation. Has no effect unless Manually is the active update option.

---

**Trim/Extend Modifier**

Select a shape. > Modify panel > Modifier List > Object-Space Modifiers > Trim/Extend

Select a shape. > Modifiers menu > Patch/Spline Editing > Trim/Extend

The Trim/Extend modifier is used primarily to clean up overlapping or open splines in a multi-spline shape so that lines meet at a single point. As with the Fillet/Chamfer modifier, this modifier operates on the splines at the sub-object level in the shape. When applied to a selection of multiple splines, Trim/Extend works as it does on a single spline.

To trim, you need intersecting splines. Click the portion of the spline you want to remove. The spline is searched along its length until it hits an intersecting spline, and deleted up to the intersection. If the section intersects at both ends, the entire section is deleted up to the two intersections. If the section is open on one end and intersects at the other, the entire section is deleted up to the intersection and the open end. If the section is not intersected, nothing happens.

To extend, you need an open spline. The end of the spline nearest the picked point is extended until it reaches an intersecting spline. If there is no intersecting spline, nothing happens. Curved splines extend in a direction tangent to the end of the spline. If the end of a spline lies directly on a
boundary (an intersecting spline), then it looks for an intersection further along.

NOTE As of version 3 of 3ds Max, Edit/Editable Spline on page 620 includes interactive trim/extend functions. The only reason to use this modifier is to apply it at a specific location on the stack.

Before and after initial use of Trim

Before and after second use of Trim on above spline

Before and after using Extend
Procedures

To trim a shape using the Trim/Extend modifier:

1. Create an open Line shape on page 584 in the form of roughly concentric overlapping circles.
2. Apply the Trim/Extend modifier.
3. Click Pick Locations.
4. Click the inner spline sections of the concentric shape to trim them away, or click the open spline segment to extend the spline.

Interface

Pick Locations Click to turn on Pick mode. While in this mode, the mouse cursor changes in appearance when over part of the spline that can be affected by the Trim/Extend modifier. Click to either trim or extend the spline, based on the settings below. Default=Auto.

Operation group

Specifies the type of operation that’s performed on the selected spline.

Auto When this is chosen, a Trim is first looked for and, if not found, an Extend is attempted. In most cases, a Trim will occur when Auto is chosen.
An Extend can occur, however, in cases where an open spline exists without intersecting other splines.

**Trim Only** Performs only trims. Turn on Pick Locations, and then click the spline section you want to trim.

**Extend Only** Performs only extends. Click Pick Locations, and then select the open spline section you want to extend.

**Infinite Boundaries** For the purposes of calculating intersections, turn this on to treat open splines as infinite in length. For example, this lets you trim one linear spline against the extended length of another line that it doesn’t actually intersect.

**NOTE** As the number of open splines in the shape increases, the chance of finding an intersection, when using Infinite Boundaries, increases as well. This can produce results you might not have expected because of projected spline intersections you hadn’t considered, particularly if you’re in Auto mode. For predictable results, avoid using Auto mode when using Infinite Boundaries.

**Intersection Projection group**

These options specify how the Trim and Extend functions determine a valid intersection.

**View** Projects the lines onto the active viewport, and judges the intersections accordingly. These are the intersections as you see them in the active viewport.

**Construction Plane** Projects the lines onto the current construction plane.

**None (3D)** Considers only true intersections as the splines exist in 3D space. They must physically intersect to be considered.

**TurboSmooth Modifier**

Make a selection. > Modify panel > Modifier List > Object-Space Modifiers > TurboSmooth

The TurboSmooth modifier, like MeshSmooth on page 1505, smoothes geometry in your scene.
The differences between the two are as follows:

- TurboSmooth is considerably faster and more memory-efficient than MeshSmooth. TurboSmooth also has an option for Explicit Normals, unavailable in MeshSmooth. See Explicit Normals on page 1824.

- TurboSmooth provides a limited subset of MeshSmooth functionality. In particular, TurboSmooth uses a single smoothing method (NURMS), can be applied only to an entire object, has no sub-object levels, and outputs a triangle-mesh object.

TurboSmooth lets you subdivide the geometry while interpolating the angles of new faces at corners and edges, and apply a single smoothing group to all faces in the object. The effect of TurboSmooth is to round over corners and edges as if they had been filed or planed smooth. Use TurboSmooth parameters to control the size and number of new faces, and how they affect the surface of the object.

Angular model (shown on the right) changed to a smooth model with TurboSmooth
Smoothing an object modeled with extrusions

You use TurboSmooth to produce a Non-Uniform Rational MeshSmooth object (NURMS for short). A NURMS object is similar to a NURBS object in that you can set different weights for each control vertex.

TurboSmooth's effect is most dramatic on sharp corners and least visible on rounded surfaces. Use TurboSmooth on boxes and geometry with crisp angles. Avoid using it on spheres and similar objects.

**TIP** To better understand TurboSmooth, create a sphere and a cube and apply TurboSmooth to both. The cube's sharp corners become rounded, while the sphere's geometry becomes more complex without changing shape significantly.

**Procedures**

**To apply TurboSmooth to an object:**

1. Select an angular object.
2. Apply the TurboSmooth modifier.
3. Set TurboSmooth parameters.
Example: To compare the speeds of TurboSmooth and MeshSmooth:

1. Create a Box primitive with Length/Width/Height Segs=3. Convert the box to editable poly format.
2. Apply MeshSmooth.
3. Set Iterations=5. This creates a heavily subdivided mesh.
4. Go to the Editable Poly > Vertex sub-object level, and turn on Show End Result.
5. Move one of the corner vertices outward. There is a significant delay before you see the result of the Move operation.
6. Perform a few more Move operations on vertices, observe the delays, and then undo (Ctrl+Z) repeatedly until the MeshSmooth modifier goes away.
7. Apply TurboSmooth.
8. Set Iterations=5. This creates a heavily subdivided mesh.
9. Go to the Editable Poly > Vertex sub-object level, and turn on Show End Result.
10. Move one of the corner vertices outward. The response is much faster.
Interface

Main group

Lets you set the basic parameters for TurboSmooth.

**Iterations** Sets the number of times the mesh is subdivided. When you increase this value, each new iteration subdivides the mesh by creating smoothly interpolated vertices for every vertex, edge, and face from the iteration before. The modifier then subdivides the faces to use these new vertices. Default=1. Range=0 to 10.
NOTE Be cautious when increasing the number of iterations. The number of vertices and faces in an object (and thus the calculation time) can increase as much as four times for each iteration. Applying four iterations to even a moderately complex object can take a long time to calculate.

Render Iterations Lets you choose a different number of smoothing iterations on page 1822 to be applied to the object at render time. Turn on Render Iters, and then use the field to its right to set the number of render iterations.

Isoline Display When on, 3ds Max displays only isolines: the object's original edges, before smoothing. The benefit of using this option is a less cluttered display. When off, 3ds Max displays all faces added by TurboSmooth; thus, higher Iterations values result in a greater number of lines. Default=off.

WARNING If you’re going to collapse the model or apply further modifiers after the TurboSmooth, you should first turn off Isoline Display. Unlike in MeshSmooth, isoline display is achieved by making all the edges "invisible," joining large groups of faces together in single "polygons." This can be especially problematic if you apply a PolyObject-based modifier afterwards, because all vertices in the interior of these "polygons" will be lost.
Explicit Normals  Lets the TurboSmooth modifier compute normals for its output, which is faster than the standard method 3ds Max uses to compute normals from the mesh object’s smoothing groups. Default=off.

Consequently, if the TurboSmooth result is used directly for display or rendering, it will generally be faster with this option turned on. Also, the quality of the normals will be slightly higher. However, if you apply any topology-affecting modifiers, such as Edit Mesh, above the TurboSmooth modifier, these normals will be lost and new ones computed, potentially affecting performance adversely. So it’s important to remember to turn on Explicit Normals only if no modifiers change the object topology after TurboSmooth takes effect.

Surface Parameters group

Lets you apply smoothing groups to the object and restrict the smoothing effect by surface properties.

Smooth Result  Applies the same smoothing group to all faces.

Separate by Materials  Prevents the creation of new faces for edges between faces that do not share Material IDs.

Separate by Smoothing Groups  Prevents the creation of new faces at edges between faces that don’t share at least one smoothing group.

Update Options group

Sets manual or render-time update options, for situations where the complexity of the smoothed object is too high for automatic updates. Note that you can also set a greater degree of smoothing to be applied only at render time, in the Main group.

Always  Updates the object automatically whenever you change any TurboSmooth settings.

When Rendering  Updates the viewport display of the object only at render time.

Manually  Turns on manual updating. When manual updating is selected, any settings you change don’t take effect until you click the Update button.

Update  Updates the object in the viewport to match the current TurboSmooth settings. Works only when you choose When Rendering or Manually.
**Turn To Mesh Modifier**

Make a selection. > Modify panel > Modifier list > Object-Space Modifiers > Turn to Mesh

Make a selection. > Modifiers menu > Conversion > Turn to Mesh

The Turn To Mesh modifier lets you apply object conversions in the modifier stack. As another example, you could use this modifier on a sophisticated patch model to which you might want to apply a tool that applies only to meshes, or convert the object to a mesh. Also, when you apply general-purpose modifiers such as Normal, Material, or UVW Map, it can be helpful to explicitly control the type of object beforehand.

**NOTE** Converting from one object type to another causes a complete caching in the modifier stack. When you have large objects in your scene, this can take up a lot of space. For example, an object that starts as a mesh, converts to a patch, and then back to a mesh takes three times as much space as a mesh that just has ordinary modifiers like Bend or UVW Map applied.

**TIP** Turn To Mesh can be useful on meshes, allowing you to invert a selection or change the selection level in a modifier that doesn't depend on topology.

**Procedures**

**Example: To translate a patch sub-object selection to a polygon sub-object selection:**

1. Select a patch model and turn on wireframe mode.
2. In the stack display, choose the Patch sub-object level.
3. Select a patch on the model.
4. Apply the Turn To Mesh modifier from the Modifier list.
5. In the stack display, right-click the Turn To Mesh modifier and choose Collapse All.
6. Click Yes in the dialog that warns you about the possibility of undesirable topological effects.
7. In the stack display (or in the selection rollout), choose the Polygon sub-object mode. The original patch selection has been preserved.
Interface

Parameters rollout

Use Invisible Edges When on, uses invisible edges to represent polygons. When off, produces a completely triangulated mesh with all visible edges. Default=on.

Sub-object Selections group

These options control the selection of sub-objects.

Preserve Passes the sub-object selection up the stack. For example, if you have an object that you have converted to an editable mesh, and you've selected a polygon, then when you apply a Turn To Mesh modifier, the polygon remains selected. Default=on.

Clear Clears the sub-object selection so that nothing is selected. Default=off.

Invert Inverts the sub-object selection. All sub-objects not currently selected are selected, and all sub-objects currently selected are deselected. Default=off.

Include Soft Selection Affects the action of sub-object Move, Rotate, and Scale functions. When these are on, 3ds Max applies a spline curve deformation to unselected vertices surrounding the transformed selected sub-object. This provides a magnet-like effect, with a sphere of influence around the transformation. Use this when you want to preserve the soft selection from beneath. For example, if Use Soft Selection is on when you select vertices on
an editable poly, and you apply Turn To Mesh with Include Soft Selection on, then the same soft selection will apply to the mesh vertices. Default=on. For more information, see Soft Selection Rollout on page 2014.

**Selection Level group**

These options set the sub-object selection level for passing up the rest of the stack.

**From Pipeline** Uses the equivalent of whatever the input object uses (patch level becomes face level, and so on). For example, if you create a box, convert it to an editable patch in patch mode, and apply a Turn To Mesh modifier to it, 3ds Max passes a sub-object selection in patch mode up the stack. The Turn To Mesh modifier takes the sub-object patch selection into account and selects the mesh faces that derive from the patch selection.

**Object** Uses Object as the selection level for passing up the rest of the stack.

**Edge** Uses Edge as the sub-object selection level for passing up the rest of the stack.

**Vertex** Uses Vertex as the sub-object selection level for passing up the rest of the stack.

**Face** Uses Face as the sub-object selection level for passing up the rest of the stack.

### Turn To Patch Modifier

Make a selection. > Modify panel > Modifier List > Object-Space Modifiers > Turn to Patch

Make a selection. > Modifiers menu > Conversion > Turn to Patch

The Turn To Patch modifier lets you apply object conversions in the modifier stack. Using the Turn To Patch modifier, you can fine-tune the conversion process such as turning quads into quad patches.

**NOTE** Converting from one object type to another causes a complete caching in the modifier stack. When you have large objects in your scene, this can take up a lot of space. For example, an object that starts as a mesh, converts to a patch, and then back to a mesh takes 3 times as much space as a mesh which just has ordinary modifiers like Bend or UVW Map applied.
TIP  Turn To Patch can be useful on patches, allowing you to invert a selection or change the selection level in a modifier that doesn’t depend on topology.

Procedures

Example: To collapse to quad patches:

1  Create a chamfer box in wireframe: Create panel > Geometry > Extended Primitives > Object Type rollout > ChamferBox button.

2  Apply a Turn To Patch modifier: Modify panel > Modifier List > Turn To Patch.

3  Right-click the stack display and choose Collapse All.

Interface

Quads to Quad Patches  Turns quad faces in meshes or polymeshes into quad patches.

NOTE  When you turn this option off, 3ds Max triangulates quads when the Turn To Patch modifier is applied to a mesh or poly object.

Sub-object Selections group

These options control the selection of sub-objects.
Preserve  Passes the sub-object selection up the stack. For example, if you have an object that you have converted from an editable mesh, and you’ve selected a polygon, then when you apply a Turn To Patch modifier, the patch, which is derived from the selected polygon, remains selected. Default=on.

Clear  Clears the sub-object selection so that nothing is selected. Default=off.

Invert  Inverts the sub-object selection. All sub-objects not currently selected are selected, and all sub-objects currently selected are deselected. Default=off.

Include Soft Selection  When these are on, 3ds Max applies a spline curve deformation to unselected vertices surrounding the transformed selected sub-object. This provides a magnet-like effect, with a sphere of influence around the transformation. Use this when you want to preserve the soft selection from beneath. For example, if Use Soft Selection is on when you select vertices on an editable mesh, and you apply Turn To Patch with Include Soft Selection on, then the same soft selection will apply to the patch vertices. Default=on.

For more information, see Soft Selection Rollout on page 2014.

Selection Level group

These options set the sub-object selection level for passing up the rest of the stack.

From Pipeline  Uses the equivalent of whatever the input object uses (patch level becomes face level, and so on.). For example, if you create a box, convert it to an editable mesh in face mode, and apply a Turn To Patch modifier to it, 3ds Max passes a sub-object selection in patch mode up the stack. The Turn To Patch modifier takes the sub-object face selection into account and selects the patches that derive from the face selection.

Object  Uses object as the selection level for passing up the rest of the stack.

Edge  Uses edge as the sub-object selection level for passing up the rest of the stack.

Vertex  Uses vertex as the sub-object selection level for passing up the rest of the stack.

Patch  Uses patch as the sub-object selection level for passing up the rest of the stack.
Turn To Poly Modifier

Make a selection. > Modify panel > Modifier List > Object-Space Modifiers > Turn to Poly

Make a selection. > Modifiers menu > Conversion > Turn to Poly

The Turn To Poly modifier lets you apply object conversions in the modifier stack. Also, when you apply the general-purpose modifiers, such as Normal, Material, or UVW Map, it can be helpful to explicitly control the type of object beforehand.

When you use Turn To Poly, you're joining triangles into polygons, so you might need to have restrictions on polygon convexity, size, and planarity. All conversions from patches produce quads and triangles. Conversions from meshes can produce arbitrarily large polygons. Mesh polygons are controlled as usual by joining together faces that are separated by invisible edges.

**NOTE** Converting from one object type to another causes a complete caching in the modifier stack. When you have large objects in your scene, this can take up a lot of space. For example, an object that starts as a mesh, converts to a patch, and then back to a mesh takes three times as much space as a mesh that has only ordinary modifiers like Bend or UVW Map applied.

**TIP** Turn To Poly can be useful on polymeshes, allowing you to invert a selection or change the selection level in a modifier that doesn’t depend on topology.

**Procedures**

**Example: To prevent interior vertices from being passed up the stack:**

1. Create an NGon in wireframe mode: Create panel > Shapes > Splines > Object Type rollout > NGon.

2. Open the Modify panel and convert the NGon to an editable mesh by right-clicking the stack display and choosing Convert to > Editable Mesh.

3. In the stack display (or in the Selection rollout), choose the Polygon sub-object mode.

4. Choose Edit > Object Properties to display the Object Properties dialog.

5. In the Display Properties group, turn off By Layer.
6 Turn on Vertex Ticks. Choose OK to close the dialog.

7 Click Cut under the Edit Geometry rollout, and make a cut from one side of the NGon to the other. Notice that an interior vertex now exists.

**NOTE** Doing this on an NGon doesn't always generate an interior vertex.

8 Apply the Turn To Poly modifier: Modify panel > Modifier List > Turn To Poly. Notice the interior vertex clears.

**Interface**

**Parameters rollout**

![Parameters rollout](image)

**Keep Polygons Convex** Does not join across edges if the resulting polygon would not be convex. "Convex" means that you can connect any two points in the polygon with a line that doesn't go outside the polygon. A polygon is not convex if you can draw a line between vertices and that line lays outside of the polygon.
Problems that can occur with non-convex polygons include the fact that changes in the geometry of the input object can result in a different topology for the Turn To Poly result. For instance, in a box, if you drag one of the top corners across the middle of the top face, the box becomes non-convex. Turn To Poly would then see this as two triangles instead of one quad, and the number of points in the result would change.

**Limit Polygon Size** Limits the number of sides to a polygon so that the surface is better defined. For example, you might want to produce a polymesh of triangles and quads, or one composed of all triangles, rather than joining together more than two triangles into pentagons, hexagons, and so on.

**Max Size** The maximum number of sides to a polygon.

**Require Planar Polygons** Creates polygons composed of flat planes. Does not join faces together across an edge if the edge has a sharper angle than the threshold listed.

**Threshold** Controls the threshold of the angle between polygonal planes.

**Remove Mid-Edge Vertices** Eliminates divisions that result from intersections with invisible edges.

**Sub-object Selections group**

These options control the selection of sub-objects.

**Preserve** Passes the sub-object selection up the stack. For example, if you have an object that you have converted to an editable mesh, and you’ve selected a polygon, then when you apply a Turn To Poly modifier, the polygon remains selected. Default=on.

**Clear** Clears the sub-object selection so that nothing is selected. Default=off.

**Invert** Inverts the sub-object selection. All sub-objects not currently selected are selected, and all sub-objects currently selected are deselected. Default=off.

**Include Soft Selection** Affects the action of sub-object Move, Rotate, and Scale functions. When these are on, 3ds Max applies a spline curve deformation to unselected vertices surrounding the transformed selected sub-object. This provides a magnet-like effect, with a sphere of influence around the transformation. Use this when you want to preserve the soft selection from beneath. For example, if Use Soft Selection is on when you select vertices on an editable mesh, and you apply Turn To Poly with Include Soft Selection on, then the same soft selection will apply to the polymesh vertices. Default=on. For more information, see **Soft Selection Rollout** on page 2014.
Selection Level group

These options set the sub-object selection level for passing up the rest of the stack.

From Pipeline Uses the equivalent of whatever the input object uses (patch level becomes face level, and so on). For example, if you create a box, convert it to an editable mesh in face mode, and apply a Turn To Poly modifier to it, 3ds Max passes a sub-object selection in face mode up the stack. The Turn To Poly modifier takes the sub-object face selection into account and selects the polygons that derive from the face selection.

Object Uses object as the selection level for passing up the rest of the stack.

Edge Uses edge as the sub-object selection level for passing up the rest of the stack.

Vertex Uses vertex as the sub-object selection level for passing up the rest of the stack.

Face Uses face as the sub-object selection level for passing up the rest of the stack.

Twist Modifier

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Twist

Make a selection. > Modifiers menu > Parametric Deformers > Twist

The Twist modifier produces a twirling effect (like wringing out a wet rag) in an object's geometry. You can control the angle of the twist on any of three axes, and set a bias that compresses the twist effect relative to the pivot point. You can also limit the twist to a section of the geometry.

NOTE When you apply the Twist modifier, the Twist gizmo's center is placed at the object's pivot point, and the gizmo lines up with the object's local axis.
Procedures

To twist an object:

1. Select an object and apply Twist.

2. On the Parameters rollout, set Twist Axis to X, Y, or Z. This refers to the axis of the Twist gizmo, not the axis of the selected object.
   You can switch between axes at any time, but only one axis setting is carried with the modifier.

3. Set the angle of the twist. Positive values produce a clockwise twist, negative values a counterclockwise twist. An angle of 360 produces a complete revolution.
   The object twists to this amount beginning at the lower limit (by default, the location of the modifier's center).

4. Set the bias of the twist.
A positive value compresses the twist at the end away from the pivot point, a negative value toward the pivot point.

**To limit the twist:**

1. Turn on Limits group > Limit Effect.

2. Set values for the upper and lower limits. These are distances in current units above and below the modifier's center, which is at zero on the gizmo's Z axis. The upper limit can be zero or positive, the lower limit zero or negative. If the limits are equal, the result is the same as turning off Limit Effect. The twist offset is applied between these limits. The surrounding geometry, while unaffected by the twist itself, is moved to keep the object intact.

3. At the sub-object level, you can select and move the modifier's center. The limit settings remain on either side of the center as you move it. This lets you relocate the twist area to another part of the object.

**Interface**

**Modifier Stack**

![Modifier Stack Diagram]

**Gizmo** You can transform and animate the gizmo like any other object at this sub-object level, altering the effect of the Twist modifier. Translating the gizmo translates its center an equal distance. Rotating and scaling the gizmo takes place with respect to its center.

**Center** You can translate and animate the center at this sub-object level, altering the Twist gizmo's shape, and thus the shape of the twisted object.

For more information on the stack display, see Modifier Stack on page 8187.
Twist Parameters rollout

Twist group

Angle Determines the amount of twist around the vertical axis. Default=0.0.

Bias Causes the twist rotation to bunch up at either end of the object. When the parameter is negative, the object twists closer to the gizmo center. When the value is positive, the object twists more away from the gizmo center. When the parameter is 0, the twisting is uniform. Range=100 to -100. Default=0.0.

Twist Axis group

X/Y/Z Specify the axis along which the twist will occur. This is the local axis of the Twist gizmo. Default=Z.

Limits group

Applies the twist effect only to vertices that lie between the lower and upper limits. The two spinners represent distance along the gizmo's Z axis (Z=0 is at the gizmo's center). When they are equal, it is the same as disabling the twist effect.

Limit Effect Applies limit constraints to the Twist modifier.

Upper Limit Sets the upper limit for the twist effect. Default=0.
**Lower Limit** Sets the lower limit for the twist effect. Default=0.

**UVW Mapping**

This group of modifiers provides various ways to manage UVW coordinates and mapping materials onto geometry.

**Unwrap UVW Modifier**

Select one or more objects. > Modify panel > Modifier List > Object-Space Modifiers > Unwrap UVW

Select one or more objects. > Modifiers menu > UV Coordinates > Unwrap UVW

The Unwrap UVW modifier lets you assign mapping coordinates to sub-object selections, and to edit the UVW coordinates of those selections. You can also use it to unwrap and edit existing UVW coordinates on an object. Maps can be adjusted to the proper fit on a Mesh, Patch, Polygon, HSDS, or NURBS model.

The Unwrap UVW modifier can be used as a self-contained UVW mapper and UVW coordinate editor, or in conjunction with the **UVW Map modifier** on page 1932. If you use Unwrap UVW in conjunction with the UVW Map modifier, it is usually so you can use a mapping method unavailable in Unwrap UVW, such as Shrink Wrap. You can animate UVW coordinates by turning on the Auto Key button and transforming the coordinates at different frames.

**NOTE** After applying the Unwrap UVW modifier, open mapping edges, or seams, appear on the modified object in the viewports. This helps you visualize the locations of mapping clusters on the object surface. You can toggle this feature and set the line thickness with the **Display setting** on page 1850.
Open UVW mapping edges (seams) shown on head model in viewport

**Self-Contained Mapper and UVW Coordinate Editor**

Rather than creating a large modifier stack by first making a sub-object selection of faces and then adding a UVW Map modifier to specify the type of mapping, you can use the Unwrap UVW modifier to do both. You can select sub-object vertices, edges, or faces/patches, store sub-object selections as named selections, map them using planar and other methods, and then edit the UVW coordinates for each sub-object selection, all from within the Unwrap UVW modifier. For example, to map a character's face using three planar maps, you could create three sub-object selections of the front and sides of the face, planar-map the selections individually, and then edit the UVW coordinates for each selection, all without leaving the Unwrap UVW modifier.
Support for Multiple Unwrap Objects

Instancing capabilities in Unwrap UVW make it easy to map a texture across several objects. You simply make your selection and then apply Unwrap UVW. When you open the editor, you’ll see the mapping coordinates for all selected objects containing the instanced modifier. The editor shows each object’s wireframe color on page 8182 so you can distinguish the different objects.

Left: Two objects’ UVW coordinates in the editor, showing wireframe colors.
Right (inset): The objects with a shared Unwrap UVW modifier in the viewport.
The UVWs of different objects typically start out in the same location in the editor, so it’s a good idea to separate them before editing. To save time, use the Pack UVs function on the Tools menu.

What Happens to Existing UVW Coordinates

When you apply the Unwrap UVW modifier, it stores the object’s current mapping coordinates in the modifier. If the object has no mapping coordinates, the modifier creates new ones by applying planar mapping. If the incoming data on the stack is a face-level or polygon-level sub-object selection, then only the UVWs for the selected faces are brought into the modifier, and the modifier’s sub-object levels are unavailable.

When the modifier is evaluated, its UVWs are reassigned to the object flowing down the pipeline. So if the UVWs upstream are changed, the changes won’t make it past the Unwrap UVW modifier. If the Unwrap modifier is operating on a selection of faces, then upstream changes to unselected faces will still be able to flow past the Unwrap modifier.

Native Support for HSDS, Polygon Object, and Patch mapping

Unwrap UVW supports polygon faces and Bezier quad and tri patch faces in addition to triangles and quads.

Below is a sample of what the various face types look like based on the incoming type. For HSDS and Poly surfaces, the basic interface remains the same, except that the maximum number of sides per polygon increases from 4 to over two billion. HSDS supports only one level of detail: the level at which the mapping was. Patches have handles on nonlinear vertices. These handles work just like regular patch handles.
Faces from HSDS and Poly surfaces; handles appear for nonlinear vertices

Pinning Textures

Although not its primary purpose, you can use the Unwrap UVW modifier to freeze UVWs. You can apply mapping after an animated deformation and have the mapping stick to the object. For example, you can apply Unwrap UVW above a Morpher modifier in the modifier stack, apply planar maps and edit the UVW coordinates. The mapping will follow the morphing geometry.

Procedures

To use Unwrap UVW with the standard mapping methods:

This procedure offers a general overview of using the basic Unwrap UVW tools available on the Modify panel and the Edit UVWs dialog on page 1856. Unwrap UVW provides many additional tools not described in this procedure, particularly in the editor.

For procedures detailing other mapping methods available with Unwrap UVW, see To use Pelt mapping on page 1900 and To use Spline mapping on page 1920.

1 Apply the modifier and a texture-mapped material to an object. Set the material to display in the viewports, set at least one viewport to be shaded (e.g., press F3 to toggle between Wireframe and Smooth+Highlights), and, if necessary, turn off Shade Selected Faces (press F2) for that viewport so the texture mapping is visible.
2 Go to the Face sub-object level of the Unwrap modifier and make a selection of contiguous faces. You'll use a single mapping type on this selection.

Within the single modifier, you can apply as many different mappings as you like to different face selections.

3 Name the face selection using the Named Selection Sets on page 217 function on the main toolbar. This makes it easy to return to the selection set in the viewports for subsequent mapping adjustments. For example, if you're working on a house, you could use names such as *roof*.

**IMPORTANT** Be sure to press Enter after typing the selection set name.

**NOTE** Naming each face selection set isn't strictly necessary, but it is highly recommended.

4 On the Map Parameters rollout, click the appropriate mapping type button (Planar, Box, etc.) and then adjust the gizmo using any combination of the transform tools (Move, Rotate, Scale) in the viewports and the Align buttons (Align X, etc.) on the Map Parameters rollout.

**TIP** You can often save time by starting with the Best Align command and then adjusting manually from there.

After each adjustment of the mapping gizmo, the texture display in the viewports updates to reflect the mapping changes, as do the green seam lines on the object that show where the open edges lie (depending on the object shape and mapping type; the seam lines don't change with Planar mapping). To cause the viewports to update in real time, turn on Edit UVWs dialog > Constant Update on page 1870.

You can also open the editor (Parameters rollout > Edit) to view the changes in the generated texture coordinates as you adjust the gizmo.

5 Click the mapping type button again to turn it off and exit mapping for this face selection.

6 Continue making and naming selections and applying mapping until the entire mesh is mapped. Use the green seam display lines as a guide. If you don't see them, make sure Parameters rollout > Display Group > Show Map Seam is on.

7 Open the Edit UVWs dialog on page 1856 (Parameters rollout > Edit). By default, the editor displays a checkered background. To view the map in the material on the object, you need to change a setting.
At the right end of the editor upper toolbar, click the drop-down list that currently reads CheckerPattern (Checker) and choose the map that's applied to the material.

The map appears as the background.

By default, all the UVW clusters display. To work on one cluster at a time, you need to filter the UVWs.

On the Edit UVWs dialog > lower toolbar, click Filter Selected Faces.

At this point, the editor shows only faces you select in the viewport, and hides the rest. You can select faces to show directly in the viewport, or choose a named selection set. In the next step, you'll use the latter method.

On the main toolbar, open the Named Selection Sets drop-down list, and choose one of your named selection sets.

The viewports show the selection as active, and the UVW coordinates for the selection appear in Edit UVWs window.

In the Edit UVWs window, select and move a UVW face.

In the viewports, the texture slides around the selected portion of the object mesh.

Choose a different selection set and edit its UVW coordinates.

Again, the viewport display reflects the editing changes.

In a viewport, drag to select a group of faces by region.

The faces' UVW coordinates display in the Edit UVWs window. This is another way of choosing what you want to work on.

As you can see, from within the Unwrap UVW modifier you can assign multiple mapping types to different, optionally named face selections, and then edit the UVW coordinates to fine-tune map placement on the geometry.

To perform quick planar mapping:

You'll find the Quick Planar Map controls on the Map Parameters rollout of the Unwrap UVW modifier.

Apply Unwrap UVW to an object.
2 Go to the Face sub-object level.

3 Select the faces to map.
   The Quick Map gizmo appears juxtaposed over the face selection, showing
   the default Averaged Normals mapping.

4 If you prefer a different orientation for the mapping, choose X, Y, or Z.

5 Click Quick Planar Map to apply the mapping. To map additional faces,
   proceed from step 3.

To export texture coordinates to a paint program:

1 Apply the Unwrap UVW modifier to your object and use the modifier
   tools to set up the mapping. Texture-coordinate clusters that will use the
   same texture area should overlap.

2 From the Edit UVWs dialog menu bar, choose Tools > Render UVW
   Template.
   This opens the Render UVs dialog:
3 Set the Width and Height values to the output resolution you want in the rendered template. You'll usually get good results by setting the desired width and then clicking Guess Aspect Ratio.

**TIP** When creating texture maps for gaming and other real-time 3D engines, be sure to set both dimensions to powers of 2: 256, 512, 1024, etc.

4 Change the remaining values as needed. By default, the template is rendered with the edges as white and opaque (alpha=1.0), and background is empty and transparent (background alpha=0.0), but you have a variety of choices here, as detailed in Render UVs Dialog on page 1910.

5 At the bottom of the dialog, click Render UV Template. This opens a new rendered frame window on page 6513 containing the rendered template as a bitmap. Inspect the output, and if changes are necessary, make them on the Render UVs dialog and re-render.
6 When you're satisfied with the results, click Save Bitmap on the rendered frame window toolbar, and then use the file dialog to specify the file type and name. Click Save to export the file.
If you want to use the rendered transparency information in the paint program, be sure to save in a format that supports the alpha channel, such as TIF or Targa.

7 Open the exported image in a paint program and use the rendered edges as a guide for painting the texture map. Save the image when done.
Be sure to paint over or erase all the edges so they don't appear in the final texture.

8 Back in 3ds Max, create a material, set the Diffuse map to Bitmap, and open the file from the previous step.

9 Apply the material to your mesh object.
The painted texture map follows the outlines set up by the exported UVs.

Interface

After applying the modifier, its panel appears, consisting of the modifier stack plus two rollouts:

**Modifier Stack display**

Normally, when you apply Unwrap UVW to an object, the modifier stack provides access to Vertex, Edge, and Face sub-object levels. These are synchronized with the corresponding selection modes on the Edit UVWs dialog on page 1856. The Vertex and Edge sub-object levels are useful for making
UVW vertex and edge selections in the viewports, where texture mapping on the object surface is more readily visible, and the Edge level is also useful for setting up edge selections that you can later convert to pelt seams.

If you apply Unwrap UVW to an active face selection of an Editable/Edit Mesh/Poly object, or to an active patch selection of an Editable/Edit Patch object, no sub-object levels are available in the Unwrap UVW modifier. You can use Unwrap UVW to edit only the selection that was active when you applied the modifier. Changing the sub-object selection in the object doesn't affect the Unwrap modifier contents, because the modifier obtains the face selection when you first apply it.

All three sub-object levels are synchronized between the modifier stack and the Selection Modes group on page 1864 on the Edit UVWs dialog. When you activate a sub-object level in one, it's also activated in the other. Similarly, selecting sub-objects in a viewport selects them in the editor and vice-versa.

**Selection Parameters rollout**

Use these settings to make or modify a sub-object selection for use by the modifier. If you've passed a face selection up the stack, for example from the Poly Select modifier, Unwrap UVW uses that instead, and makes these controls unavailable.

+ button Expands the selection by selecting all faces adjacent to selected faces.
- button Reduces the selection by deselecting all faces adjacent to non-selected faces.
**Ring** Expands an edge selection by selecting all edges parallel to the selected edges. Ring applies only to edge selections.

**Loop** Expands the selection as far as possible, in alignment with selected edges. Loop applies only to edge selections, and propagates only through junctions of even numbers of edges.

**Ignore Backfacing** When region selecting, prevents the selection of faces not visible in the viewport.

**Select By Element** Lets you select elements on page 8559.

**Planar Angle** Lets you select contiguous coplanar faces with one click. Turn this on, and then set the threshold angle value that determines which faces are coplanar. Then click a face to select it and all contiguous faces whose angles are less than the threshold value.

Planar Angle is available only at the Face sub-object level.

**Select MatID** Enables face selection by material ID on page 8633. Specify the material ID to select, and then click Select MatID.

Select MatID is available only at the Face sub-object level.

**Select SG** Enables face selection by smoothing group on page 8724. Specify the smoothing group to select, and then click Select SG.

Select SG is available only at the Face sub-object level.
Parameters rollout

Edit Displays the Edit UVWs dialog on page 1856.

Reset UVWs Resets the UVW coordinates in the Edit UVWs dialog. Clicking this is almost the same as removing and reapplying the modifier, except that a map assigned in the Edit UVWs dialog is not deleted. For example, if you forgot to turn on the Generate Mapping Coordinates check box for an object, and then applied the Unwrap UVW modifier, the modifier would have no UVW coordinates to use and its settings would be wrong. If you then go back in the Stack and turn on Generate Mapping Coordinates, you'd need to click the Reset UVWs button. When you click this button, an alert warns you that you're losing any edits you've made.

Save Saves the UVW coordinates to a UVW (.uvw) file.

Load Loads a previously saved UVW file.
Channel group

This option lets you choose a specific map channel by number, or the vertex color channel. For more information, see UVW Map modifier > Channel group on page 1950.

When you change channels, 3ds Max copies the current edits to the new channel without alerting you. If you already have edits in that channel from another modifier (Unwrap UVW or other), those edits could be overwritten. To ensure preservation of your edits, save them before changing channels and reload the saved edits as necessary.

Display group

This setting determines whether and how pelt seams and mapping cluster boundaries, also known as map seams, appear in the viewports:

Show Seam When on, pelt boundaries appear in the viewports as blue lines.

Show Map Seam When on, mapping cluster boundaries appear in the viewports as green lines. You can change this color by adjusting the Display seams color on page 1929.

Thin/Thick Seam Display The display thickness setting applies to both pelt seams and map seams:

■ Thin Seam Display Displays map seams and pelt seams on object surfaces in the viewports with relatively thin lines. The line thickness remains constant as you zoom the view in and out.

■ Thick Seam Display Displays map seams and pelt seams on object surfaces in the viewports with relatively thick lines. The line thickness increases when you zoom the view in and decreases when you zoom out. This is the default choice.

Prevent Reflattening This option is used mainly for texture baking. When turned on, the version of the Unwrap UVW modifier automatically applied by Render To Texture on page 6843, named, by default, Automatic Flatten UVs, will not reflatten the faces. Also, make sure that both Render To Texture and the modifier are using the same map channel.
Map Parameters rollout

You can apply any map type to selected faces, patches, or surfaces, and align the mapping gizmo in any of a variety of ways.

The mapping controls on the upper part of the rollout are available only at the Face sub-object level. Also, the Quick Map controls are available only when no mapping mode button (Planar, Pelt, etc.) is active. However, the seam controls on page 1854 are available at all sub-object levels.

NOTE When a mapping type button is active, you cannot change the selection without first exiting the mapping operation.
Preview Quick Map Gizmo When on, a rectangular planar mapping gizmo, applicable to the Quick Planar Map tool only, appears juxtaposed over the face selection in the viewports. This gizmo is not manually adjustable, but you can use the following control to reorient it.

X/Y/Z/Averaged Normals Choose the alignment for the quick map gizmo: perpendicular to the object's local X, Y, or Z axis, or based on the faces' average normals.

Quick Planar Map Applies planar mapping to the current face selection based on the orientation of the Quick Map gizmo.
Planar  Applies planar mapping to selected faces.
Make the selection, click Planar, adjust the mapping using the transform tools and Align buttons on the Map Parameters panel, and then click Planar again to exit.

Pelt  Applies pelt mapping to selected faces. Clicking this button activates Pelt mode, in which you can adjust the mapping and edit the pelt map on page 1898.

**NOTE** Pelt mapping always uses a single planar mapping for the entire pelt. If you’ve applied a different type of mapping, such as Box, and then switch to Pelt, the previous mapping is lost.

**TIP** For the basic method of using Pelt mapping, see this procedure on page 1900.

Cylindrical  Applies cylindrical mapping to the currently selected faces.
Make a face selection, click Cylindrical, adjust the cylinder gizmo using the transform tools and Align buttons on the Map Parameters panel, and then click Cylindrical again to exit.

**NOTE** When you apply Cylindrical mapping to a selection, 3ds Max maps each face to the side of the cylinder gizmo that most closely matches its orientation. For best results, use Cylindrical mapping with cylinder-shaped objects or object parts.

Spherical  Applies spherical mapping to currently selected faces.
Make the face selection, click Spherical, adjust the sphere gizmo using the transform tools and Align buttons on the Map Parameters panel, and then click Spherical again to exit.

Box  Applies box mapping to the currently selected faces.
Make the selection, click Box, adjust the box gizmo using the transform tools and Align buttons on the Map Parameters panel, and then click Box again to exit.

**NOTE** When you apply Box mapping to a selection, 3ds Max maps each face to the side of the box gizmo that most closely matches its orientation. For best results, use Box mapping with box-shaped objects or object parts.

Spline  Applies spline mapping to the currently selected faces. Clicking this button activates Spline mode, in which you can adjust the mapping and edit the spline map on page 1916.
Align X/Y/Z  Aligns the gizmo to the X, Y, or Z axis of the object's local coordinate system.

Best Align  Adjusts the mapping gizmo's position, orientation, and scale to fit that of the face selection, based on the selection's extents and average normals.

Fit  Scales the gizmo to the extents of the selection and centers it on the selection. Does not change the orientation.

Align To View  Reorients the mapping gizmo to face the active viewport and adjusts its size and position as necessary to fit the extents of the selection.

Center  Moves the mapping gizmo so that its pivot coincides with the center of the selection.

Reset  Scales the gizmo to fit the selection and aligns it with the object's local space.

Normalize Map  When on, scales the mapping coordinates to fit into the standard coordinate mapping space: 0 to 1. When off, the mapping coordinates are the same size as the object. The map is always tiled once in the 0-1 coordinate space; the part of the map based on its Offset and Tiling values on For example, if you take a sphere of 25 units that's planar mapped from the top, and then apply Unwrap UVW and turn off Normalize Map, then when you open the editor, the radius of the sphere's mapping coordinates is 25 units. As a result, the texture map is tiled onto the sphere surface many times. With Normalize Map on, both the sphere and the map fit into the 0-1 coordinate space, so they're the same size.

In general, for best results, leave Normalize Map on. One reason to turn it off would be to turn it off is if you want to map several elements of different proportions with a texture of a specific aspect ratio, such as brick, keeping the texture the same size on each object.

[Seam controls]

These tools, which give you different ways of specifying pelt seams, are available at all sub-object levels of the modifier. Pelt seams apply to pelt
mapping on page 1853, as well as to spline mapping on page 1853 when you use manual seams on page 1923.

**Edit Seams** Lets you specify a pelt seam by selecting edges with the mouse in the viewports.

This process is similar but not identical to standard edge selection:

- Click an edge to add it to the current selection.
- Alt+click an edge to remove it from the current selection.
- Drag to select a region.

**Point To Point Seam** Lets you specify pelt seams by selecting vertices with the mouse in the viewports. Pelt seams specified with this tool are always added to the current seam selection.

In this mode, after you click a vertex, a rubber-band line extends from the vertex you clicked to the mouse cursor. Click a different vertex to create a pelt seam, and then continue clicking vertices to create a seam from each vertex to the previous one. To start at a different point in this mode, right-click, and then click a different vertex. To stop drawing seams, click the button again to turn it off.

**NOTE** While Point To Point Seam is active, you can pan, rotate, and zoom the viewport at any time using contextual controls (middle-button drag, Alt+middle-button drag, turn mouse wheel, respectively) to access a different part of the mesh surface. You can also navigate using the ViewCube on page 86 and SteeringWheels on page 93. After doing so, 3ds Max still remembers the last vertex you clicked and draws an accurate seam at the next click. Similarly, you can adjust the viewport using the viewport control buttons on page 8113 and then return to selecting the seam. If the control requires more than a single click, such as Pan, exiting the control by right-clicking in the viewport restores the rubber-band line, extending from the last vertex you clicked.

**TIP** The algorithm Point To Point Seam uses to calculate a path might create a different seam than what you have in mind. If this happens, undo (Ctrl+Z) and specify the desired path by plotting points closer together.

**Edge Sel To Seams** Converts the current edge selection in the modifier to pelt seams. These seams are added to any existing seams.

**Exp(and) Face Sel to Seams** Expands the current face selection to meet the pelt seam border(s). If multiple seam outlines contain selected faces, the expansion takes place only for the last-selected face; all others are deselected.
Edit UVWs Dialog

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Unwrap UVW > Edit button (on Parameters rollout)

The heart of the Edit UVWs dialog is a window that displays a lattice made up of UVW faces and UVW vertices. Each UVW face, which has three or more vertices, corresponds to a face in the mesh.

The view window displays the UVWs in the 2D-image space of the map, superimposed over a grid. Thicker grid lines show the boundaries of a texture map as it would appear in image space; the lower-left corner of the rectangle has the coordinates (0,0) and the upper-right has the coordinates (1,1). Within this window, you manipulate the UVW coordinates relative to the map (or mesh) by selecting the lattice vertices, edges, or faces (collectively known as sub-objects), and transforming them.

The state of the Edit UVWs dialog, including buttons and selected options, is stored and recalled the next time you open the Edit dialog.

NOTE You can edit patch object texture coordinates as well as mesh coordinates in the Edit UVWs dialog. When editing a patch object, you can also edit the vertex handles. In addition, you can edit the manual interior handles. However, you must enable the manual interior handles before applying the Unwrap UVW modifier. To do so, at the Patch sub-object level, select one or more patches, right-click a selected patch, and then, from the quad menu > tools 1 quadrant, choose Manual Interior. The manual interior handles appear in the editor window as isolated vertices.

NOTE Certain modeling operations can leave unused (isolated) map vertices that show up in the editor window, but cannot be used for mapping. If the model is an Editable Poly or Edit Poly object, you can use the Remove Unused Map Verts button on page 1366 at the Vertex sub-object level to automatically delete these vertices.

TIP The editor can display the number of selected sub-objects. This option is available as an Unwrap UVW shortcut on page 1879 as Show Subobject Counter.

Interface

Besides the window, the editor interface consists of a menu bar, a toolbar, a lower toolbar, and, docked below the main dialog, the Options panel on page 1863.
Menu bar

The menu bar provides access to a wide range of Edit UVWs functions. See Edit UVWs Dialog Menu Bar on page 1871.

Toolbar

Contains all the controls for manipulating the texture sub-objects in the view window, navigating within the window, and setting other options. When transforming with Rotate and Scale, pressing Ctrl+Alt will allow you to
transform the selection from the point of the mouse click, instead of the selection center. The initial click specifies the center of the transform.

**Move** Lets you select and move sub-objects. Flyout options are Move, Move Horizontal, and Move Vertical. Press Shift to constrain the movement to a single axis.

**Rotate** Lets you select and rotate sub-objects.

**Scale** Lets you select and scale sub-objects. Flyout options are Scale, Scale Horizontal, and Scale Vertical. Pressing Shift as you scale constrains the transform to a single axis.

**Freeform Mode** Lets you select and move, rotate, or scale vertices, depending on where you drag. After you make a selection, the Freeform gizmo appears as a rectangular bounding box around the selected vertices. As you move the cursor over the gizmo’s various elements and inside the gizmo, the cursor’s appearance, and the result of starting to drag in this location, change:

- **Move** Position the cursor anywhere inside the gizmo and then drag to move the selection. To constrain movement to the vertical or horizontal axis, depending on how you begin dragging, press and hold Shift before dragging.

- **Rotate** Position the cursor over a gizmo edge center point, and then drag to rotate the selection about the pivot. As you drag, the amount of rotation is shown in the center of the gizmo. Ctrl+drag to rotate in five-degree increments; Alt+drag to rotate in one-degree increments. Freeform rotation respects the angle snap on page 2810 status.

- **Scale** Position the cursor over a gizmo corner and then drag to scale the selection. By default, scaling is non-uniform; if you press and hold Ctrl before dragging, scaling is uniform on the horizontal and vertical axes. Press and hold Shift before dragging to constrain scaling to the vertical or horizontal axis, depending on how you begin dragging.
By default, scaling takes place about the gizmo center. If you've moved the pivot (see following item), you can scale about the transform center instead by pressing and holding Alt before dragging.

- **Move pivot** Position the cursor over the pivot, a wireframe cross that appears by default at the center of the gizmo. When this cursor appears, drag to move the pivot. Rotation always occurs about the pivot; scaling takes place about the pivot if you press and hold Alt before dragging.

  **TIP** By default, the pivot always resets to the center of the gizmo when you make a new selection. If you prefer to retain the offset from selection to selection, you can toggle this feature with the Reset Pivot On Selection command. This command is not available in the editor interface by default; you must use the Customize User Interface dialog on page 8249 to add it.

If you Ctrl+select one or more vertices outside the gizmo, the gizmo expands to encompass the entire selection.

- **Mirror** Mirrors selected vertices and flips UVs. Flyout options are Mirror Vertical, Mirror Horizontal, Flip Horizontal, and Flip Vertical. Flip first detaches the selection along its boundary edges and then applies a Mirror Horizontal or Vertical depending on the mode.

- **Show Map** Toggles the display of the map in the editor window.

- **UV/VW/UW** By default, the UV portion of the UVW coordinates is displayed in the view window. However, you can switch the display to edit the UWs or the VWs.

  **[texture list drop-down]** Contains all the maps of the material assigned to the object.
The names of the maps assigned in the Material Editor and in the Edit UVWs dialog (via Pick Texture) appear in the list.

Below the map names are several commands:

- **Pick Texture**  Lets you use the Material/Map Browser to add and display textures that are not in the object's material.

- **Remove Texture**  Eliminates the currently displayed texture from the editor.

- **Reset Texture List**  Returns the texture list to the current state of the applied material, removing any added textures and restoring any removed textures that were part of the original material, if they still exist in the material. This command also adds any new maps in the material, so it essentially updates the UVW editor to the current state of the material.

Choose a map you want to use in the view window. For example, you might use a bump or texture map as a reference to move UVW vertices.

A checker texture named CheckerPattern (Checker), useful for checking for distorted areas of the texture mapping, is built in to the Edit UVWs dialog. By default, this texture appears as the background texture when you first open the editor after applying Unwrap UVW to an object. To cause the pattern to appear on the object in viewports set to display textures, choose it from the drop-down list, even if it's already active in the editor.

**Edit UVWs window**

The Edit UVWs window allows you to edit UVW sub-objects to adjust the mapping on a model. For example, a texture map might contain the side, top, and front views of a car. By first planar mapping the top, side, and front faces of the model at the Face sub-object level, you can adjust the texture coordinates for each selection to fit the different parts of texture map to the corresponding areas on the car.
To edit the UVW vertices, first choose a transform tool and sub-object mode, make a selection, and then click and drag in the window to transform the selection.

**Quad menu** Right-click in the window to display the quad menu, which provides access to all the transform tools, as well as a number of editor commands.

![Quad menu](image)

Commands to freeze and hide selected sub-objects and unfreeze/unhide all sub-objects are found only in the quad menu.

**Lower Toolbar**

**Absolute/Offset Mode** When this is off, 3ds Max treats values you enter into the U, V, and W fields (see following) as absolutes. When this is on, 3ds Max applies transform values you enter as relative to current values; that is, as offsets. Default=off.

**U, V, and W** These fields display the UVW coordinates for the current selection. Use the keyboard or the spinners to edit them.

These fields are active at all sub-object levels, but they always apply to vertices. With a single vertex selected, they display the current coordinates. With multiple vertices (or one or more edges or faces) selected, they display any coordinates the vertices belonging to the selection have in common; otherwise, they're blank.
**Lock Selection** Locks selection. You can move selected sub-objects without touching them.

**Filter Selected Faces** Displays UVW vertices of the object’s selected faces in the viewport, and hides the rest. When Filter Selected Faces is on, changing the viewport face selection automatically updates the display of visible faces in the editor.

**All ID’s (drop-down)** Filters the object’s material IDs. Displays texture faces that match the ID drop-down.

**Pan** Click Pan, and then drag in the window to change the visible portion.

**Tip** With a three-button mouse, you can also pan the window by dragging with the middle mouse button held down.

**Zoom** Click Zoom, and then click+drag to zoom the window.

**Tip** With a wheel mouse, you can also zoom by turning the wheel.

**Zoom Region** Click Zoom Region, and then region-select part of the window to zoom in.

**Zoom Extents** Zooms in or out to fit the texture coordinates in the window. The flyout buttons, from top to bottom, let you zoom to all texture coordinates, to the current selection, and to all clusters/elements containing any selected sub-objects.

**Grid Snap** When on, moving sub-objects tends to snap the vertex closest to the mouse cursor, which is highlighted by a square outline, to the nearest grid line or intersection.

This is the default tool on this flyout; Pixel Snap is also available.
You can set the snap strength in the Unwrap Options dialog on page 1931.

**Pixel Snap** Snaps to the nearest pixel corner when you have a bitmap in the background. Available from the Grid Snap flyout. Combine this with Center Pixel Snap on page 1871 to snap to the center of pixels rather than the corner.

**NOTE** With multiple vertices selected, all vertices snap to the nearest pixel, relatively; this can slightly alter the spatial relationships among them.

**Options panel**

By default, the Options panel, docked to the bottom of the Edit UVWs dialog, provides controls for using soft selection, specifying selection modes, and rotating the selection. The Options button lets you toggle the display of additional settings for bitmaps, viewports, and the editor.

**Soft Selection group**

The Soft Selection controls make a sub-object selection behave as if surrounded by a “magnetic field.” Unselected sub-objects within the field are drawn along smoothly while you transform the sub-object selection, the effect diminishing with distance. You can adjust this distance, or “falloff,” whether it applies to object space, texture space, or edge space, and the formula by which it diminishes.

First, set a value that encompasses sub-objects to be moved or scaled, and then transform sub-objects with a falloff effect.

**On** Activates or deactivates soft selection.

**XY/UV** Specifies object or texture space for the falloff distance. XY selects object space, UV selects texture space.

**Falloff** Sets the falloff distance. As values increase, unselected vertex colors change gradually from the selected vertex to reflect the area of influence.

**Edge Distance** Turn on to limit the falloff region by the specified number of edges between the selection and the affected vertices. The affected region is measured in terms of “edge-distance” space rather than absolute distance.
Falloff Type Transforming with soft selection affects non-selected vertices within the falloff area based on the falloff type.
The icons depict how their buttons affect falloff. The options are:

- Smooth
- Linear
- Slow Out
- Fast Out

Selection Modes group

[sub-object mode] Specifies the type of sub-object that you can select by clicking or dragging in the window. Default=Vertex.

One of the three sub-object modes can be active at a time:

- Vertex
- Edge
- Face

NOTE Selected sub-objects are colored red by default. Also, in Edge and Face sub-object modes, any shared edges are blue by default. A shared edge is one both of whose endpoints are shared by a selected edge or face; thus, it is, in effect, also selected. You can change these colors using Customize User Interface > Colors panel on page 8272.

The three sub-object levels are synchronized between the modifier stack on page 1846 of the Unwrap UVW modifier and the Selection Modes group. When you choose a sub-object level in one, it’s also activated in the other. Similarly, selecting sub-objects in a viewport selects them in the editor and vice-versa.
Select Element  When on, selecting a sub-object in a cluster causes the entire cluster to become selected. Works in all sub-object modes.

Expand Selection  Adds sub-objects to the selection.

Vertex and face expansion proceeds outwards in all available directions. Edge expansion proceeds along available UV paths. For example, to select a cluster outline, select one outer edge, and then click Expand Selection repeatedly.

Contract Selection  Shrinks the selection by deselecting the outermost sub-objects.

Paint Select Mode  Lets you “paint” a sub-object selection by dragging in the editor window. After activating this mode, move the cursor into the editor window, and then drag to select sub-objects. To exit Paint Select mode, right-click or choose a transform tool.

Paint mode selects only sub-objects that are fully inside the selection brush. The dotted circle attached to the mouse shows the size of the brush. Use the +/- buttons next to the paintbrush button to change its size.

+/- Increases and decreases the size of the Paint Select mode “brush”: the circle attached to the mouse cursor.

Loop [+/-]  Selects a loop of texture vertices, edges, or polygons. Usage is as follows:

- Vertices/Polygons  Select two or more adjacent vertices or polygons in one or more rows or columns, and then click Loop. This selects all sub-objects in line with the selection(s).

- Edges  Select one or more edges, and then click Loop. This selects all edges in line with the selected edge(s).

To extend a loop or loops at both ends, when possible, click +. To deselect the sub-objects at both ends of a loop or loops, click -. 
Ring [+/−] Selects a ring of texture vertices, edges, or polygons. Usage is as follows:

- **Vertices/Polygons** Select two or more adjacent vertices or polygons in one or more rows or columns, and then click Ring. This selects all sub-objects perpendicular to the line formed by the selection(s).

- **Edges** Select one or more edges, and then click Ring. This selects all edges in the row(s) or column(s) perpendicular to the selected edge(s).

To extend a ring or rings at both ends, when possible, click +. To deselect the sub-objects at both ends of a ring or rings, click −.

---

**Rot(ate) +90** Rotates the selection 90 degrees about its center.

**Rot(ate) -90** Rotates the selection -90 degrees about its center.

**Stitch** Rejoins a disconnected cluster of texture coordinates to its original neighbor by connecting selected vertices to their corresponding UV seam vertices. If a UV vertex has more than one corresponding UV vertex, it will be stitched to the closest one.

Stitch has three different modes, depending on which part of the button you click:

- **Stitch to Source [left arrow]** Moves the corresponding vertices to the selected vertices.

- **Stitch to Average [Stitch button]** Moves both sets of vertices to the average positions.

- **Stitch to Target [right arrow]** Moves the selected vertices to the corresponding vertices.
1. Texture vertices before stitching
2. Stitch to Source
3. Stitch
4. Stitch to Target

**Align Horizontal** Applies by default only to selected texture vertices and edges. At the Vertex level, this tool lines up the selected UV vertices horizontally in a straight line. At the Edge level, Align lines up the selected edges.

Initial vertex selection (left); after Align Horizontal (right)

At the Edge level, if you press Shift when clicking the button, Align loops through all selected edges and lines up all the edge loops of those edges horizontally. In that case it is enough to select one edge on each edge loop to line up. It will also line up UV seam edge loops.
**Align Vertical** Applies by default only to selected texture vertices and edges. At the Vertex level, this tool lines up the selected UV vertices vertically in a straight line. At the Edge level, Align lines up the selected edges.

At the Edge level, if you press Shift when clicking the button, Align loops through all selected edges and lines up all the edge loops of those edges vertically. In that case it is enough to select one edge on each edge loop to line up. It will also line up UV seam edge loops.

Aligning edges:

1. Initial edge ring selection
2. After using Align Vertical with **Shift** pressed
3. Initial edge ring selection
4. After using Align Horizontal with **Shift** pressed

**Space Horizontal** Applies by default only to selected texture vertices and edges. At the Vertex level, this tool adjusts the positions of selected UV vertices to make the horizontal distances between each pair the same. At the Edge level, Align evenly spaces selected edges horizontally.

At the Edge level, if you press Shift when clicking the button, Align loops through all selected edges and evenly spaces those edges horizontally. In that case it is enough to select one edge on each edge loop to space. It will also space UV seam edge loops.
Initial edge ring selection (left); after using Space Horizontal with Shift pressed to space each edge’s loop (right)

Space Vertical Applies by default only to selected texture vertices and edges. At the Vertex level, this tool adjusts the positions of selected UV vertices to make the vertical distances between each pair the same. At the Edge level, Align evenly spaces selected edges vertically.

At the Edge level, if you press Shift when clicking the button, Align loops through all selected edges and evenly spaces those edges vertically. In that case it is enough to select one edge on each edge loop to space. It will also space UV seam edge loops.

UV_SelectionFromBase/SelectionToBase These commands transfer sub-object selections from the base object (must be editable poly) to the texture coordinates and vice-versa. They are available only from the Customize User Interface dialog on page 8249:

- **UV_SelectionFromBase** Converts a sub-object selection from the base editable poly object to the texture coordinates in the Unwrap UVW modifier. It is available only when the Editable Poly level in the modifier stack is active. The CUI action is available from the PolyTools category.

- **SelectionToBase** Converts a sub-object selection from the texture coordinates in the Unwrap UVW modifier to base editable poly object. It is available only when the Unwrap UVW level in the modifier stack is active. The CUI action is available from the UVW Unwrap category.
Bitmap Options group

Click the Options button to toggle this group.

Use Custom Bitmap Size When on, scales the bitmap texture to the values specified by Width and Height values (see following). You can scale and re-proportion the bitmap texture in relation to the texture coordinates with these settings. This scaling affects the bitmap only as viewed in the editor; not in the material.

TIP For faster feedback when working with large textures, reduce the bitmap size. And when working with disproportionate textures, setting the dimensions closer to each other in the editor can make it easier to work.

Width Scales the bitmap along the horizontal axis.

Height Scales the bitmap along the vertical axis.

Tile Bitmap When turned on, you can repeat the bitmap in the editor, displaying tiling set in the material. You can use any part of the tiled image for setting texture coordinates. This is helpful when the sections of the texture image are packed tightly together and the mesh contains many different areas to map.

Tiles The number of times the texture image is repeated, counting outward in eight directions (the four corners and the four sides).

With Tiles=1, the result is a 3 x 3 grid. With Tiles=2, the result is a 5 x 5 grid, and so on.

Brightness Sets the brightness of the tiled bitmap. At 1.0, the brightness equals that of the original image; at 0.5 it's half the brightness; and at 0, it's black.

TIP Turning off Affect Center Tile, available in the Unwrap Options dialog on page 1927 > Display Preferences group, prevents the Brightness setting from affecting the center tile, so it's easier to find if you've turned down the brightness.

Viewport Options group

Click the Options button to toggle this group.

Constant Update When on, the viewports update in real-time, reflecting any changes to the texture coordinates as you make them. When off, the viewports update only after you finish transforming texture coordinates (that is, when you release the mouse button).
Unwrap Editor Options group

Click the Options button to toggle this group.

Show Hidden Edges Toggles the display of face edges. When turned off, only faces appear. When turned on, all mesh geometry appears.

Center Pixel Snap When Pixel Snap on page 1863 is turned on, snaps to the center of pixels of the background images instead of pixel edges.

Weld Threshold Sets the radius within which welding using Weld Selected takes effect. The setting is in UV-space distance. Default=0.01. Range=0 to 100.0.

Edit UVWs Dialog Menu Bar

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Unwrap UVW > Edit button (on Parameters rollout) > Menu bar

The Edit UVWs dialog on page 1856 menu bar provides access to a number of important editing commands. Some of these commands are replicated on the dialog toolbar and the Unwrap UVW command panel; others, such as the Mapping, Stitch, and Sketch tools, are available only from the menus.

Tip Several commands are not available in the editor interface by default; you can use the Customize User Interface dialog on page 8249 to add them.

Interface

File menu

Load UVs Loads a previously saved UVW (texture coordinates) file.

Save UVs Saves the UVW coordinates to a UVW file.

Reset All Restores the UVW coordinates to their original status.

Reset All has almost the same effect as removing and reapplying the modifier, except that a map assigned in the Edit UVWs dialog is not deleted. For example, if you forgot to turn on the Generate Mapping Coordinates check box for an object, and then applied the Unwrap UVW modifier, the modifier would have no UVW coordinates to use and its settings would be wrong. If you then go back in the modifier stack and turn on Generate Mapping Coordinates, you'd need to choose the Reset All command. When you do so, an alert warns you that you're losing any edits you've made.
**Edit menu**

These commands provide access to the different transform functions, and copy and paste selections.

**Copy** Copies the current selection (i.e., texture coordinates) into the paste buffer.

**Paste** Applies the texture mapping coordinates in the paste buffer to the current selection. Using Paste repeatedly with the same target coordinates causes the coordinates to rotate by 90 degrees each time.

Use Copy and Paste to apply the same mapping coordinates (i.e., image) to a number of different geometry faces. A typical example of usage would be in designing a game level, where you’re working with a multi-image texture map, part of which is a door image. You might want to apply the same door image to several different door polygons. First, you would select one of the door polys and position it over the door image. Next, use Copy to place its texture coordinates in the paste buffer. Then select another door poly and choose Paste or Paste Weld. The door’s texture coordinates move to the same location as the original poly. Continue selecting other door polys and pasting until all the doors are mapped.

**TIP** For best results, use comparable sets of texture coordinates for the source and destination. For example, copy a single four-sided face, and then paste another four-sided face.

**Paste Weld** Applies the contents of the paste buffer to the current selection and then welds coincident vertices, effectively fusing the source and destination selections together.

Use this function to end up with a single set of texture coordinates that’s applied to multiple geometry elements. Adjusting these texture coordinates changes the mapping for all geometry to which they’re applied.

**Move Mode** Lets you select and move sub-objects.

**Rotate Mode** Lets you select and rotate sub-objects.

**Scale Mode** Lets you select and scale sub-objects.

**Freeform Gizmo** Lets you select and transform vertices. See Freeform Mode on page 1858.

**Select menu**

These commands let you copy a viewport selection to the editor, and transfer selections among the three different sub-object modes.
**Convert Vertex to Edge** Converts the current vertex selection to an edge selection and places you in Edge sub-object mode. For an edge to be selected, both of its vertices must be selected.

**Convert Vertex to Face** Converts the current vertex selection to a face selection and places you in Face sub-object mode. For a face to be selected, all of its vertices must be selected.

**Convert Edge to Vertex** Converts the current edge selection to a vertex selection and places you in Vertex sub-object mode.

**Convert Edge to Face** Converts the current edge selection to a face selection and places you in Face sub-object mode. For a face to be selected, the current edge selection must include all of its vertices. For example, if two opposite edges of a four-sided face are selected, the edge selection includes all four of the face's vertices, so this command will select the face.

**Convert Face to Vertex** Converts the current face selection to a vertex selection and places you in Vertex sub-object mode.

**Convert Face to Edge** Converts the current face selection to an edge selection and places you in Edge sub-object mode.

**Select Inverted Faces** Selects any faces facing away from the current mapping. Available only in Face selection mode on page 1864.
This is useful in complex models for finding faces on a surface that folds in under itself, thus causing potential problems with bump mapping.
For example, add a sphere, turn off Generate Mapping Coords, and then apply Unwrap UVW. This causes the modifier to apply planar mapping from the top down, so that all faces on the bottom half of the sphere are “inverted”; that is, they face away from the mapping. In the modifier stack display, highlight the Select Face sub-object level, and then click the Edit button to open the UVW editor. Choose the Face selection mode, and then choose Select > Select Inverted Faces. In the viewports, the bottom half of the sphere turns red to indicate that the inverted faces are now selected.

**Select Overlapped Faces** Selects any faces that overlap other faces. If no face is selected, this selects all overlapping faces. If a face selection exists, this selects only overlapping faces within the selection. Available only in Face selection mode on page 1864.
When working with complex meshes, it's common for texture-coordinate faces to overlap one another, with the result that they use the same portion of the texture map. Use this command to find overlapping faces in order to separate them as needed.
**Tools menu**

Tools on this menu let you flip and mirror texture coordinates, weld vertices, combine and separate sets of texture coordinates, and sketch outlines for multiple selected vertices.

**Flip Horizontal/Vertical** Detaches the selected sub-objects along their boundary edges and then applies Mirror Horizontal or Vertical, depending on the mode.

**Mirror Horizontal/Vertical** Reverses the direction of selected sub-objects along the indicated axis and flips UVs accordingly.

**Weld Selected** Welds selected sub-objects to a single vertex, based on the Weld Threshold setting. You can set the threshold on the Options panel > Unwrap Editor Options group, as well as on the Unwrap Options dialog on page 1927 > Misc. Preferences group.

**Target Weld** Welds pairs of vertices or edges. Not available at the Face sub-object level.

Turn on Target Weld, and then drag one vertex to another vertex, or one edge to another edge. As you drag, the cursor changes in appearance to cross hairs when it’s over a valid sub-object. While this command is active, you can continue welding sub-objects, and change the sub-object level. To exit Target Weld mode, right-click in the editor window.

**Break** Applies to the current selection; works differently in the three sub-object modes. At the Vertex sub-object level, Break replaces each shared vertex with two vertices. With edges, Break requires at least two contiguous edges to be selected, and separates each edge into two. With faces, Break splits the selection off from the rest of the mesh into a new element, exactly as does Detach Edge Verts.

**Detach Edge Verts** Tries to split off the current selection into a new element. Any invalid vertices or edges are removed from the selection set before the detach.

**Stitch Selected** For the current selection, finds all the texture vertices that are assigned to the same geometric vertex, brings them all to the same spot, and welds them together. With this tool you can automatically connect faces that are contiguous in the object mesh but not in the editor.

To use Stitch Selected, first select sub-objects along an edge you want to connect (by default, this causes the shared edges to highlight), and then choose the command. In the Stitch Tool dialog on page 1924, adjust the settings, and then click OK to accept or Cancel to abort.
**Pack UVs** Distributes all texture-coordinate clusters through the texture space using one of two methods and spacing you specify. This is useful if you have several overlapping clusters and wish to separate them.

Choosing Pack UVs opens the Pack dialog on page 1897.

**Sketch Vertices** Lets you draw outlines for vertex selections with the mouse. This is useful for matching coordinate cluster outlines to sections of the texture map *en masse*, without having to move vertices one at a time.

Choosing Sketch Vertices opens the Sketch Tool dialog on page 1914. Sketch Vertices is available only in the Vertex sub-object mode.

**Relax Dialog** Opens the non-modal Relax Tool dialog on page 1906, which lets you change the apparent surface tension in a selection of texture vertices by moving vertices closer to, or away from, their neighbors. Relaxing texture vertices can make them more evenly spaced, resulting in easier texture mapping. Available at all sub-object levels.

**NOTE** This command, as well as a Relax command that lets you apply the default settings to the current selection without opening the dialog, are available as assignable keyboard shortcuts on page 1879.

**Render UVW Template** Opens the Render UVs dialog on page 1910, which lets you export texture mapping data as an image file that you can then import into 2D paint software.

**Mapping menu**

Lets you apply one of three different types of automatic, procedural mapping methods to a model. Each method provides settings so you can adjust the mapping to the geometry you’re using.

With each method, the mapping is applied to the current face selection; if there is no face selection it is applied to the entire mesh.

Here’s a quick overview of the three methods:

- Flatten mapping prevents overlap of mapping clusters, but can still cause texture distortion.
- Normal mapping is the most straightforward method, but can result in even greater texture distortion than with Flatten mapping.
- Unfold mapping eliminates texture distortion, but can result in overlapping coordinate clusters.
In many cases, one of the automatic mapping functions will provide useful results. But with certain custom or complex objects, you might get the best results with manual mapping; use a variation of the basic procedure on page 1841, or use a procedural method as a starting point for custom mapping.

**Flatten Mapping** Applies planar maps to groups of contiguous faces that fall within a specified angle threshold.
Choosing Flatten Mapping opens the Flatten Mapping dialog on page 1893.

**Normal Mapping** Applies planar maps based on different vector-projection methods.
Choosing Normal Mapping opens the Normal Mapping dialog on page 1895.

**Unfold Mapping** Unfolds the mesh so you get no face distortion, but does not guarantee that faces will not overlap.
Choosing Unfold Mapping opens the Unfold Mapping dialog on page 1926.

**Options menu**

**Load Defaults** Loads the editor settings from the file `unwrapuvw.ini` in the plugcfg directory.

**Save Current Settings as Default** Saves the editor settings to the file `unwrapuvw.ini` in the plugcfg directory. Settings saved in this way persist between sessions.

**Always Bring Up The Edit Window** When on, selecting an object with the Unwrap UVW modifier active automatically opens the Edit UVWs dialog. By default, this is off, so you must click the Parameters rollout > Edit button to open the dialog.

**Preferences** Opens the Unwrap Options dialog on page 1927.

**Display menu**

**Hide Selected** Hides all selected sub-objects and associated faces.

**Unhide All** Reveals any hidden sub-objects.

**Unfreeze All** Unfreezes any frozen sub-objects.

**NOTE** You can freeze a sub-object selection with Freeze Selected, available from the right-click menu > Display quadrant.
Filter Selected Faces When on, the editor displays UVW vertices of the viewport selection at the Face sub-object level of the modifier, and hides the rest.

This is a quick way to work on a limited selection of the texture coordinates of a complex mesh while ignoring the rest. You can turn this on, go to the Face sub-object level of the Unwrap UVW modifier, and select the portion of the object whose texture coordinates you want to edit; only those coordinates appear in the editor, and remain visible even when you change the sub-object level. To work on a different portion, return to the Face level and change the selection in the viewport; the editor window updates to the new selection automatically.

Show Hidden Edges Toggles the display of hidden face edges.

Show Edge Distortion Uses a green-to-red color range to depict distortion: how far in length texture edges are from their corresponding geometry edges. The greater the disparity in lengths (that is, the greater the distortion), the redder the edge appears in the Edit UVW dialog window. Also draws end segments of edges that are too long as white, showing the difference in length from that of the geometry edge.

Left: Texture edges the same as or very close to geometry edges in length are green.
Center: Texture edges slightly different from geometry edges in length are brown.
Right: Texture edges very different from geometry edges in length are red.

When texture edges are longer than geometry edges, white end segments depict length disparity.

Use this display as a way to view where the areas of greatest distortion are in your texture mesh. If an edge is brown or red but doesn’t have white end segments, it’s too short. If it’s brown or red and has white end segments, it’s too long, by the total length of the white segments.
**Show Vertex Connections** In Vertex sub-object mode, toggles the display of numeric labels for all selected vertices. Shared vertices are indicated by the appearance of multiple same-numbered labels.

**Show Shared Sub-objects** When turned on, for the current selection, highlights any shared vertices and/or edges. You can change the highlight color on the [Unwrap Options dialog](#) on page 1927.

### View menu

**Pan** Activates the Pan tool, which lets you move horizontally and vertically in the window by dragging the mouse.

As with the viewports, if you use a three-button mouse, you can also pan by middle-button dragging.

**Zoom** Choose Zoom, and then drag downward in the editor window to zoom out and upward to zoom in. Zooming is centered about the point you click before dragging.

If you have a wheel mouse, you can also turn the wheel to zoom. Zooming is centered about the mouse cursor location.

**Zoom Region** To zoom to a specific area, choose Zoom Region, and then drag a rectangle in the editor window.

**Zoom Extents** Zooms in or out to fit all UVW vertices in the editor window.

**Zoom Extents Selected** Zooms in or out to fit all selected UVW vertices in the editor window.

**Zoom To Gizmo** Zooms the active viewport to the current selection.

**Zoom Extents Selected** Zooms in or out to fit all selected UVW vertices in the window.

**Show Grid** Displays a grid in the background of the editor window.

Default=on.

**Show Map** Displays a texture map in the background of the editor window.

Set the image via the drop-down list at the right end of the editor toolbar.

**Update Map** Causes the displayed texture map to reflect any changes to the texture, such as tiling settings or a different bitmap.
**Unwrap UVW Shortcuts**

To use keyboard shortcuts for the Unwrap UVW modifier, the Keyboard Shortcut Override Toggle on page 8420 must be on.

See also:
- Unwrap UVW Modifier on page 1837
- Keyboard Shortcuts on page 8419
- Keyboard Panel on page 8250
- Customize User Interface Dialog on page 8249

In general, this table includes only functions that have default keyboard shortcuts and functions with descriptions that are not documented in the Unwrap UVW reference topics.

<table>
<thead>
<tr>
<th>Unwrap UVW Function</th>
<th>Keyboard Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow Selections Inside Transform Gizmo</td>
<td></td>
<td>Lets you select vertices inside the gizmo by CTRL+clicking or ALT+clicking a vertex. When turned on, you can move only by dragging over empty space.</td>
</tr>
<tr>
<td>Always Bring Up The Edit Window</td>
<td></td>
<td>When on, the Edit UVWs dialog automatically opens when you access the Unwrap UVW modifier.</td>
</tr>
<tr>
<td>Blend Tiles To Background</td>
<td></td>
<td>Lets you blend the image in the Edit UVWs dialog with the background color. At 0 the image will be hidden while at 1 it will be at full intensity.</td>
</tr>

**UVW Editor Dialogs**

These topics describe support dialogs for the Unwrap UVW modifier.

**Flatten Mapping Dialog**

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Unwrap UVW > Edit button (on Parameters rollout) > Mapping menu > Flatten Mapping
The Flatten Mapping method of procedural mapping applies planar maps to groups of contiguous faces that fall within a specified angle threshold. It prevents overlap of mapping clusters, but can still cause texture distortion. The Flatten Mapping dialog lets you control how clusters are defined and mapped.

See also:

- Normal Mapping Dialog on page 1895
- Unfold Mapping Dialog on page 1926

Interface

![Flatten Mapping dialog](image)

**Face Angle Threshold** The angle used to determine the clusters to be mapped. As the Flatten Map gathers faces to be mapped, it uses this parameter to determine which faces get put in a cluster. This is the maximum angle that can exist between faces in a cluster.

The higher this number, the larger the clusters will be, with consequently greater distortion introduced as a result of texture faces' proportions deviating from their geometry-equivalent faces.

**Spacing** Controls the amount of space between clusters.

The higher this setting, the larger the gap that appears between clusters.

**Normalize Clusters** Controls whether the final layout will be scaled down to 1.0 unit to fit within the standard editor mapping area. If this is turned off, the final size of the clusters will be in object space, and they'll probably be much larger than the editor mapping area. For best results, leave this turned on.
Rotate Clusters Controls whether clusters are rotated to minimize the size of their bounding box. For instance, the bounding box of a rectangle rotated 45 degrees occupies more area than one rotated 90 degrees.

Fill Holes When turned on, smaller clusters will be placed in empty spaces within larger clusters to take the most advantage of the available mapping space.

By Material IDs When on, ensures that no cluster contains more than one material ID after flattening.

OK Accepts the settings, closes the dialog, and performs the mapping as specified.

Cancel Undoes any changes and closes the dialog.

Set As Default Makes the current settings the defaults for the current session.

Normal Mapping Dialog

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Unwrap UVW > Edit button (on Parameters rollout) > Mapping menu > Normal Mapping

The Normal Mapping method of procedural mapping applies planar maps based on different vector-projection methods. It is the most straightforward method, but can result in even greater texture distortion than with Flatten mapping on page 1893. The Normal Mapping dialog lets you control how clusters are defined and mapped.

See also:

- Flatten Mapping Dialog on page 1893
- Unfold Mapping Dialog on page 1926
Interface

![Normal Mapping Interface](image)

(drop-down) Sets the mapping method:
- Back/Front
- Left/Right
- Top/Bottom
- Box No Top
- Box
- Diamond

Spacing Controls the amount of space between clusters. The higher this setting, the larger the gap that appears between clusters.

Normalize Clusters Controls whether the final layout will be scaled down to 1.0 unit to fit within the standard editor mapping area. If this is turned off, the final size of the clusters will be in object space, and they'll probably be much larger than the editor mapping area. For best results, leave this turned on.

Rotate Clusters Controls whether clusters are rotated to minimize the size of their bounding box. For instance, the bounding box of a rectangle rotated 45 degrees occupies more area than one rotated 90 degrees.

Align By Width Controls whether the width or the height of the clusters is used to control the layout of the clusters.

OK Accepts the settings, closes the dialog, and performs the mapping as specified.
Cancel Undoes any changes and closes the dialog.

Set As Default Makes the current settings the defaults for the current session.

Pack UVs Dialog

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Unwrap UVW > Edit button (on Parameters rollout) > Tools menu > Pack UVs

The Pack UVs dialog contains controls for clusters.

Interface

(dropdown) Sets the packing method:

- **Linear Packing** Uses a linear method to lay out the faces. This method is fast but not very efficient, and tends to leave a lot of unused UV space.

- **Recursive Packing** Slower than the Linear method, but packs the faces more efficiently.

**Spacing** Controls the amount of space between clusters.

The higher this setting, the larger the gap that appears between clusters.

**Normalize Clusters** Controls whether the final layout will be scaled down to 1.0 unit to fit within the standard editor mapping area. If this is turned off, the final size of the clusters will be in object space, and they’ll probably be much larger than the editor mapping area. For best results, leave this turned on.
**Rotate Clusters** Controls whether clusters are rotated to minimize the size of their bounding box. For instance, the bounding box of a rectangle rotated 45 degrees occupies more area than one rotated 90 degrees.

**Fill Holes** When turned on, smaller clusters will be placed in empty spaces within larger clusters to take the most advantage of the available mapping space.

**OK** Accepts the settings, closes the dialog, and performs the packing as specified.

**Cancel** Undoes any changes and closes the dialog.

**Set As Default** Makes the current settings the defaults for the current session.

---

**Pelt Map Parameters Dialog**

Unwrap UVW Modifier > Face sub-object level > Map Parameters rollout > Pelt > Edit Pelt Map

*Pelt mapping* on page 1853 is useful for mapping organic models such as characters and creatures. This feature gives you a special editor with a virtual stretcher and springs that let you easily “pull” a complex UVW map flat. The result more closely approximates the actual shape of the object than other mapping methods, making it easier to create convincing texture maps.

The primary function of the Pelt Map Parameters dialog is to let you stretch out the UVW coordinates into a flat, unified map that you can then use for texturing. When the dialog is open, the *stretcher* appears in the Edit UVWs dialog window as a circle of points, each of which is attached to a vertex on a pelt seam. You can manipulate these vertices exactly as any other vertex in the editor, selecting, rotating, moving, etc. Other special functions available on the dialog let you straighten out stretcher vertices, snap them to the pelt seams, and so on.
The stretcher points surround the pelt UVs in the Edit UVWs dialog window.

The lines connecting the stretcher vertices to the pelt-seam vertices function as springs that pull the pelt seams outward in an animated simulation. After you set up the pelt UVs and the stretcher shape, you run the simulation by clicking the Simulate Pelt Pulling button. Depending on the results, further adjustment and simulation might be required.

While Pelt mode is active and the Edit UVWs dialog is open, most standard UVWs editing functions are also available. So, for example, instead of stretching the entire pelt, you could select a subset of UVs to stretch. To access any commands that are unavailable in Pelt mode, such as Mapping menu commands, simply close the Pelt Map Parameters dialog.
Procedure

To use Pelt mapping:

1. Apply Unwrap UVW to the object.

2. Make an edge selection that you can later convert to pelt seams. It's not absolutely necessary to do this at this point, but the Edge sub-object level of the modifier gives you handy Ring and Loop tools as well as buttons to expand and shrink the edge selection automatically.

   **TIP** Creating the pelt seams is more art than exact science. Visualize the way the mesh should lie flat, and then select edges so the UVs can split in a natural way.

3. Go to the Face sub-object level of the modifier and select the faces to pelt map. To select all faces, press Ctrl+A. If you're not pelt-mapping the entire mesh, you can skip this step.

4. If you made an edge selection in step 2, click Map Parameters rollout > Edge Sel To Seams. This copies the edge selection to pelt seams. If you didn't specify the pelt seams at the Edge sub-object level of the modifier, turn on Edit Seams or Point To Point Seam and then specify seams in the viewports.

   The pelt seams appear on the mesh as blue lines.

5. If you're not pelt-mapping the entire mesh, you probably want to map a region enclosed by a pelt seam. Click a face within the region to map and then click Exp. Face Sel to Pelt Seams.

   This expands the face selection to the full size of the region defined by the pelt seam.

   **NOTE** You can pelt map only one such region at a time.

6. On the Map Parameters rollout, click Pelt.

   This opens the Pelt Map Parameters dialog. It also opens the Edit UVWs dialog, if necessary, and displays the pelt UVWs and the stretcher in the editor window. By default, the stretcher appears as a circle of points centered on the pelt UVWs, with only the stretcher vertices selected. Also, springs, represented as dashed lines, connect the stretcher points and the pelt-seam vertices.
7 If necessary, rotate the Pelt UVs so that the mapping coordinates are oriented correctly, and rotate the stretcher so that the springs form a symmetrical pattern. Typically you're looking for left-right symmetry.

**TIP** Using Ctrl+click adds to the existing selection, as in the viewports.

8 On the Pelt Map Parameters dialog, click Start Pelt.

The springs contract, pulling the pelt seam vertices toward the stretcher points. The internal UV vertices are also affected by this action. You can adjust the extent to which they're affected with the Decay setting on the Pelt Options rollout.

9 The simulation runs continuously until you stop it by clicking the Stop Pelt button. Do so when you’re satisfied with the solution, or would like to adjust something.

10 Continue adjusting the stretcher points, mapping vertices, dialog settings, etc., and re-running the solution until you get the desired results. If things get out of hand, simply undo, or click Reset and start over.

**Interface**

The primary Pelt Map commands are activated via the buttons on the Quick Pelt rollout. Other functions on this dialog let you adjust various stretching parameters.
Quick Pelt rollout

These are the main controls for the simulation, in which the springs attached to the stretcher pull the pelt seam vertices out, flattening the UVs. For best
results, alternate between running the simulation (click Start Pelt) and relaxing the mesh.

**Pelt group**

**Start Pelt** Runs the simulation, pulling the pelt seam vertices towards the stretcher points. The simulation runs continuously until you stop it by pressing Esc or clicking Stop Pelt (the same button). You can also stop it by clicking Reset, or Commit or Cancel at the bottom of the dialog.

Pelt affects only selected texture vertices. However, if no texture vertices are selected, it affects all of them.

**Reset** Stops the simulation if it’s running, and returns the pelt and stretcher to their original condition.

You can also reset the pelt by exiting pelt mapping mode by clicking either Commit or Cancel, and then clicking the Pelt button again.

**Simulation Samples** The number of samples around each pelt-seam point used in the simulation. A higher value results in a greater pulling effect. Default=5. Range=1 to 50.

**Show Local Distortion** When on, depicts the differences between texture vertices and mesh vertices for visible faces; that is, faces selected in the viewport when Filter Selected Faces on page 1862 is on. For more information, see Show Edge Distortion on page 1877.

Normally, when showing edge distortion, 3ds Max takes the entire mesh into account. This can result in an unrealistic depiction of distortion when you use pelt mapping on only part of a mesh (for example, the head of a character). For a more accurate depiction of distorted edges with respect to the part of the mesh that you’re currently pelt-mapping, turn on this option, turn on Filter Selected Faces, and select in the viewport only the faces that you’re currently pelt-mapping.

**Relax group**

**Start Relax** Normalizes the distances between mapping vertices. The relaxation process runs continuously until you stop it by pressing Esc or clicking Stop Relax (the same button).

Relax affects only selected texture vertices. However, if no texture vertices are selected, it affects all of them.

**Settings** Opens the Relax Tool dialog on page 1906 for setting relax parameters. While this dialog is open, you can start the relax by clicking its buttons or the Start Relax button on the Pelt Map dialog.
Pelt Options rollout

Stretcher group

These tools help adjust the stretcher shape.

**Straighten Stretcher** Lets you specify a polygonal outline for the stretcher by moving points. When this mode is active, move one stretcher vertex, and then move a second, non-adjacent point to line up all intervening vertices in a straight line between the two. This process is fully interactive; as you move the second vertex, the intervening vertices continually change position to maintain the straight line. Continue moving vertices to create a polygonal outline; to quit, click Straighten Stretcher again.

**NOTE** While Straighten Stretcher is active, you can pan and zoom the editor window at any time using contextual controls (middle-button drag or turn mouse wheel, respectively) to access a different part of the window. After doing so, 3ds Max still remembers the last vertex you dragged and draws a straight line between it and the next one you drag. Similarly, you can adjust the window using the control buttons on page 1862 and then return to straightening the stretcher. If the control requires more than a single click, such as Pan, exit the control by right-clicking in the window and then return to straightening the stretcher.

**TIP** To create a symmetrical outline for the stretcher, create the outline on one side and then use Mirror Stretcher (see following).

**Snap To Seams** Aligns all the stretcher points to the edge seams on the pelt UVs. This causes the stretcher to take on the pelt outline.

**TIP** For best results, use this command only after stretching.

**Mirror Stretcher** Mirrors the stretcher points from one side of the mirror axis (see following) to the other. By default, Mirror Stretcher mirrors the points from the right side to the left.

**Mirror Axis** Lets you specify the orientation of the mirror axis. The axis takes the form of three yellow lines forming a T. The leg of the T indicates the side that will be mirrored when you use Mirror Stretcher (see preceding), and the crossbar indicates the axis across which the mirroring will occur. Default=0.0. Range=0.0 to 360.0.
Select group

These commands let you select all the stretcher points or the pelt UVs. As with other selection methods, you can press and hold Ctrl when you use either of these to add to the current selection. That is, to select all stretcher points and pelt UVs, click one button, press and hold Ctrl, and then click the other button.

Select Stretcher Selects all stretcher points.

Select Pelt UVs Selects all pelt texture vertices.

Springs group

These parameters control the springs that are used to stretch the pelt. In most cases you won’t need to change these values, except possibly for Pull Strength.

Pull Strength The magnitude of the stretching action when you click Simulate Pelt Pulling. Default=0.1. Range=0.0 to 0.5.

If the stretching is too gradual, increase Pull Strength for a more forceful stretching action.

Dampening Applies a dampening or inhibiting factor to the pulling action. The higher the Dampening value, the greater the inhibition of the stretcher. Default=0.16. Range=0.0 to 0.5.

Stiffness Sets the rate at which the springs pull. The higher the Stiffness value, the more abrupt the pulling action. Default=0.16. Range=0.0 to 0.5.

Decay The rate of falloff of the influence of each pelt-seam vertex on the other mapping vertices. Higher Decay values typically result in significantly greater stretching, or undesirable results. For best results, keep the Decay value low. Default=0.25. Range=0.0 to 0.5.

Lock Open Edges Locks the open edges in place. This typically applies to using the stretcher on a partial selection of mapping vertices in the pelt region. When Lock Open Edges is on, selected vertices next to unselected vertices tend to stay in place during stretching. When Lock Open Edges is off, the selected vertices tend to pull away from the unselected vertices.

Commit/Cancel

Commit Saves changes and closes the dialog.

Cancel Discards changes and closes the dialog.
Relax Tool Dialog

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Unwrap UVW > Edit button (on Parameters rollout) > Edit UVWs dialog > Make a selection. > Tools menu > Relax Dialog

The Relax Tool dialog offers an advanced toolset for modifying the spacing of selected texture coordinates parametrically, for the purpose of eliminating or minimizing distortion in texture maps.

The dialog provides three different methods for relaxing vertices, plus several numeric parameters and two check boxes. You can use Relax to separate texture vertices that are too close together to texture easily, and to resolve overlapping areas.

The dialog is non-modal, which means that you can work directly in the editor while keeping the dialog open. You can make a selection of texture vertices, apply relaxation, make a different selection, apply relaxation, and so on, without having to close the Relax Tool dialog.

**TIP** When using Relax with complex objects, you might find that vertices in interior sections of the texture mesh don’t relax properly because they have nowhere to go. In such cases, try making a seam: Select an edge loop or part of a loop, and then use the Break on page 1874 function to separate the mesh at the seam. Alternatively, you could make a face selection and then use Detach Edge Verts. For example, Select Overlapped Faces > Expand Selection > Detach Edge Verts will break the selection away from the mesh into a new UV element.

**TIP** Effective use of the Relax tools requires that the geometry and texture vertices be in the same order. If you get unexpected results using Relax, try mirroring the texture vertices to reverse their order.

Procedures

To relax texture coordinates:

1. Use the Edit UVWs dialog to select the texture-coordinate vertices to relax.
   
   You can make this selection at any sub-object level (Vertex, Edge, or Face), but Relax always works on vertices.

2. On the Tools menu, choose Relax Dialog.
This opens the Relax Tool dialog.

3 Choose the relax method. Three are available from the drop-down list:
   ■ Relax By Face Angles
   ■ Relax By Edge Angles
   ■ Relax By Centers

   The default method is Relax By Edge Angles; this usually gives the best results.

4 Do either of the following:
   ■ Set the other options and then click Apply. This applies the Amount and Stretch settings for the specified number of iterations. As the relaxing progresses, a message appears showing you which frame is being processed. A frame is equivalent to an iteration.

   ■ Click Start Relax. This ignores the Iterations setting and initiates a continuous relax process, during which you can change any of the other parameters to see the results in real time.

The appropriate relax method and other settings depend on a variety of conditions, including the complexity and topology of the mesh, so experimentation is usually required. Relaxing is undoable, so if one method doesn't work, undo and try another.
To use Relax to fix overlapping faces:

This procedure provides general guidelines for resolving overlapping texture faces. It might not work in every case, but it should give you a starting point for correcting most situations.

1. Open the Edit UVWs dialog and in the Selection Modes group, click Face Sub-object Mode.

2. From the Edit UVWs dialog > Select menu, choose Select Overlapping Faces.
   Only the overlapping faces are selected.

3. Click Expand Selection to select faces surrounding the overlapping faces.
   This gives the overlapping faces a larger area in which to spread out.

4. From the Tools menu, choose Relax Dialog.

5. On the Relax Tool dialog, set Stretch to an intermediate value. If the overlapping is considerable, use 0.5 or higher. If it's relatively small, try 0.1 to 0.3.

6. Click Apply.
   If this seems to help, continue clicking Apply, or just click Start Relax, and wait until the overlapping is resolved. If not, undo (Ctrl+Z) and try using Relax By Face Angles instead, or increase the Amount value, or change the Stretch value, or use combinations of the above.
Interface

[relax method] The method used to relax the texture vertices. Choose from the drop-down list:

- **Relax By Face Angles**  Relaxes the vertices based on the shape of the faces. It tries to align the geometric shape of the face to the UV face. This algorithm is mainly used to remove distortion and not so much to remove overlap, and is best suited for simpler shapes.

- **Relax By Edge Angles**  This default method is similar to Relax By Face Angles except that it uses the edges that are attached to the vertices as the shape to match. It typically works better than Relax By Face Angles but tends to take longer to reach a solution. This method is best suited for more complex shapes.

- **Relax By Centers**  The original Relax method from previous versions of 3ds Max. It relaxes vertices based off the centroids (centers of mass) of their faces. It does not take into account the face or edge shapes/angles so it is mainly useful for removing overlap or for faces that are mostly rectangular.

**Iterations** The number of times the Relax settings are applied when you click Apply. Each iteration is applied successively, to the results of the previous iteration. Range=0 to 100000, Default=100.

**Amount** The strength of the relaxation applied per iteration. Range=0.0 to 1.0. Default=0.1.

**Stretch** The amount of stretching that can occur. Stretching is useful mainly to resolve overlapping texture vertices, at the cost of reintroducing distortion into the texture mesh. Range=0.0 to 1.0. Default=0.0.
Keep Boundary Points Fixed Controls whether vertices at the outer edges of the texture coordinates are moved. Default=off.
When off, the outer edge of the texture mesh can float, allowing a wider range of the available texture-mapping space to be used. Typically you would keep this off when relaxing an entire element or cluster, so 3ds Max can minimize distortion by moving the edges.
When relaxing an interior subset of vertices, it is recommended you turn this on to prevent the selected vertices from overlapping unselected vertices. For Relax By Edge and Face Angles, turn this off until you get a good solution for the outer boundaries of the mesh and then turn it on to resolve the interior sections.

Save Outer Corners Preserves the original positions of texture vertices farthest away from the center. Available only with the Relax By Centers method.

Start Relax Initiates the relax process on a continuous basis, ignoring the Iterations setting. During this time, you can change the other dialog settings and see the results in real time.
To halt the relax process, click outside the dialog, press Esc, or click the same button (“Stop Relax”). To revert to the previous mapping, use Undo (Ctrl+Z).

Apply Begins the relaxation process using the current settings. As relaxation takes place, a textual progress indicator appears at the bottom of the dialog, showing the current iteration (Process frame) and the total number of iterations being processed.
To abort the relaxation process, press Esc. You can then use Undo (Ctrl+Z) to return to the prior state, if necessary.

Set As Default Saves all current settings as the Relax defaults, so they are recalled from session to session.

Render UVs Dialog

Unwrap UVW modifier > Edit button (on Parameters rollout) > Tools menu > Render UVW Template

The Render UVs dialog, part of the Unwrap UVW editor on page 1856, lets you export a model's texture mapping data as a template; a bitmapped image file. You can then import this template into a 2D paint program, apply color as needed, and then bring it back into 3ds Max as a texture map to apply to the model. The exported file looks like a screen shot of the editor window, but without any background texture, and has the added options of setting color and alpha options for both the edges and the area they cover.
For a procedure that covers usage of this dialog, see To export texture coordinates to a paint program: on page 1844.

**Interface**

**Width/Height** The horizontal and vertical dimensions of the output (rendered) template image in pixels.

**Guess Aspect Ratio** Adjusts the Height value to produce an output aspect ratio based on the Width value and the dimensions of the UV grid.

For instance, if a rectangular UV grid measures 20 x 100 units and you click Guess Aspect Ratio, it would try to keep the bitmap at the 1:5 aspect ratio. This makes painting on the bitmap easier because the bitmap is at the correct aspect ratio for the mesh.
WARNING Using this function can result in Height value that is not a power of 2. If your mesh is destined for a real-time renderer, adjust the resulting Height value to the nearest power of 2 after using Guess Aspect Ratio. For example, if it sets Height to 650, change it to 512 before rendering the template.

Force 2-Sided When on, all UV edges are rendered into the template. When off, only UV edges of faces facing the viewer are included; edges of back-facing faces are not rendered.

Fill group

Fill is the coloring applied to the rendered bitmap in the face areas between edges. By default, there's no fill; the bitmap color is black, and the alpha channel is fully transparent. You can change this to a solid color or to shading derived from the mesh and lighting in the scene, or from the normal directions.

NOTE The overlap color overrides the fill color. For example, if Show Overlap is on and all visible faces overlap other faces, all faces will show the overlap color, ignoring the fill color.

[color swatch] Shows the fill color used for faces when Mode is set to Solid. To change the color, click the swatch.

Alpha Sets the alpha-channel value for the fill areas when Mode=Solid, Normal, or Shaded. When Mode=None, the fill alpha is always 0.0 (transparent). Range=0.0 (transparent) to 1.0 (opaque). Default=1.0.

The alpha channel is included with the rendered image only when you save in a format that supports transparency, such as TIF or Targa.

Mode Specifies the method used for filling faces in the rendered template.

■ None: No fill is rendered. This setting ignores the Alpha value, and sets fill alpha to 0.0; that is, fully transparent.

■ Solid: Renders faces using the fill color specified by the swatch at the top of the Fill group.

■ Normal: Renders each vertex's normals into the bitmap. The result looks similar to a normal map.

■ Shaded: Uses a simple lighting setup to render shading across the UV surface.

Show Overlap When on, fills faces that overlap other faces with the overlap color, shown in the color swatch to the right. Default=on.
To change the overlap color, click the color swatch.

**Edges group**

[**color swatch**] Shows the color used for rendered edges. To change the color, click the swatch.

**Alpha** Sets the alpha-channel value for edges. Range=0.0 (transparent) to 1.0 (opaque). Default=1.0.

The alpha channel is included with the rendered image only when you save in a format that supports transparency, such as TIF or Targa.

**Visible Edges** When on, edges are rendered using the specified edge color. Default=on.

**Invisible Edges** When on, hidden edges are rendered using the specified edge color. Default=off.

Hidden edges are most often found dividing mesh polygons into triangles. They aren't present in polygon objects.

**Seam Edges** When on, seam (outside) edges are rendered using the specified seam color. Default=on.

To change the seam color, click the color swatch. The default color (green) is the same as that used for seam edges in the Edit UVWs dialog, but the two can be changed separately.

---

**Render UV Template** Renders the template bitmap in a new rendered frame window on page 6513.

To save the rendered frame, click the Save Bitmap button.

---

**NOTE** This command renders the normalized UV space, from (0,0) to (1,1), as depicted in the editor by a dark blue outline. For best results, make sure the texture UVs fill this space but don't exceed its bounds.

---

**TIP** To turn off the background texture, which tends to obscure the UV space outline, click the Show Map button on the upper toolbar.
Sketching Tool Dialog

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Unwrap UVW > Edit button (on Parameters rollout) > Tools menu > Sketch Vertices

If you need to match a contiguous selection of texture vertices to an outline in a bitmap, whether an irregular shape, a straight line, or a geometric shape, you can use the Sketch tool to perform the operation quickly, rather than dragging the vertices one at a time.

Procedures

Example: To sketch texture vertices free form:

You can start with the vertices already selected, or use the Sketch tool to select them. In this example, we’ll assume the latter.

1. Choose Sketch Vertices.
2. In the Sketch Tool dialog, next to Select By, choose Drag Selection, if necessary.
3. Next to Align To, choose Free Form, if necessary.
4. Make sure Show Vertex Order and Interactive Mode are turned on. Leave Drag Cursor Size at the default setting.
5. Click OK to close the dialog.
   The mouse cursor takes the form of a circle, which means you’re in “drag select” mode.
6. In the editor window, drag the cursor over the vertices to select, and then release the mouse button.
   As you drag, each vertex is assigned a consecutive number. When you release the mouse button, the cursor turns into a pencil, which means you’re in “sketch” mode.

   **NOTE** Before you start sketching, each successive mouse click alternates between drag and sketch modes.

7. In the editor window, drag a wavy line.
   The selected vertices follow the line in numeric order, spreading out evenly over its length. To start the sketch over, release the mouse button, and then drag again.
Alternatively, if you press and hold Alt, and then press and release the mouse button, you'll draw a straight line by moving the mouse. Click and move again to draw connected straight-line segments.

You can combine free-form and straight-line sketching freely:

- To append a free-form line to a straight-line segment, release the Alt key and then begin dragging.
- To append a straight-line segment to a free-form line, press and hold Alt as you drag, and then release the mouse button and move the mouse.

8 To exit the Sketch tool, right-click in the editor window.

Interface

Select by lets you choose how to select the vertices to sketch:

- **Pick Selection** lets you pick the vertices one by one. When you click OK, a Pick cursor appears comprising a + sign and the letter P; when the cursor is over a vertex, the + sign becomes larger. To finish picking, right-click, and then drag to sketch. After sketching, you return to Pick mode, and so on. To exit, right-click.

- **Drag Selection** lets you pick multiple vertices by dragging. When you click OK, the mouse cursor appears as a circle. After you drag to select vertices, release the mouse button, and then drag (or Alt+click) to sketch. As with Pick Selection, the mouse cursor continues to alternate between Select and Sketch modes until you right-click to exit.
Use Current Selection  Uses the current selection; you cannot change the selection while using the tool. If the current selection is edges or faces, Sketch uses all vertices attached to selected sub-objects.

Align To  Lets you choose how to sketch:
- Free Form  Drag to sketch free form (like drawing with a pencil), or Alt+click to sketch connected
- Line  Drag to sketch a single, straight line segment.
- Box  Drag diagonally to sketch a rectangle.
- Circle  Drag outward to sketch a circle, and then move the mouse in a circle to rotate the circle.

Show Vertex Order  Displays numbered labels that indicate the order in which vertices were selected and will spread out during sketching.

Interactive Mode  Shows vertex positioning as you sketch. Turn off for faster feedback.

Drag Cursor Size  Sets the size of the mouse cursor used while dragging a selection. Default=8. Range=1 to 15.

OK  Accepts the changes and closes the dialog.

Cancel  Undoes any changes and closes the dialog.

Set As Default  Makes the current settings the defaults for the current session.

Spline Map Parameters Dialog

Unwrap UVW Modifier > Face sub-object level > Map Parameters rollout > Spline

Spline mapping on page 1853 is useful for mapping curved objects with a cylindrical cross-section, such as a snake or tentacle, as well as curved flat surfaces such as a winding road. This feature lets you use any spline to specify mapping on a mesh surface, as well as manipulate the mapping gizmo via cross-sections for greater accuracy. The result more closely approximates the actual shape of such objects than other mapping methods, making it easier to create convincing texture maps.

The following illustration shows two objects that were created by extruding a circular polygon along an S-shaped spline. Such objects have no native
mapping coordinates. The object on the left uses simple planar mapping, with the plane parallel to its largest dimension. The object on the right uses spline mapping, with the spline (also used to extrude the polygon) inside the object.

Working with Cross-sections

You can adjust spline mapping in two ways:

- **By manipulating the assigned spline.** To use this method, you must exit the modifier, select the spline, and then transform it or its sub-objects (typically the vertices). To see the results of such manipulation, you must re-select the mapped object, go to the Face sub-object level, and then click the Spline button.

- **By manipulating the cross-sections in the Unwrap modifier.** This is the recommended method because it provides better feedback. Thus, it is important to make sure the spline fits the mapped object well before applying the spline mapping. If you have problems manipulating the cross-sections, sometimes the fastest way to recover is to delete the Unwrap UVW modifier and start fresh with a new one.
When manipulating cross-sections, keep the following points in mind:

- When Spline mode is active (that is, the Spline Map Parameters dialog is open), you can select and transform only cross-sections. To select cross-sections, use standard methods, such as clicking, Ctrl+clicking, region-selecting, and, to select all cross-sections, Ctrl+A. Selected cross-sections are yellow, and unselected ones are orange.

- All cross-section transforms take place in the Local coordinate system.

- Moving a cross-section on the Z axis always moves it along the length of the spline used for mapping. However, doing so does not change the mapping between the moved cross-section and the next one. For example, moving a cross-section closer to its neighbor does not compress the intervening texture coordinates. The main reason for having cross-sections close together is for finer control over mapping within complex areas of the model.

- With the Planar mapping method, it’s important to use well-formed mesh objects; that is, objects without narrow bends, with evenly spaced tessellating edges that cross the “track” perpendicular to its sides. In particular, avoid objects with the following two characteristics:
  - Narrow bends. In particular, this type of shape can cause tessellating edges that connect to the same side instead of crossing the “track,” as shown in the following illustration.
“Fan” edges, where several edges share a single endpoint. This can cause the type of mapping anomalies shown in the following illustration.
Procedure

To use Spline mapping:

1. Create a mesh object to map, and a spline with which to specify the mapping. Position the spline *inside* the mesh object. For best results, always center the spline inside the mesh.

   **TIP** To create the spline from a series of edges, use *Create Shape from Selection* on page 2285.

2. Apply Unwrap UVW to the mesh object.

3. Go to the Face sub-object level, and then select the faces to map. To map the entire object (that is, all faces), leave all faces unselected.

5. Click the Pick Spline button, and then select the spline to use for mapping. Either click the spline in the viewport or press H and select it by name. At this point, or if you already applied a spline, the mapping gizmo appears around the spline, showing the outlines and cross-sections.
If necessary, modify the mapping by transforming the cross-sections in the viewports and adjusting the Spline Map Parameters dialog settings. Keep in mind that changes affect only the mapping on selected faces, unless no faces are selected, in which case changes affect the mapping on all faces.

If you use the Planar mapping method, make sure the cross-sections are parallel to the flat surface. One way to do so is to select all the cross-sections (press Ctrl+A), then click the Align To: Face button, and then click a face on the surface.
Interface

**Spline group**

These settings are for overall mapping.

**Pick Spline** Lets you specify a spline to use for mapping. Click this button and then select the spline. After you specify the spline, its name appears in the space above the button.

If the spline contains several elements, the element used for mapping is the one you click.

**Mapping** Lets you specify how the modifier projects the map onto the mesh.

- **Circular** Use for objects with a circular cross-section, like a tube. With circular projection, the cross-sections are circular by default. You can change the mapping by transforming these cross-sections. For example, you can create a spiral mapping effect by rotating the cross-sections around their local Z axes by successively greater amounts.

- **Planar** Use for flat objects, like a road.
With planar projection, the cross-sections are lines. For best results, make sure the cross-sections are parallel to the mesh surface, and perpendicular to the spline used for mapping. In most cases, this happens by default.

**Use Manual Seams** When on, uses the pelt seam on page 1854 as the texture border. When off, uses the green seam line built in to the spline-mapping gizmo.

This option is available only with Circular mapping, and works best with relatively simple objects with open ends.

**Cross Section group**

After you assign a spline in the Spline group (see preceding), 3ds Max applies the spline mapping to the object, creating a cross-section for each vertex in the spline. The settings in this group let you manipulate the cross-sections. To select a cross-section, click it. To select all cross-sections, press Ctrl+A.

In Spline mode you can transform selected cross-sections in the local coordinate system, moving, rotating, and scaling them as you like to adjust the texture coordinates.

**NOTE** If you have two cross-sections close together with very different orientations or scaling values, the mapping might show visual anomalies (such as pinched UVs) as the Unwrap modifier interpolates quickly from one section to the next.

**Fit** Resizes selected cross-sections to match the adjacent geometry.

**NOTE** With asymmetrical geometry, Fit might give unexpected results because it adjusts the cross-section to the closest parts of the neighboring geometry along the cross section's local X and Y axes. In such cases, you might need to transform the cross-section manually to get the best fit.

**Add** Lets you add cross-sections for finer control over the interpolation of the mapping between cross-sections. Click this button and then click the spline where you want to add a cross-section. The mouse cursor changes to a crosshairs when over the spline. Continue adding cross-sections as necessary, and then click the button again to exit Add mode.

**Remove** Deletes any selected cross-sections. The end cross-sections cannot be deleted.

**Align To:**

- **Section** Aligns the selected cross-sections to another cross-section. Select the cross-sections to align, click Section, and then click the target.
cross-section. Aligned cross-sections pick up the orientation and scale of
the target.

- **Face**  Aligns the selected cross-sections to a mesh face on the modified
  object. Select the cross-sections to align, click Face, and then click the face
to align them to.
  This tool is most useful with Planar mapping.

**Reset Count to**  Lets you specify the number of evenly spaced cross-sections.
Set the numeric value and then click the Reset Count To button.
This tool is useful when the mapping spline has many vertices, and you want
to reduce the number of cross-sections to a manageable number.

**Commit/Cancel**

**Commit**  Applies changes and closes the dialog, exiting spline-mapping mode.
**Cancel**  Discards changes and closes the dialog, exiting spline-mapping mode.

**Stitch Tool Dialog**

Select an object. > Modify panel > Modifier List > Object-Space Modifiers >
Unwrap UVW > Edit button (on Parameters rollout) > Tools menu > Stitch
Selected

After you've separated your object's UVW coordinates into clusters, either
manually or using one of the automatic tools on the Mapping menu on page
1875, you can use the Stitch tool to recombine specific clusters by merging
对应 edges.

**NOTE** You can stitch together only two clusters at a time. If the current sub-object
selection is shared by more than one cluster, then “majority rules”: Stitch attaches
the cluster that shares the most sub-objects. If the number of sub-objects shared
by multiple other clusters is the same, 3ds Max attaches the cluster whose shared
sub-objects were chosen first.

**Procedures**

**To stitch two clusters together:**

1  In the “source” cluster, select sub-objects along an edge you want to
connect.
By default, this causes the shared edges to highlight in the “target” object(s).

2 Choose Stitch Selected.
The clusters are connected.

3 Adjust the settings on the Stitch Tool dialog.
Feedback takes place in real time.

4 Click OK to accept or Cancel to abort.

Interface

Align Clusters Moves the target cluster to the source cluster, and rotates the target cluster into place if necessary. When off, the target cluster remains in its original position and orientation. Default=on.

TIP If your clusters overlap after stitching with Align Clusters turned on, cancel the stitching, and then position and align them as you want them after stitching. Then use the Stitch tool with Align Clusters turned off.

Scale Clusters Resizes the target cluster to a size comparable to that of the source cluster. Takes effect only when Align Clusters is on. Default=on.
Bias When Scale Clusters is off, Bias sets the extent to which attached sub-objects are moved from their original positions. At Bias=0, the sub-objects remain in their original positions in the source cluster. At Bias=1, sub-objects remain in their original positions in the target cluster. At in-between settings, their positions are averaged between the two.

When Scale Clusters is on, Bias sets where 3ds Max derives the scaling of the target cluster(s). At Bias=0, the scale is fully derived from the stitched edges on the source. At Bias=1, the scale is fully derived from the stitched edges on the target. At in-between settings, the scaling is averaged between the two.

OK Accepts the changes and closes the dialog.

Cancel Undoes any changes and closes the dialog.

Set As Default Makes the current settings the defaults for the current session.

Unfold Mapping Dialog

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Unwrap UVW > Edit button (on Parameters rollout) > Mapping menu > Unfold Mapping

The Unfold Mapping method of procedural mapping eliminates texture distortion, but can result in overlapping coordinate clusters. The Unfold Mapping dialog lets you control how faces are unfolded.

See also:

■ Flatten Mapping Dialog on page 1893
Normal Mapping Dialog on page 1895

Interface

(\textit{drop-down}) Sets the unfold method by specifying whether 3ds Max will start unfolding with the closest or farthest face angle, with respect to distance. In almost all cases, you'll get better results with Walk To Closest Face.

\begin{itemize}
  \item **Walk To Closest Face**
  \item **Walk to Farthest Face**
\end{itemize}

\textbf{Normalize Clusters} Controls whether the final layout will be scaled down to 1.0 unit to fit within the standard editor mapping area. If this is turned off, the final size of the clusters will be in object space, and they'll probably be much larger than the editor mapping area. For best results, leave this turned on.

\textbf{OK} Accepts the settings, closes the dialog, and performs the mapping as specified.

\textbf{Cancel} Undoes any changes and closes the dialog.

\textbf{Set As Default} Makes the current settings the defaults for the current session.

Unwrap Options Dialog

Select an object. > Modify panel > Modifier List > Object-Space Modifiers > Unwrap UVW > Edit button (on Parameters rollout) > Edit UVWs dialog > Options menu > Preferences

Set preferences for the Unwrap UVW editor using controls in the Unwrap Options dialog.
Chapter 9  Modifiers
Colors group

Contains color swatches to customize the display of the UVW lattice. With certain maps, the default colors may become difficult to see. Use these swatches to choose colors that work better for your specific map.

To change a color, click its swatch, and then use the Color Selector on page 371 to choose a new one.

Line Color Specifies the color of the UVW lattice lines. Default=white.

Handle Color The color assigned to patch handles. Default=yellow.

Show Shared Subs When turned on, non-selected sub-objects shared by the current selection are highlighted in this color. In most cases, the shared sub-objects are edges. With a single vertex, the shared sub-objects are vertices. Defaults=on, blue.

Selection Color Specifies the color of selected UVW sub-objects. Default=red.

Gizmo Color The color assigned to the Freeform gizmo on page 1858. Default=orange.

Display Seams When on, lets you assign a distinctive color to coordinate clusters' boundaries that appears in the viewports. Defaults=on, green.

Show Grid When on, the grid lines are visible. Defaults=on, dark blue.
You can also set the grid size on page 1931.

Background Color The color assigned to the background where the texture map isn't displayed. Default=dark gray.

(drop-down) Lets you assign a fill pattern to selected faces. Default=Cross Hatch Horizontal/Vertical.

Display Preferences group

Contains controls affecting the map display in the view window.

Render Width Specifies the width resolution of the image displayed in the view window. This does not change the size of the image, but only the resolution.

Render Height Specifies the height resolution.

Use Custom Bitmap Size When turned on, scales the bitmap texture to the values specified by Width and Height. You can adjust these settings to scale and reproportion the bitmap texture in relation to the texture coordinates.
This scaling doesn't affect the bitmap in the material, but only as viewed in the editor.

**TIP** When working with large textures, reduce the bitmap size for faster feedback. And when working with disproportionate textures, setting the dimensions closer to each other in the editor can make it easier to work.

**Tiles** The number of times the texture image is repeated, counting outward in eight directions (the four corners and the four sides).

With Tiles=1, the result is a 3 x 3 grid. With Tiles=2, the result is a 5 x 5 grid, and so on.

You can toggle the tiling feature with the Tile Bitmap check box, described below.

**Tile Brightness** Sets the brightness of the tiled bitmap. At 1.0, the brightness equals that of the original image; at 0.5 it’s half the brightness; and at 0, it’s black.

This is the same setting as Brightness in the UVWs editor > Bitmap Options group (available with Show Options).

**Tile Bitmap** When turned on, you can repeat the bitmap in the editor, displaying tiling set in the material.

You can use any part of the tiled image for setting texture coordinates. This is helpful when the sections of the texture image are packed tightly together and the mesh contains many different areas to map.

**Affect Center Tile** When turned on, the Brightness setting affects all tiles equally. When off, the center, or “home,” tile always remains at full brightness, so you can easily distinguish the home tile from the copies.

**Constant Update in Viewports** Affects the adjusting of UVW vertices in the viewport while you move the mouse. Default=off (the effect of adjusting the UVW vertices does not appear in the viewport until you release the mouse).

**Show Image Alpha** Displays the alpha channel of the background image in the editor, if it exists.

**Show Hidden Edges** Toggles the display of face edges. When turned off, only faces appear. When turned on, all mesh geometry appears.

**Blend Tile to Background** Affects the color to which tiles set to Brightness less than 1.0 blend. When turned off, tiles blend to black. When turned on, tiles blend to the background color on page 1929.
Misc. Preferences

Center Pixel Snap When turned on, snaps to the center of pixels of the background images instead of pixel edges.

Grid Snap When on, snaps to grid edges and intersections.

Vertex Snap When on, snaps to texture-coordinate vertices.

Edge Snap When on, snaps to texture-coordinate edges.

Weld Threshold Sets the radius within which welding using Weld Selected on page 1874 takes effect. The setting is in UV-space distance. Default=0.01. Range=0 to 10.

Grid Size Sets the spacing of horizontal and vertical grid lines. Default=0.1. Setting Grid Size to 0 effectively turns off the grid. At the highest value, 1.0, the grid is the same size as the texture.

Snap Str(length) Sets the grid snap on page 1862 strength. Default=0.2. Range=0 to 0.5. Setting the strength to 0 effectively turns off snapping. At values less than 0.3, grid snapping tends to go to grid edges. At the highest value, 0.5, grid snapping goes only to grid intersections.

Selection Preferences

Soft Selection Edge Distance When Soft Selection on page 1863 is turned on, limits the falloff region by the specified number of edges between the selection and the affected vertices. The affected region is measured in terms of "edge-distance" space rather than absolute distance. Default=16.

Single Click Hit Size Sets how far away you can click from a sub-object to select it. Default=4. Range=1 to 10.

Selected Tick Size Sets the size of the square icon the editor window uses to indicate selected vertices. Default=2. Range=1 to 10.

OK/Cancel/Defaults Click OK to accept, or Cancel to cancel the changes in the dialog. Click Defaults to restore all settings in this dialog to default values.
UVW Map Modifier

Select an object. > Modify panel > Modifier List > UVW Map
Select an object. > Modifiers menu > UV Coordinates UVW Map

By applying mapping coordinates to an object, the UVW Map modifier controls how mapped and procedural materials appear on the surface of an object. Mapping coordinates specify how bitmaps are projected onto an object. The UVW coordinate system is similar to the XYZ coordinate system. The U and V axes of a bitmap correspond to the X and Y axes. The W axis, which corresponds to the Z axis, is generally only used for procedural maps. A bitmap's coordinate system can be switched in the Material Editor to VW or WU, in which case the bitmap is rotated and projected so that it is perpendicular to the surface.

Mapping a sphere and a box.
By default, primitive objects such as spheres and boxes have mapping coordinates, as do loft objects and NURBS surfaces. Scanned, imported, or hand-constructed polygonal or patch models do not have mapping coordinates until a UVW Map modifier is applied.

**NOTE** Drawings that are imported or linked from Autodesk Architectural Desktop and Autodesk Revit do retain the mapping coordinates that were assigned to objects by those products.

If you apply a UVW Map modifier to an object with built-in mapping coordinates, the applied coordinates take precedence if map channel on page 8627 1 in the UVW Map modifier is used. The Generate Mapping Coordinates option, available during the creation of primitives, uses map channel 1 by default.

You use the UVW Map modifier to:

- Apply one of the seven types of mapping coordinates to an object on a specified map channel. A diffuse map on map channel 1 and a bump map on map channel 2 can have different mapping coordinates and can be controlled separately by using two UVW Map modifiers in the modifier stack.

- Apply one of the seven types of mapping coordinates to an object.

- Transform the mapping gizmo to adjust map placement. Objects with built-in mapping coordinates lack a gizmo.

- Apply mapping coordinates to an object with no mapping coordinates, an imported mesh, for example.

- Apply mapping at the sub-object level.

**Map Channels**

You can control the type of mapping coordinates and the placement of the mapping gizmo for each bitmap in a material that uses multiple bitmaps by assigning explicit map channels to the bitmaps. In the Material Editor you assign each map a different channel number, then you add multiple UVW Map modifiers to the object's modifier stack, each UVW Map modifier is set to a different map channel. To change the type of mapping or gizmo placement for a particular bitmap, you select one of the UVW Map modifiers in the modifier stack and change the parameters. You can change the name of a UVW Map modifier in the Edit Modifier Stack dialog to correlate the modifier to the bitmap.
Transforming UVW Map Gizmos

Changing a map’s location by moving the gizmo.

The UVW Map gizmo projects mapping coordinates onto an object. You can position, rotate, or scale a gizmo to adjust map coordinates on an object; you can also animate the gizmo. Gizmo transformations remain in effect if you select a new map type. For example, if you scale a spherical mapping gizmo and then switch to planar mapping, then the planar mapping gizmo is also scaled.

Gizmo Display for Different Map Types

For planar, spherical, cylindrical and shrink wrap maps, a short yellow line indicates the top of the map. The green edge of the gizmo indicates the right side of the map. On a spherical or cylindrical map the green edge is the seam where the left and right edge meet. Gizmo must be selected in the modifier display hierarchy to display the gizmo.
Gizmos for different projection types
Left to right: planar, cylindrical, box, and spherical

Effects of Transforming the UVW Map Gizmo

Moving the gizmo changes the center of projection and affects all types of mapping. Rotating the gizmo changes the orientation of the map, which affects all types of mapping. Uniform scaling does not affect spherical or shrink-wrap mapping. Non-uniform scaling affects all types of mapping.

If you scale a gizmo smaller than the geometry, then a tiling effect is created, unless scaling has no effect on the map type in use. Tiling based on gizmo size is in addition to tiling values set in the Material Editor Coordinates rollout for the map or the UVW Map modifier tile controls.
The size of the gizmo affects how the mapping is applied to an object.

**Manipulators for UVW Map**

The UVW Map modifier has graphic manipulators to help you adjust the mapping dimensions and tiling when Real-World Map Size is off. When Real-World Map Size is on, you can adjust positioning only for the Planar and Box mapping types.

Manipulators are visible and usable while the Select And Manipulate button on page 2838 is active. This button is on the default toolbar on page 8034. When you move the mouse over a manipulator, the manipulator turns red to show that dragging or clicking it will have an effect. Also, a tooltip appears, showing the object name, the parameter, and its value.

For more information on using the UVW Map manipulators, see the Procedures section on page 1938.

**UV width/length manipulators** In a viewport, drag the edges of the UVW Map gizmo to change the width or height.
UV tiling manipulators In a viewport, drag the small circle next to the U edge or V edge to adjust the tiling in that dimension.

Tile Controls

Use the UVW Tile controls if you want a map to repeat. Tiled maps are useful for bricks on a wall, or tiles on a floor. Rather than creating one large map, seamless maps can be tiled to surface a large area without visible seams, to give the illusion of a large map.

Tiling in the UVW Map modifier affects only the objects that use this modifier. Tiling a map in the Material Editor affects tiling on all the objects that use the material.

Material and UVW Map tiling are multiplied. For example, if a map in the Material Editor has a tile value of 2 on one axis, and a UVW Map modifier has a tiling value of 3 on the same axis, then the result is a tiling value of 6.

Objects with No Mapping Coordinates

If you render an object that doesn't have mapping coordinates or a UVW Map modifier, and the object uses a material with 2D bitmaps or 3D procedural maps that use explicit map channels, then a Missing Map Coordinates on page 6198 alert is displayed. The alert lists both the name of the object and the UVW channels or Vertex Color channels that are missing the coordinates. For example: (UVW 2): Torus01.

Mapping Selection Sets or Grouped Objects

You can apply one UVW Map modifier to a selection of objects. One large mapping gizmo will encompass the entire selection unless the Use Pivot Points option is turned on in the modifiers rollout before applying the UVW Map modifier. If the Use Pivot Points option is used then each object is encompassed with its own mapping gizmo.

If any of the objects in the selection has had its pivot point shifted in the Hierarchy > Pivot panel, and you use the Use Pivot Points option with the UVW Map modifier, then the mapping gizmos are centered to the pivot points rather than the object center and the mapping may be tricky to position the way you want.

Real-World Mapping

The idea behind real-world mapping is to simplify the use of texture mapped materials which are scaled correctly with the geometry in the scene. This
feature gives you the ability to create a material and specify the actual width and height of a 2D texture map in the material editor. When you assign that material to an object in the scene, the texture map appears in the scene with the correct scaling.

There are two parts to the equation in order for real-world mapping to work. First, the correct style of UV texture coordinates must be assigned to the geometry. Basically, the size of the UV space needs to correspond to the size of the geometry. Therefore, a new switch, called Real-World Map Size, has been added to many of the dialogs and rollouts where you can generate texture coordinates. Any dialog or rollout in which you have the option to turn on Generate Mapping Coords, also has a switch where you can turn on Real-World Map Size.

**NOTE** There are a few primitive objects that do not have a Real-World Map Size switch. These are Torus Knot, Hedra, Prism and RingWave.

The other part of the equation is in the material editor. When you create a material and use a 2D texture map, you now see a new switch in the Coordinates rollout called Use Real-World Scale. When this switch is turned on, the default, the Width and Height spinners are enabled that let you specify the horizontal/vertical offsets and size of the texture map in current display units on page 8366.

**NOTE** Autodesk VIZ scenes with objects using real-world mapping coordinates will display differently when opened in 3ds Max. This is because real-world mapping coordinates is not the default method of generating mapping coordinates in 3ds Max.

### Procedures

**To apply the UVW Map modifier:**

1. Assign a mapped material to an object.

2. On the Modify panel, choose UVW Map from the Modifier List.

3. Adjust the mapping parameters.

By default, the UVW Map modifier uses planar mapping on map channel 1. You can change the type of mapping and the map channel to suit your needs. There are seven types of mapping coordinates, ninety-nine map channels, tiling controls, and controls to size and orient the mapping gizmo in the UVW Map modifier.
NOTE  If a UVW Map modifier is applied to multiple objects, the UVW Map gizmo is defined by the selection, and the mapping that results is applied to all the objects.

To use multiple UVW channels in the same object:

1  Assign Map channel 1 to an object. You can do this by either turning on Generate Mapping Coordinates in the Parameters rollout of any primitive, or by assigning a UVW Map modifier with channel 1 chosen. Generate Mapping Coordinates uses map channel 1 by default.

2  Assign a UVW Map modifier (or a second one, if you're using the first to assign channel 1). Choose channel 2 for this modifier. Both coordinate channels are now assigned to the geometry. The next step is to assign a mapped material that uses both channels.

3  Create a material with two maps. You can do this using a Composite map, or a Blend material with two maps, or you can have one map assigned to Diffuse and another assigned to Bump. Perhaps the easiest way to see the effect is to composite two maps, with the second map containing an alpha channel.

4  Go to the level of one of the maps and, in the Mapping list, choose Explicit Map Channel 2. The other map is already assigned channel 1 by default.

5  Assign the mapped material to the object. You can switch between viewing the maps in the viewport using the Show Map In Viewport control in the Material Editor. You can adjust the mapping of channel 2 without altering the mapping of channel 1 if you've assigned two UVW Map modifiers. Render the scene to see the effect.

To use the XYZ to UVW option:

The XYZ to UVW option is used to make a 3D procedural texture, like Cellular, follow the animated surface of an object. If the object stretches, so does the 3D procedural texture. Currently, it cannot be used with NURBS objects and is unavailable if a NURBS object is selected.

1  In the Top viewport, create a box.

2  Create a material with a Cellular diffuse map.
3 In the Material Editor, on the Coordinates rollout of the Cellular map, open the Source drop-down list, and choose Explicit Map Channel. On the Coordinates rollout, the Map Channel parameter activates, leave the value at 1.

4 Assign the material to the box.

5 On the Modify panel, choose UVW Map from the Modifier List.

6 On the UVW Map modifier, turn on XYZ to UVW. By default, the Map Channel value is 1.

7 Render the Front viewport. The cellular pattern renders normally on the surface of the box.

8 Right-click over the object and choose Convert To: > Convert to Editable Mesh from the Transform (lower-right) quadrant of the quad menu. The box is converted to an editable mesh.

9 On the Modify panel, click to turn on Vertex on the Selection rollout.

10 In the Front viewport, select the top vertices of the box, and move them up.

11 Render the Front viewport again. The cellular pattern stretches with the box. This effect is enabled by the XYZ to UVW option. To see the difference, we will change the Source option in the Coordinates rollout in the Material Editor.

12 In the Material Editor, locate the diffuse Cellular material.

13 On the Coordinates rollout of the Cellular diffuse map, open the Source drop-down list and choose Object XYZ.

14 Render the Front viewport. The cellular pattern is no longer stretched.
To transform the UVW Map gizmo:

1. On the Modify panel, choose the UVW Mapping modifier in the stack display.
2. In the stack display, choose the Gizmo sub-object level.
   The gizmo changes to a yellow color, with one green edge.
   The green edge indicates the right edge of the texture.
3. Move, scale, or rotate the gizmo in the viewports, or use the Length and Width controls in the UVW Map modifier.
   Transforming the map gizmo shifts the bitmap, allowing you to orient and move the map on the object's surface.

To use manipulators to control the width and length:

1. On the Modify panel, choose the UVW Map modifier in the stack display.
   You can also be at the Gizmo level of the modifier.
2. On the default main toolbar, click to turn on Select And Manipulate.
   The UVW Map modifier's gizmo turns green, showing it is now a manipulator. Also, two small circles appear next to two of the gizmo's edges.
3. Drag an edge of the gizmo to adjust the width or length.
   A tooltip shows the new width or length value.

To use manipulators to control tiling:

1. On the Modify panel, choose the UVW Map modifier in the stack display.
   You can also be at the Gizmo level of the modifier.
2 On the default main toolbar, click to turn on Select And Manipulate. The UVW Map modifier's gizmo turns green, showing it is now a manipulator. Also, two small circles appear next to two of the gizmo's edges.

3 Drag one of the circles to adjust tiling in the U or V dimension. A tooltip shows which dimension you are adjusting, and the new tiling value in that dimension.

Interface

Modifier Stack

Gizmo sub-object level Enables gizmo transformations. At this sub-object level you can move, scale, and rotate the gizmo in the viewports to position the mapping. In the Material Editor, you turn on the Show Map in Viewport option to make the map visible in a shaded viewport, the map moves on the surface of the object as you transform the gizmo.
Mapping group

Determines the type of mapping coordinates used. Different kinds of mapping are distinguished by how the map is geometrically projected onto the object and how the projection interacts with the object's surfaces.

**Planar** Projects the map from a single plane flat against the object, somewhat like projecting a slide.
Planar projection is useful when only one side of an object needs to be mapped. It is also useful for obliquely mapping multiple sides, and for mapping two sides of a symmetrical object.

![Planar map projection](image)

**Cylindrical** Projects the map from a cylinder, wrapping it around an object. Seams where the edges of the bitmap meet are visible unless a seamless map is used. Cylindrical projection is useful for objects that are roughly cylindrical in shape.
Cylindrical map projection

Cap Applies planar mapping coordinates to the caps of the cylinder.

NOTE If the ends of the object geometry are not at right angles to the sides, the Cap projection bleeds onto the sides of the object.

Spherical Surrounds the object by projecting the map from a sphere. You see a seam and mapping singularities at the top and bottom of the sphere where the bitmap edges meet at the sphere's poles. Spherical mapping is useful for objects that are roughly spherical in shape.
Spherical map projection

**Shrink Wrap** Uses spherical mapping, but truncates the corners of the map and joins them all at a single pole, creating only one singularity. Shrink-wrap mapping is useful when you want to hide the mapping singularity.
Shrink-wrap projection

Box  Projects the map from the six sides of a box. Each side projects as a planar map, and the effect on the surface depends on the surface normal. Each face is mapped from the closest box surface whose normal most closely parallels its own normal.
Box projection (shown on a box and on a sphere)

**Face** Applies a copy of the map to every face of an object. Pairs of faces sharing a hidden edge are mapped with the full rectangular map. Single faces with no hidden edge are mapped with a triangular portion of the map.
Face projection

**XYZ to UVW** Maps 3D procedural coordinates to UVW coordinates. This "sticks" the procedural texture to the surface. If the surface stretches, so does the 3D procedural map. Use this option with procedural textures, like *Cellular* on page 6279, on objects with animated topologies. Currently, XYZ to UVW cannot be used with NURBS objects and is disabled if a NURBS object is selected.

**NOTE** In the Material Editor's Coordinates rollout for the map, set Source to Explicit Map Channel. Use the same map channel in the material and UVW Map modifier.
A sphere with a 3D procedural texture is copied, and the copies are stretched.

Right: Using XYZ to UVW on the object enables the 3D procedural texture to stick and stretch with the surface.

**Length, Width, Height** Specify the dimensions of the UVW Map gizmo. The default scale of the mapping icon is defined by the largest dimension of the object when you apply the modifier. You can animate the projection at the gizmo level. Note the following facts about these spinners:

- The dimensions are based on a bounding box of the gizmo. The Height dimension is unavailable for the Planar gizmo: It does not have depth. Likewise, the dimensions for Cylindrical, Spherical, and Shrink Wrap mapping all display the dimensions of their bounding box and not their radiuses. No dimensions are available for the Face map: Each face on the geometry contains the entire map.

- The three dimensions are set to 1 or 2, depending on map type and dimensions, when you load files created in Autodesk VIZ or earlier versions of 3ds Max. (This maintains compatibility with files from previous releases, in which gizmos were scaled non-uniformly to adjust their dimensions.).
The dimensions essentially become scale factors rather than measurements. You can reset the values to dimensions by clicking the Fit or Reset buttons, which will lose the original non-uniform scaling.

**U Tile, V Tile, W Tile** Let you specify the dimensions of the UVW map, for tiling the image. These are floating-point values, which you can animate to displace the map's tiling over time.

**Flip** Reverses the image about the given axis.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found on the applied material's Coordinates rollout on page 6201. Default=off.

When on, the Length, Width, Height and Tiling spinners are unavailable.

**Channel group**

Each object can have up to 99 UVW mapping coordinate channels. The default mapping (from the Generate Mapping Coordinates toggle) is always channel 1. The UVW Map modifier can send coordinates to any channel. This lets you have many different sets of coordinates on the same face simultaneously.

**Map Channel** Sets the map channel. The UVW Map modifier defaults to channel 1, so mapping behaves in the default fashion (and in the fashion of earlier software releases) unless you explicitly change to another channel. Default=1. Range=1 to 99

To use the additional channels, you must not only choose a channel in the UVW Map modifier, but also assign an explicit map channel at the map level of the material assigned to the object. You can use many UVW Map modifiers in the modifier stack, each one controlling the mapping coordinates of different maps in a material.

**Vertex Color Channel** Define the channel as a vertex color channel by choosing this option. Be sure to match any material mapping in the coordinates rollout to be Vertex Color as well, or by using the Assign Vertex Colors utility on page 6477.

The Map channels are accessed in various places in 3ds Max, as follows:

- **Generate Mapping Coords** This check box, in the creation parameters of most objects, assigns Map channel 1 when turned on.

- **UVW Map Modifier** Contains options for channels 1 through 99. This lets you specify which UVW coordinates are used by this UVW Map
modifier. The modifier stack can pass these channels simultaneously for any face.

- **UVW XForm and Unwrap UVWs**  These two modifiers also contain Channel option buttons.

- **Material Editor Channel Assignment**  You assign the channel to be used by a map in the Coordinates rollout at the map level in the Material Editor.

- The assignment varies depending on the type of map:

  - **2D Maps**
    In the Mapping list for the Texture option, you can choose Explicit Map channel, Vertex Color Channel, Planar from Object XYZ, or Planar from World XYZ.

  - **3D Maps**
    At the top of the Coordinates rollout, there is a Source list where you can choose an Explicit Map Channel, Vertex Color Channel, Object XYZ, or World XYZ. Use the Map Channel spinner to define the channel number.

- **NURBS Surface Objects and Sub-Objects**  Let you specify which Map channel the surface uses.

**Alignment group**

X/Y/Z  Select one of these to flip the alignment of the mapping gizmo. Each specifies which axis of the gizmo is aligned with the local Z axis of the object.

---

**NOTE**  These options aren't the same as the Flip check boxes beside the U/V/W Tile spinners. The Alignment option buttons actually flip the gizmo orientation, while the Flip check boxes flip an assigned map’s orientation.

**Manipulate**  When on, a gizmo appears on the object that lets you change parameters in the viewport. When Real-World Map Size is on, Manipulate is available only with the Planar and Box mapping types. For more information, see **Manipulators for UVW Map** on page 1936.
**TIP** Turn on snapping to adjust the mapping precisely.

**Fit** Fits the gizmo to the extents of the object and centers it so that it's locked to the object's extents. Unavailable when Real-World Map Size is on.

**Center** Moves the gizmo so that its center coincides with the center of the object.

**Bitmap Fit** Displays the standard bitmap file browser so that you can pick an image. Unavailable when Real-World Map Size is on.

For planar mappings, the map icon is set to the aspect ratio of the image. For cylindrical mapping, the height (rather than the radius of the gizmo) is scaled to match the bitmap. For best results, first use the Fit button to match the radius of the object and gizmo, and then use Bitmap Fit.

**Normal Align** Click and drag on the surface of the object to which the modifier is applied. The origin of the gizmo is placed at the point on the surface where the mouse is pointing; the XY plane of the gizmo is aligned to the face. The X axis of the gizmo lies in the object's XY plane.
Normal Align respects smoothing groups and uses the interpolated normal based on face smoothing. As a result, you can orient the mapping icon to any part of the surface, rather than having it "snap" to face normals.

**View Align** Reorients the mapping gizmo to face the active viewport. The size of the icon is unchanged.

**Region Fit** Activates a mode in which you can drag in the viewports to define the region of the mapping gizmo. The orientation of the gizmo is not affected. Unavailable when Real-World Map Size is on.

**Reset** Deletes the current controller controlling the gizmo and plugs in a new one initialized using the Fit function. Any animation to the gizmo is lost. As with all the alignment options, you can cancel the reset operation by clicking Undo.

**Acquire** Effectively copies the UVW coordinates from other objects. When you pick an object from which you want to acquire UVWs, a dialog prompts you whether the acquire should be done in an absolute or relative fashion. If you choose Absolute, the acquired mapping gizmo is positioned exactly on top of the mapping gizmo you pick. If you choose Relative, the acquired mapping gizmo is positioned over the selected object.

### Display group

![Display settings](image)

This setting determines whether and how mapping discontinuities, also known as seams, appear in the viewports. The seams appear only when the Gizmo sub-object level is active. The default seam color is green; to change it, go to Customize menu > Customize User Interface > Colors tab, and then from the Elements drop-down list, choose UVW Map.

The options are:

- **Show No Seams**  Mapping boundaries don't appear in the viewports. This is the default choice.
■ **Thin Seam Display**  Displays mapping boundaries on object surfaces in the viewports with relatively thin lines. The line thickness remains constant as you zoom the view in and out.

■ **Thick Seam Display**  Displays mapping boundaries on object surfaces in the viewports with relatively thick lines. The line thickness increases when you zoom the view in and decreases when you zoom out.

**UVW Mapping Add Modifier**

Select an object. > Modify panel > Modifier List > UVW Mapping Add

Select an object. > Channel Info on page 6486 > Add a channel.

The UVW Mapping Add modifier is added to an object's modifier stack when you add a channel in the Channel Info utility on page 6486. You can also add the modifier explicitly by choosing it from the Modifier List. It has no user interface.

To merge the results of the add operation into the object's geometry, collapse the modifier stack after adding.

**UVW Mapping Clear Modifier**

Select an object. > Modify panel > Modifier List > UVW Mapping Clear

Select an object. > Channel Info on page 6486 > Clear a channel.

The UVW Mapping Clear modifier is added to an object's modifier stack when you clear a channel with the Channel Info utility on page 6486. You can also add the modifier explicitly by choosing it from the Modifier List.

To merge the results of the deletion into the object's geometry, collapse the modifier stack after deleting.

**Interface**

**Map Channel**  Specifies the map channel to clear. This is equivalent to clearing a specific channel in the Channel Info utility. If the specified map channel doesn't exist, the modifier has no effect.
UVW Mapping Paste Modifier

Select an object. > Channel Info on page 6486 > Copy and then paste a channel.

The UVW Mapping Paste modifier is added to an object’s modifier stack when you paste a channel in the Channel Info utility on page 6486. It isn’t available from the modifier list, and has no user interface.

To merge the results of the paste operation (for example, a vertex selection) into the object’s geometry, collapse the modifier stack after pasting.

UVW XForm Modifier

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > UVW XForm

Select an object. > Modifiers menu > UV Coordinates > UVW XForm

Use the UVW XForm modifier to adjust tiling and offset in existing UVW coordinates on page 8754. If you have an object with complex UVW coordinates already applied (such as a Loft object, or a parametric object with generated coordinates), you can apply this modifier to adjust those coordinates further.

For example, if you create a torus and turn on Generate Mapping Coordinates, the UVW coordinates work perfectly with the torus, but if you want to tile or move the coordinates, you would previously have needed to do it at the material/map level. Now you can apply a UVW XForm modifier to alter the built-in coordinates. You can use a Mesh Select or Edit Mesh modifier to apply a UVW Adjust to sub-object selections, as well. This is handy if you want to rotate the mapping on a particular portion of an object.
**Interface**

![Interface Diagram](image)

**Mapping group**

*U Tile, V Tile, W Tile* Alter the tiling along any of the three coordinate axes.

*Flip* Reverses the direction of the map along the specified axis.

*U Offset, V Offset, W Offset* Move the map in the direction of the specified axis coordinate.

*Rotation* Rotates the map.

*Rotate About Center* When active, the map rotates about the center of the object. If this is applied to a sub-object selection, it uses the center of that selection.

When this is turned off, the map rotates about the corner of the U and V coordinate gizmo.
**Channel group**

Specifies whether to apply the transform to a mapping channel or a vertex color channel, and which channel to use. For more information on these channels, see *UVW Map Modifier* on page 1932.

**Map Channel** Specifies a UVW channel to use for the mapping, and use the spinner to its right to set the channel number.

**Vertex Color Channel** Uses the vertex color channel for the mapping.

---

**Apply To Entire Object** If the UVW Xform modifier is applied to an active sub-object selection, such as face or patch, this switch controls whether the settings of the UVW Xform modifier affect only the original sub-object selection or affect the entire object.

### Vertex Weld Modifier

Select a mesh, patch, or PolyMesh object. > Modify panel > Modifier List > Vertex Weld

Select a mesh, patch, or PolyMesh object. > Modifiers menu > Mesh Editing > Vertex Weld

The Vertex Weld modifier behaves like the Weld feature in Editable Mesh or Editable Patch and welds all vertices that fall within the threshold setting. Vertex Weld is very useful for cleaning up meshes that have vertices that are close or overlapping, but not welded.

The results of three Vertex Weld threshold settings

---

Vertex Weld Modifier | 1957
Procedures

Example: To apply the Vertex Weld modifier to a mesh:

1. Create a box with Length, Width, and Height set to 40.
2. Right-click the box and choose Convert to > Convert to Editable Poly.
3. Set the sub-object mode to polygon, and select Polygon 6.
   
   **TIP** Watch the listing at the bottom of the Selection rollout to see which polygon is selected.

   By deleting the polygon, you create an open mesh.
5. Apply a Turn To Poly modifier, and set the Selection Level to Object.
6. Apply a Mirror modifier, and set Mirror Axis to X.
7. Turn on Copy, and set Offset to –40.
   The reflection of the box shares a common seam but the vertices along the seam are not welded.
8. Apply a Vertex Weld modifier to cement the two boxes into one element.

**NOTE** This combination of steps can be streamlined by using the Symmetry modifier on page 1803, which will mirror the mesh and weld it in a single operation.

Interface

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Threshold: 0.1</td>
</tr>
</tbody>
</table>

**Threshold** The value of the Threshold setting delegates how close vertices can be before they are automatically welded together. Default=0.1
NOTE A higher threshold setting will result in welding more vertices, thus removing smaller faces and details. If the threshold is set too high, the mesh will begin to deform.

A threshold setting of 5.5 removes all detail, making the model unrecognizable.

**VertexPaint Modifier**

Select an object. > Modify panel > Modifier List > VertexPaint
Select an object. > Modifiers menu > Mesh Editing > Vertex Paint
Select an object. > Utilities panel > More > Assign Vertex Colors > Click Assign To Selected. > Modify panel

The VertexPaint modifier lets you paint vertex colors onto an object. You're not restricted to only vertex-level painting. Using sub-object selection, you can also control which vertices get painted, face-by-face. All faces sharing a vertex have the adjacent corner shaded as well. The resulting painted object receives a coarse gradient across each face.

The amount of color that 3ds Max applies to a vertex depends on the distance of the vertex from the position of the paint cursor on the face. The more you select a face, the more it changes to the new color. The Opacity button also controls the strength of the color. 3ds Max shades the color, so if you have one green vertex and two white vertices for one face, for example, you'll see a gradient on that face.

VertexPaint modifier also lets you paint values for the vertex alpha and illumination channels. These channels affect the transparency and shading of vertex colors, respectively.
Notes and Tips

For best results with VertexPaint, keep the following in mind:

- VertexPaint is automatically applied to the selected object when you click Assign Vertex Colors on page 6477 > Assign To Selected. It is not available directly from the Modify panel or Modifiers menu.
- To render vertex colors, assign a Vertex Color map on page 6355, as described in To render vertex colors on page 1963.
- If you select faces using the selection tools of the VertexPaint modifier, you restrict your painting to the selected faces, as opposed to all faces. This allows you to sharply define the edges of your painted selection.
- You can streamline the painting process by using the Brush Presets tools on page 8044.
- Each VertexPaint modifier works internally to itself, and cannot modify existing vertex coloring. To paint over existing coloring, use the Condense to single layer on page 1982 function.

About Map Channels and Vertex Color, Vertex Alpha, and Vertex Illum

When using vertex paint, it is helpful to understand how 3ds Max manages vertex color, alpha, illumination, and map channels. 3ds Max stores and manages all of these different pieces of information using the same underlying system.

The map channels are defined as triple-value channels (tuples) with a unique integer ID number ranging from \(-2\) to 99. The first five map channels have specific and familiar usages:

- **Channel (2):** UVW “second pass” texture mapping coordinates
- **Channel (1):** UVW standard texture mapping coordinates
- **Channel (0):** RGB vertex color
- **Channel (−1):** FLOAT vertex alpha (really only 1 value needed)
- **Channel (−2):** RGB vertex illumination

Every geometric vertex of a mesh or poly object can be assigned up to 102 channel values (99 + 3).
The reason for the negative numbering scheme for the vertex alpha and illumination channels is actually historic: It serves to preserve the meaning of existing map-channel data in older scene files before vertex alpha and illumination were added.

You can paint on any arbitrary channel, and to use one or more channels for any arbitrary meaning for a given vertex. It is useful in development of content for games to paint on arbitrary map channels numbered higher than those used for texture mapping (such as channels 3, 4, 5). These can be used to store logical information about a vertex: for example, whether it is “slippery” or “explosive.”

You can assign a single vertex a stack of map channels that carry different meanings. When you collapse the modifier stack, 3ds Max preserves these map channels.

The VertexPaint modifier takes this into consideration through its simple exposure of map channel IDs for display and painting.

About Painting in Layers

The layer system allows you to paint changes on a single layer, then make another layer on top of that, and paint additional changes. This can be used to store different versions or variations of your vertex color painting.

Every layer has a blending mode that it uses to determine how it combines with the other layers. You can assign vertex colors using the Assign Vertex Colors utility on page 6477, then add another layer, change the layer mode operator to Lighten, and paint with a white paintbrush to lighten up areas. Fifteen different modes are available, and many tasks can be accomplished using paint layers.

One of the primary advantages of VertexPaint is its use of the modifier stack as a kind of image-composite stack. Each VertexPaint modifier serves as a single layer in the composite. You can move layers up and down the stack, enable and disable them, and flatten the stack using Condense to single layer on page 1982.

Backward Compatibility

If you load an older file that uses a previous version of the VertexPaint modifier, then the legacy modifier will be loaded when the file is opened.

The legacy modifier has not been changed, and the two modifiers are not inherently compatible in terms of their data format during loading and saving.
If you have vertex color data in a legacy VertexPaint modifier, you can use the Condense to single layer tool on page 1982 of the new modifier to migrate the vertex colors into the new modifier.

**Procedures**

**To add scene lighting into an object's vertex color:**

1. Select the objects in the scene that you want to color.
2. On the Modify panel, choose VertexPaint from the modifier list. The floating Paintbox on page 1969 appears, docked to the left edge of the viewports.
3. Open the Assign Vertex Colors rollout.
   
   **NOTE** This rollout provides the same tools as found in the Assign Vertex Colors utility.

4. In the Light Model group, choose Lighting + Diffuse.
5. Click Assign.

6. On the Vertex Paintbox, turn on Vertex Color Display Shaded to see the vertex lighting in the vertex color map.

**To paint vertex colors on an object:**

1. Select the scene objects to paint.

2. On the Modify panel, choose VertexPaint from the Modifier List. The Vertex Paintbox appears.

3. Choose the color you want to paint with by clicking the large color swatch below the Paintbrush button. This opens the Color Selector.

5. Adjust the strength of the color by entering a percentage value in the Opacity field.
6 Click Vertex Color Display Unshaded to see the vertex colors without shading.

7 Click the Paint button and move the cursor over the selected object in the viewport.

8 When the cursor displays over the object, press and hold down the left mouse button and drag to paint the object.

**TIP** The cursor displays the size of the brush. Use the Size spinner to change to a larger or smaller brush.

To see vertex colors in a viewport:

1 Right-click the object with painted vertices, and choose Properties from the quad menu.

2 In the Display Properties group, turn on the toggle for Vertex Color. Vertex Color is one item on a drop-down list. The other items are Vertex Illumination, Vertex Alpha, Map Channel Color (which uses the spinner immediately below the list), and Soft Selection Color. Viewports can display only one of these vertex channels at a time.

3 Click OK.

To render vertex colors:

1 Open the Material Editor, and apply a Standard material to the object.

2 Click the map button for the Diffuse component.

3 In the Material/Map Browser, choose Vertex Color as the map, and then click OK. Now, when you render the scene, the rendering shows the painted vertices.
To animate the opacity of a vertex color layer

1. Choose the layer you wish to animate, by highlighting the Vertex Paint modifier in the stack that corresponds to that layer.
2. Turn on the Auto Key button.
3. On the floating vertex paintbox, in the Layer group move the Opacity slider. This sets a key for the opacity.
4. Move the time slider to another frame and again change the value using the Opacity slider.
5. Click Play to see the animated opacity in the viewport.

To animate vertex color using UVW XForm modifier:

You can use the UVW XForm modifier in conjunction with a specific vertex paint layer to modulate vertex color effects in the viewport.

1. Apply a UVW XForm modifier directly above the VertexPaint layer (modifier) you want to modulate.
2. Set the Channel type on the UVW XForm modifier to Vertex color.
3. Animate the U, V, and W spinners using identical values. For example, animate UVW from 1 to 0 over the length of the animation. This will attenuate the RGB values of the underlying vertex color results uniformly. It will effectively dim out the vertex color result directly below the UVW XForm modifier.

**NOTE** Any additional vertex paint layers applied above the UVW XForm modifier in the stack for the selected object(s) will be unaffected

**TIP** You can add multiple UVW XForm modifiers in your stack in this way, giving some progressive control over modulated vertex colors. The effect is always additive, however, and cannot be weight-blended.

To paint under an existing layer and view the result:

1. Select an object that has several VertexPaint modifiers displayed in the stack.
2. In the modifier stack, activate the VertexPaint modifier that is the layer you want to paint on.
Turn on the Show End Result toggle.
Now, when you paint on the layer, you will see the painting taking place under the top layer.

**Interface**

**Parameter rollout**

The controls in this group are identical to the selection controls found in the Selection group on page 1976 of the Paintbox rollout.
Channel group

These controls specify which channel type the vertex paint layer will affect, and which map channel number you'll paint on.

- **Vertex Color**  Choose this to paint on a vertex color layer.
- **Vertex Illum**  Choose this to paint on a vertex illumination layer.
- **Vertex Alpha**  Choose this to paint on a vertex transparency layer.
- **Map Channel**  Choose this to paint on a specifically named or numbered map channel.

  **Map channel spinner**
  Specifies the channel number. Available only when Map Channel is chosen.

**NOTE** If you have painted on a layer and then change the channel setting, the painted information will be moved to the new channel. For example if you select Vertex Color and paint, then turn on Vertex Illum, the painted information will be removed from the Vertex Color channel and applied to the Vertex Illum channel instead.

**Name** If a channel has a name defined it will appear here. Channels can be named using the **Channel Info Utility** on page 6486.

---

**Ignore underlying color** When turned on, VertexPaint ignores whatever vertex colors it receives from below it on the stack. As a result, you will see the layer's raw colors on an otherwise white object. The blend mode has no effect (it behaves like Normal mode) because the base color is considered transparent, so the layer is not blended with anything.

The purpose of this toggle is to isolate a layer from the colors below, to help the user visualize the layer's raw data. The layer is not completed isolated when this is on, because layers above it can still affect the result. The user needs to disable those layers or turn off Show End Result to see the current layer in complete isolation.

The Ignore Base Color toggle should *only* be needed when the object at the bottom of the stack already has some vertex colors baked in. In other cases, you can just disable the paint layers or whichever modifiers are adding vertex colors to the object. In that case, the active paint layer would not receive any vertex colors from below itself on the stack. As a result, it treats all base color as transparent and the layer colors are displayed in the raw (not blended with anything).
NOTE Per-vertex layer opacity is not passed up the stack. A paint layer modifier makes a yes/no decision about whether an object below it has vertex colors or not, and will subsequently treat all base colors as transparent or all as opaque. So if you paint even a single vertex using Edit Mesh, for example, the object is considered to have vertex colors, and a paint layer will blend its colors with the (predominantly white) mesh instead of treating the mesh as transparent.

Preserve Layer When on, the modifier will not be deleted by any Condense To Single Layer operation. Since Condense To Single Layer performs two independent actions (creating a new baked-color modifier and then deleting existing modifiers), this option allows access to only the first part of the functionality when necessary. That is, you can bake colors into a new paint layer, without being forced to have the old modifiers deleted.

Edit Displays the Vertex Paintbox floater on page 1969 if it has been closed.
Assign Vertex Color rollout

This rollout gives you access to the same controls found in the Assign Vertex Colors utility on page 6477. They let you take the scene lighting information and bake it into the vertex channel system.
VertexPaint Paintbox

Select an object. > Modify panel > Modifier List > VertexPaint > Paintbox dialog (Click Edit in the Parameters rollout if it isn’t displayed.)

Select an object. > Modifiers menu > Mesh Editing > Vertex Paint > Paintbox dialog (Click Edit in the Parameters rollout if it isn’t displayed.)

Select an object. > Utilities panel > More > Assign Vertex Colors > Click Assign To Selected > Modify panel > Modifier List > VertexPaint > Paintbox dialog (Click Edit in the Parameters rollout if it isn’t displayed.)

The VertexPaint modifier’s Paintbox is a floating toolbox with various vertex painting tools. The Paintbox is launched automatically after the VertexPaint modifier on page 1959 has been applied to one or more objects. You can close the Paintbox by clicking the X button in the upper-right corner of its window. To open it again, click the Edit button in the Parameters rollout of the VertexPaint Modifier.

NOTE If a VertexPaint modifier is assigned to the object, you can also display the Paintbox by clicking Edit in the Assign Vertex Color utility.
Vertex Color Display controls

Control the display of the vertex paint in the viewport by using the four icons at the top of the floating panel. You can easily switch between shaded and unshaded vertex color modes, or turn off the display of vertex color and or texture maps.

**NOTE** The first three of these buttons stay highlighted when you click them, to indicate which shading mode is active. Toggle Texture Display simply performs the action without becoming highlighted.

**NOTE** These controls have no effect on wireframe viewports, but work for all shaded viewports, including Lit Wireframe.

- **Vertex color display – unshaded** Displays the currently selected object in vertex color display mode. This mode is identical to the one offered by the Object Properties menu (right click on object, select Properties > Turn On Vertex Color in the Display Properties group, making sure that Shaded is off.)

  This has no effect on wireframe, but works on lit wireframe and all other shaded display modes.

- **Vertex color display – shaded** Displays the currently selected object in vertex color display mode, with viewport lighting (shading). This mode is identical to the one offered by the Object Properties menu (right click on object, select Properties > Turn On Vertex Color in the Display Properties group, making sure that Shaded is on.)

- **Disable vertex color display** Displays the currently selected object in its current shading mode without showing vertex colors.
**Toggle texture display**  Displays or hides texture maps on the currently selected object.

**Viewport Channel Display selector**

This menu allows you to select which one of the map channels to paint on:

- **Vertex colors**  Choosing this lets you display the vertex color channel in the viewport.

- **Vertex alpha**  Choosing this lets you display and paint the vertex transparency channel in the viewport.

- **Vertex Illum**  Choosing this lets you display and paint the vertex lighting channel in the viewport.

- **Map Channel**  Choosing this lets you define a numbered map channel to paint on. Define the channel ID number with the Map Channel Display spinner.

**Map channel display in viewport flyout**

What you see is what you paint, so whatever you select will both be displayed and activated for painting.
NOTE  You cannot paint on all channels simultaneously as you could in the previous version of the vertex paint modifier.

**Map Channel Display Spinner**  This control lets you to numerically select a channel other than the 3 conventional ones listed above, for display only. If the channel you select is currently used for mapping coordinates, you'll see red/yellow/green colors corresponding to the UVW values.

You might choose map channels above the standard channel 1, 2, 3 that do typically get used for texture mapping. But you will need to keep track of your own conventions, and/or use the Channel Info utility to track what has been allocated for each object.

The Map Channel Display Spinner is only available when the Map Channel display button. If you assign a new vertex paint modifier or create a new layer and choose a particular numeric map channel, then select Map Channel display, the spinner will become available.

**Lock button**  The Lock button makes the Display Channel setting unavailable, and automatically sets Display Channel to whatever channel you choose on the Modify panel > Channel rollout. Keep this turned on, to ensure that you're always displaying what you're painting.

If you want to glance at another channel without stopping your current paint session, turn off the lock and then switch the display channel. When you are finished, switch back and turn the lock back on.
Vertex Paintbrush group

Here are the controls that let you access the paintbrush and the paint. You can choose color to paint with, from a color selector or from the scene. Choose to adjust the brush size or envelope, or launch advanced paintbrush options such as pressure sensitivity.

**Paint All** Performs a traditional paint fill operation on the current object or sub-object selection. In the case of sub-object selections (vertices, faces, elements) the fill will honor those selections. In the case of soft-selection Paint all will do a “faded” fill, slowly tapering off the opacity based on the soft selection settings.

As with the Paint button, this will either paint on the current layer, if one is open in the Modify panel, or else it will create a new vertex paint layer instanced across the selected objects.

**Paint** Starts the painting process. Once it is turned on, you can start painting on the current selection, by moving the cursor into the viewport and over the object.

If there is a Vertex Paint modifier highlighted in the Modify panel, you will be painting into that layer. But if the selected objects do not currently have a vertex paint layer highlighted in the modify panel, then a dialog appears
letting you create a new modifier. This will be instanced across all the selected objects.

You will not see the results of your brush strokes, unless the proper display mode is set (above). Be sure your display mode and your paint target match. For example – if you are painting on the alpha channel, be sure you are displaying the alpha channel. If you are painting on the color channel, display the color channel. Brush strokes will use the color specified in the color swatch directly below the Paint button.

See Painter Options Dialog (VertexPaint Modifier) on page 1989 for more painting options.

**Erase all** Erases all painting applied to the currently selected objects via the current VertexPaint modifier. This allows you to see through the underlying color of the object’s vertices. This underlying color might come from the object’s original vertex color, or from another vertex paint layer directly below it in the modifier stack. This supports soft selection as well.

**Erase** Turns the brush into an eraser that will remove paint from the currently selected objects. Erase mode will actually erase any painting applied to the currently selected objects for the current layer of paint (allowing the true color of the original objects vertices to be seen, or the vertex paint layer immediately below the current one).

**Pick color from object** Allows you to choose a color from the currently selected objects. The color is taken from a single vertex; region selection is not supported. The choice must occur near a vertex, or no color will be chosen. You can drag across a vertex of interest to pick up its color. Because this button enters a mode, it must be clicked to leave the mode, or you can choose another mode to turn it off.

**Color swatch** The color swatch indicates the current color that will be used when painting begins. Clicking the swatch launches the standard color selector. Here you can change the color that will be used on the next brush stroke. It provides standard Hue, Saturation, and Brightness selection, along with Red, Green, and Blue selection and numerical entry.
**Opacity** Controls the opacity of paint being applied to the currently selected objects in a single paint stroke (actually, any time before mouse up). This value represents the percentage of new paint that will blend into the color already applied to the selected objects. Successive paint strokes will continue to add this color until it overpowers the underlying color completely. The maximum value is 100% and 0% is the minimum value. A value of 50 percent will blend equally with the underlying vertex color in a single stroke (before mouse up).

The brush opacity serves to clamp the effect of each brush stroke, taken as a whole. If you pick a low opacity amount, then a single brush stroke will have only a small effect, no matter how much you scrub. This allows improved control over the density of a glaze of color, with an even glazing across all the painted vertices.

**Size** Controls the diameter of the brush, as seen in the viewport. Size values range from zero to 9,999,999 and must be chosen appropriately for the size and resolution of geometry you are painting.

**Brush Options** Opens the Painter Options dialog on page 1989, where you can access advanced paintbrush controls. These are the standard set of Painter Interface options. The same options can be seen, for example in the Skin modifier, for painting weights.

Here you will find a rich selection of brush configuration tools that change the way your brush strokes apply color to the selection. Includes tools for mirror painting mode and using pressure sensitivity.

**Palette** Click to display the Color Palette on page 1984, which lets you create, edit, and manage custom palettes for use with VertexPaint.

**Selection group**
Tools in this group let you choose sub-object selection levels. You can select vertices, faces or elements. Includes the option to ignore backfacing so you can limit your selection to sub-objects that face toward you, and also provides access to standard soft selection options.

This creates a mask that will let you determine what is being affected by your paint strokes, and any other operations you might apply, such as blurring or color adjustment. Erase functionality will also honor this mode selection.

**NOTE** Soft Selection is supported on the various sub-object selection modes.

**Select vertex** Allows you to select vertices from the currently selected objects. Once selected, only these vertices will be available for painting.

**Select face** Allows you to select faces in the currently selected objects. Once selected, only these faces will be available for painting.

**Select element** Allows you to select elements in the currently selected objects. Once selected, only these elements will be available for painting.

**Ignore Backfacing** When this is on, prevents you from mistakenly selecting sub-objects facing away from the user.

**Soft Selection** The same soft-selection options on page 2014 found in Editable Mesh and Editable Poly are available by clicking this button.

**Image Adjustment group**

Tools in this group allow you to perform overall color adjustment or image blurring without using the paint brush in the viewport.
Adjust Color Displays the Adjust Color dialog on page 1982, where you can find sliders for adjusting HLS or RGB values, preview the adjustment effect, and apply it.

Blur Smoothes the pixels in the image so there is less contrast and color difference. Use this to get rid of harsh edges such as shadows created by the Assign Vertex Colors utility.

Blur Amount spinner Blurs currently selected channel values (for example, vertex color, alpha) for the currently selected objects. Also supports sub-object selection of vertices, faces, and elements. With soft selections, the final blurred value is computed, and then combined with the original color according the selection; a 50 percent soft selection means that a vertex will become a fifty-fifty combination of its original color and the blurred color. Successive clicks of the Blur button will successively blur the previous results, eventually washing out painting effects entirely.
Blur is useful for softening vertex color lighting information that is automatically generated by the Assign Vertex Color utility or rollout. Assign Vertex Color computes intensities per vertex. This is especially useful for low-resolution geometry and high-frequency lighting changes.

Blur Brush Lets you apply blurring by using the same brush techniques and settings that you use to apply color. The Blur Brush respects sub-object selection and the Blur Strength setting.

Layers group

Layer Mode: Normal
Opacity

1978 | Chapter 9  Modifiers
**Mode** The layer mode drop-down list allows you to select a specific operator for this paint layer. The operator selected affects base color, alpha, illumination, and other information coming up from layers below it, or from the base object itself. The chosen operator controls how the incoming color is combined with any newly painted colors for the current level.

This mode is changeable at any time, without destroying previously painted information in layers above, below, or in the current paint layer. The following modes are supported per paint layer:

- **Normal** The layer color completely overwrites the base color.

- **Overlay** The color cast is shifted towards the layer color and contrast might be increased.
  It's useful when you want to make an object appear a different color but in the same lighting conditions. A fully bright or dark channel is never affected however, so if Red=100% and Green=0% in the base color, then neither the red nor green channels can be affected by the layer color.

- **Screen** Each RGB channel is moved towards full brightness, depending on the layer color. The result is at least as bright (never darker) than the original. Black is transparent in this mode.

- **Multiply** Each RGB channel is moved towards zero, depending on the layer color. The result is at least as dark (never brighter) than the original. White is transparent in this mode.

- **Lighten** Whichever color is brighter, the layer or the base, is used as the output. It operates on the whole color, and *not* channel-by-channel.

- **Darken** Whichever color is darker, the layer or the base, is used as the output. It operates on the whole color, and *not* channel-by-channel.

- **Color dodge** Emulates the effect of "dodging" a color print in a darkroom; the result is at least as bright (never darker) than the original.
  For each RGB channel, if the layer is at full value in that channel, the output channel will be at full value. Even if the layer value is less than full value, the output is still strongly brightened in that channel. For example, a medium-red layer color will add a significant red brightness to the output.

- **Color burn** Emulates the effect of "burning" a color print in a darkroom; the result is at least as dark (never brighter) than the original. For each RGB channel, if the layer is zero in that channel, the output channel will be zero. Even if the layer value is above zero, the output is still strongly darkened in that channel. For example, a medium red layer color will significantly reduce blue and green brightness in the output.
The next four Light modes essentially offer compromises between the destructive effect of Normal Mode and the toning effect of Overlay mode. Try using medium-value desaturated layer colors, since the light modes can be too destructive with bright, vivid layer colors. A neutral grey layer color is transparent in any of the light modes.

- **Soft light**  Very similar to Overlay, but even more gentle, and it does not tend to increase contrast as much.

- **Hard light**  More like Normal mode than Overlay, it will change color cast somewhat. It is fairly destructive like Normal mode, especially with bright layer colors.

- **Vivid light**  Brighter layer colors produce a Color Dodge effect, while darker layer colors produce a Color Burn effect, although the effect is generally weaker than Dodge or Burn.

- **Linear light**  For each RGB channel, if the layer color is more than 50 percent bright in that channel, the output will be brightened, and if the layer is less then 50 percent bright, the output will be darkened. As an example, if you want the top of your image to be twice as bright, and the bottom to be half as bright, use a gradient from 75 percent gray to 25 percent gray, top to bottom.

The next four modes are used to control the HSV channel values of the image instead of using RGB channel value.

- **Hue**  The output color has the saturation and value of the base color, with the hue of the layer color.

- **Saturation**  The output has the hue and value of the base color, and the saturation of the layer color.

- **Color**  The output has the value of the base color, and the hue and saturation of the layer color.

- **Luminosity**  The output has the hue and saturation of the base color, and the brightness value of the layer color.

---

**NOTE** Using the show end result button in the modifier stack for the current paint layer will allow you to interactively paint under any over laying paint layers (vertex paint modifiers that are above the current one in the object’s modifier stack). This allows you to see the final results of your paint strokes for any paint layer in the stack.
Opacity Slider Allows you to set the opacity of the current vertex paint layer, from 0 to 100 percent. 100 percent Opacity means that the current layer is entirely opaque: you cannot see through it to the layer directly under it or to the base vertex colors of the objects being painted.

The opacity of a layer is animatable. Simply turn on Auto Key, move the time slider and adjust the spinner value. This will set a keyframe.

NOTE If you painted on the layer with a brush opacity less than 100 percent, then colors stored in the layer can already be less than full opacity, and the final opacity at any vertex is a product of the two values. If you vertex had only 50 percent opacity worth of paint applied to it, and the layer is 50 percent opaque, then the vertex will appear 25 percent opaque overall.

Be aware that the paint opacity is different from the vertex alpha channel. Values less than 100 percent incrementally reveal any vertex color, alpha information, and so on, coming from vertex paint layers beneath it, or the base object’s original information. Opacity values can be changed for the current layer at any time. Since vertex paint layers are preserved in the modifier stack you can return to a particular layer at any time and adjust its opacity to tune an object’s final appearance.

NOTE The opacity for a specific paint layer should not be confused with “alpha” information for a given vertex. Opacity controls the mixing of painted information in the modifier stack for the currently active map channel (whether it be color information, alpha, illumination, or any arbitrary map channel from 1 to 99). Alpha Channel information (by convention) is intended to be used specifically to indicate the transparency of all combined color information for a given vertex.

Another way to think about the opacity slider is that it is identical to the amount spinner. The difference between them is that opacity is for the entire layer, where as amount is for the current brush stroke (between a mouse down and mouse up period when painting). Changing the amount spinner after painting does not affect what is already displayed on the screen; where changing the opacity layer does. In the end, the current vertex paint layer being applied generates a final color that is the combine result of amount and opacity. The whole concept should be quite natural to any Adobe Photoshop user. However, Photoshop is able to display a light grey and dark grey quilt as a background to give a visual cue about layer opacity, whereas 3ds Max does not support this same display cue. So in 3ds Max, more attention is required of the artist to understand the opacity of each vertex on each layer.

Opacity numeric entry field Allows you to enter an opacity amount. Range=0 (completely transparent) to 100 (totally opaque).
New Layer Click to create a new VertexPaint layer. Clicking new layer displays a New Layer dialog.

Delete Layer Click to delete the current VertexPaint layer. This removes the modifier from the stack.

Condense to single layer Click to condense all vertex coloring into a single layer in the current VertexPaint modifier. Use this to modify existing vertex coloring within the current modifier.

Condensing layers is a two-part operation: First 3ds Max adds a new VertexPaint modifier to the stack, combining vertex coloring applied directly with Editable Mesh/Polygon and from previous VertexPaint layers according to the settings described above. Second, it deletes any prior VertexPaint modifiers.

If Preserve Layer has been turned on for a particular VertexPaint layer, then its colors are “baked” into the new VertexPaint modifier, but the preserved layer isn’t deleted from the stack.

Adjust Color Dialog (VertexPaint Modifier)

Select an object. > Modify panel > Modifier List > VertexPaint > VertexPaint Paintbox > Click the Adjust Color button.

Select an object. > Modifiers menu > Mesh Editing > Vertex Paint > VertexPaint Paintbox > Click the Adjust Color button.

Select an object. > Utilities panel > More > Assign Vertex Colors > Click Assign to Selected > Modify panel > Modifier List > VertexPaint > VertexPaint Paintbox > Click the Adjust Color button.

The Adjust Color dialog lets you adjust the color of currently selected vertices. If there is no active vertex sub-object selection, it affects all vertices equally.
Interface

HSV  (The default.) When chosen, the first three sliders are labeled HSV, and adjust the colors' hue, saturation, and value.

RGB  When chosen, the first three sliders are labeled RGB, and adjust the colors' red, blue, and green components.

See Red, Green, Blue / Hue, Saturation, Value on page 8698.

Preview When on, vertex color adjustments are previewed interactively in shaded viewports (provided that on the Paintbox, Vertex Color Display - Unshaded or Vertex Color Display - Shaded is active). Default=on.

Contrast slider Lets you adjust the contrast of the vertex colors.

Histogram and Input-Level Spinners

Histogram Graphically shows the distribution of colors in the vertex selection, as well as the current shadow, gamma, and highlight input levels.
The shadow, gamma, and highlight input levels can help you adjust 3ds Max viewport color to better match your target hardware display (such as a game engine).

**Shadow level** Adjusts the level of shadow display.

**Gamma level** Adjusts the gamma display. This value is a gamma correction.

**Highlight level** Adjusts the level of highlight display.

When you adjust a level, the corresponding arrow moves on the histogram, to indicate the current setting. (However, you can’t graphically drag the arrows.)

---

**Apply** Click to apply the current settings to vertex colors, without closing the dialog.

**Reset** Click to restore dialog settings to their defaults.

---

**Color Palette (VertexPaint Modifier)**

Select an object. > Modify panel > Modifier List > VertexPaint > VertexPaint Paintbox > Click the Palette button.

Select an object. > Modifiers menu > Mesh Editing > Vertex Paint > VertexPaint Paintbox > Click the Palette button.

Select an object. > Utilities panel > More > Assign Vertex Colors > Click Assign to Selected > Modify panel > Modifier List > VertexPaint > VertexPaint Paintbox > Click the Palette button.

The VertexPaint modifier’s Color Palette lets you create and maintain color palettes for use with vertex paints. You can save or load palettes as Color Clipboard (CCB) files, which are also used by the Color Clipboard utility on page 378.

**NOTE** The Palette remembers the last palette you used. This is not affected by File > Set. However, the active palette is saved in the file `3dsmax.ini` on page 60, so deleting the INI file causes the palette to revert to the default grayscale palette.
Procedures

To use the palette to choose a color:

- On the List or Swatch panel, click the color.
  The color appears as the active color on the VertexPaint Paintbox, in the swatch just below the Erase button.

To change the color of a color swatch:

1. Double-click the swatch.
   A Color Selector on page 371 appears.

2. Use the Color Selector to change the swatch’s color.
   This version of the Color Selector is modeless on page 8641, so after choosing a color you can either close it, or leave it open to change another swatch.

To use the color picker:

1. In the Palette’s List panel, highlight the name of a color.

2. Click the Color Picker button to turn it on.
   The cursor changes to an eyedropper icon.

3. Without depressing the mouse button, drag to an area where you want to pick a color.
   You can obtain colors from viewports, the 3ds Max user interface, or anywhere on the Windows desktop.

4. When you depress the mouse button, the picker obtains the color below the cursor. You can drag while the mouse button is depressed. While you do, the color swatch in the palette and the larger swatch on the Paintbox update.

5. Release the mouse to pick the color you want.
   The color in the Palette and the active color in the Paintbox are both updated.

To change a color’s name:

1. In the List panel, click the name twice (more slowly than a double-click).
   The name changes to an editable field.
2 Enter a new name or edit the existing one, and then press Enter. Press Esc to cancel the name change.

To save a palette to a file:

1 Right-click the List panel or the Swatch panel. The Palette's pop-up menu on page 1989 appears.
2 Choose Save As from the menu. A Save Color Clipboard File dialog appears.
3 Use the dialog to give the palette a name (and optionally, a directory location other than the default), and then click OK to save the CCB file.

To load a palette from a file:

1 Right-click the List panel or the Swatch panel. The Palette's pop-up menu on page 1989 appears.
2 Choose Load from the menu. A Load Color Clipboard File dialog appears.
3 Choose the CCB palette file you want to load, and then click OK.
Interface

New Click to add a new color to the palette.

The only limit to the number of colors a palette can have is a file size or memory limitation.
Delete Click to delete the active color.

Copy Click to copy the active color.

Paste Click to paste a copied color to the active swatch.

Color Picker Highlight a color in the palette, turn this button on to activate the picker, then drag anywhere on the Windows desktop. The color is picked when you release the mouse. (See the procedure “To use the color picker,” above.)

List panel Displays the colors in the palette, along with their names.

Swatch panel Displays the colors in the active palette. The swatch panel doesn’t list the names of colors, but each color’s name appear as a tooltip when the mouse is over the swatch.
List and Swatch Panel Right-Click Menu

When you right-click the List panel or the Swatch panel, a pop-up menu appears.

**Copy** Copies the active color.
This is the same as clicking Copy.

**Paste** Pastes a color to the active swatch.
This is the same as clicking Paste.

**New** Adds a color to the palette.
This is the same as clicking New.

**Delete** Deletes the active color.
This is the same as clicking Delete.

**Save As** Displays a *Save As* dialog on page 7441 that lets you enter a name for the CCB file, then save it.
By default, Color Clipboard files are saved in the `\images` directory below the 3ds Max root directory.

**Load** Displays a file open dialog that lets you choose a CCB palette file to load.

**View** Displays a text-editor window with the current CCB palette file. If no CCB file has been loaded or saved, choosing View has no effect.
The first 12 lines of a CCB file contain integer RGB values. This part of the file is used by the Color Clipboard utility on page 378 and ignored by the Color Palette dialog. The remaining lines of the file include floating-point RGB values and color names.

Painter Options Dialog (VertexPaint Modifier)

Modify panel > Skin modifier > Parameters rollout > Weight Properties group > Painter Options button

VertexPaint modifier > Floating Vertex Paintbox > Brush Options button

Edit/Editable Poly object or Poly Select modifier > Soft Selection rollout > Paint Soft Selection group > Brush Options button

Edit/Editable Poly object > Paint Deformation rollout > Brush Options button

VertexPaint Modifier | 1989
The Painter Options dialog for the Skin modifier appears when you click the Painter Options button.

This same dialog is used by the VertexPaint modifier to control the brush envelope, use pressure sensitivity, or enter mirror painting mode. The dialog is accessed through the Brush Options button on the floating Vertex Paintbox.

The dialog is also used by the Paint Soft Selection and Paint Deformation tools available for poly objects.

Interface

**Brush Properties group**

**Min. Strength** Sets the minimum vertex weight to paint.

**Max. Strength** Sets the maximum vertex weight to paint.
Min. Size  Sets the minimum size for the paint gizmo.

Max. Size  Sets the maximum size for the paint gizmo.

**Brush strength falloff curve**  This graph determines how the brush weight falls off as the distance increases from the center of the brush. The controls on this graph are similar to those on a loft deformation dialog on page 781.

Additive  When on, brush strokes add to existing vertex weights.

**Quick Brush Falloff Types**  Set the brush falloff to linear, smooth, slow, fast, or flat.

**Display Options group**

The options in this group determine the appearance of the paint gizmo.

**Draw Ring**  A ring appears as part of the paint gizmo.

**Draw Normal**  A normal arrow appears as part of the paint gizmo.

**Draw Trace**  Draws a trace (temporary mark) that shows the path of the brush stroke on the surface.

**Normal Scale**  Sets the scale of the normal arrow in the paint gizmo.

**Marker**  Displays a circular marker at the end of the normal arrow. The value next to Marker sets the height of the marker.

**Pressure Options group**

**Enable Pressure Sensitivity**  Turns on pressure sensitivity for the paint gizmo brush.

**Pressure Affects**  Selects the brush parameter to be affected by pressure sensitivity. Choose from four options: None, Strength, Size, or both size and strength (Size/Str).

**Predefined Str Pressure**  Turn this option on to use a predefined strength pressure. Click the button to view and edit the falloff curve for the strength.

**Predefined Size Pressure**  Turn this option on to use a predefined size pressure. Click the button to view and edit the falloff curve for the size.
Mirror group

Mirror Turn this option on to mirror the paint gizmo on the other side of the object. Choose an axis from the drop-down menu. The paint gizmo is mirrored about the selected axis in the world coordinate system.

Offset Offsets the mirror plane by the value you specify.

Gizmo Size Changes the mirror gizmo size to a value you specify.

Misc group

Tree Depth Determines the size of the quad tree used for hit testing. Tree Depth relates to the amount of memory set aside for weight painting. Larger values mean faster interaction but more memory use.

Update On Mouse Up Prevents the system from updating viewports when the mouse button is pressed. This can save time in your workflow.

Lag Rate Determines how often the stroke updates the painted surface. Higher values update the surface less often.

Volume Select Modifier

Modify panel > Make a selection. > Modifier List > Vol. Select

Make a selection. > Modifiers menu > Selection Modifiers > Volume Select

The Volume Select modifier lets you make a sub-object selection of vertices or faces for passing up the stack to another modifier or modifiers. The sub-object selection is completely separate from the underlying parametric geometry of the object. Like other selection methods, Volume Select works with single or multiple objects.
Faces and vertices selected using box volumes.

Volume Select lets you use one of three gizmos or another object to define a volume of space as the selection area, to which you can then apply modifiers. You can move the selection over an object and animate it.

When applied, Volume Select begins with the current geometry in the object’s stack, whether it’s a whole object or a sub-object selection (for example, from an Edit Mesh on page 1321 or another Volume Select modifier).
Top: Original mesh with select gizmo showing
Bottom: Modification made after applying Volume Select modifier

**Patches**

As of version 4, patch objects coming up the modifier stack are not converted to a mesh by this modifier. A patch object input to the Volume Select modifier retains its patch definition. Files that contain patch objects with the Volume Select modifier from previous versions of 3ds Max will be converted to meshes to maintain backward compatibility.

**Scaling Compatibility**

The Volume Select gizmo scales along with its object. Thus, if you apply a Volume Select modifier, and then change the scale of your object (with the toolbar Scale function on page 918) the selection doesn't change. In other words, all three transforms affect the Volume Select gizmo and its object identically.
**Volume Select Center**

The Volume Select modifier has a center as well as a gizmo. This lets you alter the center for non-animated transforms. However, if you animate a rotation about the offset center, you achieve animation of both rotation and translation.

**Procedures**

**To apply and use volume selection:**

1. Select an object and apply the Vol. Select modifier. The Parameters rollout appears.
2. In the Stack Selection Level group, choose Object, Vertex, or Face to specify the kind of geometry you want to work with.
3. In the Select By group, choose one of the four volume types: Box, Sphere, Cylinder, or Mesh Object.
   If you choose Mesh Object, you should then click the None button and select an object to use as the selection volume.
4. Choose a selection method and type (defined in the following Interface section). You can change these choices as you work, depending on the particular selection you're trying to make.
5. Once the selection is complete, you can do the following:
   - Apply modifiers to the selection.
   - Transform the Volume Select gizmo at the sub-object level, changing the selection in the process.
   - Combine these options. See the following example.

**Example: To animate a volume selection:**

1. Apply Volume Select to an object.
2. Make a sub-object selection of the object's geometry at Face or Vertex level, and apply a geometric modifier, such as Bend on page 1165, to the selection.
3. Move to a nonzero frame and begin animation. Adjust parameters on the geometric modifier, then move to another frame.
4 In the stack, return to the Volume Select modifier. Choose the Volume Select gizmo sub-object. Move the gizmo and its geometry selection to another part of the object.

5 Repeat this process on other frames. Optionally, you can return to the geometric modifier and change its parameters at any frame.

During playback, you see the effect of an animated geometric modifier moving over the object.

**Interface**

**Modifier Stack**

![Modifier Stack Interface](image)

**Gizmo sub-object** You can transform and animate the gizmo to change the selection. Translating the gizmo translates its center an equal distance. Rotating and scaling the gizmo takes place with respect to its center.

**Center sub-object** You can translate and animate the center, which affects rotation or scaling of the Volume Select modifier’s gizmo.

For more information on the Stack Display, see Modifier Stack on page 8187.
Parameters rollout

- Stack Selection Level:
  - Object

      - Map
      - Vertex Color

- Alignment:
  - Fit
  - Center
  - Reset
  - Auto Fit
Stack Selection Level group

Object/Vertex/Face  Volume Select provides three selection levels. Vertex and Face levels put the modifier stack in sub-object selection. You can make one sub-object selection for each Volume Select modifier. You can then toggle the one selection between Face and Vertex level to send either up the stack. Object (top) level lets you modify the whole object while retaining any sub-object selection.

Selection Method group

Replace  Clears any selection passed up the stack to the Volume Select modifier, and then selects geometry within the volume.

Add  Selects all geometry within the volume, adding to any previous selection.

Subtract  Deselects all geometry within the volume.

Invert  Reverses the entire selection set. Geometry that was unselected becomes selected, and vice versa.

Selection Type group

Let's you determine whether selected faces are wholly or partially within the defined volume when you set Stack Selection Level to Face.

Window  Selects only faces with all three vertices within the selection volume.

Crossing  Selects faces with only one vertex within the selection volume.

Select By group

These controls let you define the selection with a primitive, a mesh object, or by surface characteristics.

Volume: Box/Sphere/Cylinder  To define the selection space using a standard primitive-shaped gizmo, choose one of these. You can then scale, rotate, or move the gizmo anywhere around the object.

Volume: Mesh Object  Choose this option to use another object to define the selection space. After choosing Mesh Object, click the button below it (labeled "None" by default), and then select an object to use as the volume.

Besides mesh objects, you can use patch objects and NURBS objects. In addition, if you turn on Soft Selection rollout > Use Soft Selection, you can use spline objects and particle systems to define the selection. This latter option is quite powerful because the selection changes as the particles move.
Mesh object button  Click this button, then select an object to define the selection space. You don't need to choose Mesh Object first, but you do need to choose Mesh Object to use the object as a volume. After you select an object, its name appears on the button. This button is labeled "None" if no object has been chosen.

NOTE  The selection depends on a volume intersecting the object. If a gizmo or object is scaled down and moved inside an object, no selection occurs because no geometry is within the volume of the gizmo.

Surface Features  Defines the selection by surface characteristics instead of a geometric volume. While this doesn't have much to do with volume, it was added because Volume Select is a procedural modifier, whereas Mesh Select on page 1500 is explicit. Now, even if your topology changes, Volume Select will consistently select the faces or vertices using a particular material or smoothing group.

Indicate which type of surface characteristic to base selection on by choosing one of the following:

Material ID  Specifies a material ID. All faces or vertices using the ID indicated by the spinner value are selected.

Sm Group  Specifies a smoothing group. All faces or vertices using the ID indicated by the spinner value are selected.

Texture Map  Specifies a texture map from the scene. Click the map button (labeled "None" by default) to choose a texture map to use for selection. All faces or vertices using that texture map will be selected. When using the Texture Map option, you can also specify a mapping channel or the vertex color channel using the Map/Vertex Color radio buttons and spinner.

NOTE  You must apply mapping to the object below Vol. Select in its stack for the Texture Map selection to work. That is, the Vol. Select modifier must have mapping coordinates passed up the stack so it can use a texture map for selection.

NOTE  If you set Selection Type to Window, vertices will be selected if all the faces they touch use the specified material or smoothing group. If you set Selection Type to Crossing, vertices will be selected if they touch any face using the specified material or smoothing group.

Alignment group

These controls are generally used when the gizmo has been transformed out of its original orientation to the object.
**Fit** Resizes the gizmo to fit around the object or previous selection in the stack. Maintains any previous rotation.

**Center** Recenters the gizmo on the object or previous selection in the stack. Maintains any previous scale or rotation.

**Reset** Returns the gizmo to its default size and orientation. Cancels the effect of all previous transforms.

**Auto Fit** When on, automatically adjusts the gizmo size and shape to fit the object as you change the underlying topology (for example, transforming vertices).

**Soft Selection rollout**

These controls, available only at the Vertex stack selection level, let you set a gradual falloff of influence between selected and unselected vertices. See [Soft Selection Rollout (Edit/Editable Mesh)](page 2014) on page 2014.

**NOTE** Soft Selection does not apply to materials or smoothing groups. However, if there was already a weighted selection passed up the stack, a Volume Select set to Material or Smoothing Group mode and *not* set to Replace will preserve the selection.

---

**Wave Modifier**

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Wave

Make a selection. > Modifiers menu > Parametric Deformers > Wave

The Wave modifier produces a wave effect in an object's geometry. You can use either of two waves, or combine them. Wave uses a standard gizmo and center, which you can transform to increase the possible wave effects.

The [Wave](page 2979) space warp has similar features, and is useful for applying effects to a large number of objects.
An object with the Wave modifier applied. Amplitude 1 and 2 can be changed, creating different profiles.

See also:
■ Ripple Modifier on page 1650

Procedures
To make an object wavey:

1 Select an object and apply the Wave modifier.

TIP To see the effect clearly, apply Wave to a broad, flat object that has many segments.

2 Set one or both values for amplitude, or the vertical height of the wave in current units.
Amplitude 1 produces a sine wave from one edge to the other, while Amplitude 2 creates a wave between the opposite edges. Switching a value from positive to negative reverses the position of peaks and troughs.
Set the length of the wave and the distance in current units between crests of both waves. The greater the length, the smoother and more shallow the wave for a given amplitude.

To add a phase effect:
- Set a phase value to shift the wave pattern over the object. Positive numbers move the pattern in one direction, while negative numbers move them in the other. This effect is especially clear when animated.

To add a decay effect:
- Set a decay value to increase or decrease the amplitude. A decay value decreases the amplitude as the distance from the center increases. As the Decay value increases, the wave is concentrated at the center and flattens until it disappears (completely decays).
Interface

Modifier Stack

Gizmo  At this sub-object level, you can transform and animate the gizmo like any other object, altering the effect of the Wave modifier. Translating the gizmo translates its center an equal distance. Rotating and scaling the gizmo takes place with respect to its center.

Center  At this sub-object level, you can translate and animate the center, altering the Wave gizmo's shape, and thus the shape of the wavy object.

For more information on the stack display, see Modifier Stack on page 8187.

Parameters rollout

Amplitude 1/Amplitude 2  Amplitude 1 produces a sine wave along the gizmo's Y axis, while Amplitude 2 creates a wave along the X axis (although peaks and troughs appear in the same direction with both). Switching a value from positive to negative reverses the positions of peaks and troughs.

Wave Length  Specifies the distance in current units between the crests of both waves.
**Phase** Shifts the wave pattern over the object. Positive numbers move the pattern in one direction, while negative numbers move it in the other. This effect is especially clear when animated.

**Decay** Limits the effect of the wave generated from its origin. A decay value decreases the amplitude at increasing distance from the center. As this value increases, the wave is concentrated at the center and flattened until it disappears (completely decays).

---

**Welder Modifier**

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > Welder

Welder smooths a mesh that has a tear in it. Welder welds either the vertices or face normals on page 8654 of an Editable Mesh on page 2192. To “weld” normals means to make nearby vertices use the same normal.

Welder is meant for use with Cloth meshes on page 1204 that you have cached using a Point Cache modifier on page 1574. Add the Welder modifier to the stack above the Point Cache modifier. You don’t need to use Welder if the Cloth modifier is still active in the stack.

In the illustration, the cloth consists of two planes, and the edges of the front half of the join between the planes have been selected.
Two planes of cloth to weld
Welding normals with Don’t Weld Sel Edges on (the default)
At the rear half of the join, normals on either plane are matched within the Threshold distance.
Welding normals with Don’t Weld Sel Edges off
Normals are matched all along the join.
Welding vertices with Don’t Weld Sel Edges on (the default)

Welding vertices joins the plane geometry, but only at the rear half of the join are normals matched.
Welding normals with Don’t Weld Sel Edges off
Vertices are joined and normals are matched all along the join.

Interface

**Threshold**  Sets a threshold for welding vertices. When two vertices are within this distance, they are welded for smoothing purposes. Default=0.1.

**Verts/Normals**
- **Verts**  When chosen, smooths the mesh based on the proximity of vertices.
- **Normals** (The default.) When chosen, smooths the mesh based on face normals.

**Don’t Weld Sel Edges** When on, Welder does not weld selected edges. For example, you might not want to smooth the creases between the panels of a mesh created by Garment Maker on page 1266. You must select the edges at a lower level of the stack. Default=on.

---

**XForm Modifier**

Modify panel > Make a selection. > Modifier List > Object-Space Modifiers > XForm

Make a selection. > Modifiers menu > Parametric Deformers > XForm

Use the XForm (short for Transform) modifier to apply transformations (Move, Rotate, Scale) to objects. The XForm has two main functions:

- To animate transformations of a sub-object selection. You can also animate the position of the modifier's center.
- To transform an object at any point in the stack.

**NOTE** The Linked XForm modifier on page 1484 is a variant of XForm. Linked XForm has no gizmo or center of its own. Instead, a given selection is “linked” to another object, which supplies its gizmo and center. Using Linked XForm, you can link a sub-object selection directly to the coordinate system of another object.

---

**Using XForm**

XForm provides a gizmo and center for any geometry it receives from the stack whether it’s a sub-object selection or the whole object. XForm has no parameters. When you move the XForm modifier gizmo, the center moves with it, along with the geometry.

You can reposition the XForm center separately from the gizmo.

**Offsetting XForm Center**

At the XForm Center sub-object selection level, only the Move transform is available. This lets you reposition the center. When you return to the Gizmo
level, you can rotate or scale the selection around the offset center. The center position and gizmo transformations are all animatable.

**Scaling with XForm**

When you scale an object with a toolbar Scale tool, 3ds Max applies the effect to the object after all the modifiers in the stack. In some cases you might want to squash or stretch an object before applying geometric or edit modifiers. XForm makes this possible.

By applying XForm and scaling its gizmo, you can place the scaling operation anywhere in the stack.

**Using XForm with Volume Select**

You can combine the XForm and Volume Select modifiers on page 1992 to animate sub-object selections. This combination makes it possible to animate both the effect of a modifier on the selection (Volume Select) and a transformation of that selection (XForm).

**Procedures**

**To use the XForm modifier:**

1. Choose a location in an object's stack and apply the XForm modifier. The Gizmo sub-object level is automatically activated. All transform buttons are available on the toolbar.

2. Move to a nonzero frame and turn on Auto Key to animate the next step.

3. Transform the gizmo.
   As you transform the gizmo, the selected geometry is transformed with it.

**To use XForm as a scaling modifier:**

1. Apply XForm to an object or a sub-object selection.

2. Scale the gizmo.
   The rescaled geometry becomes "part of the stack" because the scale transform is carried with XForm, instead of being applied after the modifiers.
Interface

This modifier has no parameters, but you can transform the XForm gizmo and the XForm center. If you switch the selection level to the XForm center, only the Move transform is available. This lets you offset the center and transform the gizmo around it. Both offset and gizmo transformations are animatable.
Surface Modeling

Surface modeling is more free-form than geometric (parametric) modeling. Although you can create Patch and NURBS primitives from the Create panel, more often a surface model begins when you use the quad menu on page 8052 or the modifier stack on page 8187 to “collapse” a parametric model to some form of editable surface. Once you have done so, a variety of tools let you shape the surface. A lot of surface modeling work is done by editing sub-objects on page 8732 of the surface object.

![Three types of surface models: patch (left); mesh (center); NURBS (right)](image)

Subdivision Surfaces

A subdivision surface is a surface that has been divided into more faces while retaining the object's general shape. You perform subdivision to add detail to an object, or to smooth it out.

3ds Max supports two kinds of subdivision surfaces:

- The HSDS modifier on page 1464 provides hierarchical subdivision surfaces, which you can use to add fine detail to an object.
The MeshSmooth modifier on page 1505 and TurboSmooth modifier on page 1818 provide smoothing. Related closely to these are the Subdivision Surface rollout on page 2325 controls for editable poly on page 2240 objects, with which you can subdivide a surface without the need for a modifier.

**NOTE** These controls are not available with the Edit Poly modifier.

The latter type works best as a finishing tool for models.

## Soft Selection Rollout

Select an editable patch, editable mesh, editable poly, editable spline, an object that has an Edit Mesh, Edit Patch, or Edit Spline modifier applied to it, or an object that has a comparable Select modifier applied to it. > Modify panel > Choose a sub-object level. > Soft Selection rollout

The Soft Selection controls allow you to partially select sub-objects in the vicinity of an explicit selection. This causes the explicit selection to behave as if surrounded by a "magnetic field." Partially selected sub-objects within the field are drawn along smoothly as you transform the sub-object selection; the effect diminishes with distance or the "strength" of the partial selection.

This falloff is visible in the viewports as a color gradient surrounding the selection, conforming to the first part of the standard color spectrum: ROYGB (red, orange, yellow, green, blue). Red sub-objects are those you select explicitly. The highest-value soft-selected sub-objects are reddish-orange; they have the same selection value as red sub-objects, and respond the same way to manipulation. Orange sub-objects have a slightly lower selection value, and respond to manipulation a bit less strongly than do red and reddish-orange vertices. Yellow-orange sub-objects have an even lower selection value, and then yellow, green-yellow, and so on. Blue sub-objects are effectively unselected and don't respond to manipulation, except as required by neighboring soft-selected sub-objects.

Normally, you designate a soft selection procedurally, by setting parameters and then selecting sub-objects. You can also “paint” a soft selection explicitly on poly objects. See Paint Soft Selection group on page 2021.

By default, the soft-selection region is spherical without regard to geometric structure. Alternatively, you can use the Edge Distance option on page 2017 to limit the selection to vertices in contiguous faces.
If a sub-object selection is passed up the modifier stack, and Use Soft Selection is on, the results of modifiers that deform the object, such as Bend and XForm, are affected by the Soft Selection parameter values.

The controls in this dialog let you modify Soft Selection parameters. All sub-object levels share the same Soft Selection parameter values. Soft Selection is available for NURBS, mesh, poly, patch, and spline objects.

**Procedure**

To edit a soft selection in the viewport:

This procedure describes usage of the Customize User Interface > Edit Soft Selection Mode feature for editing the Falloff, Pinch, and Bubble values for soft selection.

For more information, including a list of feature sets with which Edit Soft Selection Mode is available, see Edit Soft Selection Mode on page 2019.

1. From the Customize menu, choose Customize User Interface; this opens the Customize User Interface dialog to the Keyboard panel. From the Group drop-down menu on the dialog, choose the feature set with which you wish to use Edit Soft Selection Mode, such as Editable Poly.

2. In the group’s Action list, check the action for Edit Soft Selection Mode (or Edit Soft Selection). If it’s not already assigned, or you wish to change the keyboard shortcut, highlight the action and use the standard method
to set a Hotkey. Alternatively, switch to one of the other panels and set, for example, a toolbar button for the action. When finished, close the dialog.

3 Select an object to edit and activate the feature set from step 1. On the Modify panel, go to the sub-object level you wish to edit, such as Vertex.

4 If necessary, expand the Soft Selection rollout and turn on Use Soft Selection.

5 Make a sub-object selection.
   The viewport shows your selection in red and the surrounding, soft-selected sub-objects in a color gradient.

6 Press the hotkey for Edit Soft Selection mode, or otherwise activate the action.
   The mouse cursor switches to the Falloff symbol.

7 Press and hold the mouse button, and drag vertically: upward to increase the Falloff value, or downward to decrease Falloff.
   As you drag, the color gradient changes to show the modified Falloff, as does the Falloff value on the Soft Selection rollout.

8 When you've finished editing the Falloff, release the mouse button and then click once.
   The mouse cursor switches to the Pinch symbol.

9 Drag to adjust the Pinch value.

10 When you've finished editing Pinch, release the mouse button and then click once.
   The mouse cursor switches to the Bubble symbol.
11 Drag to adjust the Bubble value.

12 You can continue cycling through the three editing modes by releasing the drag and then clicking once.

13 To finish using Edit Soft Selection Mode, right-click in the active viewport.

Interface

Use Soft Selection Affects the action of Move, Rotate, and Scale functions at sub-object levels of the editable object or Edit modifier, as well as the action of deformation modifiers applied to the object if they are operating on a sub-object selection (the latter also applies to the Select modifiers). When on, 3ds Max applies a spline curve deformation to the unselected sub-objects surrounding the selection you transform. To take effect, this check box must be on before transforming or modifying the selection.

Edge Distance When on, limits the soft-selection region to the specified number of edges between where you select and the maximum extent of the
soft selection. The affected region is measured in terms of "edge-distance" space, along the surface, rather than real space.

This option is useful in cases where you want to select only contiguous sections of geometry. For example, if a bird's wing is folded back against its body, selecting the wing tip with Soft Selection would affect body vertices as well. But if you turn on Edge Distance, set the numeric value to the distance (in edges) along the wing that you wish to affect, and then set Falloff to an appropriate value, selecting and then moving the wing tip would move only the wing geometry.

Affect Backfacing When on, deselected faces whose normals face in the opposite direction to the average normal of the selected sub-objects are affected by the soft-selection influence. In the case of vertices and edges, this applies to the normals of faces to which they're attached. Turn off Affect Backfacing when you want to manipulate faces of a thin object, such as a thin box, but don't want to affect faces on the other side of the object.

**NOTE** Affect Backfacing is not available when editing splines.

Falloff Distance in current units from the center to the edge of a sphere defining the affected region. Use higher falloff settings to achieve more gradual slopes, depending on the scale of your geometry. Default=20.

**NOTE** The region specified by the Falloff setting is depicted graphically in the viewports as a color gradient in vertices and/or edges (or, with editable polys and patches, optionally in faces). The gradient ranges from the selection color (normally red) to the non-selected sub-object color (normally blue). In addition, this gradient is updated in real time as you change the Falloff setting.

**NOTE** If Edge Distance on page 2017 is on, the Edge Distance setting limits the maximum falloff amount.

Pinch Raises and lowers the top point of the curve along the vertical axis. Sets the relative "pointedness" of the region. When negative, a crater is produced instead of a point. At a setting of 0, Pinch produces a smooth transition across this axis. Default=0.

Bubble Expands and contracts the curve along the vertical axis. Sets the relative "fullness" of the region. Limited by Pinch, which sets a fixed starting point for Bubble. A setting of 0 for Pinch and 1.0 for Bubble produces the smoothest bulge. Negative values for Bubble move the bottom of the curve below the surface, creating a "valley" around the base of the region. Default=0.
(soft selection curve) Graphically displays how Soft Selection will work. You can experiment with a curve setting, undo it, and try another setting with the same selection.

**Shaded Face Toggle** Displays a color gradient corresponding to the soft selection weights on faces within the soft selection range. Available only when editing patch and poly objects.

If the **Vertex Color display property** on page 291 of an editable poly or editable patch object is off, clicking the Shaded Face Toggle button will turn on Soft Selection Color shading. If the object already has an active Vertex Color setting, clicking the Shaded Face Toggle overrides the previous setting and changes it to Soft Selection Color.

**NOTE** Use the Undo command if you do not want to change your vertex color shading properties.

**Lock Soft Selection** Locks the soft selection in order to prevent changes to the procedural selection.

Using Paint Soft Selection (see following) turns on Lock Soft Selection automatically. If you turn it off after using Paint Soft Selection, the painted soft selection is lost and cannot be restored with Undo.

**Edit Soft Selection Mode**

In addition to the controls described in the preceding section, you can edit the soft selection in the viewports with interactive controls based on a Customize User Interface action named Edit Soft Selection Mode. This mode is available for the following feature sets:

- Editable Mesh surface
- Editable Poly surface
- Edit Mesh modifier
- Edit Patch modifier
- Edit Poly modifier
- Edit Spline modifier
- HSDS modifier
- Mesh Select modifier
- MeshSmooth
- Patch Select modifier
- Poly Select modifier
- Projection modifier
- Vol. Select modifier

For each feature set, open the Customize User Interface dialog from the Customize menu, and choose the feature from the Group drop-down list. For many feature sets, but not all, the Edit Soft Selection Mode keyboard shortcut is set to 7 by default. For the rest, such as Editable Poly, you must set the keyboard shortcut with the Customize User Interface controls.

For the basic method of using Edit Soft Selection Mode, follow this procedure on page 2015.

To enter Edit Soft Selection Mode, press the keyboard shortcut (or click the toolbar button, etc.) assigned in Customize User Interface. When active, drag to use the current mode and click to switch to the next mode. To exit, right-click in the active viewport.

The three Edit Soft Selection Mode modes, along with their mouse-cursor symbols, are:

- **Falloff**
- **Pinch**
- **Bubble**
Paint Soft Selection group

Paint Soft Selection lets you specify a soft selection explicitly by dragging the mouse over the selection. The Paint Soft Selection functionality is available at sub-object levels with Editable Poly objects, as well as with objects with the Edit Poly or Poly Select modifier applied. You can work in one of three painting modes: Paint, Revert, and Blur.

**TIP** You can streamline the painting process by using the Brush Presets tools on page 8044.

**Paint** Lets you paint a soft selection on the active object using the current settings. Drag the mouse cursor over the object surface to paint the selection.

**Blur** Lets you paint to soften the outlines of an existing painted soft selection.

**Revert** Lets you paint to reverse a soft selection on the active object using the current settings. Drag the mouse cursor over the object surface to reverse the selection.

**NOTE** Revert affects only a painted soft selection, not a soft selection made by normal means. Also, Revert uses only the Brush Size and Brush Strength settings, not the Selection Value setting.

**Selection Value** The maximum relative selection of the painted or reverted soft selection. The values of surrounding vertices within the brush radius fall off towards a value of 0. Default=1.0.

**Brush Size** The radius of the circular brush used for painting the selection.

**Brush Strength** The rate at which painting a soft selection sets the painted sub-objects to the maximum value. A high Strength value reaches the full value quickly, while a low value requires repeated applications to reach full value.
Brush Options Opens the Painter Options dialog on page 1989, with settings for brush-related properties.

Collapse Utility

Utilities panel > Utilities rollout > Collapse button

The Collapse utility lets you combine the stack operations of one or more selected objects into an Editable Mesh on page 2192 or the stack result, and, optionally, perform a Boolean on page 713 operation on them at the same time.

IMPORTANT You can't undo the results of using the Collapse utility. Before you use it, save a copy of your work file, or use Hold on page 242.

NOTE You can also collapse an object’s stack from the modifier stack right-click menu on page 8200, and convert a selection to editable surfaces on page 2013 with the transform quadrant of the quad menu on page 8052. These changes are undoable.

Procedures

To collapse the stack of an object into an editable mesh:

1 On the Utilities panel, click the Collapse button.
2 Select the object or objects that you want to collapse.
3 Click the Collapse Selected button.

   All modifiers are removed from the modifier stack and the object becomes an editable mesh.

To collapse the stack of an object into an editable surface other than mesh:

1 On the Utilities panel, click the Collapse button.
2 On the Collapse rollout, set Output Type to Modifier Stack Result.
3 Select the object or objects that you want to collapse.
4 Apply a modifier that outputs the desired ultimate surface type, such as Turn To Poly on page 1830 or Turn To Patch on page 1827.
5 Click the Collapse Selected button.
All modifiers are removed from the modifier stack and the object becomes an editable surface of the type indicated by the modifier.

To subtract multiple objects from another object:
The Boolean compound object restricts you to combining objects one at a time. With the Collapse utility, you can perform Boolean operations on several objects simultaneously.

1 For the purposes of this procedure, we'll call the object to have shapes subtracted from Main. Create and arrange Main and the objects to subtract from it. For example, you might have several boxes penetrating a sphere (Main) in different places; subtracting them will produce box-shaped cutouts in the sphere's surface.

2 Select Main, and then select the objects to be subtracted from it. The first object you select before collapsing is the one from which the others are subtracted.

3 On the Utilities panel, click the Collapse button.

4 On the Collapse rollout, set Output Type to Mesh, if necessary.

5 In the Collapse To group, choose Single Object.

6 Turn on Boolean, and then choose Subtraction.

7 Click the Collapse Selected button.

All objects you selected after Main, the first object, are subtracted from Main.
Selected Object group

Displays the name of the current selection. If more than one object is selected, "[Number] Objects Selected." displays.

Collapse Selected Collapses the selected objects. The method of collapse depends on the settings of the options below this button.

Output Type group

Specifies the type of object that results from the collapse.
Modifier Stack Result The resultant object will be the same as if you had collapsed its stack. In most cases, this results in a mesh object, as when using the Mesh option. However, if the object has an Edit Patch modifier so that its stack produces a patch, then the result will be a patch object rather than a mesh. Likewise, a shape with Edit Spline modifiers becomes an editable spline. When this option is used, the Collapse To options are unavailable, and all selected objects remain independent objects.

Mesh All selected objects become editable meshes regardless of their type before they were collapsed.

Collapse To group

Specifies how the selected objects are combined. These options are available only when you choose the Mesh option.

Multiple Objects Collapses each object in the selection but maintains each as an independent object. When this option is selected, the Boolean options are disabled.

Single Object Collapses all selected objects into a single, editable mesh object.

Boolean Performs Boolean operations on the selected objects. During the Boolean calculation, a progress bar appears along with a Cancel button. If any objects in the Boolean operation fail, that object is skipped, but the Collapse proceeds. The result is not a Boolean compound object, but a single editable mesh. The type of Boolean is specified by the following option.

Union Combines the several objects, removing intersecting geometry.

Intersection Removes all but the intersecting geometry.

Subtraction Maintains the first object selected while subtracting the subsequently selected objects. For example, to subtract several cylinders from a box, click to select the box, hold down Ctrl, and region-select the cylinders.

Close Exits the Collapse utility.

Graphite Modeling Tools

The Graphite Modeling Tools set, also known as the modeling ribbon, represents a new paradigm for editing mesh and polygonal objects. Its customizable, context-based interface provides all (and only) tools directly specific to the modeling task, and it minimizes onscreen clutter by giving you access to relevant parameters only as you need them. The Ribbon controls include all
existing Edit/Editable Poly tools as well as a plethora of new tools on page 2026 for creating and editing geometry.

NOTE Most tools on the modeling ribbon have two-part tooltips; the first part contains a brief description of the tool, and sometimes lists important options. The second part, when available, describes how to use the tool, and with certain tools lists secondary options.

NOTE The vertical modeling ribbon is available only as a Customize User Interface action that switches the ribbon orientation between horizontal and vertical. To access it, open the Customize User Interface dialog on page 8249, set Category to Modeling: Graphite Tools, and use the Toggle Modeling Ribbon Orientation action (see this procedure on page 2031). The vertical ribbon feature set is identical to that of the horizontal ribbon, except that it can be docked left and right, rather than top and bottom, and is always maximized.

New Tools

Many of the new modeling and texture-mapping features in Autodesk 3ds Max 2010 come from an existing plug-in known as PolyBoost. This topic lists and links to all of the PolyBoost tools now available in the modeling ribbon and elsewhere in 3ds Max.

NOTE In most cases, this list includes only major tools and toolsets, not variants or settings, which can be found nearby in the help.

PolyBoost tools for modifying vertex selections in the Cloth modifier are available on the Group rollout on page 1249.

The Ribbon Interface

The modeling ribbon takes the form of a toolbar that can float or dock in a horizontal or vertical configuration. The toolbar contains three tabs: Graphite Modeling Tools, Freeform, and Selection.

Each tab contains a number of panels whose presence depends on the context, such as the active sub-object level. You can use a right-click menu to determine which panels appear, and you can also tear off panels so they float independently on the interface. You can adjust the panel size horizontally by dragging either end, and when you make it smaller, the panels adjust automatically to fit. The same controls that were previously available directly then become available from drop-down menus.

The main tab on the modeling ribbon is the Graphite Modeling Tools tab, and its first panel, Polygon Modeling, provides a subset of Modify panel tools: sub-object level (Vertex, Edge, Border, Polygon, Element); stack level, preview options for sub-object selection, and more. At any time you can show or hide any available panel with the right-click menu.

Using the Ribbon

The Graphite Modeling Tools interface takes the form of a highly customizable, context-sensitive toolbar containing three tabs: Graphite Modeling Tools, Freeform, and Selection. Each of these comprises a number of panels whose availability depends on the context.

The ribbon can assume a horizontal or vertical configuration and either configuration can float or be docked. The horizontal version can be maximized (Show Full Ribbon) or minimized to tabs or panel titles. By default, the ribbon is horizontal, minimized to panel titles, and is docked immediately above the viewports (below the main toolbar), as shown in the following illustration.
NOTE When the ribbon is horizontal, you can attach the Quick Access toolbar to its bottom edge. For details, see Quick Access Toolbar on page 7995.

The basic unit of ribbon organization is the panel; each panel contains a related set of tools. The most important panel, and the only one that appears by default on the ribbon when no qualifying object is selected, is the Polygon Modeling panel on page 2045. This panel contains global controls for making the other panels available, switching sub-object levels, toggling soft selection, and more.

Procedures

This section includes some basic procedures for getting started with the modeling ribbon. For more information about using and configuring the ribbon, be sure to read Modeling Ribbon Controls on page 2036.

To activate the modeling ribbon:

By default, 3ds Max starts with the horizontal configuration of the modeling ribbon open, minimized to panel titles, and docked to the top of the interface, just above the viewports. If you close it and quit the program, it does not automatically reopen when you restart.

Do either of the following:

- On the main toolbar, click the Graphite Modeling Tools (Open) button.
- At the bottom of the Tools menu, click Graphite Modeling Tools.

Each of these is a toggle: If the ribbon is closed, it opens it, and if open, it closes it.

To switch the ribbon orientation:

By default, the ribbon uses a horizontal configuration, but you can change it to vertical using Toggle Modeling Ribbon Orientation, an action available from the Customize User Interface dialog.

1. On the menu bar, choose Customize > Customize User Interface to open the Customize User Interface dialog on page 8249.
2 Choose whether to make the Toggle Modeling Ribbon Orientation command available from the keyboard, a toolbar, a quad menu or a regular menu, and click the corresponding tab on the dialog. This procedure shows how to add the command as a toolbar button. To use a different interface item, see the respective topic in the Customize User Interface Dialog help section.

3 Click the Toolbars tab and set Category to Modeling: Graphite Tools. This category contains only two actions: One to toggle the ribbon interface (already available on the main toolbar and Tools menu) and the other to toggle the orientation.

4 Drag the Toggle Modeling Ribbon Orientation from the list to a toolbar and then close the dialog.
   By default, the button text is “Toggle Modeling Ribbon Orientation,” of which only the central part is visible on the button.

5 To customize the button, right-click the button, choose Edit Button Appearance, and use the Edit Button Appearance dialog on page 8258 controls to change the button to your liking.

6 Click the new button.
   The first time, the ribbon switches to vertical orientation. Thereafter, clicking the button toggles the orientation.

   **NOTE** The vertical ribbon is always maximized.

To minimize or maximize the ribbon:

The ribbon in its horizontal orientation has three different minimize/maximize states. This procedure describes two ways to switch among them:

   **NOTE** The vertical ribbon is always maximized.

➢ Do either of the following:
   ■ Click the minimize/maximize button on the ribbon. If you hold the mouse over the button, a tooltip describes what happens when you click.
Right-click an empty portion of the ribbon, such as the area above the panels, to open the right-click menu, and then access the Minimize submenu on page 2044. The current state has a check mark next to it; choose a different one from the menu.

To convert an object to editable poly or Edit Poly format:

For most ribbon functions to be available, a single editable poly on page 2240 or Edit Poly on page 1332 object must be selected, and the corresponding stack level must be active. If the object you want to work with is not in the required format, you can use the ribbon to convert it.

1. Select an object.
2. If the ribbon is minimized, open the Polygon Modeling panel; otherwise, open the panel expansion.
3. Choose Convert To Poly or Apply Edit Poly Mod.
This converts the object or applies the modifier, respectively, and switches to Modify mode if necessary.

**NOTE** You could also use Collapse Stack if the stack collapses to an editable poly object. However, if you collapse a primitive object such as a Teapot with non-format-specific modifiers such as Bend, the result is an editable mesh object, which is not compatible with the modeling ribbon.

To start using the modeling ribbon with an editable poly or Edit Poly object:

You can use the modeling ribbon tools with a selected editable poly or Edit Poly object when the corresponding stack level is active and the software is in Modify mode.

Once you become familiar with the ribbon, you can accomplish just about any polygon-modeling task without resorting to the Modify panel. At that point, you can hide the command panel most of the time while working in 3ds Max, thus recovering valuable screen real estate.

1. Select an editable poly or Edit Poly object (to convert an object, see the preceding procedure).
To use the ribbon tools, Modify mode must be active; that is, the Modify panel must be the current command panel (whether or not the command panel is displayed).

2 Check the wide button on the Polygon Modeling panel:

![Modify Mode Button](image)

If it says Modify Mode, click the button to switch to Modify mode. If it says anything else, proceed to the next step without clicking.

3 If the Editable Poly or Edit Poly stack level is active, the applicable panels then become available. If the ribbon is maximized or minimized to panel titles, the panels are readily apparent. If the ribbon is minimized to tabs, you can see all available open panels on a tab by clicking the tab (see Minimize submenu on page 2044).

If the object is already in a required format but has modifiers other than Edit Poly applied, one of which is active, you need to switch to the Editable Poly or Edit Poly stack level. You can do so using the Next/Previous Modifier buttons on the Polygon Modeling panel.

For instance, consider an editable poly object with the Cloth modifier applied. When the Cloth modifier is active on the stack, the ribbon looks like this:

![Cloth Modifier](image)

Note that the wide button on the Polygon Modeling panel shows the modifier name.
The Next/Previous Modifier buttons enable navigation up and down the
stack, respectively. When navigation in only one direction is possible,
the other button is disabled.

In this example, you would use the Previous Modifier button,
thus accessing the Editable Poly level of the modifier stack.

4 Use the Next/Previous Modifier buttons to go to the Editable Poly or Edit
Poly stack level.

Modeling Ribbon Controls

Most ribbon-configuration controls are available from right-click menus. This
topic details these controls as well as others for customizing the ribbon setup.

NOTE When you reconfigure the ribbon and then exit 3ds Max, the changes are
automatically saved in the two files in the folder MaxModelingRibbon.Config.xml
and MaxManaged.cui. These files are saved in the system path on page 8293, in the
UI directory. By default, this is C:\Documents and Settings\[user name]\Local
Settings\Application Data\Autodesk\3dsmax\[3ds max version]\enu\UI. The next
time you start 3ds Max, it reads the previous ribbon status from these files and
restores it.

To return the ribbon to its default configuration, quit 3ds Max, delete both
MaxModelingRibbon.Config.xml and MaxManaged.cui from the system UI path
(be sure to make backup copies first), and restart.

Floating and Docking the Modeling Ribbon and its Panels

- To dock a floating horizontal ribbon to the top or bottom of the interface,
or the vertical ribbon left or right, drag it to the desired location and, when
the mouse cursor changes to a horizontal strip, release it. Alternatively,
right-click the title bar and choose the desired docking location from the
Dock submenu.

- To float the docked ribbon, drag it by the left end (horizontal) or top
(vertical) away from the docked location. The cursor changes from a
horizontal strip to a rectangle to let you know when releasing it will cause
it to float.
To float a panel by itself, drag it by the title bar (bottom edge or right side) away from the ribbon or panel group. If Show Panel Titles on page 2045 is off, there’s still a small bar at the bottom of docked panels on the horizontal ribbon by which you can drag the panel. However, this bar is not available on non-expanding panels on the vertical ribbon when Show Panel Titles is off.

To move a floating panel or group, drag it by the title or by the “thumbs”: the gray extensions on either side of a floating panel group. You can see the thumbs on the panels in the following illustration.

NOTE By default, panel thumbs are transparent and appear only when the mouse cursor is over the panel. However, on panels that contain spinners, the thumbs are always visible.

To dock a panel to a floating panel or panel group, drag the first to the others until a “landing zone” (rectangular outline, as shown in the illustration) appears on the target, and then release the mouse button.

Thereafter you can move the panel group as a unit.

To return a floating panel or panel group to the ribbon, drag it to the ribbon. If the panel’s “home” tab is active, a rectangular outline appears where it will dock when you release the mouse button. If the panel’s home tab is not active, the tab highlights. If a panel group contains a mix, a combination of the aforementioned conditions occur.
Similarly, to change a panel's position on the ribbon, drag it to the desired location.

**Resizing the Modeling Ribbon**

When the horizontal ribbon floats, you can resize it horizontally by dragging either end. When you reduce the size of the maximized ribbon, the panel contents automatically scale down to fit within the current width, first by dropping labels and ultimately by replacing the visible panel contents with the panel title. At that point, you need to click the panel to view its contents.
Center: ... at medium width, and ...

Bottom: ... fully reduced

NOTE Panels also sometimes scale down when the ribbon is more crowded. This happens when you access a sub-object level, which opens additional panels, or if you add optional panels.

- When the vertical ribbon floats, you can resize it both horizontally and vertically by dragging a vertical or horizontal edge, respectively. When you reduce the vertical ribbon height, the panel contents do not scale; rather, a scroll bar becomes available for scrolling through the panels.
Additional Controls

- To use a panel tool, click its button. To learn its function, hover the mouse cursor over it for a moment and read the tooltip.
NOTE  Certain tools, such as Use Soft Selection, open a contextual settings/options panel when active. The contextual panel always opens on all tabs of the ribbon, even if the panel with the tool floats. If you like, you can use the right-click menu to turn it off on other panels.

■ Contextual panels open at the right end of the ribbon. Like any other panel, you can drag them to another location on the ribbon if you wish.

The Soft Selection and Slice Mode contextual panels have been moved closer to the left end of the ribbon.

When the ribbon is minimized to panel titles, contextual panels are indicated with “---” on both sides of the panel title, as shown in the following illustration:

Interface

In addition to the modeling tools provided by the panel buttons and other controls, the modeling ribbon provides interface-management functions in the form of buttons and a context-sensitive right-click menu.

Buttons

Button-type ribbon controls let you expand panels, pin the expansions, and more; all are described in this section.

[open panel expansion] At the bottom or right side of every panel is the title bar; if Show Panel Titles on page 2045 is off, a thin bar takes its place. If the title bar contains a small arrowhead, that means it can be expanded to show additional controls. To expand the panel, click the title.
The panel expansion remains open as long the mouse cursor stays on it. To close it, simply move the mouse away.

![Panel Expansion Example](image)

**Left:** Click the panel title bar ...

**Right:** ... to open the panel expansion.

**NOTE** When the ribbon is minimized to panel titles, panels expand fully when opened, so further expansion is inapplicable.

**TIP** If you like, you can “pin” open a panel expansion (see following).

**[pin/unpin panel expansion]** At the left end of the title bar of an expanded panel is a small button with a pushpin icon (see preceding illustration). To “pin” the panel expansion, thus locking it open, click this button. To allow it to close, “unpin” it by clicking the button again.

**NOTE** When Show Panel Titles on page 2045 is off, the “pin” icon takes the form of a small circle.

**Return Panels to Ribbon** Restores all panels in the group to the modeling ribbon. Each panel returns to its previous tab and location on the ribbon, before it was floated. Available only on floating panels.
**Toggle Orientation** Switches the panel group layout between vertical and horizontal. Available only on floating panels.

Top: Floating panel group in vertical orientation  
Bottom: Floating panel group in horizontal orientation

**Minimize** Click this button, found on the horizontal ribbon to the right of the tab titles, to cycle through the three minimize/maximize options: Minimize to Panel Titles, Minimize to Tabs, Show Full Ribbon. For details, see Minimize submenu on page 2044.

**Right-click menu**

When you right-click the ribbon or a floating panel group, different commands and submenus appear, depending on where you click. Following is a comprehensive listing of available right-click-menu commands.

**Add to Quick Access Toolbar** Copies the button to the Quick Access toolbar on page 7995, leaving the original in place on the ribbon. Available only when right-clicking a modeling-ribbon button.
To remove the button from the Quick Access toolbar, right-click the button and choose Remove From Quick Access Toolbar.

**Minimize submenu** Choose one of the three Minimize settings, available only for the horizontal ribbon:
- **Minimize to Tabs** The ribbon shows only tab names. To access the panels, click a tab; this maximizes the ribbon temporarily. When you move the mouse cursor away from the ribbon, it minimizes again.

![Graphite Modeling Tools, Freeform, Selection]

In this mode, additional controls on some panels are available on the panel expansion, indicated by a small arrowhead next to the panel title when the panels are expanded. Click the title to open the expansion.

- **Minimize to Panel Titles** The ribbon shows tabs and panel titles. To access a panel, mouse over its title.

![Graphite Modeling Tools, Freeform, Selection]

In this mode, each panel expands to show all controls automatically; no further expansion is available.

- **Show Full Ribbon** Maximizes the ribbon so each panel always shows all or most of its controls.

![Graphite Modeling Tools, Freeform, Selection]

In this mode, additional controls on some panels are available on the panel expansion, indicated by a small arrowhead next to the panel title. Click the title to open the expansion.

**Tabs submenu** Toggles visibility of the three tabs: Graphite Modeling Tools on page 2045, Freeform on page 2155, and Selection on page 2180.

**Panels submenu** Lists all panels available for the active tab. Visible panels have check marks next to their names; hidden ones don’t. To toggle a panel, click its name in the list.

**NOTE** Floating panels do not appear in the list; to enable control over the visibility of a floating panel, return it to the ribbon.
Show Panel Titles When on, a panel title appears at the bottom or side of each panel (depending on orientation). When off, the panel titles are replaced by thin horizontal strips on the horizontal ribbon; you can drag these away from the ribbon to float the panels. However, on the vertical ribbon, turning of Show Panel Titles simply removes the title bars.

NOTE When Minimize to Panel Titles is active, panel titles always appear. Also, floating panels always have titles.

Graphite Modeling Tools Tab

Modeling ribbon > Graphite Modeling Tools tab

The Graphite Modeling Tools tab contains the tools you use most often for polygon modeling, organized into separate panels for easy, convenient access.

Polygon Modeling Panel

Modeling ribbon > Graphite Modeling Tools/Freeform/Selection tab > Polygon Modeling panel

NOTE The Polygon Modeling panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the Freeform tab and Selection tab via the right-click menu.

The Polygon Modeling panel includes tools for switching sub-object levels, navigating the modifier stack, converting objects to editable poly and Edit Poly, and more.

Because this is perhaps the most commonly used panel, we recommend that you float it separate from the modeling ribbon (“tear” it off by dragging the panel label), and use the rest of the ribbon minimized, to maximize screen real estate.
Recommended setup: The modeling ribbon is docked and minimized, while the Polygon Modeling panel floats.

See also:

- Editable Poly Surface on page 2240

**Interface**

Polygon Modeling panel on minimized ribbon
NOTE The sub-object level buttons on the Polygon Modeling panel provide the same selection-conversion features as their counterparts on the Modify panel. For details, see this note on page 1347.

**Vertex** Accesses the Vertex sub-object level, which lets you select a vertex beneath the cursor; region selection selects vertices within the region.
**Edge** Accesses the Edge sub-object level, which lets you select a polygon edge beneath the cursor; region selection selects multiple edges within the region.

**Border** Accesses the Border sub-object level, which lets you select a sequence of edges that borders a hole in the mesh. A border comprises only connected edges with faces on only one side of them, and is always a complete loop. For example, a default box primitive doesn't have a border, but the teapot object has a couple of them: one each on the lid, the body, and the spout, and two on the handle. If you create a cylinder and delete one end, the row of edges around that end forms a border.

When Border sub-object level is active, you can't select edges that aren't on borders. Clicking a single edge on a border selects that whole border.

You can cap a border, either with the [Cap function](#) on page 1392 or by applying the [Cap Holes modifier](#) on page 1185. You can also connect borders between objects with the [Connect compound object](#) on page 695.

**NOTE**

The Edge and Border sub-object levels are compatible, so if you go from one to the other, any existing selection is retained.

**Polygon** Accesses the Polygon sub-object level, which lets you select polygons beneath the cursor. Region selection selects multiple polygons within the region.

**Element** Accesses the Element sub-object level, which lets you select all contiguous polygons in an object. Region selection lets you select multiple elements.

**NOTE**

The Polygon and Element sub-object levels are compatible, so if you go from one to the other, any existing selection is retained.

**Modify Mode/[stack level]** Switches to the Modify panel, or if the Modify panel is active, shows the current modifier stack level.
Usage examples:

■ if any object is selected and any command panel other than the Modify panel is active, the button label reads “Modify Mode.”

■ For an object with no modifiers, if the Modify panel is active and the object type is anything other than editable poly or Edit Poly, the button is unavailable; otherwise the button shows the object type, such as “Editable Poly.”

■ If the Modify panel is active and the current stack level is a modifier, the button shows the name of the modifier.

**TIP** When the Modify panel is active, you can navigate the modifier stack with the Next/Previous Modifier controls.

**Toggle Command Panel** Toggles visibility of the command panel.

**NOTE** Clicking this button always makes the Modify panel active.

**Pin Stack** Locks the modifier stack and modeling ribbon controls to the currently selected object so they remain with that object regardless of subsequent changes in selection.

**TIP** Pin Stack is useful for transforming another object while keeping your place in the modified object’s stack.

**Show End Result (off/on)** Shows the selected object as it appears after all modifications in the stack have taken place, regardless of your current position in the stack.

When this toggle is off, the object appears as modified up to the current modifier in the stack.

**Next/Previous Modifier** Moves up or down the stack, respectively, making the next highest or lowest modifier current.
Equivalent to clicking the entry above or below the current one in the modifier stack.

**Preview** This option lets you preview a sub-object selection before committing to it. You can preview at the current sub-object level, or switch sub-object levels automatically based on the mouse position. The choices are:

- **Preview Off**  No preview is available.

- **Preview SubObject** Enables previewing at the current sub-object level only. As you move the mouse over the object, the sub-object under the cursor highlights in yellow. To select the highlighted object, click the mouse.
  
  To select multiple sub-objects at the current level, press and hold Ctrl, move the mouse to highlight more sub-objects, and then click to select all highlighted sub-objects.

![Polygon sub-object selection preview with Ctrl held down](image)
To deselect multiple sub-objects at the current level, press and hold Ctrl+Alt, move the mouse to highlight more sub-objects, and then click a selected sub-object. This deselects all highlighted sub-objects.

**Preview Multi**  Works like Preview SubObject, but also switches among the Vertex, Edge, and Polygon sub-object levels on the fly, based on the mouse position. For example, if you position the mouse over an edge, the edge highlights, and then clicking activates the Edge sub-object level and selects the edge. To select multiple sub-objects of the same type, press and hold Ctrl after highlighting a sub-object, move the mouse to highlight more sub-objects, and then click to activate that sub-object level and select all highlighted sub-objects. To deselect multiple sub-objects at the current sub-object level, press and hold Ctrl+Alt, move the mouse to highlight more sub-objects, and then click a selected sub-object. This deselects all highlighted sub-objects. Note that this method does not switch sub-object levels.

**NOTE** When Ignore Backfacing (see following) is off, you’ll see backfacing vertices and edges highlight while previewing a sub-object selection.

**Ignore Backfacing** Toggles selection of backfacing sub-objects. When on, selection of sub-objects affects only those facing you. When off (the default), you can select any sub-object(s) under the mouse cursor, regardless of their visibility or facing.

**Use Soft Selection** Toggles Soft Selection on page 2014 and the Soft Selection Panel on page 2053, with settings for controlling how Soft Selection works. Available only at sub-object levels. When off, transforming a sub-object selection affects only those sub-objects. When on, partially selects sub-objects near an explicit selection, depicted as a color gradient. Transforming then falls off with distance from explicitly selected sub-objects.
NOTE When the modeling ribbon is maximized or the Polygon Modeling panel floats, the following controls appear on the Polygon Modeling panel expansion.

**Collapse Stack** Same as *Collapse All* on page 1052: Collapses the selected object’s entire stack to an editable object that preserves the cumulative effect of the collapsed modifiers on the base object. See *Collapsing the Stack* on page 1051.

You can use the Graphite Modeling Tools with an object that results from collapsing the stack only if it’s an editable poly.

**Convert to Poly** Converts the object to editable poly format and switches to Modify mode.

This is the quickest way to start using the Graphite Modeling Tools on an object.

**Apply Edit Poly Mod** Applies the *Edit Poly modifier* on page 1332 to the object and switches to Modify mode.
Generate Topology Opens the Topology dialog on page 2057 with tools for adjusting the object’s geometric makeup.

Symmetry Tools Opens the Symmetry Tools dialog on page 2062 with controls for making models symmetrical.

Full Interactivity Toggles the level of feedback for the QuickSlice and Cut tools, as well as all settings dialogs. Available with editable poly objects, but not the Edit Poly modifier.

When on (the default), the final result is always visible as you use the mouse to manipulate the tool or change a numeric setting. With Cut and QuickSlice, when Full Interactivity is turned off, only the rubber-band line is visible until you click. Similarly, with numeric settings in dialogs, the final result is visible only when you release the mouse button after changing the setting.

The state of Full Interactivity doesn't affect changing a numeric setting from the keyboard. Whether it's on or off, the setting takes effect only when you exit the field by pressing Tab or Enter, or by clicking a different control in the dialog.

Soft Selection Panel

Modeling ribbon > Graphite Modeling Tools/Freeform/Selection tab > Polygon Modeling panel > Use Soft Selection

NOTE The Polygon Modeling panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the Freeform tab and Selection tab via the right-click menu.

The Soft Selection panel opens when Use Soft Selection is on, and provides controls for modifying how Soft Selection works. For details, see Soft Selection Rollout on page 2014
**Interface**

When on, you can change Soft Selection parameters interactively with the keyboard and mouse. For details, see [this procedure](#) on page 2015 and [this section](#) on page 2019.

**Paint**  Paint a soft selection on the active object using the current settings. When active, opens the [Paint Soft Selection panel](#) on page 2056 for controlling how painting works.

Drag the mouse cursor over the object surface to paint the selection.

**TIP** You can streamline the painting process by using the [Brush Presets tools](#) on page 8044.

**Lock**  Locks the soft selection in order to prevent changes to the procedural selection.

**NOTE** Painting the soft selection turns on Lock Soft Selection automatically. If you turn it off after using Paint Soft Selection, the painted soft selection is lost, and cannot be restored with Undo.

**Shaded**  When on, displays a color gradient corresponding to the soft selection weights on faces within the soft selection range.
Shaded makes it easier to see the soft-selection area, especially with complex models.

**Use Backfaces** When on, deselected faces whose normals face in the opposite direction to the average normal of the selected sub-objects are affected by the soft-selection influence. In the case of vertices and edges, this applies to the normals of faces to which they’re attached.

**TIP** Turn off Use Backfaces when you want to manipulate faces of a thin object, such as a thin box, but don’t want to affect faces on the other side of the object.

**NOTE** When the modeling ribbon is maximized or the Soft Selection panel floats, the following controls appear on the Soft Selection panel expansion.

**Use Edge Distance** When on, limits the soft-selection region to the specified number of edges (use the adjacent numeric setting) between where you select and the maximum extent of the soft selection. The affected region is measured in terms of "edge-distance" space, along the surface, rather than real space.

This option is useful in cases where you want to select only contiguous sections of geometry. For example, if a bird’s wing is folded back against its body, selecting the wing tip with Soft Selection would affect nearby body vertices as well. But if you turn on Use Edge Distance, set the numeric value to the distance (in edges) along the wing that you wish to affect, and then set Falloff to an appropriate value, selecting and then moving the wing tip would move only the wing geometry.

**Falloff** Distance in current units from the center to the edge of a sphere defining the affected region. If Edge Distance is on, Falloff is measured in edges and the Edge Distance setting limits the maximum falloff amount.

**NOTE** The region specified by the Falloff setting is depicted graphically in the viewports as a color gradient in vertices and/or edges (or, with editable polys and patches, optionally in faces). The gradient ranges from the selection color (red by default) to the non-selected sub-object color (blue by default). In addition, This gradient is updated in real time as you change the Falloff setting.

**Pinch** Adjusts the slope of the curves on either side of the top point of the soft-selection falloff curve (visible on the command panel). Default=0.
Pinch sets the relative "pointedness" of the region. When negative, a crater is produced instead of a point. At a setting of 0, Pinch produces a smooth transition across this axis.

**Bubble** Expands and contracts the soft-selection falloff curve (visible on the command panel) along the vertical axis. Sets the relative "fullness" of the region. Default=0. Bubble is limited by Pinch, which sets a fixed starting point for Bubble. A setting of 0 for Pinch and 1.0 for Bubble produces the smoothest bulge. Negative values for Bubble move the bottom of the curve below the surface, creating a "valley" around the base of the region.

**Paint Soft Selection Panel**

Modeling ribbon > Graphite Modeling Tools/Freeform/Selection tab > Polygon Modeling panel > Use Soft Selection > Soft Selection panel > Paint

**NOTE** The Polygon Modeling panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the Freeform tab and Selection tab via the right-click menu.

**Interface**

**Blur** Paint with Blur to soften the outlines of an existing painted soft selection.
**Revert** Paint with Revert to reverse a soft selection on the active object using the current settings.

**Options** Opens the Painter Options dialog on page 1989, with settings for brush-related properties.

**NOTE** When the modeling ribbon is maximized or the Paint Soft Selection panel floats, the following controls appear on the Paint Soft Selection panel expansion.

- **Value** The maximum relative selection of the painted or reverted soft selection. The values of surrounding vertices within the brush radius fall off towards a value of 0. Default=1.0.
- **Size** The radius of the circular brush used for painting the selection.
- **Strength** The rate at which painting a soft selection sets the painted sub-objects to the maximum value. A high Strength value reaches the full value quickly, while a low value requires repeated applications to reach full value.

---

**Topology dialog**

Modeling ribbon > Graphite Modeling Tools/Freeform/Selection tab > Polygon Modeling panel [expansion] > Generate Topology

**NOTE** The Polygon Modeling panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the Freeform tab and Selection tab via the right-click menu.

The topology tools rework an object’s mesh subdivision into procedurally generated patterns. You can apply a topology pattern over an entire surface or a selected section.

The various topology tools are described following. The descriptions for the tools are only suggestions of what the tools can be used for, and you can combine multiple tools to create new patterns. Try experimenting with applying a tool several times to generate a different pattern. A typical use of these tools could be to first generate a topology pattern of some sort, and then extrude or bevel different parts to form a structure.
**Interface**

**NOTE** The topology tools work at the object level and all sub-object levels. To confine a tool’s effect to the current sub-object selection, press and hold Shift before clicking.

Also, all tools have assignable CUI action items on page 8249 available in the PolyTools category, as noted in the descriptions.

---

Wall  Generates a wall-type topology with bricks of different sizes.  
CUI action: TopoWall

Tiles  Generates a tile type topology.  CUI action: TopoTiles
Bricks Generates brick topology.

**IMPORTANT** This tool requires one edge to be selected. The direction of the edge determines which way is "up" on the bricks. The tool works only if the selected edge is within quad topology.

CUI action: TopoBrick

Hive Generates hive-type topology.

**IMPORTANT** This tool requires one edge to be selected. The direction of the edge determines which way is "up." The tool works only if the selected edge is within quad topology.

CUI action: TopoHive

Tiles2 Works like Tiles (see preceding), but the resulting tiles are slightly more random.

CUI action: TopoTiles2

Mosaic Generates mosaic topology, with random bricks of different sizes.

CUI action: TopoMosaic

Floor Works like Tiles (see preceding), but generates the pattern in a crossing direction.

CUI action: TopoFloor

Floor2 Works like Wall (see preceding), but generates the pattern in a crossing direction.

CUI action: TopoFloor2
Skin Generates a skin-type topology, with rounded patches.
CUI action: TopoSkin

Holer Generates "holes" in the topology.
If you press Alt the result is more chaotic and less rounded, because it removes vertices with only two edges going from them.
CUI action: TopoHoler

Diamond Changes the direction of the edges to a regular diagonal pattern.
CUI action: TopoEdgedir

Simplify Simplifies the topology by removing random parts, but keeping certain areas of edges intact.
CUI action: TopoSimplify

Chaos Generates a chaotic topology, with randomly shaped patches.
CUI action: TopoChaos

Fours Generates a tile-type topology, which consists of mostly larger quads.
CUI action: TopoFours

Stars Generates a random smoothed-stars topology.
CUI action: TopoStars

Cross Generates a topology with crosses.
CUI action: TopoCross

![Planks](image)

**Planks** Generates a plank-type topology, with "planks" of different sizes.

CUI action: TopoPlanks

![Planks2](image)

**Planks2** Similar to Planks (see preceding) but with broader planks.

CUI action: TopoPlanks2

![Planks3](image)

**Planks3** Generates a topology with large crosses of "planks."

CUI action: TopoPlanks3

![Planks4](image)

**Planks4** Similar to Planks (see preceding) but with longer planks.

CUI action: TopoPlanks4

![Tatter](image)

**Tatter** Generates "holes" in the topology, separated by rows of polygons.

The three numeric settings apply to Tatter only, before applying the tool.

- **Size** Determines the overall size of the generated holes.
- **Iterations** Determines the number of different sizes for the generated holes.
- **Smooth** Determines how rounded the generated holes will be.

CUI action: TopoTatter

**ScrapVerts** Removes all vertices in the mesh with two edges going from them.

CUI action: TopoScrapV

**Plane** Creates a Plane object and converts it to editable poly format for quick testing of the different tools. The value of the "S" parameter determines the number of segments in the plane.
Symmetry Tools dialog

Modeling ribbon > Graphite Modeling Tools/Freeform/Selection tab > Polygon Modeling panel [expansion] > Symmetry Tools

NOTE The Polygon Modeling panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the Freeform tab and Selection tab via the right-click menu.

These are tools for making models symmetrical when using the Symmetry modifier on page 1803 is not an option, such as when working with morph targets. You can model one side of the model and apply these tools to make it symmetrical about an axis.

The symmetry is based on an object you pick that is symmetrical about the chosen axis. It then determines which vertices are symmetrical and enables you to use that information on any other model sharing the same vertex count. The Symmetry tool works in the object’s local coordinate system.

Interface

Pick Main Model Click this button and then select the object on which to base the symmetry. The software then calculates the symmetry based on the specified axis with the specified Tolerance value (see following).
After calculating the symmetry, the software selects all non-symmetrical vertices in the model, including vertices in the center seam.

**Axis** The axis on which to base the symmetry, in the object’s local coordinate system.

The center of the axis is determined by the pivot point of the picked object. Changing the axis recalculates the symmetry for the picked model.

**Tolerance** The distance in world units that the software uses to determine whether two vertices are symmetrical. If the picked model is not completely symmetrical, increase this value slightly.

**Make Symmetrical group**

+ To +/- To + Use these buttons to make the model symmetrical on the chosen axis. Click to make everything on the minus side of the axis symmetrical to the plus side. Click to make everything on the plus side of the axis symmetrical to the minus side.

**Flip Symmetry** Works like a mirror tool by switching the vertex positions on the chosen axis.

**Vertex positions group**

**Copy Selected** Use this tool to copy the currently selected vertices’ positions.

**Paste** Use this tool to paste the vertex positions that you copied with the Copy Selected tool.

For example, you can copy the closed eyes or a certain mouth shape from one model to another. You can also copy positions from an editable poly object and paste them into an Edit Poly modifier.

**Modify Selection Panel**

Modeling ribbon > Graphite Modeling Tools/Selection tab > Modify Selection panel

**NOTE** The Modify Selection panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the Selection tab via the right-click menu.
The Modify Selection panel provides tools for adding to and subtracting from sub-object selections, both in general and with respect to loops and rings.

**Interface**

Modify Selection panel on minimized ribbon

Modify Selection panel on maximized ribbon, with expansion
**Grow** Expands the selection area outward in all available directions. For this function, a border is considered to be an edge selection.

With **Shrink** and **Grow**, you can add or remove neighboring elements from the edges of your current selection. This works at any sub-object level.

**Shrink** Reduces the sub-object selection area by deselecting the outermost sub-objects. If the selection size can no longer be reduced, the remaining sub-objects are deselected.

**Loop** Selects a loop or loops based on the current sub-object selection. Loop on the modeling ribbon differs from Loop on the Modify panel in that the latter works only on edges, while the former works at all sub-object levels.
Usage:

- **Vertex** Select sets of neighboring vertices and apply to select loops. If you select a single vertex, Loop selects all vertices on loops passing through the vertex.

Using Loop at the Vertex level

- **Edge** Select one or more edges and apply to select loops.

Using Loop at the Edge level

- **Polygon** Select sets of neighboring polygons and apply to select loops. If you select a single polygon, Loop selects all polygon loops that pass through the poly.
Using Loop at the Polygon level

Loop Cylinder Ends (on Loop drop-down) Selects vertex and edge loops along the top and bottom edges of a cylinder. Select an edge or a pair of adjacent vertices along the top and/or bottom edge of a cylinder, and then apply to select a loop.

Grow Loop Grows a loop based on current sub-object selection. Select part of one or more loops (an edge, or two or more adjacent vertices or polygons), and then click Grow Loop to select sub-objects at the end(s) of the loops.

Shrink Loop Reduces the extent of selected loops by removing sub-objects from the ends. Does not apply to circular loops. Select one or more non-circular loops and then click Shrink Loop to deselect sub-objects at the end(s) of the loops.

Loop Mode When on, selecting sub-objects can also automatically select an associated loop. For sub-object specifics, see the expanded tooltip.
Usage:

- **Vertex/Polygon** Select two or more adjacent sub-objects to select the associated loop(s).

- **Edge** Select one or more edges to select the associated loop(s).

To deselect a loop with Loop Mode active, hold Alt while making a selection described preceding.

- **Dot Loop** Selects loops with gaps. Select an edge or sets of two or more adjacent vertices or polygons in a row or column (to indicate the loop direction) and apply. To change the spacing, use the Dot Gap setting.

- **Dot Loop Opposite (on Dot Loop drop-down)** Selects vertex/polygon loops with gaps. Select sets of two or more adjacent vertices or polygons in a row or column (to indicate the loop direction) and apply. Starts with a different sub-object from Dot Loop. To change the spacing, use the Dot Gap setting.

- **Dot Loop Cylinder (on Dot Loop drop-down)** Selects edges or vertices in a non-continuous loop around the top and bottom edges of a cylinder, with the selection pattern determined by the Dot Gap setting available on the panel expansion. To use with edges, first select an edge on the top or bottom edge of a cylinder. To use with vertices, first select two or more adjacent vertices on the top or bottom edge of a cylinder.

- **Ring** Selects a ring or rings based on the current sub-object selection.

Usage:

- **Vertex** Select sets of neighboring vertices and apply to select rings.
Using Ring at the Vertex level

- **Edge** Select one or more edges and apply to select rings.

Using Ring at the Edge level

- **Polygon** Select sets of neighboring polygons and apply to select rings. If you select a single polygon, selects both the loop and ring the poly belongs to.
**Grow Ring** Grows one or more edge rings in steps. Available only at the Edge and Border sub-object levels.
Select one or more edges and then apply to select any available rings at either end of the current ring(s).

**Shrink Ring** Reduces the extent of selected edge rings by removing edges from the ends. Does not apply to circular rings. Available only at the Edge and Border sub-object levels.
Usage: Select one or more non-circular rings and then click Shrink Ring to deselect edges from the ends of the rings.

**Ring Mode** When on, selecting enough sub-objects to indicate the ring direction automatically selects the ring.
Sub-object level:

- **Vertex/Polygon** Select two or more adjacent sub-objects to select the ring(s) they’re on.
- **Edge** Select one or more edges to select the ring(s) they’re on.

To deselect a ring with Ring Mode active, hold Alt while selecting an edge in a selected ring.
**Dot Ring** Selects edge rings with gaps, based on the current selection. To change the spacing, use the Dot Gap setting.

**NOTE** When the modeling ribbon is maximized or the Modify Selection panel floats, the following controls appear on the Modify Selection panel expansion.

**Outline** Selects the border (outside members) of the current sub-object selection and deselects the rest. At the Polygon level, to select an edge border, use Shift (switches to Edge sub-object level).

**Similar** Adds to the current sub-object selection based on the characteristics of selected sub-objects and the settings on the drop-down for this tool. The availability of options and results depend on the sub-object level and the current selection. The options are:

- **Edge Count** Selects vertices with the same number of edges going from them as the selected vertices, or polygons with the same number of sides as the selected polygons.

- **Edge Length** Selects vertices with roughly the same combined length of connected edges as the selected vertices, or edges with roughly the same lengths as selected edges.

- **Face Count** Selects vertices with the same number of surrounding faces as the selected vertices.

- **Face Areas** Selects vertices or edges with roughly the same combined areas of surrounding faces as the current selection.

- **Topology** Selects edges whose endpoint vertices have the same number of neighboring edges and faces as the selected edges, or polygons whose vertices have the same edge count as the selected faces.

- **Normal Direction** Selects vertices, edges, or polygons with roughly the same normal directions on page 8654 as the current selection.

Graphite Modeling Tools Tab | 2071
Also see: Select By Numeric on page 2191.

**Fill** Selects all sub-objects between two selected sub-objects.

Usage: Select two objects to designate diagonally opposite corners of the area to be filled, and then click Fill.

Using Fill at the Vertex level

Using Fill at the Polygon level

**Fill Hole** Selects all sub-objects within an enclosed area, as designated by an outline selection and a freestanding selection inside the outline.
Outline an area with a selection, select a sub-object within the area, and click Fill Hole. The selected part must stand free from the surrounding selection, so, for example, a selected polygon in the hole should not be adjacent to any selected polygons around the hole.

Using Fill Hole at the Vertex level

Using Fill Hole at the Edge level
Using Fill Hole at the Polygon level

**StepLoop** Selects a loop between two selected sub-objects on the same loop.
Select two sub-objects on the same loop and apply StepLoop to select all sub-objects between them using the shortest distance.

Using StepLoop at the Vertex level

**StepLoop Longest Distance** (on StepLoop drop-down) Selects a loop between two selected sub-objects on the same loop using the longest distance, if possible.
Select two sub-objects on the same loop and apply StepLoop to select all sub-objects between them using the longest distance, if the complete loop is closed.

Step Mode Use Step Mode to select a loop in steps, increasing the loop length by selecting individual sub-objects.

Access the desired sub-object level and turn on Step Mode. Select a sub-object and then Ctrl+click to select another sub-object on the same loop. This also selects all sub-objects between the two in the shortest distance.

To select an edge or vertex loop at a cylinder end, use Shift+Ctrl+click to select the second and subsequent sub-objects.

If you select a sub-object not on the current loop, you start a new loop, and can then use Step Mode for that loop.

Dot Gap Specifies the extent of gaps between sub-objects in a loop selected with Dot Loop, or between edges in a ring selected with Dot Ring.

Edit Panel

Modeling ribbon > Graphite Modeling Tools/Freeform tab > Edit panel

NOTE The Edit panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the Freeform tab via the right-click menu.

The Edit panel provides a variety of tools for modifying mesh objects, including transform constraints, edge and loop creation, and editing texture coordinates.
Interface

Edit panel on minimized ribbon

Edit panel at Object level

Edit panel at sub-object levels

Preserve UVs When on, you can edit sub-objects without affecting the object’s UV mapping. You can choose any of an object’s mapping channels to preserve or not; see Preserve UVs Settings, following. Default=off.
Without Preserve UVs, there is always a direct correspondence between an object's geometry and its UV mapping. For example, if you map an object and then move vertices, the texture moves along with the sub-objects, whether you want it to or not. If you turn on Preserve UVs, you can perform minor editing tasks without changing the mapping.

Original object with texture map (left); Scaled vertices with Preserve UVs off (center); Scaled vertices with Preserve UVs on (right)

**TIP** For best results with Preserve UVs at the vertex level, use it for limited vertex editing. For example, you'll usually have no trouble moving a vertex within edge or face constraints. Also, it's better to perform one big move than several smaller moves, as multiple small moves can begin to distort the mapping. If, however, you need to perform extensive geometry editing while preserving mapping, use the Channel Info utility on page 6486 instead.

**Preserve UVs Settings (on Preserve UVs drop-down)** Opens the Preserve Map Channels dialog on page 2355, which lets you specify which vertex color channels and/or texture channels (map channels) to preserve. By default, all vertex color channels are off (not preserved), and all texture channels are on (preserved).

**TIP** You can open the Preserve Map Channels dialog quickly by Shift+clicking the Preserve UVs button.

**Tweak (UVs)** When on, you can adjust the UVW mapping on your model directly in the viewport by dragging over the vertices of the model to pull the texture vertices around.

By tweaking UVs with this tool you can quickly adjust areas of stretching in the UVW mapping without the need to add any modifiers. Use the spinner to choose the desired mapping channel and then start the tool. When finished tweaking, right-click to exit the tool.
Drag a vertex to adjust the UVs

When working with Tweak, it’s useful to have a material applied to the model that enables you to easily spot stretching in the mapping. A checker map is suitable for this purpose.

**TIP** To see the modified texture coordinates that result from using the Tweak tool, apply an *Unwrap UVW modifier* on page 1837 and then click the Edit button on the modifier’s Parameters rollout.

**Repeat Last** Repeats the most recently used command.

For example, if you extrude a polygon, and want to apply the same extrusion to several others, select the others, and then click Repeat Last.

You can apply a spline extrusion of a single polygon (left) repeatedly to other single polygons (1) or to multiple polygon selections, contiguous (2) or not (3).
NOTE  Repeat Last does not repeat all operations. For example, it does not repeat transforms. To determine which command will be repeated when you click the button, check the tooltip for the Repeat Last button on the command panel, which gives the name of the last operation that can be repeated. If no tooltip appears, nothing will happen when you click the button.

**QuickSlice** Lets you quickly slice the object without having to manipulate a gizmo. Make a selection, click QuickSlice, and then click once at the slice start point and again at its endpoint. You can continue slicing the selection while the command is active.

To stop slicing, right-click in the viewport, or click QuickSlice again to turn it off.

With QuickSlice on, you can draw a line across your mesh in any viewport, including Perspective and Camera views. The mesh is sliced interactively as you move the line endpoint.

NOTE  At the Object level, QuickSlice affects the entire object. To slice only specific polygons, use QuickSlice on a polygon selection at the Poly sub-object level.
NOTE At the Polygon or Element sub-object level, QuickSlice affects only selected polygons. To slice the entire object, use QuickSlice at any other sub-object level, or at the object level.

SwiftLoop Place edge loops by clicking. Turn on, then click anywhere to insert an edge loop automatically, perpendicular to the edge closest to where you click. Continue clicking edges or right-click to exit.

NOTE As you move the mouse cursor over the object surface, a real-time preview shows where the loop will be created when you click.

Additional features include the ability to slide edges or edge loops in different ways. Following are the different functions of the tool, which depend on which keyboard keys are pressed:

■ Shift Click to insert an edge loop and adjust the new loop to the flow of the surrounding surface.

■ Ctrl Click to select an edge loop and automatically activate the Edge sub-object level.

■ Alt Drag a selected edge loop to slide the edge loop between its bounding loops.

■ Ctrl+Alt Same as Alt but also straightens out the loop (if necessary) when you start to drag.

■ Ctrl+Shift Click to remove an edge loop.

Use NURMS Applies smoothing via the NURMS method and opens the Use NURMS Panel on page 2084. As implemented in Edit/Editable Poly, NURMS is an easy-to-use, procedural mesh-smoothing method that gives you overall control over smoothing parameters.

You control the degree of smoothing with the main Iteration setting, and, optionally the Iteration setting in the Render group as well.
**Cut** Lets you create edges from one polygon to another or within polygons. Click at the start point, move the mouse and click again, and continue moving and clicking to create new connected edges. Right-click once to exit the current cut, whereupon you can start a new one, or right-click again to exit Cut mode.

While cutting, the mouse cursor icon changes to show the type of sub-object it’s over, to which the cut will be made when you click. The following illustration shows the three different cursor icons.
Top: Cutting to a vertex
Center: Cutting to an edge
Bottom: Cutting to a polygon
Cut is available at the object level and all sub-object levels.

**NOTE** You can use Cut with Turn for enhanced productivity. For more information, see this procedure on page 1368.
**Paint Connect** When on, you can paint connections interactively between edges and vertices.

Paint Connect offers a variety of operational modes, depending on which key or keys are pressed:

- **Normal** Drag to paint connections between edges.
- **Shift** Drag to paint connections between edges in the middle of the edges.
- **Ctrl** Drag to select and connect vertices.
- **Alt** Click to remove a vertex.
- **Ctrl+Shift** Click to remove an edge loop.
- **Ctrl+Alt** Click to remove an edge.
- **Shift+Alt** Drag to paint a double connection (two parallel edges) between edges.

**TIP** After using Paint Connect to create a loop that changes direction, you can “quadify” the corner polygons with Build Corner on page 2140.

**Set Flow (on Paint Connect drop-down)** When on, using Paint Connect automatically repositions new edges to fit the shape of the surrounding mesh.

**Constraints** Lets you use existing geometry to constrain sub-object transformation. Choose the constraint type:

- **None:** No constraints. This is the default option.
- **Edge:** Constrains sub-object transformations to edge boundaries.
- **Face:** Constrains sub-object transformations to individual face surfaces.
- **Normal:** Constrains each sub-object’s transformations to its normal, or the average of its normals. In most cases, this causes sub-objects to move perpendicular to the surface.
NOTE This constraint works like the Push modifier on page 1640, including the fact that it operates on unmodified base normals. Edited normals are unsupported.

When set to Edge, moving a vertex will slide it along one of the existing edges, depending on the direction of the transformation. If set to Face, the vertex moves only on the polygon’s surface.

NOTE You can set constraints at the Object level, but their use pertains primarily to sub-object levels. The Constraints setting persists at all sub-object levels.

Use NURMS Panel

Modeling ribbon > Edit panel > Use NURMS

The Use NURMS panel opens when the Use NURMS on page 2080 button on the modeling ribbon > Edit panel is active, and provides access to all controls for how NURMS smoothes object surfaces.
Interface

**Iterations** Sets the number of iterations used to smooth the poly object. Each iteration generates all polygons using the vertices created from the previous iteration. Range=0 to 10.

When the Iterations check box in the Render group (see following) is off, this setting controls iterations both in the viewports and at render time. When the check box is on, this setting controls iterations only in the viewports.

**WARNING** Use caution when increasing the number of iterations. The number of vertices and polygons in an object (and thus the calculation time) can increase as much as four times for each iteration. Applying four iterations to even a moderately complex object can take a long time to calculate. To stop calculation and revert to the previous iteration setting, press Esc.

**Smoothness** Determines how sharp a corner must be before polygons are added to smooth it. A value of 0.0 prevents the creation of any polygons. A value of 1.0 adds polygons to all vertices even if they lie on a plane.

When the Smoothness check box in the Render group (see following) is off, this setting controls smoothness both in the viewports and at render time. When the check box is on, this setting controls smoothness only in the viewports.

**Show Cage** Toggles the display of a two-color wireframe that shows the editable poly object before modification or subdivision. The cage colors are shown as swatches to the right of the check box. The first color represents
unselected sub-objects, and the second color represents selected sub-objects. Change a color by clicking its swatch.

The cage displays the original structure of the edited object.

Typically this feature is used in conjunction with the NURMS Subdivision feature, or with the MeshSmooth modifier on page 1505, because it lets you easily toggle visibility of the unsmoothed base object while simultaneously viewing the smoothed result, but it works with any modifier. When used with a modifier, turn on Show End Result to make Show Cage available.

**TIP** Show Cage is particularly helpful when used with the Symmetry modifier on page 1803.

**Isoline Display** When on, 3ds Max displays only isolines: the object's original edges, before smoothing. The benefit of using this option is a less cluttered display. When off, 3ds Max displays all faces added by NURMS Subdivision; thus, higher Iterations settings (see Display group on page 2328) result in a greater number of lines. Default=on.
NOTE Applying a modifier to an Editable Poly object cancels the effect of the Isoline Display option; the wireframe display reverts to showing all polygons in the object. This is not, however, always the case with the MeshSmooth modifier. Most deformation and mapping modifiers maintain the isoline display, but others, such as the selection modifiers (except Volume Select) and the Turn To ... modifiers, cause the interior edges to be displayed.

[cage display] Shows the colors used for the cage display (see preceding). To change a color, click its swatch.

Update Updates the object in the viewport to match the current MeshSmooth settings. Works only when you choose When Rendering or Manually.

Update: Choose how the software is to update the mesh:
- **Always** Updates the object automatically whenever you change any MeshSmooth settings.
- **When Rendering** Updates the viewport display of the object only at render time.
- **Manually** Any settings you change don’t take effect until you click the Update button.

Smooth Result Applies the same smoothing group to all polygons.
Separate By

**Smoothing Groups** Prevents the creation of new polygons at edges between faces that don't share at least one smoothing group.

**Material IDs** Prevents the creation of new polygons for edges between faces that do not share Material IDs.

Render group

Applies a different number of smoothing iterations and/or a different Smoothness value to the object at render time.

**TIP** Use a low number of iterations and/or a lower Sharpness value for modeling, and higher values for rendering. This lets you work quickly with a low-resolution object in the viewports, while producing a smoother object for rendering.

**Iterations** Lets you choose a different number of smoothing iterations on page 2328 to be applied to the object at render time. Turn on Iterations, and then use the spinner to its right to set the number of iterations.

**Smoothness** Lets you choose a different Smoothness value on page 2329 to be applied to the object at render time. Turn on Smoothness, and then use the spinner to its right to set the smoothness value.

Geometry (All) Panel

Modeling ribbon > Graphite Modeling Tools/Freeform tab > Geometry (All) panel

**NOTE** The Geometry (All) panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the Freeform tab via the right-click menu.

The Geometry (All) panel provides a subset of modeling tools from the *Edit Geometry rollout* on page 1409 and adds *Cap Poly* on page 2095 for creating a polygon from a vertex or edge selection and the *Quadrify* on page 2097 tools for converting polygons to quadrilaterals.
Interface

Geometry (All) panel on minimized ribbon

Geometry (All) panel on maximized ribbon, with expansion

Graphite Modeling Tools Tab | 2089
Relax. Applies the Relax function to the current selection, using the Relax dialog settings (see following). Relax normalizes mesh spacing by moving each vertex toward the average location of its neighbors. It works the same way as the Relax modifier on page 1643.

At the object level, Relax applies to the entire object. At sub-object levels, Relax applies only to the current selection.

NOTE To open the Relax Settings dialog, use the drop-down or Shift+click the Relax button.

Relax Settings (on Relax drop-down) Opens the Relax dialog on page 2357, which lets you specify how the Relax function is applied.

Create. Lets you create new geometry. How this button behaves depends on which level is active:

- **Object, Polygon, and Element levels**. Lets you add polygons in the active viewport. After you turn on Create, click three or more times in succession anywhere, including on existing vertices, to define the shape of the new polygon. To finish, right-click.

  While creating a polygon at the Polygon or Element level, you can delete the most recently added vertex by pressing Backspace. You can do this repeatedly to remove added vertices in reverse order of placement.

  You can start creating polygons in any viewport, but all subsequent clicks must take place in the same viewport.

  **TIP** For best results, click vertices in counterclockwise (preferred) or clockwise order. If you use clockwise order, the new polygon will face away from you.
■ **Vertex level**  Lets you add vertices to a single selected poly object. After selecting the object and clicking Create, click anywhere in space to add free-floating (isolated) vertices to the object. The new vertices are placed on the active construction plane unless object snapping is on. For example, with face snapping on, you can create vertices on object faces.

■ **Edge and Border levels**  Lets you create an edge between a pair of non-adjacent vertices on the same polygon. Click Create, click a vertex, and then move the mouse. A rubber-band line extends from the vertex to the mouse cursor. Click a second, non-adjacent vertex on the same polygon to connect them with an edge. Repeat, or, to exit, right-click in the viewport or click Create again. Edges you create separate the polygons. For example, by creating an edge inside a quadrilateral polygon, you turn it into two triangles.

[Attach](#)  Lets you attach other objects in the scene to the selected poly object. After activating Attach, click an object to attach to the selected object. Attach remains active, so you can continue clicking objects to attach them. To exit, right-click in the active viewport or click the Attach button again.

You can attach any type of object, including splines, patch objects, and NURBS surfaces. Attaching a non-mesh object converts it to editable-poly format. When you attach an object, the materials of the two objects are combined in the following way:

■ If the object being attached does not have a material assigned, it inherits the material of the object it is being attached to.
Handle inherits material from the cup it is being attached to.

- Likewise, if the object you're attaching to doesn't have a material, it inherits the material of the object being attached.
- If both objects have materials, the resulting new material is a multi/sub-object material on page 6120 that includes the input materials. A dialog appears offering three methods of combining the objects' materials and material IDs. For more information, see Attach Options Dialog on page 2233.
  
  Attach remains active in all sub-object levels, but always applies to objects.

**NOTE** To attach objects from a list, use the drop-down or Shift+click the Attach button.

**Attach from List (on Attach drop-down)** Lets you attach other objects in the scene to the selected mesh. Click to open the Attach List dialog, which works like Select From Scene on page 206 to let you choose multiple objects to attach.
Collapse (Sub-object levels only) Collapses groups of contiguous selected sub-objects by welding their vertices to a vertex at the selection center.
Using collapse on a vertex selection

Using collapse on a polygon selection

Detach (Sub-object levels only) Detaches the selected sub-objects and the polygons attached to them as a separate object or element(s).

With an Editable Poly object, when you click Detach, the software prompts you for the options specified on the Detach dialog. With an Edit Poly object, Detach on the Modify panel automatically uses those settings. To change them, click Detach Settings (see following).

On the modeling ribbon, with an Edit Poly object, click Detach to open the Detach dialog, or Shift+click Detach to detach using the current settings.
Cap Poly: Creates a single polygon from a vertex or edge selection and selects the polygon. Available at all sub-object levels except Polygon and Element.

Select vertices or edges and then click Cap Poly.

**TIP** To cap an entire border, for best results use Cap Poly at the Border sub-object level.

Using Cap Poly with a vertex selection

Using Cap Poly with an edge selection
Using Cap Poly with a border selection

When capping an edge selection, the software uses the edge vertices to determine the feasibility of creating a polygon. When using Cap Poly at the Vertex or Edge level, the software requires a non-overlapping counter-clockwise sequence of selected sub-objects. Consider the example shown in the following illustration, in which the goal is to cap all border edges or vertices:
The software first determines the geometric center of the selected sub-objects (the small green disc), and then shoots out “rays” in counter-clockwise order from that location to find the locations of vertices from which to form a polygon. In this case, it finds vertex 6 before it finds vertex 7, but vertex 7 actually precedes vertex 6 when going around the border in counter-clockwise order. As a result, Cap Poly cannot form the polygon because the vertices it finds are in the wrong order.

In such cases, apply Cap Poly at the Border sub-object level.

**Quadrify** ... A set of tools for converting triangles to quadrilaterals. Click the visible tool to apply it, or choose another tool from the drop-down list.

- **Quadrify All**  Removes edges from the entire object to convert triangles to four-sided polygons.

- **Quadrify Selection**  Removes edges from the current sub-object selection to convert triangles to four-sided polygons.
- **Select Edges from All**  Selects edges that would be removed in a Quadrify All operation.
  To see the selection, go to the Edge sub-object level.

- **Select Edges from Selection**  Selects edges that would be removed in a Quadrify All operation.
  To see the selection, go to the Edge sub-object level.

**TIP**  For best results, the geometry to quadrify should be fairly uniform.

**TIP**  Another way to convert a mesh to quads is with the Quadify Mesh modifier on page 1641.

**Slice Plane (sub-object levels only)**  Creates a gizmo for a slice plane that you can position and rotate to specify where to slice. Also enables the Slice and Reset Plane buttons; click Slice to create new edges where the plane intersects the geometry.

If you use Slice Plane from the modeling ribbon, the Slice, Split, and Reset Plane controls are available on the Slice Mode contextual panel on page 2098.

If snapping is off, you see a preview of the slice as you transform the slice plane. To perform the slice, click the Slice button.

**NOTE**  At the Polygon or Element sub-object level, Slice Plane affects only selected polygons. To slice the entire object, use Slice Plane at any other sub-object level, or at the object level.

**Slice Mode Panel**

Any sub-object level > Modeling ribbon > Graphite Modeling Tools/Freeform tab > Geometry (All) panel > Click Slice Plane.

The Slice Mode contextual panel is available on the modeling ribbon when the Slice Plane on page 2098 tool is active. It provides tools for performing the slice and resetting the slice plane position, as well as an option for splitting the mesh while slicing.
Interface

**Slice** Performs the slice operation at the location of the slice plane. Available only when Slice Plane is on. This tool slices the poly just like the “Operate On: Polygons” mode of the Slice modifier on page 1727.

**Split** When on, the QuickSlice and Cut operations create double sets of vertices at the points where the edges are divided. This lets you easily delete the new polygons to create holes, or animate the new polygons as separate elements.

**Reset** Returns the Slice plane to its default position and orientation. Available only when Slice Plane is on.

**[Sub-object] Panel**

Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Any sub-object level > [Sub-object] panel
The Polygon Modeling panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the other tabs via the right-click menu. The [sub-object] panel is available only on the Graphite Modeling Tools tab.

When you access a sub-object level on the Polygon Modeling panel, a corresponding contextual panel with controls for editing at that level opens on the ribbon. The sub-object panels are:

**Vertices Panel**

Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Access the Vertex sub-object level > Vertices panel

Vertices are points in space: They define the structure of other sub-objects (edges and polygons) that make up the poly object. When you move or edit vertices, the connected geometry is affected as well. Vertices can also exist independently; such isolated vertices can be used to construct other geometry but are otherwise invisible when rendering.

At the editable poly Vertex sub-object level, you can select single and multiple vertices and move them using standard methods.
Interface

Extrude

Extrude lets you extrude vertices manually via direct manipulation in the viewport. Click this button, and then drag vertically on any vertex to extrude it.

Extruding a vertex moves it along a normal and creates new polygons that form the sides of the extrusion, connecting the vertex to the object. The extrusion has the same number of sides as the number of polygons that originally used the extruded vertex.

Following are important aspects of vertex extrusion:

- When over a selected vertex, the mouse cursor changes to an Extrude cursor.
- Drag vertically to specify the extent of the extrusion, and horizontally to set the size of the base.
- With multiple vertices selected, dragging on any one extrudes all selected vertices equally.
- You can drag other vertices in turn to extrude them while the Extrude button is active. Click Extrude again or right-click in the active viewport to end the operation.
NOTE To open the Extrude Vertices dialog, choose Extrude Settings from the drop-down or Shift+click the Extrude button.

Extrude Settings (on Extrude drop-down) Opens the Extrude Vertices dialog on page 2350, which lets you perform extrusion via interactive manipulation. If you click this button after performing a manual extrusion, the same extrusion is performed on the current selection as a preview and the dialog opens with Extrusion Height set to the amount of the last manual extrusion.

Chamfer Click this button and then drag vertices in the active object. To chamfer vertices numerically, click the Chamfer Settings button and use the Chamfer Amount value.

If you chamfer multiple selected vertices, all of them are chamfered identically. If you drag an unselected vertex, any selected vertices are first deselected. Each chamfered vertex is effectively replaced by a new face that connects new points on all edges leading to the original vertex. These new points are exactly
<chamfer amount> distance from the original vertex along each of these edges. New chamfer faces are created with the material ID of one of the neighboring faces (picked at random) and a smoothing group which is an intersection of all neighboring smoothing groups.

For example, if you chamfer one corner of a box, the single corner vertex is replaced by a triangular face whose vertices move along the three edges that led to the corner. Outside faces are rearranged and split to use these three new vertices, and a new triangle is created at the corner.

Alternatively, you can create open space around the chamfered vertices; for details, see Chamfer Vertices dialog on page 2344.
NOTE To open the Chamfer Vertices dialog, choose Chamfer Settings from the drop-down or Shift+click the Chamfer button.

**Chamfer Settings (on Chamfer drop-down)** Opens the Chamfer Vertices dialog on page 2344, which lets you chamfer vertices via interactive manipulation and toggle the Open option.

If you click this button after performing a manual chamfer, the same chamfer is performed on the current selection as a preview and the dialog opens with Chamfer Amount set to the amount of the last manual extrusion.

**Weld** Combines contiguous, selected vertices that fall within the tolerance specified in Weld dialog on page 2359. All edges become connected to the resulting single vertex.

**Using Weld at the Vertex level**

Vertices farther apart than the Threshold distance are not welded.

Weld is best suited to automatically simplifying geometry that has areas with a number of vertices that are very close together. Before using Weld, set the Weld Threshold via the Weld dialog on page 2359. To weld vertices that are relatively far apart, use Target Weld on page 1366 instead.

NOTE To open the Weld Vertices dialog, choose Weld Settings from the drop-down or Shift+click the Chamfer button.

**Weld Settings (on Weld drop-down)** Opens the Weld dialog on page 2359, which lets you specify the weld threshold.
**Remove** Deletes selected vertices and combines the polygons that use them. The keyboard shortcut is Backspace.

Removing one or more vertices deletes them and retriangulates the mesh to keep the surface intact. If you use Delete instead, the polygons depending on those vertices are deleted as well, creating a hole in the mesh.

**WARNING** Use of Remove can result in mesh shape changes and non-planar polygons.

**Break** Creates a new vertex for each polygon attached to selected vertices, allowing the polygon corners to be moved away from each other where they were once joined at each original vertex. If a vertex is isolated or used by only one polygon, it is unaffected.

**Target Weld** Allows you to select a vertex and weld it to a neighboring target vertex. Target Weld works only with pairs of contiguous vertices; that is, vertices connected by a single edge.
In Target Weld mode, the mouse cursor, when positioned over a vertex, changes to a + cursor. Click and then move the mouse; a dashed, rubber-band line connects the vertex to the mouse cursor. Position the cursor over another, neighboring vertex and when the + cursor appears again, click the mouse. The first vertex moves to the position of the second and the two are welded. Target Weld remains active until you click the button again or right-click in the viewport.

NOTE When the modeling ribbon is maximized or the Vertices panel floats, the following controls appear on the Vertices panel expansion.

**Weight** Sets the weight of selected vertices. Used by the NURMS subdivision option on page 2326 and by the MeshSmooth modifier on page 1505. Increasing a vertex weight tends to pull the smoothed result toward the vertex.

**Remove Isolated Verts** Deletes all vertices that don’t belong to any polygons.

**Remove Unused Map Verts** Certain modeling operations can leave unused (isolated) map vertices that show up in the Unwrap UVW editor on page 1856, but cannot be used for mapping. You can use this button to automatically delete these map vertices.

**Edges Panel**

Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Access the Edge sub-object level > Edges panel

NOTE The Polygon Modeling panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the other tabs via the right-click menu. The Edges panel is available only on the Graphite Modeling Tools tab.

An edge is a line connecting two vertices that forms the side of a polygon. An edge can’t be shared by more than two polygons. Also, the normals of the two polygons should be adjacent. If they aren’t, you wind up with two edges that share vertices.

At the editable poly Edge sub-object level, you can select single and multiple edges and transform them using standard methods.
**Interface**

Extrude Lets you extrude edges manually via direct manipulation in the viewport. Click this button, and then drag vertically on any edge to extrude it.

When extruding a vertex or edge interactively in the viewport, you set the extrusion height by moving the mouse vertically and the base width by moving the mouse horizontally.
Extruding an edge moves it along a normal and creates new polygons that form the sides of the extrusion, connecting the edge to the object. The extrusion has either three or four sides; three if the edge was on a border, or four if it was shared by two polygons. As you increase the length of the extrusion, the base increases in size, to the extent of the vertices adjacent to the extruded edge’s endpoints.

Following are important aspects of edge extrusion:

■ When over a selected edge, the mouse cursor changes to an Extrude cursor.

■ Drag vertically to specify the extent of the extrusion, and horizontally to set the size of the base.

■ With multiple edges selected, dragging on any one extrudes all selected edges equally.

■ You can drag other edges in turn to extrude them while the Extrude button is active. Click Extrude again or right-click in the active viewport to end the operation.

NOTE To open the Extrude Edges dialog, choose Extrude Settings from the drop-down or Shift+click the Extrude button.
Extrude Settings (on Extrude drop-down) Opens the Extrude Edges dialog on page 2350, which lets you perform extrusion via interactive manipulation. If you click this button after performing a manual extrusion, the same extrusion is performed on the current selection as a preview and the dialog opens with Extrusion Height set to the amount of the last manual extrusion.

Chamfer Click this button and then drag edges in the active object. To chamfer edges numerically, click the Chamfer Settings button and change the Chamfer Amount value.

If you chamfer multiple selected edges, all of them are chamfered identically. If you drag an unselected edge, any selected edges are first deselected.

An edge chamfer "chops off" the selected edges, creating a new polygon connecting new points on all visible edges leading to the original vertex. The new edges are exactly <chamfer amount> distance from the original edge along each of these edges. New chamfer faces are created with the material ID of one of the neighboring faces (picked at random) and a smoothing group which is an intersection of all neighboring smoothing groups.

For example, if you chamfer one edge of a box, each corner vertex is replaced by two vertices moving along the visible edges that lead to the corner. Outside faces are rearranged and split to use these new vertices, and a new polygon is created at the corner.

Using Chamfer at the Edge level

Alternatively, you can create open space around the chamfered edges; for details, see Chamfer Edges dialog on page 2344.
NOTE To open the Chamfer Edges dialog, choose Chamfer Settings from the drop-down or Shift+click the Chamfer button.

Chamfer Settings (on Chamfer drop-down) Opens the Chamfer Edges dialog on page 2344, which lets you chamfer edges via interactive manipulation and toggle the Open option.

If you click this button after performing a manual chamfer, the same chamfer is performed on the current selection as a preview and the dialog opens with Chamfer Amount set to the amount of the last manual chamfer.

Weld Combines selected edges that fall within the threshold specified in Weld dialog on page 2359.

You can weld only edges that have one polygon attached; that is, edges on a border. Also, you cannot perform a weld operation that would result in illegal geometry (e.g., an edge shared by more than two polygons). For example, you cannot weld opposite edges on the border of a box that has a side removed.

NOTE To open the Weld dialog, choose Weld Settings from the drop-down or Shift+click the Weld button.

Weld Settings (on Weld drop-down) Opens the Weld dialog on page 2359, which lets you specify the weld threshold.

Bridge Connects border edges on an object with a polygon “bridge.” Bridge connects only border edges; that is, edges that have a polygon on only one side. This tool is particularly useful when creating edge loops or profiles.

There are two ways to use Bridge in Direct Manipulation mode (that is, without opening the Bridge Edges settings dialog):

- Select two or more border edges on the object, and then click Bridge. This immediately creates the bridge between the pair of selected borders using the current Bridge settings, and then deactivates the Bridge button.

- If no qualifying selection exists (that is, two or more selected border edges), clicking Bridge activates the button and places you in Bridge mode. First click a border edge and then move the mouse; a rubber-band line connects the mouse cursor to the clicked edge. Click a second edge on a different border to bridge the two. This creates the bridge immediately using the current Bridge settings; the Bridge button remains active for connecting
more edges. To exit Bridge mode, right-click the active viewport or click the Bridge button.

The new polygons that result from a Bridge operation are automatically selected; you can see this by accessing the Polygon sub-object level.

Using Bridge at the Edge level

**NOTE** Bridge always creates a straight-line connection between edges. To make the bridge connection follow a contour, apply modeling tools as appropriate after creating the bridge. For example, bridge two edges, and then use **Bend** on page 1165.

**NOTE** To open the Bridge Edges dialog, choose Bridge Settings from the drop-down or Shift+click the Bridge button.

**Bridge Settings (on Bridge drop-down)** Opens the Bridge Edges dialog on page 2341, which lets you add polygons between pairs of edges via interactive manipulation.

**Remove** Deletes selected edges and combines the polygons that use them.
Removing one edge is like making it invisible. The mesh is affected only when all or all but one of the edges depending on one vertex are removed. At that point, the vertex itself is deleted and the surface is retriangulated.

To delete the associated vertices when you remove edges, press and hold Ctrl while executing a Remove operation, either by mouse or with the Backspace key. This option, called Clean Remove, ensures that the remaining polygons are planar.

Left: The original edge selection  
Center: Standard Remove operation leaves extra vertices.  
Right: Clean Remove with Ctrl+Remove deletes the extra vertices.

Edges with the same polygon on both sides usually can’t be removed.
WARNING Use of Remove can result in mesh shape changes and non-planar polygons.

**Split** Divides the mesh along the selected edges. This does nothing when applied to a single edge in the middle of a mesh. The vertices at the end of affected edges must be separable in order for this option to work. For example, it would work on a single edge that intersects an existing border, since the border vertex can be split in two. Additionally, two adjacent edges could be split in the middle of a grid or sphere, since the shared vertex can be split.

**Target Weld** Allows you to select an edge and weld it to a target edge. When positioned over an edge, the cursor changes to a + cursor. Click and move the mouse and a dashed line appears from the vertex with an arrow cursor at the other end of the line. Position the cursor over another edge and when the + cursor appears again, click the mouse. The first edge is moved to the position of the second, and the two are welded. You can weld only edges that have one polygon attached; that is, edges on a border. Also, you cannot perform a weld operation that would result in illegal geometry (e.g., an edge shared by more than two polygons). For example, you cannot weld opposite edges on the border of a box that has a side removed.

**Spin** Spins the selected edge or edges in the polygon, changing the direction. Select one or more edges and then apply Spin to change how the edges subdivide the mesh. Normally the edge spins clockwise, but if you hold Shift, the edges spin counterclockwise.

**Insert Vertices** Inserts vertices in selected edges. Select edges, set the number of vertices to insert in each, and click Insert Vertices. The inserted vertices are spaced evenly along each selected edge. Also, the Vertex sub-object level is activated and the new vertices are selected.
NOTE When the modeling ribbon is maximized or the Edges panel floats, the following controls appear on the Edges panel expansion.

Create Shape From Selection After selecting one or more edges, click this button to create a spline shape from the selected edges. A Create Shape dialog appears, letting you name the shape and set it to Smooth or Linear. The new shape's pivot is placed at the center of the poly object.
An edge selection (top); a smooth shape (center); a linear shape (bottom)

**Weight** Sets the weight of selected edges. Used by the NURMS subdivision option on page 2326 and by the MeshSmooth modifier on page 1505. Increasing an edge weight tends to push the smoothed result away.

**Crease** Specifies how much creasing is performed on the selected edge or edges. Used by the NURMS subdivision option on page 2326 and by the MeshSmooth modifier on page 1505. At low settings, the edge is relatively smooth. At higher settings, the crease becomes increasingly visible. At 1.0, the highest setting, the edge becomes a hard crease.

**Border Edges Panel**

Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Access the Border sub-object level > Border Edges panel

**NOTE** The Polygon Modeling panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the other tabs via the right-click menu. The Border Edges panel is available only on the Graphite Modeling Tools tab.

A border is a linear section of a mesh that can generally be described as the edge of a hole. This is usually a sequence of edges with polygons on only one
side. For example, a box primitive on page 389 doesn’t have a border, but the teapot on page 416 object has several: on the lid, on the body, on the spout, and two on the handle. If you create a cylinder and then delete an end polygon, the adjacent row of edges forms a border.

At the editable poly Border sub-object level, you can select single and multiple borders and transform them using standard methods.

**Interface**

Extrude Lets you extrude a border manually via direct manipulation in the viewport. Click this button, and then drag vertically on any border to extrude it.

Extruding a border moves it along a normal and creates new polygons that form the sides of the extrusion, connecting the border to the object. The extrusion can form a varying number of additional sides, depending on the geometry near the border. As you increase the length of the extrusion, the base increases in size, to the extent of the vertices adjacent to the extruded border’s endpoints.

Following are important aspects of border extrusion:

■ When the mouse cursor is over a selected border, it changes to an Extrude cursor.
■ To specify the extent of the extrusion, drag vertically, and to set the size of the base, drag horizontally.

■ With multiple borders selected, dragging on any one extrudes all selected borders equally.

■ While the Extrude button is active, you can extrude other borders in turn by dragging them. Click Extrude again or right-click in the active viewport to end the operation.

**NOTE** To open the Extrude Edges dialog, choose Extrude Settings from the drop-down or Shift+click the Extrude button.

**Extrude Settings (on Extrude drop-down)** Opens the Extrude Edges dialog on page 2350, which lets you perform extrusion via interactive manipulation. If you click this button after performing a manual extrusion, the same extrusion is performed on the current selection as a preview and the dialog opens with Extrusion Height set to the amount of the last manual extrusion.

**Bridge** Connects pairs of borders on an object with polygon “bridges.” There are two ways to use Bridge in Direct Manipulation mode (that is, without opening the Bridge Settings dialog):

■ Select an even number of borders on the object, and then click Bridge. This immediately creates the bridge between each pair of selected borders using the current Bridge settings, and then deactivates the Bridge button.

■ If no qualifying selection exists (that is, two or more selected borders), clicking Bridge activates the button and places you in Bridge mode. First click a border edge and then move the mouse; a rubber-band line connects the mouse cursor to the clicked edge. Click a second edge on a different border to bridge the two. This creates the bridge immediately using the current Bridge settings; the Bridge button remains active for connecting more pairs of borders. To exit Bridge mode, right-click the active viewport or click the Bridge button.

The new polygons that result from a Bridge operation are automatically selected; you can see this by accessing the Polygon sub-object level.
Using Bridge at the Border level.

**NOTE** Bridge always creates a straight-line connection between border pairs. To make the bridge connection follow a contour, apply modeling tools as appropriate after creating the bridge. For example, bridge two borders, and then use **Bend** on page 1165.

**NOTE** To open the Bridge Borders dialog, choose Bridge Settings from the drop-down or Shift+click the Bridge button.

**Bridge Settings (on Bridge drop-down)** Opens the Bridge dialog on page 2339, which lets you connect pairs of borders via interactive manipulation.

**Chamfer** Click this button and then drag a border in the active object. The border need not be selected first.

If you chamfer multiple selected borders, all of them are chamfered identically. If you drag an unselected border, any selected borders are first deselected. A border chamfer essentially “frames” the border edges, creating a new set of edges paralleling the border edges, plus new diagonal edges at any corners. These new edges are exactly `<chamfer amount>` distance from the original edges. New chamfer faces are created with the material ID of one of the neighboring faces (picked at random) and a smoothing group which is an intersection of all neighboring smoothing groups. Alternatively, you can create open space around the chamfered borders, essentially cutting away at the open edges; for details, see **Chamfer Edges dialog** on page 2344.
NOTE To open the Chamfer Edges dialog, choose Chamfer Settings from the drop-down or Shift+click the Chamfer button.

**Chamfer Settings (on Chamfer drop-down)** Opens the Chamfer Edges dialog on page 2344, which lets you chamfer borders via interactive manipulation and toggle the Open option.

If you click this button after performing a manual chamfer, the same chamfer is performed on the current selection as a preview and the dialog opens with Chamfer Amount set to the amount of the last manual chamfer.

![Connect](image)

**Connect** Creates new edges between pairs of selected border edges. The edges are connected from their midpoints.

You can connect only edges on the same polygon.

Connect will not let the new edges cross. Thus, for example, if you select all four edges of a four-sided polygon and then click Connect, only neighboring edges are connected, resulting in a diamond pattern.

NOTE To open the Connect Edges dialog, choose Connect Settings from the drop-down or Shift+click the Connect button.

**Connect Settings (on Connect drop-down)** Lets you preview the Connect and specify the number of edge segments created by the operation. To increase the mesh resolution around the new edge, increase the Connect Edge Segments setting.

NOTE When the modeling ribbon is maximized or the Border Edges panel floats, the following controls appear on the Border Edges panel expansion.

![Create Shape From Selection](image)

**Create Shape From Selection** After selecting one or more borders, click this button to create a spline shape from the selected edges. A Create Shape dialog appears, letting you name the shape and set it to Smooth or Linear. The new shape's pivot is placed at the center of the poly object.

**Weight** Sets the weight of selected borders. Used by the NURMS subdivision option on page 2326.

Increasing an edge weight tends to push the smoothed result away.

**Crease** Specifies how much creasing is performed on the selected border or borders. Used by the NURMS subdivision option on page 2326.
At low settings, the border is relatively smooth. At higher settings, the crease becomes increasingly visible. At 1.0, the highest setting, the border is not smoothed at all.

Polygons/Elements Panel

Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Access the Polygon or Element sub-object level > Polygons/Elements panel

NOTE The Polygon Modeling panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the other tabs via the right-click menu. The Polygons or Elements panel is available only on the Graphite Modeling Tools tab.

A polygon is a closed sequence of three or more edges connected by a surface. Polygons provide the renderable surface of editable poly objects.

At the editable poly Polygon sub-object level you can select single and multiple polygons and transform them using standard methods. At the Element sub-object level you can select and edit groups of contiguous polygons. For further distinctions between polygon and element, see Editable Poly > Selection rollout on page 2248.

Interface

The Polygons panel includes all of the following controls, while the Elements panel includes only the Flip on page 2124 and Insert Vertex on page 2130 functions.
Extrude

Extrude lets you perform manual extrusion via direct manipulation in the viewport. Click this button, and then drag vertically on any polygon to extrude it.

Extruding polygons moves them along a normal and creates new polygons that form the sides of the extrusion, connecting the selection to the object. Following are important aspects of polygon extrusion:

■ When over a selected polygon, the mouse cursor changes to an Extrude cursor.

■ Drag vertically to specify the extent of the extrusion, and horizontally to set the size of the base.

■ With multiple polygons selected, dragging on any one extrudes all selected polygons equally.

■ You can drag other polygons in turn to extrude them while the Extrude button is active. Click Extrude again or right-click in the active viewport to end the operation.
Chamfer box showing extruded polygon

**NOTE** To open the Extrude Polygons dialog, choose Extrude Settings from the drop-down or Shift+click the Extrude button.

**Extrude Settings (on Extrude drop-down)** Opens the Extrude Polygons dialog on page 2349, which lets you perform extrusion via interactive manipulation. If you click this button after performing an extrusion, the same extrusion is performed on the current selection as a preview and the dialog opens with Extrusion Height set to the amount of the last manual extrusion.

**Bevel** Lets you perform manual beveling via direct manipulation in the viewport. Click this button, and then drag vertically on any polygon to extrude it. Release the mouse button and then move the mouse vertically to outline the extrusion. Click to finish.

- When over a selected polygon, the mouse cursor changes to a Bevel cursor.
- With multiple polygons selected, dragging on any one bevels all selected polygons equally.
- You can drag other polygons in turn to bevel them while the Bevel button is active. Click Bevel again or right-click to end the operation.
**Polygon beveled outward (left) and inward (right)**

**NOTE** To open the Bevel Polygons dialog, choose Bevel Settings from the drop-down or Shift+click the Bevel button.

**Bevel Settings (on Bevel drop-down)** Opens the Bevel Polygons dialog on page 2337, which lets you perform beveling via interactive manipulation. If you click this button after performing a bevel, the same bevel is performed on the current selection as a preview and the dialog opens with the same settings used for the previous bevel.

**Bridge** Connects two polygons or polygon selections on an object with a polygon “bridge.” There are two ways to use Bridge in Direct Manipulation mode (that is, without opening the Bridge Settings dialog):

- Make two separate polygon selections on the object, and then click Bridge. This creates the bridge immediately using the current Bridge settings, and then deactivates the Bridge button.

- If no qualifying selection exists (that is, two or more discrete polygon selections), clicking Bridge activates the button and places you in Bridge mode. First click a polygon and move the mouse; a rubber-band line connects the mouse cursor to the clicked polygon. Click a second polygon to bridge the two. This creates the bridge immediately using the current Bridge settings; the Bridge button remains active for connecting more pairs.
of polygons. To exit Bridge mode, right-click the active viewport or click the Bridge button.

Using Bridge at the Polygon level

**NOTE** Bridge always creates a straight-line connection between polygon pairs. To make the bridge connection follow a contour, apply modeling tools as appropriate after creating the bridge. For example, bridge two polygons, and then use **Bend** on page 1165.

**NOTE** To open the Bridge Polygons dialog, choose Bridge Settings from the drop-down or Shift+click the Bridge button.

**Bridge Settings (on Bridge drop-down)** Opens the Bridge dialog on page 2339, which lets you connect pairs of polygon selections via interactive manipulation.

**GeoPoly** Untangles a polygon and organizes the vertices to form a perfect geometric shape. Select polygons and apply to make a geometric shape. If several adjacent polygons are selected the result is averaged among the polygons.

**Flip** Reverses the directions of the normals of selected polygons, hence their facing.

2124 | Chapter 10  Surface Modeling
**Hinge** Lets you perform a manual hinge operation via direct manipulation in the viewport. Make a polygon selection, click this button, and then drag vertically on any edge to hinge the selection. The mouse cursor changes to a cross when over an edge.

The hinge edge needn't be part of the selection. It can be any edge of the mesh. Also, the selection needn't be contiguous.

Hinging polygons rotates them about an edge and creates new polygons that form the sides of the hinge, connecting the selection to the object. It's essentially an extrusion with rotation, with the exception that, if the hinge edge belongs to a selected polygon, that side is not extruded. The manual version of Hinge From Edge works only with an existing polygon selection.

**TIP** To avoid inadvertently hinging about a backfacing edge, turn on Ignore Backfacing.

**NOTE** To open the Hinge Polygons From Edge dialog, choose Hinge Settings from the drop-down or Shift+click the Hinge button.

**Hinge Settings (on Hinge drop-down)** Opens the Hinge From Edge dialog on page 2352, which lets you hinge polygons via interactive manipulation. If you click this button after performing a manual hinge, the dialog opens with Angle set to the extent of the last manual hinge.
Inset Performs a bevel with no height; that is, within the plane of the polygon selection. Click this button, and then drag vertically on any polygon to inset it.

- When over a selected polygon, the mouse cursor changes to an Inset cursor.
- With multiple polygons selected, dragging on any one insets all selected polygons equally.
- While the Inset button is active, you can drag other polygons in turn to inset them. To end the operation, click Inset again or right-click.

Inset works on a selection of one or more polygons. As with Outline, only the outer edges are affected.

NOTE To open the Inset Polygons dialog, choose Inset Settings from the drop-down or Shift+click the Inset button.

Inset Settings (on Inset drop-down) Opens the Inset Polygons dialog on page 2353, which lets you inset polygons via interactive manipulation.

If you click this button after performing a manual inset, the same inset is performed on the current selection as a preview and the dialog opens with Inset Amount set to the amount of the last manual inset.

NOTE When the modeling ribbon is maximized or the Polygons panel floats, the following controls appear on the Polygons panel expansion.
Outline lets you increase or decrease the outside edge of each contiguous group of selected polygons.

Outline is often used after an extrusion or bevel to adjust the size of the extruded faces. It doesn’t scale the polygons; only changes the size of the outer edge. For example, in the following illustration, note that the sizes of the inner polygons remain constant.
Extruded polygons (top), outline expanded (middle), outline reduced (bottom)

Note that inner polygons do not change size.
NOTE To open the Outline Polygons dialog, choose Outline Settings from the drop-down or Shift+click the Outline button.

Outline Settings (on Outline drop-down) Opens the Outline Polygons dialog, which lets you perform outlining by a numeric setting.

![Extrude on Spline](image)

Extrude on Spline Extrudes the current selection along a spline.

You can extrude a single polygon (1) or a selection of contiguous (2) or non-contiguous polygons (3). Extrusion 2 uses Taper Curve and Twist (available via Settings). Extrusion 3 uses Taper Amount; each extrusion has a different curve rotation.

Make a selection, click Extrude Along/On Spline, and then select a spline in the scene. The selection is extruded along the spline, using the spline's current orientation, but as though the spline's start point were moved to the center of each polygon or group.

NOTE To open the Extrude Polygons Along Spline dialog, choose Extrude On Spline Settings from the drop-down or Shift+click the Extrude On Spline button.

Extrude On Spline Settings (on Extrude On Spline drop-down) Opens the Extrude Polygons Along Spline dialog on page 2347, which lets you extrude along splines via interactive manipulation.
**Insert Vertex** Lets you subdivide polygons manually. Applies to polygons, even if at the element sub-object level. After turning on Insert Vertex, click a polygon to add a vertex at that location. You can continue subdividing polygons as long as the command is active. To stop inserting vertices, right-click in the viewport, or click Insert Vertex again to turn it off.

**Loops Panel**

Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Vertex, Edge, or Polygon sub-object level > Loops panel

**NOTE** The Polygon Modeling panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the other tabs via the right-click menu. The [sub-object] panel is available only on the Graphite Modeling Tools tab.

The Loops panel features are for working with edge loops, and include tools for creating loops within polygons and at a distance, automatically adjusting a new loop to an object’s shape, random paths, and more.

All of the Loops panel tools are available at the Edge level; other sub-object levels provide a subset or none. At the Polygon level, only Insert Loop and Remove Loop are available. The Vertex level provides Connect, Distance connect, Insert/Remove Loop, and Build End/Corners.
Interface

Loops panel at the Edge level on minimized ribbon

Loops panel on maximized ribbon, with expansion
Loops panel floating, with expansion

**Connect (Vertex level)** Creates new edges between pairs of selected vertices.

Connect does not let the new edges cross. Thus, for example, if you select all four vertices of a four-sided polygon and then click Connect, only two of the vertices will be connected. In this case, to connect all four vertices with new edges, use **Cut** on page 1417.

**Connect (Edge level)** Creates new edges between pairs of selected edges using the current Connect Edges dialog settings. Connect is particularly useful for creating or refining edge loops.

**NOTE** You can connect only edges on the same polygon. Also, Connect will not let the new edges cross. For example, if you select all four edges of a four-sided polygon and then click Connect, only neighboring edges are connected, resulting in a diamond pattern.
Connecting two or more edges using the Settings dialog creates equally spaced edges. The number of edges is set in the dialog. When you click the Connect button, the current dialog settings are applied to the selection.

**Connect Settings (on Connect drop-down)** Opens the Connect Edges dialog on page 2345, which lets you preview the Connect results, specify the number of edge segments created by the operation, and set spacing and placement for the new edges.

**TIP** You can open the Connect Edges dialog quickly by Shift+clicking the Connect button.

**Distance Connect** Creates edge loops between vertices and edges across distance and other topology.
Usage depends on the sub-object level:
- **Vertex** Select two end vertices and apply to connect them across the intervening mesh.
Edge  Select two parallel edges and apply to connect them across the intervening mesh.

NOTE  At the Edge level, if a complete (closed) loop is possible (for instance, around a sphere), Distance Connect automatically creates one.
**Flow Connect** Connects selected edges across one or more edge rings and adjusts the new loop position to fit the shape of the surrounding mesh.

Select an edge ring and apply Flow Connect. For each selected edge, Flow Connect creates a loop through the ring and adjusts the new edges to follow the physical outline of the mesh.

**Left top:** Selected edge ring; **Left bottom:** Selected edge with Auto Ring on

**Right:** After applying Flow Connect, showing the corrected shape after creating the loop

**TIP** To automatically select the ring before connecting, based on the edge selection, turn on Auto Ring first (see following).

**Auto Ring (on Flow Connect drop-down)** When on and you use Flow Connect, creates a full edge loop automatically.

Usage: Turn on Auto Loop, select one or more edges, and apply Flow Connect. For each selected edge, Flow Connect creates a loop through its entire ring and adjusts the new edges to follow the physical outline of the mesh.

**Insert Loop** Creates one or more edge loops based on the current sub-object selection and selects the results.
Usage depends on the sub-object level:

- **Vertex** Select one or more pairs of adjacent vertices and apply to insert edge loops between each pair of adjacent vertices.

- **Edge** Two options are available:
  - **Normal** Select one or more edges and apply to insert edge loops going through the edge ring that each selected edge is on.

---

Using Insert Loop at the Vertex level

Using Insert Loop at the Edge level
- **Shift** Opens the Connect Edges dialog on page 2345 so you can set the number of inserted edges and control Pinch and Slide settings interactively.

- **Polygon** Select one or more pairs of adjacent polygons and apply to insert edge loops going through the centers of each pair (parallel to the selection).

![Using Insert Loop at the Polygon level](image)

**Remove Loop** Removes loops at the current subobject level, and automatically deletes all leftover vertices.

Usage depends on the sub-object level:

- **Vertex** Select one or more pairs of adjacent vertices (to indicate the loop direction) and then click Remove Loop.
Using Remove Loop at the Vertex level

- **Edge** Select one or more edges, and then click Remove Loop. This removes all loops on which the edges reside.

Using Remove Loop at the Edge level

- **Polygon** Select one or more pairs of adjacent polygons (to indicate the loop direction) and then click Remove Loop. Alternatively, removing a single polygon removes all edge loops on which the polygon resides.
NOTE Removing a polygon loop is equivalent to removing the boundary edge loops.

Set Flow Adjusts selected edges to fit the shape of the surrounding mesh.
Usage: Select one or more edges and apply. To automatically adjust each edge's entire loop, first turn on Auto Loop.
Use the spinner to set the flow interactively.

Auto Loop (on Set Flow drop-down) When on, using Set Flow automatically selects loops for the selected edge(s).
Usage: Select one or more edges, turn on Auto Loop, and then apply Set Flow. Each selected edge's loop is automatically selected, and then Set Flow is applied to each loop.

NOTE When the modeling ribbon is maximized or the Loops panel floats, the following controls appear on the Loops panel expansion.

Build End Builds a quad ending to two parallel loops based on the vertex or edge selection.
Select two vertices at the ends of parallel loops ending at the same polygon or the edge connecting them and apply to build a quad ending to two parallel loops.

Using Build End at the Vertex level

Using Build End at the Edge level

**NOTE** Build End works only when exactly two parallel loops end at the same side of the same internal edge.

**Build Corner** Builds a quad corner based on the vertex or edge selection to make an edge-loop turn.
Usage depends on the sub-object level:

- **Vertex** Select vertices that terminate two loops that travel at right angles and end at adjacent sides of the same quad polygon and apply.

- **Edge** Select edges that connect two adjacent sides of a quad polygon and apply. Typically, these are edges where edge loops turn 90-degree corners.
Loop Tools Opens the Loop Tools dialog on page 2143, with features for adjusting loops.

Random Connect Connects selected edges, randomizing the positions of the created edges.
Select two or more contiguous edges to connect and then click Random Connect. This connects the edges, randomizing the positions of the created edges. The Jitter setting determines the extent of the randomization.

Using Random Connect at the Edge level

To make a full loop, first turn on Auto Loop (see following) or hold Shift as you click Random Connect. For this, only one selected edge is required.

Auto Loop (on Random Connect drop-down) When on, applying Random Connect makes as full a loop as possible.
Turn on Auto Loop and then apply Random Connect to one or more selected edges. The random-connection function is applied to all edges on the selected edges’ rings.

Set Flow Speed The speed by which adjusting the Set Flow on page 2139 spinner changes the flow of the selected edges.
Loop Tools dialog

Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Edge sub-object level > Loops panel [expansion] Loop Tools

**NOTE** The Polygon Modeling panel is visible by default only on the Graphite Modeling Tools tab but can be made visible on the other tabs via the right-click menu. The [sub-object] panel is available only on the Graphite Modeling Tools tab.

The Loop Tools dialog contains tools for adjusting inter-loop distance, curving loops, and more.

**Interface**

![Loop Tools dialog]

**AutoLoop** Automatically loops selected edges before applying a tool.

**[2Loops]** Select two or more parallel edges and adjust the spinner to change the distance between them. To change the rate at which the spinner works, use the Percent setting.
When AutoLoop is on, automatically selects the loops on which selected edges reside before adjusting the spacing.

[3Loops] Select one or more edges and adjust the spinner to change the positions of the edges on either side of the selected loop. To change the rate at which the spinner works, use the Percent setting.

Center Centers edges or edge loops on their edge rings and places the vertices in the middle of the edges. Select one or more edges and apply.

Space Spaces vertices evenly along the selected edges.

To space loops at the ends of cylinders, hold Shift and then click Space.
**Curve** Adjusts each set of selected edges or open edge loops into smooth curves. The curvature of each loop is determined by the positions of selected vertices along the loop. This is analogous to how splines work in that the resulting curve is smoothly interpolated among the selected vertices.

**NOTE** Curve supports open edge loops only; it does not work on closed (circular) edge loops.

To use, select vertices whose positions on the edge loops will determine the extents of the resulting curves, then select edges or edge loops to be adjusted, and then apply Curve.

If AutoLoop is on, loops on which selected edges reside are automatically selected before adjusting. And if Space Loops is on, all vertices are adjusted to be evenly spaced along their loops.

![Image](184x385 to 495x497)

Left: Initial selection of vertices  
Center: Initial selection of edges  
Right: After applying Curve with both AutoLoop and Space Loop on

**Straight** Straightens each set of selected edges or edge loops. Select edges or edge loops and apply.
To straighten loops at the ends of cylinders, hold Shift and then click Straight.

**Space loop**  Spaces all vertices evenly along the loop when using Curve and Straight.

**Circle** Adjusts each set of selected edges and edge loops into the form of a circle. To apply to loops at the top and bottom edges of a cylinder, hold Shift while clicking Circle.

For each loop or set of edges to apply Circle to, at the Vertex level, select a vertex on a closed loop whose position represents the radius of the desired circle, or on an open loop to designate the start of the circle. Then, at the Edge level, select a loop or an edge on the loop. If the latter, turn on AutoLoop on the Loop Tools dialog, and then click Circle.

**NOTE** After making the necessary vertex and edge selections, you can apply Circle at the object level or any sub-object level.

The following illustration shows using Circle with closed loops on a cylindrical object.
Center: The initial vertex selection, indicating the desired radii of the circles

Right: After clicking Circle while holding Shift, so the cylinder end loops are included.

The Space Loop check box has no influence on this tool.

Relax Smoothes the curvature of each set of selected edges or edge loops. To apply to loops at the top and bottom edges of a cylinder, hold Shift while clicking Relax. To increase the relax effect, apply several times.

The Space Loop check box has no influence on this tool. If AutoLoop is on, the software automatically loops the initial selection before applying the tool.

Additional Panels

Modeling ribbon > Graphite Modeling Tools tab

The panels described in this topic provide tools for subdividing meshes, changing triangulation, aligning objects and sub-objects, hiding and unhiding sub-objects, and setting properties such as smoothing. These panels are available only on the Graphite Modeling Tools tab of the modeling ribbon.

Subdivision Panel

The Subdivision panel provides tools for increasing mesh resolution parametrically for smoothing, displacement, and tessellation. It is available at the object level and at all sub-object levels.

MeshSmooth Smoothes the object using the current settings. This command uses subdivision functionality similar to that of the MeshSmooth modifier on page 1505 with NURMS Subdivision, but unlike NURMS subdivision, it applies the smoothing instantly to the selected area of the control mesh.
Smoothing a low-poly object with NURMS subdivision

MeshSmooth Settings (on MeshSmooth drop-down) Opens the MeshSmooth Selection dialog on page 2354, which lets you specify how smoothing is applied.

TIP You can open the MeshSmooth Selection dialog quickly by Shift+clicking the MeshSmooth button.

Tessellate Subdivides all polygons in the object based on the Tessellation settings on page 2358.

Tessellation is useful for increasing local mesh density while modeling. You can subdivide any selection of polygons. Two tessellation methods are available: Edge and Face.

Tessellate Settings (on Tessellate drop-down) Opens the Tessellate Selection dialog on page 2358, which lets you specify how smoothing is applied.

TIP You can open the Tessellate Selection dialog quickly by Shift+clicking the Tessellate button.

Use Displacement Opens the Displacement panel, with parameters for setting how to subdivide the mesh for displacement. For details, see Subdivision Displacement Rollout (Polymesh)subdivision displacement rollouteditable polyeditable polysubdivision displacement rollout on page 2330.
Triangulation (Tris) Panel

The Triangulation panel, also labeled “Tris” in some configurations, appears at all sub-object levels except Vertex, and provides tools for changing how polygons are subdivided into triangles for rendering purposes. The Retriangulate tool is available only at the Polygon and Element levels.

![Triangulation panel]

**Edit** lets you modify how polygons are subdivided into triangles by drawing internal edges, or **diagonals** on page 8551.

In **Edit Triangulation** mode, you can see the current triangulation in the viewport, and change it by clicking two vertices on the same polygon.

To edit triangulation manually, turn on this button. The hidden edges appear. Click a polygon vertex. A rubber-band line appears, attached to the cursor. Click a non-adjacent vertex to create a new triangulation for the polygon.
**TIP** For easier editing of triangulation, use the Turn command instead (see following).

**Turn** Lets you modify how polygons are subdivided into triangles by clicking diagonals. When you activate Turn, the diagonals on page 8551 become visible as dashed lines in wireframe and edged-faces views. In Turn mode, click a diagonal to change its position. To exit Turn mode, right-click in the viewport or click the Turn button again.

Each diagonal has only two available positions at any given time, so clicking a diagonal twice in succession simply returns it to its original position. But changing the position of a nearby diagonal can make a different alternate position available to a diagonal.

For more information on how to use Turn with the enhanced Cut tool, see this procedure on page 1368.

**Retriangulate** Lets 3ds Max automatically do its best triangulation on the polygon or polygons currently selected.

Retriangulate attempts to optimize how selected polygons are subdivided into triangles.
**Align Panel**

The Align panel provides tools for aligning objects and sub-object selections with the view or grid, or simply flattening a mesh. It is available at the object level and at all sub-object levels.

**Make Planar** Forces all selected sub-objects to be coplanar. The plane's normal is the average surface normal of the selection. At the Object level, forces all vertices in the object to become coplanar.

**TIP** One application for Make Planar is making a flat side on an object. Normally, you would use a contiguous selection set. If the selection includes vertices on various parts of the object, the vertices are still made planar, but with distorting effects on the rest of the geometry.

**To View** Aligns all vertices in the object to the plane of the active viewport. At sub-object levels, this function affects only selected vertices or those belonging to selected sub-objects.

In orthographic viewports, aligning to the view has the same effect as aligning to the construction grid when the home grid is active. Aligning to a perspective viewport (including camera and light views), reorients the vertices to a plane that is parallel to the camera's viewing plane. This plane is perpendicular to the view direction that is closest to the vertices' average position.
Above: Selected polygons in Perspective view

Below: Same polygons aligned to Front view

To Grid. Aligns all vertices in the selected object to the plane of the current view. At sub-object levels, aligns only selected sub-objects.

This command aligns the selected vertices to the current construction plane. The current plane is specified by the active viewport in the case of the home grid. When using a grid object, the current plane is the active grid object.

X/Y/Z Makes all selected sub-objects planar and aligns the plane with the corresponding plane in the object's local coordinate system. The plane used is the one to which the button axis is perpendicular; so, for example, clicking the X button aligns the object with the local YZ axis.

At the Object level, makes all vertices in the object planar.
Visibility Panel

Use the Visibility panel for hiding and unhiding sub-object selections. When working with complex geometry, hiding the parts you’re not modeling directly can help speed your work. It is available at all sub-object levels except Edge and Border.

- **Hide Selected** hides selected sub-objects.
- **Hide Unselected** hides unselected sub-objects.
- **Unhide All** restores hidden sub-objects to visibility.

Properties Panel

Use the Properties panel to adjust mesh smoothing, vertex colors, and material IDs. It is available at the object level and at all sub-object levels; the availability of commands depends on the level.
Hard

Turns off smoothing for the entire model. Removes all polygons in the model from any smoothing groups, resulting in a uniform faceted appearance.

Hard Selected

Turns off smoothing for selected polygons. Removes selected polygons in the model from any smoothing groups, resulting in a uniform faceted appearance for those polygons.

Smooth

Enables smoothing for the entire object. Sets Auto Smooth to 180.0 and applies it to all polygons in the model.

Smooth Selected

Enables smoothing for selected polygons. Sets Auto Smooth to 180.0 and applies it to selected polygons.

Smooth 30

Enables moderate smoothing for the entire object. Sets Auto Smooth to 30.0 and applies it to all polygons in the model, assigning smoothing groups as necessary.

Smooth 30 Selected

Enables moderate smoothing for selected polygons. Sets Auto Smooth to 30.0 and applies it to selected polygons.
Color  Click the color swatch to set the vertex color for selected vertices or polygons.
For more information on vertex color, see Assign Vertex Colors Utility on page 6477.

Illum  Click the color swatch to set the illumination color for selected vertices or polygons.
For more information on vertex illumination, see Assign Vertex Colors Utility on page 6477.

Alpha  Assign an alpha (transparency) value to selected vertices or polygons.
The spinner value is a percentage; zero is completely transparent and 100 is completely opaque.
For more information on vertex alpha, see Assign Vertex Colors Utility on page 6477.

Smoothing Groups  Opens a dialog for working with smoothing groups. For details, see Polygon: Smoothing Groups rollout on page 2310.

Opens the Material IDs dialog for setting material IDs and selecting by ID and sub-material name. For details, see Polygon: Material IDs rollout on page 2309.

Freeform Tab

Modeling ribbon > Freeform tab
The Freeform tab contains tools for freehand creation and modification of polygon geometry, available on the PolyDraw and Paint Deform panels. In
addition, the following panels are hidden but available on the Freeform tab from the right-click menu:

- Polygon Modeling Panel on page 2045
- Modify Selection Panel on page 2063
- Edit Panel on page 2075

**PolyDraw Panel**

Modeling ribbon > Graphite Modeling Tools/Freeform tab > PolyDraw panel

**NOTE** The PolyDraw panel is visible by default only on the Freeform tab but can be made visible on the Graphite Modeling Tools tab via the right-click menu.

PolyDraw provides tools for quickly sketching out and editing a mesh on the main grid, projected onto the surface of another object, or on the selected object itself, depending on the Draw On on page 2160 setting.

The tools have different effects depending on which combination of the Ctrl, Shift, and Alt keys you press, as described in the following definitions. PolyDraw does not require that a particular sub-object level be active, but we recommend that you use them at the Vertex level for improved visual feedback with certain tool effects. To exit a PolyDraw tool, click its button again or right-click in the active viewport.
Interface

PolyDraw panel on minimized ribbon

PolyDraw panel on maximized ribbon, with expansion

PolyDraw panel floating, with expansion

Freeform Tab | 2157
Step Build  With Step Build you can build and edit a surface vertex by vertex and polygon by polygon. Works at the object level and all sub-object levels. Right-click to exit the tool.

Following are the different functions of the tool, depending on which keyboard keys are pressed:

- **Normal** Click to place vertices on the grid or surface.
- **Shift** Drag over freestanding vertices to fill in the gaps with quad polygons. This always creates a polygon from the closest four vertices.
- **Ctrl** Click a polygon to delete it. The vertices remain so that if you accidently create a face in the wrong place it’s easy to delete the face and draw again closer to the vertices you want.
- **Alt** Click a vertex to remove it.
- **Ctrl+Alt** Click an edge to remove it.
- **Ctrl+Shift** Click to place and select vertices, or to select existing vertices. Each time you place and/or select four vertices, Step Build automatically creates a polygon. It includes the last two vertices from the previously created polygon in the new selection, so you need only click twice to create the next polygon. To clear the selection, release the keys.
- **Shift+Alt** Move the mouse cursor (without dragging) over vertices to select them, and then click to create a polygon from the selected vertices. Useful for creating non-quad polygons. To clear the selection, release the keys.
- **Ctrl+Shift+Alt** Drag to move a vertex around on the grid or surface. At the Vertex sub-object level, a vertex highlights when you move the mouse near enough to start dragging it.

**NOTE** While Step Build is active, vertex ticks on page 167 are always visible for the selected object. If you don’t see them at levels other than Vertex, make sure the object’s display properties on page 288 are set to By Object.
Extend

With the Extend tool you can work on the open edges of the object; those on the border of the surface that have only one polygon attached. Following are the different functions of the Extend tool:

- **Normal** Drag from border vertices to create polygons.
- **Shift** Drag from border edges to create polygons.
- **Shift+Ctrl** Drag between two edges to create a polygon.
- **Ctrl** Click to delete a polygon and its isolated vertices.
- **Ctrl+Shift+Alt** Drag to move a vertex around on the grid or surface.

You can also use Extend to edit the object in screen space, thus moving sub-objects perpendicular to the view direction. You do not need to change the active coordinate system to use this method.

- **Alt** Drag from border vertices to create polygons in screen space.
- **Alt+Shift** Drag from border edges to create polygons in screen space.
- **Alt+Ctrl** Drag to move a vertex around in screen space.

Drag

With the Drag tool you can move individual sub-objects around on the surface or grid. The options are:

- **Normal** Move vertices by dragging them.

**NOTE** With Drag on at the Vertex sub-object level, moving the mouse cursor around automatically selects the vertex that will be moved when you drag the mouse.

- **Shift** Move edges by dragging them.
- **Ctrl** Move polygons by dragging them.
- **Shift+Ctrl** Move edge loops by dragging them.
- **Shift+Ctrl+Alt** Move elements by dragging them.
You can also use Drag to move sub-objects in screen space; that is, perpendicular to the current view direction. You do not need to change the active coordinate system to use this method.

- Alt Drag vertices to move them in screen space.
- Alt+Shift Drag edges to move them in screen space.
- Alt+Ctrl Drag polygons to move them in screen space.

Optimize
Optimize meshes quickly by sketching away details. The tool options are:

- **Normal** Click edges to collapse them, combining two vertices into one.
- Shift Drag from one vertex to the next to target-weld the two, combining the first with the second. If you continue dragging to further vertices you can weld several vertices with a single stroke.
- Ctrl Drag between vertices to connect them with edges.
- Alt Remove a vertex by clicking it.
- Shift+Ctrl Remove an edge loop by clicking an edge on the loop.
- Shift+Alt Remove an edge ring by clicking an edge in the ring.
- Ctrl+Alt Remove an edge by clicking it.
- Shift+Ctrl+Alt Move a vertex by dragging it.

**Draw On:** Choose the entity type to draw on:

- **Grid** PolyDraw creates geometry on the grid of the active viewport. This drawing mode is particularly suited to orthographic viewports, but also works well in perspective viewports.

- **Surface** PolyDraw creates geometry on an object that you specify.
Click the Pick button and then select a different object to draw on. The button then contains the name of that object. Use any of the PolyDraw tools (Strips, etc.) to draw on the object. To change the surface, click the button again and choose a different object to draw on.

- Selection  PolyDraw creates geometry on the selected object.

- Pick  Designates an object to draw on for the Draw On: Surface option (see preceding).
After setting the Draw On option to Surface, click the Pick button, and then click an object to draw on. To remove the object, click the button again.

- Shapes  Draw polygon shapes on the grid or a surface.
Drag to set the polygon outline on the grid or an object surface. After drawing a polygon, optionally use Solve Surface to create a workable mesh from the shape.
While Draw Polygon is active, the following keyboard alternatives are available:
  ■ Ctrl Click to delete a polygon.
  ■ Ctrl+Shift+Alt Drag to move a polygon.

- Topology  Draw lines that form a grid of quads. As you draw eligible quads, Topology fills them in with polygons, creating a mesh from the grid. Right-click to exit the tool.
If Auto Weld (see following) is on, the software automatically attaches the created mesh to the selected object and welds border vertices that are close together. This way you can continue adding to the surface of the selected object.

When Auto Weld is off, drawing with Topology always creates a new object. The Minimum Distance on page 2165 value determines the resolution of the lines. If the value is too small some faces might be missed in the polygon creation. The default value, 10.0, with the unit type set to pixels should work well in most cases.

While Draw Topology Pattern is active, the following keyboard alternatives are available:

- Shift Drag to continue a line from the closest existing endpoint.
- Ctrl Click to delete a line.

Auto Weld When on, automatically attaches the mesh that you create with Topology to the selected object and welds border vertices that are close together.

When off, drawing with Topology always creates a new object.

Splines Draw splines on a surface or grid. You can then make these splines renderable or use them in a lofting operation to create quick details.
Set the Draw On option, click Splines, and then drag to draw the splines on the desired base. All splines are combined into a single, separate object. While Splines is active, the following keyboard alternatives are available:

- Ctrl Click to delete a spline.
- Ctrl+Shift+Alt Drag to move the closest spline.

**Strips** Paint strips of polygons that curve to follow the mouse direction.

The Strips tool lets you quickly lay out the topology foundation for a mesh object. While Strips is active, the following keyboard alternatives are available:

- Shift Starts painting from the closest existing edge.
- Alt While drawing, press and drag to an open edge in the current object (but not on the same strip) to add a polygon between where you press Alt and the edge you drag to. Alternatively, press Alt before drawing and then drag between two open edges to connect them with a new polygon.

**Surface** Drag to paint a surface onto an object or the grid.

To start the surface from an existing border edge, hold Shift before starting to draw. This prevents drawing overlapping polygons.

To delete a polygon and any resulting isolated vertices while Surface is active, Shift+click it.

**Branches** Paint multi-segmented extrusions from polygons with optional tapering to form "branches."

**NOTE** Drawing branches always starts from the selected object; it doesn’t use the Draw On: (Grid/Surface/Selection) setting.

The extrusions are aligned to the screen. The Branch Taper value (see following) determines the difference in size between the first and the last polygon in the
branch, while **Minimum Distance** on page 2165 lets you set the distance between segments in the extrusion.

Activate the tool and then drag from polygons on the selected object to draw branches.

- **Normal** Drag to draw extruded branches from the polygon closest to the mouse.
- **Shift** Drag to draw extruded branches from selected polygon(s).
- **Ctrl** Click to select a polygon (at the Polygon sub-object level only).
- **Ctrl+Alt** Click to select/deselect additional polygons (at the Polygon sub-object level only).

**NOTE** When the modeling ribbon is maximized or the Paint Deform panel floats, the following controls appear on the Paint Deform panel expansion.

**Branch Taper** The amount by which branches taper as you draw them. A negative value makes the branch dwindle in size; a positive value makes it get thicker, and 0 keeps it the same size as the starting polygon. A value of -1.0 makes the end of the branch as small as possible, while values lower than -1.0 cause the branch to shrink to the minimum partway through and then enlarge the rest of the way.

**New Object** Creates a new, “empty” editable poly object, accesses the Vertex sub-object level, and keeps the current PolyDraw tool active. Immediately after clicking New Obj you can use the PolyDraw tools to add geometry.

**Solve Surface** Takes a polygon shape such as one painted with the Shapes tool and tries to create a workable mesh, adding edges so that the result is a clean shape composed mainly of quadrilateral polygons. Or, if Solve To Quads (see following) is off, the result is mostly triangles.

**TIP** Solve Surface works best when the starting shape is mostly in the form of "strips," where the two sides of the polygon are fairly close together.
Angle Affects the way Solve Surface connects vertices. With flat shapes, the default value of 35 works best. With curved surfaces, however, Solve Surface might produce better results at higher values.

Solve to Quads When on, using Solve Surface (see preceding) results in mostly four-sided polygons. When off, Solve Surface produces mainly triangles.

Offset The distance that PolyDraw uses for creating geometry on (or moving it across) the grid or object surface (depending on the Draw On setting).

Minimum Distance The shortest distance you need to drag the mouse before the next step in the tool is taken.

For example, when using the Shapes on page 2161 tool, this value determines the minimum distance, in pixels or world units, between the vertices the software creates as you draw.

To determine how to measure Minimum Distance, choose one of the following:

- **in Pixels** Uses pixels to specify the minimum distance you need to drag the mouse before the next step in the tool is taken.

- **in Units** Uses world units to specify the minimum distance you need to drag the mouse before the next step in the tool is taken.

Paint Deform Panel

Modeling ribbon > Graphite Modeling Tools/Freeform tab > Paint Deform panel

**NOTE** The Paint Deform panel is visible by default only on the Freeform tab but can be made visible on the Graphite Modeling Tools tab via the right-click menu.
Paint Deform provides tools for deforming mesh geometry interactively and intuitively by dragging the mouse over an object surface. The primary tools are Shift, for moving vertices with falloff in the direction you drag the mouse, and Push/Pull, for moving vertices inward and outward. Additional tools include Smudge, Flatten, Noise, and more.

Paint Deform tools work the same way at the object level and at all sub-object levels, and are independent of any sub-object selection. To exit a Paint Deform tool, click its button again or right-click in the active viewport.

Interface
**Shift** Move sub-objects around in screen space (perpendicular to the viewing direction) with an adjustable falloff effect. The Shift tool is roughly equivalent to using the Move tool with Soft Selection, but no initial selection is necessary.

![Image of Shift tool](image_url)

**Using Shift on a mesh object**

Shift affects only vertices within the brush area when you start to drag; to affect other vertices, release and then drag again. When you activate the Shift tool, its Options panel on page 2175 opens with settings for adjusting the tool’s effect. These settings are also available via the following keyboard modifiers:

- **Ctrl** Drag vertically to change the radius of the **Falloff** on page 2176 (black) circle.
- **Shift** Drag vertically to change the radius of the **Full Strength** on page 2176 (white, inner) circle.
- **Shift+Alt** Drag vertically to change the **Strength %** on page 2176 value.

**NOTE** Revert on page 2174 works with the Shift tool only after you use another Paint Deform tool, such as Push/Pull.

![Image of Push/Pull tool](image_url)

**Push/Pull** Drag the brush to move vertices outward; Alt+drag to move them inward.
Using Pull (left) and Push (right) on a mesh object

Following is a list of other effects available with keyboard alternatives:

- Ctrl Reverts on page 2174 to the previous saved state.
- Shift Relaxes on page 2168 the mesh.
- Ctrl+Shift Resizes the brush.
- Shift+Alt Changes the brush strength.

Change brush size, strength, and other settings on the Paint Options Panel on page 2177.

Relax/Soften Drag the brush to smooth out the surface; for example, to round off corners.

NOTE With most other brushes, you can apply Relax/Soften by dragging with Shift held down.
Using Relax/Soften on a mesh object

Following is a list of effects available with keyboard alternatives:

- Alt Drag the brush to relax the mesh without shrinking.
- Ctrl Reverts on page 2174 to the previous saved state.
- Ctrl+Shift Resizes the brush.
- Shift+Alt Changes the brush strength.

Change brush size and strength on the Paint Options Panel on page 2177.

**Smudge** Drag to move vertices around. Smudge is roughly equivalent to the Shift tool, but updates the area of effect continually as you drag, and doesn’t use falloff.
Using Smudge on a mesh object

Following is a list of effects available with keyboard alternatives:

- Alt Drag the brush to move vertices horizontally only (prevents movement in normal direction).
- Ctrl Reverts on page 2174 to the previous saved state.
- Shift Relaxes on page 2168 the mesh.
- Ctrl+Shift Resizes the brush.
- Shift+Alt Changes the brush strength.

Change brush size and strength on the Paint Options Panel on page 2177.

Drag the brush to flatten convex and concave areas.
Using Flatten on a mesh object

Following is a list of effects available with keyboard alternatives:

- Ctrl Reverts on page 2174 to the previous saved state.
- Shift Relaxes on page 2168 the mesh.
- Ctrl+Shift Resizes the brush.
- Shift+Alt Changes the brush strength.

Change brush size and strength on the Paint Options Panel on page 2177.

**Pinch/Spread** Move vertices closer together by dragging, or spread them apart with Alt+drag.
Using Pinch (left) and Spread (right) on a mesh object

Following is a list of additional effects available with keyboard alternatives:

- **Ctrl Reverts** on page 2174 to the previous saved state.
- **Shift Relaxes** on page 2168 the mesh.
- **Ctrl+Shift** Resizes the brush.
- **Shift+Alt** Changes the brush strength.

Change brush size and strength on the [Paint Options Panel](on page 2177).

**Noise** Drag to add convex noise to the surface, or **Alt+drag** to add concave noise.
Using Noise on a mesh object

Following is a list of additional effects available with keyboard alternatives:

- **Ctrl** Reverts on page 2174 to the previous saved state.
- **Shift** Relaxes on page 2168 the mesh.
- **Ctrl+Shift** Resizes the brush.
- **Shift+Alt** Changes the brush strength.

Change brush size, strength, and other settings on the Paint Options Panel on page 2177.

**Exaggerate** Makes the features of the painted surface more pronounced by moving convex areas outward and concave areas inward.
Using Exaggerate on a mesh object

Following is a list of effects available with keyboard alternatives:

- Alt Inverts the exaggeration, making convex areas concave and vice-versa.
- Ctrl Reverts on page 2174 to the previous saved state.
- Shift Relaxes on page 2168 the mesh.
- Ctrl+Shift Resizes the brush.
- Shift+Alt Changes the brush strength.

Change brush size, strength, and other settings on the Paint Options Panel on page 2177.

Revert Paint to restore the mesh to its previous shape, before the last use of Commit (see following).

If you haven’t used Commit yet, Revert goes back to the object’s initial shape.

Following is a list of effects available with keyboard alternatives:

- Shift Relaxes on page 2168 the mesh.
- Ctrl+Shift Resizes the brush.
- Shift+Alt Changes the brush strength.

Change brush size and strength on the Paint Options Panel on page 2177.
NOTE  Revert works with Shift on page 2167 only after you use another Paint Deform tool, such as Push/Pull.

Commit  Sets the restore buffer to the current state of the object.
After using Commit, using Cancel or the Revert brush (see preceding) returns the model to its shape when you last used Commit.

Cancel  Removes any changes made with Paint Deform since the last Commit.
If you haven’t used Commit, returns the model to its initial shape.

Shift Options Panel

Modeling ribbon > Graphite Modeling Tools/Freeform tab > Paint Deform panel > Enable Shift tool.

NOTE  The Paint Deform panel is visible by default only on the Freeform tab but can be made visible on the Graphite Modeling Tools tab via the right-click menu.

This panel opens when the Shift tool is active, and provides settings for modifying its effects.

Interface

Shift Options panel on minimized ribbon
**Full Strength** The area of the Shift-tool painting brush within which sub-objects move at the same rate that you drag the brush. This area is depicted as a white circle inside a black one. Sub-objects outside the Full Strength circle but within the Falloff circle (see following) move at a gradually slower rate.

To adjust Full Strength interactively, use Shift+drag.

**Falloff** The area within which dragging the mouse with the Shift tool active gradually decrease the effect, going from full strength (within the white circle) to no effect (outside the black circle).

To adjust Falloff interactively, use Ctrl+drag.

---

**NOTE** When the modeling ribbon is maximized or the Shift Options panel floats, the following controls appear on the Shift Options panel expansion.

**Strength %** The overall rate at which the Shift tool deforms an object. For subtler effects, lower the Strength % value.

To adjust Strength % interactively, use Shift+Alt+drag.

---

**Use Selected Verts** When on, the Shift tool affects selected vertices only. Applies at the object level and all sub-object levels.

When off (the default), the Shift tool affects all vertices in the selected object.

**Ignore Backfacing** When on, the Shift tool affects only sub-objects facing you.

When off (the default), the Shift tool affects all sub-object(s) in the selected object within the Falloff range, regardless of their visibility or facing.

**Freeze Axis X/Y/Z** Click to activate any combination of X, Y, and Z. When an axis button is on, the Shift tool is prevented from moving sub-objects on the object’s corresponding local axis.

**TIP** To limit the Shift tool’s effect to a particular axis, turn on Freeze Axis for the other two axes.

**Freeze Selected Edges X/Y/Z** Click to activate any combination of X, Y, and Z. When an axis button is on, the Shift tool is prevented from moving selected edges on the object’s corresponding local axis. Unselected edges move freely.
Applies at all sub-object levels.

For example, to allow Shift to cause vertical deformation only on the upper half of an object, first access the Edge sub-object level and select the upper half of the object, turn on Freeze Selected Edges > X and Y, and activate the Shift tool. Then, at the object level or at any sub-object level, using Shift on the upper half of the object prevents horizontal deformation.

**Paint Options Panel**

Modeling ribbon > Graphite Modeling Tools/Freeform tab > Paint Deform panel > Enable a tool other than Shift (Push/Pull, etc.).

**NOTE** The Paint Deform panel is visible by default only on the Freeform tab but can be made visible on the Graphite Modeling Tools tab via the right-click menu.

This panel opens when Paint Deform on page 2165 tools other than Shift are active, and provides settings for modifying their effects.

**NOTE** Only Size and Strength settings are available for Relax/Soften, Flatten, Pinch/Spread, Smudge, and Revert; additional settings are available for the rest.
Interface

Size The radius of the circular deform brush.

NOTE With most brushes, you can change the size interactively by dragging with Ctrl+Shift held down.

Strength The overall rate at which the deform tool deforms an object. For subtler effects, lower the Strength value.

NOTE With most brushes, you can change the strength interactively by dragging with Shift+Alt held down.

Offset The maximum amount by which painting with a deform tool can change the mesh without lifting the mouse button. Applies only when Cap Offset is on (see following).

NOTE When the modeling ribbon is maximized or the Paint Options panel floats, the following controls appear on the Paint Options panel expansion.

Cap Offset When on, dragging the brush continuously stops deforming at the Offset amount (see preceding). To increase the offset, release the mouse button and then start again.
When off, dragging the brush continuously keeps applying the offset without limit.

**Normal Direction** Choose the direction in which mesh deformation occurs when painting:
- **Original** Uses the normals that the vertices had when you began using the tool. This way you can keep adding strokes without having the vertices go off in unexpected directions.
- **Deformed** The normals are updated after each stroke so the tool keeps pushing from the current state.
- **Brush** Uses the normal from the brush (gizmo) when you started the stroke.
- **View** Pushes towards or away from the view direction.
- **Transform X/Y/Z** Moves vertices along the corresponding world axis.

**Refresh Normals** Resets the brush to use each polygon’s current normal direction when deforming, rather than the original. Available only with Normal Direction=Original.

When off, painting always deforms in the original direction of the polygon’s normal.

**TIP** For automatic refreshing of the deform direction, set Normal Direction to Deformed (see preceding).

**Brush Options** Opens the Painter Options dialog on page 1989 for adjusting brush properties, display options, and more.

**Noise Options** These settings apply only to the Noise brush on page 2172:
- **Seed** Generates a random starting point for the noise deformation from the number you set. Affects only subsequent painting, not existing results.
- **Scale** Sets the size of the noise effect (not strength). Larger values produce smoother noise, lower values more jagged noise.
- **Turbulence** Determines the extent of noise variation. Lower values are less rough than higher values.

## Selection Tab

Modeling ribbon > Selection tab

The Selection tab of the modeling ribbon provides a variety of specialized tools for making sub-object selections. For example, you can select concave or convex areas, sub-objects that face the viewpoint, or point in a certain direction, and more.

**NOTE** The Selection tab panels appear only when a sub-object level is accessed. When no object is selected, or an object is selected but no sub-object level is active, the Selection tab is empty by default.

You can use the right-click menu > Panels submenu to make the Polygon Modeling panel available on the Selection tab, which you can then use to access and change sub-object levels.

## General Selection Panels

Access a sub-object level. > Modeling ribbon > Selection tab > Select/Stored Selections/Selection Sets panel

The general selection panels comprise the Select panel for selecting sub-objects based on certain topologies; the Stored Selections panel for saving, restoring, and combining sub-object selections; and the Selection Sets panel for copying and pasting named sub-object selection sets.

**Select panel**

The Select panel includes the Tops, Open, and Patterns tools for sub-object selection at all levels, plus the Hard tool for selecting edges at the borders of smoothing groups and additional selection tools for polygons.
Tops Selects the tops of extruded sections of the model. The actual results depend on the sub-object level:

- **Vertex** Selects the vertices of the tops of extruded polygons.
- **Edge** Selects the edge outlines of the tops of extruded polygons.
- **Polygon** Selects the tops of extruded polygons.
**Tops of Current Selection (on Tops drop-down)** Selects the tops of extruded sections of the model within the current selection, and deselects all remaining sub-objects. For details, see Tops (preceding).

**Open** Selects all “open” sub-objects.

The current sub-object level determines the actual results:

- **Vertex** Selects all border vertices; that is, vertices on edges with only one polygon.
- **Edges** Selects all border edges; that is, edges with only one polygon.
- **Polygon** Selects all border polygons; that is, polygons that have one or more edges with only one polygon.

**Hard** Selects all edges in a model whose faces do not share the same smoothing groups. Available only at the Edge sub-object level.

**Non-Quads** Selects all non-quadrilateral polygons; that is, polygons with more or fewer than four sides. Available only at the Polygon sub-object level.

**NOTE** When the modeling ribbon is maximized or the Select panel floats, the following controls appear on the Select panel expansion.

**Patterns** Grows the current selection and turns it into a pattern that depends on the initial selection. Make a selection and then choose a Patterns option from the drop-down list. All options work at all sub-object levels except for One Ring, which works only for polygons.

You can use the Pattern tools for a variety of purposes, such as making complex surface details or laying out building structures.
The options are as follows:

- **Pattern 1-8** Each numbered Pattern option provides a different way of forming a pattern. Some are fast-growing while others are slower; some tend to form cubic patterns while others are more broken up. The effect depends very much on the initial selection and thus can be somewhat unpredictable, so the best way to use the patterns is to experiment until you find a result you like.

- **Growlines** Grows the selection to lines with gaps of unselected lines. For example, if you select a whole polygon loop and apply Growlines, the selection grows by selecting alternating polygon loops starting with the initial selection.

- **Checker** Grows the selection and forms a checker pattern.

- **Dots** Grows the selection and forms a pattern where all selected sub-objects have gaps between them.

- **One Ring** Grows a single polygon ring around the initial selection. Available only at the Polygon level.

**By Vertex** When on, you can select sub-objects only by selecting a vertex that they use. When you click a vertex, all sub-objects that use the selected vertex are selected. Not available at the Vertex sub-object level.

**By Mat ID** Selects polygons corresponding to the Material ID specified in the adjacent ID field. Type or use the spinner to specify an ID, then click By Mat ID.

**By Angle** When on, selecting a polygon also selects neighboring polygons based on the angle setting to the right of the check box. This value determines the maximum angle between neighboring polygons to select. Available only at the Polygon sub-object level.

For example, if you click a side of a box and the angle value is less than 90.0, only that side is selected, because all sides are at 90-degree angles to each other. But if the angle value is 90.0 or greater, all sides of the box are selected. This function speeds up selection of contiguous areas made up of polygons that are at similar angles to one another. You can select coplanar polygons with a single click at any angle value.

**By Smoothing Group** Displays a dialog that shows the current smoothing groups. Select all polygons that belong to a group by clicking the corresponding numbered button and clicking OK.
If Clear Selection is on, any previously selected polygons are first deselected. If Clear Selection is off, the new selection is added to any existing selection.

**Stored Selections panel**

This panel provides tools for quickly and easily storing and retrieving selections as well as performing some basic operations between stored selections. You can also use the tools for transferring a selection from one model to another. This is especially useful when working with morph targets if you need to change the same area on multiple models.

![Image of stored selections panel]

**Copy Store 1** / **Copy Store 2** Places the current sub-object selection in the Store 1 or Store 2 buffer.

When a buffer contains a stored selection, its Copy button turns blue. When empty, the button background is white.

**Paste Store 1** / **Paste Store 2** Selects sub-objects at the current level based on the contents of the corresponding Store buffer, replacing the current selection. To retain the current selection, press Shift before clicking Paste Store.

Does not clear the buffer.

**Add 1+2** Combines the two stored selections and applies the selection at the current sub-object level, emptying both Store buffers.

TIP To use a third store, assign the Store and Paste CUI actions on page 8249 available in the PolyTools category. This store works only with the CUI versions of the commands.
Use Copy Store 1 and Copy Store 2 on different sub-object selections and then use Add 1 + 2 to select all sub-objects in both store buffers.

**Subtract 1-2** Selects Store 1 except for where it overlaps with Store 2. Clears both buffers.

**Intersect** Selects the overlap (if any) of the sub-object selections in Store 1 and Store 2.

**Clear** Clears the stored selections, emptying both buffers.

**Selection Sets panel**

This panel provides controls for copying and pasting sub-object selection sets. When the ribbon is maximized or the panel floats, the panel label is shortened to “Sets.”

The controls let you copy and paste named selection sets on page 185 of sub-objects between objects. Start by creating one or more named selection sets, copy one, select a different object, go to the same sub-object level, and then paste the set.

**NOTE** This function uses sub-object IDs, so if the target object’s geometry differs from that of the source object, the pasted selection will probably comprise a different set of sub-objects.

**Copy** Opens a dialog that lets you specify a named selection set to place into the copy buffer.
Select By Panels

Access a sub-object level. > Modeling ribbon > Selection tab > “By ...” panels

The Select By panels provide a variety of methods for making sub-object selections procedurally. For example, you can use By Surface to select concave or convex areas of a model, or By Pivot to select the outer areas of a model.

Following is a linked list of all the Select By panels:

- By Surface panel on page 2186
- By Normal panel on page 2187
- By Perspective panel on page 2187
- By Random panel on page 2188
- By Half panel on page 2189
- By Pivot Distance panel on page 2190
- By View panel on page 2190
- By Symmetry panel on page 2191
- By Numeric panel on page 2191
- By Color panel on page 2192

By Surface panel

Select sub-objects by the degree of concavity or convexity. Choose Concave or Convex and then specify the selection with the value spinner.

NOTE To see the resulting change in selection after switching between Concave and Convex, adjust the numeric setting.
Concave/Convex From the drop-down, choose to select sub-objects in concave or convex areas.

[value spinner] Adjust to change the number of selected sub-objects. Low values (including negative numbers) select sub-objects only in areas of extreme concavity or convexity, and increasing the value expands the selection from there.

By Normal panel

Selects sub-objects based on their normal directions on the World axes. Choose an axis, optionally turn on Invert, and then set an Angle value.

NOTE To see the resulting change in selection after switching the axis or toggling Invert, adjust the Angle setting.

Angle The amount by which a sub-object’s normal direction can deviate from the specified axis and still be selected. The higher this value, the more sub-objects are selected.

X/Y/Z The direction in which a sub-object’s normal must point in the World coordinate system to be selected.

Invert Reverses the direction of normal selection.

For example, using the Z option by itself selects upward-facing sub-objects, while turning on Invert instead selects downward-facing sub-objects.

NOTE Invert simply inverts the selection, so the Angle setting works in reverse when it’s on: Higher values select fewer sub-objects and vice-versa.

By Perspective panel

Selects sub-objects based on the extent to which they point toward the user in the active viewport. You can think of it as projecting a selection onto the model from the current view.
Set the Angle value, optionally toggle Outline, and then click Select.

**NOTE** The CUI on page 8249 action for this command, found in Group: Main UI > Category: PolyTools, is PerspectiveSelect. When you use the shortcut, the tool automatically uses an Angle value of 30.0, and when applied at the Edge sub-object level, it always uses Outline mode.

**Angle** The amount by which a sub-object’s normal direction can deviate from the view axis (an imaginary line between the viewpoint and the sub-object) and still be selected. The higher this value, the more sub-objects are selected.

**Outline** When on, By Perspective selects only the outermost sub-objects as defined by the Angle setting.

**Select** Makes the selection based on the current settings.

**By Random panel**

Use these tools to select sub-objects at random by number or percentage, and to expand or shrink the current selection, also at random.

Choose to select random sub-objects by number (#) or percent (%), set the respective numeric value, and then click Select. Or, to select random sub-objects within the current selection, click Select Within Current Selection on the Select drop-down. To expand or shrink the current selection at random, click Random Grow or Random Shrink.

**Number** Enables random selection by number.

Click #, set the desired number of sub-objects to select, and then click Select.
Percent Enables random selection by percentage. Click %, set the desired number of sub-objects to select, and then click Select.

Select Makes the selection based on the current settings.

Select Within Current Selection (on Select drop-down) Selects random sub-objects within the current selection based on the Random-panel settings.

Random Grow Grows the selection by selecting random unselected sub-objects near the current selection. This function has no parameters; it does not use the # or % setting.

Random Shrink Shrinks the selection by deselecting random sub-objects. This function has no parameters; it does not use the # or % setting.

By Half panel

Selects half of the mesh on the specified axis. The selection is based on area, not the number of sub-objects. Choose the axis on which to select half the mesh, then click Invert Axis or Select.

The center of the mesh is determined by the location of its pivot on page 3762. If you change the pivot position, apply Reset XForm Utility on page 912 and then collapse on page 2022 the mesh. If you use the Collapse utility, be sure to choose the Modifier Stack Result option.

X/Y/Z Choose the axis on which to select half the mesh.
Invert Axis  Toggles inverting the Select By Half selection, and makes the selection. Choose the axis on which to select half of the mesh, and then click Invert to make the selection. Click again to select the other half.

Select  Makes the selection based on the current settings.

By Pivot Distance panel
Selects sub-objects based on distance from the object’s pivot on page 3762. If you change the pivot position, apply Reset XForm Utility on page 912 and then collapse on page 2022 the mesh. If you use the Collapse utility, be sure to choose the Modifier Stack Result option.

% From Pivot  The distance beyond which to select sub-objects, expressed as a percentage of the object’s size. If the pivot is centered, a value of 100.0 means the whole object is unselected; values below that result in selection of the outer parts of the model, growing inward as the value decreases.

By View panel
Selects and grows sub-objects based on the current view and inwards into the view. The closest part of the model is selected first; higher values grow the selection farther into the view.

Grow From Perspective View  The distance to select sub-objects, starting with the closest part of the object to the view. At 0.0, no sub-objects are selected; low values select only the closest sub-objects, and higher values select increasingly farther sub-objects.
**By Symmetry panel**

In a symmetrical model, mirrors the current sub-object selection on the specified local axis. The center of the object is determined by the location of the object's pivot on page 3762.

X/Y/Z Choose the local axis on which to mirror the current sub-object selection.

**By Numeric panel**

Enables selecting vertices by the number of connected edges or polygons by the number of sides.

At the Vertex level, selects vertices with the same, less than, or more than the number of connected edges specified by the Edges setting. At the Polygon level, selects polygons with the same, less than, or more than the number of sides specified by the Sides setting. Available only at the Vertex and Polygon sub-object levels.

Click the =, <, or > button, set the desired number of connected edges (for vertices) or sides (for polygons) as the Edges value, and then click Select.

**By Numeric panel at the Vertex level**

**By Numeric panel at the Polygon level**

=/< Choose to base the selection on whether the qualifying sub-objects match the specified value (=) or are less than (<) or more than (>) the value.

**Edges** Selects vertices with (same as; less than; more than) the Edges number of edges connected to them. Available only at the Vertex sub-object level.
**Sides**  Selects polygons with (same as; less than; more than) the Sides number of sides. Available only at the Polygon sub-object level.

**Select**  Makes the selection based on the current settings.

**By Color panel**

Select vertices by color or illumination value. Available only at the Vertex sub-object level. For more information about vertex colors, see Assign Vertex Colors Utility on page 6477.

From the drop-down, choose Color or Illumination, use the color swatch and RGB settings to specify the color or illumination value and range to match, and then click Select.

**Color/ Illumination**  From the drop-down, choose to select vertices by Color or Illumination.

[**color swatch**]  Displays the Color Selector on page 371, where you can specify a color to match.

**RGB [Range]**  Specifies a range for the color match. All three RGB values in the vertex color or illumination must either match the color specified by the color swatch in Select By Vertex Color, or be within plus or minus the values in the Range spinners. Default=10.

**Select**  Makes the selection based on the current settings.

### Editable Mesh Surface

Create or select an object. > Quad menu > Transform quadrant > Convert To: submenu > Editable Mesh
Create or select an object. > Modify panel > Right-click the base object in the stack. > Convert to: Editable Mesh

Create or select an object. > Utilities panel > Collapse button > Collapse Selected button

Editable Mesh on page 8559, like the Edit Mesh modifier, provides controls for manipulating a mesh object made up of triangular faces as an object and at three sub-object levels: vertex, edge and face. You can convert most objects in 3ds Max to editable meshes, but for open spline objects, only vertices are available, because open splines have no faces or edges when converted to meshes.

To make a sub-object selection on a non-editable mesh object (for example, a primitive) for passing up the stack to a modifier, use the Mesh Select modifier on page 1500.

Once you make a selection with Editable Mesh, you have these options:

- Use the options supplied on the Edit Geometry rollout to modify the selection. Later topics discuss these options for each of the mesh components.
- Transform or Shift+clone the selection, as with any object.
- Pass the selection to a later modifier in the stack. You can apply one or more standard modifiers to the selection.
- Use the options on the Surface Properties rollout to alter the surface characteristics of selected mesh components.

**NOTE** Because Edit Mesh modifier functionality is almost identical to that of editable mesh objects, features described in the Editable Mesh topics also apply to objects with Edit Mesh applied, except as noted.

**TIP** Editable Poly on page 2240 is similar to Editable Mesh, but lets you work with polygons of four or more sides, and provides a greater range of functionality.

**TIP** You can exit most Editable Mesh command modes, such as Extrude, by right-clicking in the active viewport.

See also:

- Edit Modifiers and Editable Objects on page 1052
- Modifying at the Sub-Object Level on page 1054
Procedures

To produce an editable mesh object:
First select the object, and then do one of the following:
■ Right-click the object and choose Convert To Editable Mesh from the Transform quadrant.
■ Use the Collapse utility on page 2022.
■ Apply a modifier to a parametric object that turns the object into a mesh object in the stack, and then collapse the stack. (For example, you can apply a Mesh Select modifier.)
■ Apply an Edit Mesh or Mesh Select modifier to an object.
■ Import a non-parametric object, such as that found in a 3DS file.
■ Import a 3ds Max object using Application menu on page 7989 > Import > Merge.

Converting an object to an editable mesh removes all parametric controls, including the creation parameters. For example, you can no longer increase the number of segments in a box, slice a circular primitive, or change the number of sides on a cylinder. Any modifiers you apply to an object are collapsed as well. After conversion, the only entry left on the stack is "Editable Mesh."

Maintaining an object's creation parameters:
As described in the above procedure, you can convert an existing object to an editable mesh, which replaces the creation parameters in the stack with "Editable Mesh." The creation parameters are no longer accessible or animatable. If you want to maintain the creation parameters, you can use the following modifiers:
■ Edit Mesh Modifier on page 1321
■ Mesh Select Modifier on page 1500
Interface

**Modifier Stack display**

**Show End Result** Normally, if you apply a modifier such as Twist to an editable-mesh object and then return to the Editable Mesh stack entry, you cannot see the effect of the modifier on the object's geometry. But if you turn on Show End Result while in sub-object level, you can see the original sub-object selection as a yellow mesh, the final object as a white mesh, and the original editable mesh as an orange mesh.

**Selection rollout**

See Selection Rollout (Editable Mesh) on page 2198.

**Named Selections**

**Copy** Places a named selection into the copy buffer.

**Paste** Pastes a named selection from the copy buffer.

For more information, see Named Selection Sets on page 217.

**Selection Information**

At the bottom of the Selection rollout is a text display giving information about the current selection. If no objects or more than one sub-object are selected, the text gives the number of objects and the type selected. If a single sub-object is selected, the text gives its identification number and type.

*NOTE* When the current sub-object level is Polygon or Element, selection information is given in faces.

**Soft Selection rollout**

Soft Selection controls affect the action of sub-object Move, Rotate, and Scale functions. When these are on, 3ds Max applies a spline curve deformation to
unselected vertices surrounding the transformed selected sub-object. This provides a magnet-like effect with a sphere of influence around the transformation.

For more information, see Soft Selection Rollout on page 2014.

**Edit Geometry rollout**

The Edit Geometry rollout on page 2220 provides various controls for editing an editable mesh object and its sub-objects. For information specific to the different sub-object levels, see the topics in this section.

**Working with Mesh Sub-Objects**

This topic describes how to work with sub-object selections when you are editing an Editable Mesh on page 2192.

**See also:**
- Edit Modifiers and Editable Objects on page 1052
- Modifying at the Sub-Object Level on page 1054
- Modifier Stack Controls on page 8187
- Editable Mesh on page 8559
- Editable Poly on page 8559

**Selecting and Transforming**

In selecting and transforming sub-object geometry, you use standard techniques:

- Clicking any vertex, edge, or face/polygon/element selects it.
- Holding down Ctrl lets you add to or subtract from the selection with single clicks.
- Holding down Alt lets you a subtract from the selection with single clicks, or with Window/Crossing selections.
- Beginning a selection outside the object starts a region selection. Holding down Ctrl during region selection lets you add to the selection.
Once you’ve made a sub-object selection, you can use the Spacebar to lock the selection while you’re working with it.

**Using Sub-Object Selection**

With either an editable mesh (or Edit Mesh modifier) or a Mesh Select modifier, you can store three separate sub-object selections: one for each selection level (vertex, face, and edge). These selection sets are saved with the file. With sub-object selections, you have these options:

- Choose one of the selection sets to pass geometry up the stack to other modifiers. Only one selection set is active at a time.
- Change to one of the other selection sets at any time.
- Use named selection sets on page 217 for sub-object geometry you want to reuse.
  
  In modeling a character head, for example, you might have a number of different vertex selections for forehead, nose, and chin. Such selections can be difficult to re-create, so named sets give you easy access to the original selection when you want to rework a particular area.

**Cloning Sub-Object Geometry**

Using Shift+transform with a selection of vertices or faces displays the Clone Part Of Mesh dialog. This lets you determine whether you want to "Clone To Object" or "Clone To Element." Click the desired option, optionally giving the cloned object a new name, then click OK.

- If you choose Clone To Object, the cloned copy becomes a plain mesh object, entirely separate from the original object. The new object is given the name in the field to the right of the Clone To Object radio button.
- If you choose Clone To Element, the selection is cloned in its new position and remains part of the original object.

**Animating Sub-Object Geometry**

When you work with an editable mesh, you can directly transform and animate a sub-object selection. In effect, the selection works like any other object.
Selection Rollout (Editable Mesh)

The Selection rollout provides buttons for turning different sub-object levels on and off, working with named selections and handles, display settings, and information about selected entities.

When you first access the Modify panel with an editable mesh selected, you're at the Object level, with access to several functions available as described in Editable Mesh (Object) on page 2200. You can toggle the various sub-object levels, and access relevant functions by clicking the buttons at the top of the Selection rollout.

Clicking a button here is the same as selecting a sub-object type in the Modifier Stack display. Click the button again to turn it off and return to the Object selection level.

The Selection rollout also allows you to display and scale vertex or face normals on page 8654

150 Faces Selected

Vertex: Turns on Vertex sub-object level, which lets you select a vertex beneath the cursor; region selection selects vertices within the region.
**Edge** Accesses the Edge sub-object level, which lets you select the edge of a face or polygon beneath the cursor; region selection selects multiple edges within the region. At the Edge sub-object level, selected hidden edges are displayed as dashed lines, allowing for more precise selection.

**Face** Accesses the Face sub-object level, which lets you select a triangular face beneath the cursor; region selection selects multiple triangular faces within the region. If a selected face has a hidden edge and Shade Selected Faces on page 8379 is off, the edge is displayed as a dashed line.

**Polygon** Accesses the Polygon sub-object level, which lets you select all coplanar faces (defined by the value in the Planar Threshold spinner) beneath the cursor. Usually, a polygon is the area you see within the visible wire edges. Region selection selects multiple polygons within the region.

**Element** Accesses the Element sub-object level, which lets you select all contiguous faces in an object. Region selection lets you select multiple elements.

**By Vertex** When on, and you click a vertex, any sub-objects (at the current level) that use that vertex are selected. Also works with Region Select.

**NOTE** When By Vertex is on, you can select sub-objects only by clicking a vertex, or by region.

**Ignore Backfacing** When on, selection of sub-objects selects only those sub-objects whose normals are visible in the viewport. When off (the default), selection includes all sub-objects, regardless of the direction of their normals.

**NOTE** The state of the Backface Cull setting in the Display panel does not affect sub-object selection. Thus, if Ignore Backfacing is off, you can still select sub-objects, even if you can't see them.

**Ignore Visible Edges** This is enabled when the Polygon face selection method is chosen. When Ignore Visible Edges is off (the default), and you click a face, the selection will not go beyond the visible edges no matter what the setting of the Planar Thresh spinner. When this is on, face selection ignores the visible edges, using the Planar Thresh setting as a guide.
Generally, if you want to select a “facet” (a coplanar collection of faces), you set the Planar Threshold to 1.0. On the other hand, if you’re trying to select a curved surface, increase the value depending on the amount of curvature.

■ **Planar Thresh**  (Planar Threshold) Specifies the threshold value that determines which faces are coplanar for Polygon face selection.

**Show Normals** When on, 3ds Max displays normals on page 8654 in the viewports. Normals are displayed as blue lines.
Show normals is not available in Edge mode.

■ **Scale**  Specifies the size of the normals displayed in the viewport when Show is on.

**Delete Isolated Vertices** When on, 3ds Max eliminates any isolated vertices when you delete a contiguous selection of sub-objects. When off, deleting a selection leaves all vertices intact. Not Available at the Vertex sub-object level. Default=on.
An isolated vertex is one that has no associated face geometry. For example, if Delete Isolated Vertices is off and you delete a rectangular selection of four polygons, all clustered about a single central point, the point remains, suspended in space.

**Hide** Hides any selected sub-objects. Edges cannot be hidden.

| Tip | The Select Invert command on the 3ds Max Edit menu is useful for selecting faces to hide. Select the faces you want to focus on, choose Edit > Select Invert, then click the Hide button. |

**Unhide All** Restores any hidden objects to visibility. Hidden vertices can be unhidden only when in Vertex sub-object level.

### Editable Mesh (Object)

Select an editable mesh object or object with the Edit Mesh modifier applied.
> Modify panel

Select an editable mesh object. > Quad menu > Tools 1 quadrant > Top-Level

Editable Mesh (Object) controls are available when no sub-object levels are active. These controls are also available at all sub-object levels, and work the same at each level, except as noted in **Edit Geometry Rollout (Mesh)** on page 2220.

---

2200 | Chapter 10  Surface Modeling
Interface

Edit Geometry rollout

See Edit Geometry Rollout (Mesh) on page 2220 for detailed descriptions of these controls.
Surface Properties rollout

Specifies surface approximation settings for subdividing the editable mesh. These controls work like the surface approximation settings for NURBS surfaces on page 2416. They are used when you apply a displacement map on page 6059 to the editable mesh.

**NOTE** The Surface Properties rollout is available only for editable mesh objects; it does not appear in the Modify panel for an object to which the Edit Mesh modifier is applied. With Edit Mesh-modified objects, you can use the Disp Approx modifier on page 1310 to the same effect.

**Subdivision Displacement** When on, faces are subdivided to accurately displace the mesh, using the method and settings you specify in the Subdivision Presets and Subdivision Method group boxes. When off, the mesh is displaced by moving existing vertices, the way the Displace modifier on page 1313 does. Default=off.

**Split Mesh** Affects the seams of displaced mesh objects; also affects texture mapping. When on, the mesh is split into individual faces before it is displaced;
this helps preserve texture mapping. When off, the mesh is not split and an internal method is used to assign texture mapping. Default=on.

**TIP** This parameter is required because of an architectural limitation in the way displacement mapping works. Turning Split Mesh on is usually the better technique, but it can cause problems for objects with clearly distinct faces, such as boxes, or even spheres. A box’s sides might separate as they displace outward, leaving gaps. And a sphere might split along its longitudinal edge (found in the rear for spheres created in the Top view) unless you turn off Split Mesh. However, texture mapping works unpredictably when Split Mesh is off, so you might need to add a Displace Mesh modifier on page 1068 and make a snapshot on page 950 of the mesh. You would then apply a UVW Map modifier on page 1932 and then reassign mapping coordinates to the displaced snapshot mesh.

**Subdivision Presets group & Subdivision Method group**

The controls in these two group boxes specify how the displacement map is applied when Subdivision Displacement is on. They are identical to the Surface Approximation controls on page 2737 used for NURBS surfaces.

**Editable Mesh (Vertex)**

Select an editable mesh object. > Modify panel > Selection rollout > Vertex

Select an editable mesh object. > Modify panel > Modifier Stack display > Expand Editable Mesh. > Vertex

Select an editable mesh object. > Quad menu > Tools 1 quadrant > Vertex

Vertices are points in space: they define the structure of faces. When vertices are moved or edited, the faces they form are affected as well. Vertices can also exist independently; such isolated vertices can be used to construct faces but are otherwise invisible when rendering.

At the Editable Mesh (Vertex) sub-object level, you can select single and multiple vertices and move them using standard methods.

**See also:**

- Editable Mesh Surface on page 2192
Procedures

To weld mesh vertices:

You can use either of two methods to combine several vertices into one, also known as welding. If the vertices are very close together, use the Weld function. You can also use Weld to combine a number of vertices to the average position of all of them.

Alternatively, to combine two vertices that are far apart, resulting in a single vertex that’s in the same position as one of them, use Target Weld.

TIP Welding vertices is considerably easier with poly objects. See this procedure: To weld polygon vertices: on page 1359

1  To use Weld:
   1  On the Selection rollout, turn on Ignore Backfacing, if necessary. This ensures that you’re welding only vertices you can see.
   2  Select the vertices to weld.
   3  If the vertices are very close together, go to the Edit Geometry rollout > Weld group and click Selected. If that doesn’t work (you get a “No vertices within weld threshold.” message), proceed to the next step.
   4  Increase the numeric value to the right of the Selected button. This is the threshold value; the minimum distance that vertices can be apart from each other to be welded.
   5  Click Selected again. At this point, one of three things happens: None, some, or all of the vertices are welded. If the latter, you’re done. If either of the others occurs, proceed to the next step.
   6  Continue increasing the threshold value and clicking Selected until all of the vertices are welded.

2  To use Target Weld:
   1  On the Selection rollout, turn on Ignore Backfacing, if necessary. This ensures that you’re welding only vertices you can see.
   2  Find two vertices you want to weld, and determine the ultimate location of the resulting vertex. You can weld any two vertices, but for best results the two should be contiguous; that is, they should be connected by a single edge.
For this example, we'll call the vertices A and B, and the resulting vertex will be at vertex B's location.

3 Click the Target button.
The button stays highlighted, to indicate that you're now in Target Weld mode.

4 Drag vertex A to Vertex B.
While you're dragging, the mouse cursor image is a four-headed, +-shaped arrow. When over an eligible target vertex, the cursor changes to a crosshairs.

**TIP** If you have trouble dragging in the proper direction, open the Axis Constraints toolbar on page 8039 and click the XY button.

5 Release the mouse button.
The pair is welded. The resulting vertex remains at vertex B's position, and you exit Target Weld mode.

**TIP** If you have trouble combining the two vertices, try increasing the Pixels value with the spinner to the right of the Target button.

You remain in Target Weld mode, and can continue to weld pairs of vertices.

6 Exit Target mode by right-clicking in the active viewport or clicking the Target button again.

**To select vertices by color:**

1 On the Surface Properties rollout, click the Existing Color swatch, and specify the color of vertex you want in the Color Selector.

2 Specify ranges in the RGB Range spinners. This lets you select vertices that are close to the specified color, but don't match exactly.

3 Click the Select button.
All vertices matching the color, or within the RGB range, are selected.
You can add to the selection by holding Ctrl as you click the Select button, and you can subtract from the selection by holding the Alt key.
**TIP** You can select all vertices of the same color by first selecting the vertex you want matched, dragging a copy of the Edit Color swatch to the Existing Color swatch, and then clicking the Select button. (If you want an exact match, be sure to set the RGB Range spinners to 0 first.)

**Interface**

**Selection rollout**

For information on the Selection rollout settings, see *Editable Mesh* on page 2195.

**Soft Selection rollout**

Soft Selection controls affect the action of sub-object Move, Rotate, and Scale functions. When these are on, 3ds Max applies a spline curve deformation to unselected vertices surrounding the transformed selected sub-object. This provides a magnet-like effect with a sphere of influence around the transformation.

For more information, see *Soft Selection Rollout* on page 2014.
Edit Geometry rollout

See Edit Geometry Rollout (Mesh) on page 2220 for detailed descriptions of these controls.
Surface Properties rollout

These controls let you set the weight and color for vertices.

**Weight** Displays and lets you change vertex weights for NURMS operations (see MeshSmooth Modifier on page 1505).

**Edit Vertex Colors group**

Use these controls to assign the color, illumination color (shading), and alpha (transparency) values of selected vertices.

- **Color** Click the color swatch to change the color of selected vertices.
- **Illumination** Click the color swatch to change the illumination color of selected vertices. This lets you change the illumination of a vertex without changing the vertex's color.
- **Alpha** Lets you assign an alpha (transparency) value to selected vertices. The spinner value is a percentage; zero is completely transparent and 100 is completely opaque.

**Select Vertices By group**

**Color/Illumination** These radio buttons let you choose to select vertices by vertex color value or vertex illumination value. Set the desired options and then click Select.
**Color Swatch** Displays the current color to match. Click to open the Color Selector, where you can specify a different color.

**Select** Depending on which radio button is selected, selects all vertices whose vertex color or illumination values either match the color swatch, or are within the range specified by the RGB spinners.

**Range** Specifies a range for the color match. All three RGB values in the vertex color or illumination color must either match the color specified by the Color swatch in Select By Vertex Color, or be within a range determined by adding and subtracting the Range values from the displayed color. Default=10.

For example, if you've chosen Color and set the color swatch to medium gray (R=G=B=128), and are using the default Range values of 10,10,10, then clicking the Select button selects only vertices set to RGB color values between 118,118,118 and 138,138,138.

---

**Editable Mesh (Edge)**

Select an editable mesh object. > Modify panel > Selection rollout > Edge

Select an editable mesh object. > Modify panel > Modifier Stack display > Editable Mesh rollout > Edge

Select an editable mesh object. > Quad menu > Tools 1 quadrant > Edge

An edge is a line, visible or invisible, forming the side of a face and connecting two vertices. Two faces can share a single edge.

At the Editable Mesh (Edge) sub-object level, you can select single and multiple edges and transform them using standard methods.

**See also:**

- [Editable Mesh Surface](#) on page 2192

**Procedures**

**To create a shape from one or more edges:**

1. Select the edges you want to make into shapes.
2. On the Edit Geometry rollout, click Create Shape From Edges.
3 Make changes, as needed, on the Create Shape dialog that appears.
   ■ Enter a curve name or keep the default.
   ■ Choose Smooth or Linear as the Shape Type.
   ■ Turn on Ignore Hidden Edges to exclude hidden edges from the calculation, or turn this feature off.

4 Click OK.
   The resulting shape consists of one or more splines whose vertices are coincident with the vertices in the selected edges. The Smooth option results in vertices using smooth values, while the Linear option results in linear splines with corner vertices.

   When you region-select edges, all edges are highlighted, including hidden edges, which are displayed as dashed lines. As a default, the Create Shape function ignores the hidden edges, even though they're selected. Turn off Ignore Hidden Edges if you want to include the hidden edges in the calculation.

   If the selected edges are not continuous, or if they branch, the resulting shape will consist of more than one spline. When the Create Shape function runs into a branching 'Y' in the edges, it makes an arbitrary decision as to which edge produces which spline. If you need to control this, select only those edges that will result in a single spline, and perform Create Shape repeatedly to make the correct number of shapes. Finally, use Attach in the Editable Spline to combine the shapes into one.
Top: Original object

Bottom: Object with edges selected
Top: Selected edges removed from original object

Bottom: Unwanted edges removed

**Interface**

**Selection rollout**

See *Editable Mesh* on page 2195 for information on the Selection rollout settings.
**Soft Selection rollout**

Soft Selection controls affect the action of sub-object Move, Rotate, and Scale functions. When these are on, 3ds Max applies a spline curve deformation to unselected vertices surrounding the transformed selected sub-object. This provides a magnet-like effect with a sphere of influence around the transformation.

For more information, see *Soft Selection Rollout* on page 2014.

See *Edit Geometry Rollout (Mesh)* on page 2220 for detailed descriptions of these controls.
Surface Properties rollout

These controls affect the visibility of the edges. Invisible edges (also called construction lines) appear in the viewports when Edges Only is turned off in the Display command panel, or when you're editing at the Edge sub-object level. The visibility of edges is primarily of importance when an object is being rendered using a wireframe material.

Visible Makes selected edges visible.

Invisible Makes selected edges invisible, so they won't be displayed in Edges Only mode.

Auto Edge group

Auto Edge Automatically determines edge visibility based on the angle between the faces that share the edge, with the angle set by the Threshold spinner to its right.

Clicking Auto Edge can have one of three effects, depending on which radio button is active (Set means to make an invisible edge visible; Clear means to make a visible edge invisible):

- **Set and Clear Edge Vis** Can change the visibility of all selected edges depending on the Threshold setting.

- **Set** Makes previously invisible edges visible only if they exceed the Threshold setting; does not clear any edges.

- **Clear** Makes previously visible edges invisible only if they are less than the Threshold setting; does not make any edges visible.
Editable Mesh (Face/Polygon/Element)

Select an editable mesh object. > Modify panel > Selection rollout > Face/Polygon/Element

Select an editable mesh object. > Modify panel > Modifier Stack display > Editable Mesh rollout > Face/Polygon/Element

Select an editable mesh object. > Quad menu > Tools 1 quadrant > Face/Polygon/Element

A face is the smallest possible mesh object: a triangle formed by three vertices. Faces provide the renderable surface of an object. While a vertex can exist as an isolated point in space, a face cannot exist without vertices.

At the Editable Mesh (Face) level, you can select single and multiple faces and transform them using standard methods. This is also true for the Polygon and Element sub-object levels; for the distinctions between face, polygon, and element, see Editable Mesh > Selection rollout on page 2195.

See also:
- Editable Mesh Surface on page 2192

Interface

Selection rollout

For information on the Selection rollout settings, see Editable Mesh on page 2195.

Soft Selection rollout

Soft Selection controls affect the action of sub-object Move, Rotate, and Scale functions. When these are on, 3ds Max applies a spline curve deformation to unselected vertices surrounding the transformed selected sub-object. This provides a magnet-like effect with a sphere of influence around the transformation.

For more information, see Soft Selection Rollout on page 2014.

See [Edit Geometry Rollout (Mesh)](page2220) for detailed descriptions of these controls.
Surface Properties rollout

These controls let you work with face normals, material IDs, smoothing groups, and vertex colors.

Normals group

**Flip** Reverses the direction of the surface normals of the selected faces.

**Unify** Flips the normals of an object so that they all point in the same direction, usually outward. This is useful for restoring an object’s faces to their original orientations. Sometimes normals of objects that have come into 3ds Max as part of a DXF file are irregular, depending on the methods used to create the objects. Use this function to correct them.
**Flip Normal Mode** Flips the normal of any face you click. To exit, click this button again or right-click anywhere in 3ds Max interface.

**TIP** The best way to use Flip Normal mode is to set up your viewport to display with Smooth+Highlight and Edged Faces on. If you use Flip Normal mode with default settings, you’ll be able to flip a face away from you, but you won’t be able to flip it back. For best results, turn off Ignore Backfacing in the Selection rollout. This lets you click any face and flip the direction of its normal, regardless of its current direction.

**Material group**

**Set ID** Lets you assign a particular material ID to selected sub-objects for use with multi/sub-object materials and other applications. Use the spinner or enter the number from the keyboard. The total number of available IDs is 65,535.

**Select ID** Selects sub-objects corresponding to the Material ID specified in the adjacent ID field. Type or use the spinner to specify an ID, then click the Select ID button.

**[Select By Name]** This drop-down list shows the names of sub-materials if an object has a Multi/Sub-Object material assigned to it. Click the drop arrow and choose a sub-material from the list. The sub-objects that are assigned that material are selected. If an object does not have a Multi/Sub-Object material assigned, the name list is unavailable. Likewise, if multiple objects are selected that have an Edit Patch, Edit Spline, or Edit Mesh modifier applied, the name list is inactive.

**NOTE** Sub-material names are those specified in the Name column on the material's Multi/Sub-Object Basic Parameters rollout; these are not created by default, and must be specified separately from any material names.

**Clear Selection** When on, choosing a new ID or material name deselects any previously selected sub-objects. When off, selections are cumulative, so new ID or sub-material name selections add to the existing selection set of patches or elements. Default=on.

**Smoothing Groups group**

Use these controls to assign selected faces to different smoothing groups, and to select faces by smoothing group.

To assign faces to one or more smoothing groups, select the faces, and then click the number(s) of the smoothing group(s) to assign them to.
Select by SG (Smoothing Group) Displays a dialog that shows the current smoothing groups. Select a group by clicking the corresponding numbered button and clicking OK. If Clear Selection is on, any previously selected faces are first deselected. If Clear Selection is off, the new selection is added to any previous selection set.

Clear All Removes any smoothing group assignments from selected faces.

Auto Smooth Sets the smoothing groups based on the angle between faces. Any two adjacent faces will be put in the same smoothing group if the angle between their normals is less than the threshold angle, set by the spinner to the right of this button.

Threshold This spinner (to the right of Auto Smooth) lets you specify the maximum angle between the normals of adjacent faces that determines whether those faces will be put in the same smoothing group.

Edit Vertex Colors group

Use these controls to assign the color, illumination color (shading), and alpha (transparency) values of vertices on the selected face(s).

Color Click the color swatch to change the color of vertices on the selected face(s). Assigning vertex colors at the face level prevents blending across the face(s).

Illumination Click the color swatch to change the illumination color of vertices on the selected face(s). This lets you change the illumination without changing the vertex’s color.

Alpha Lets you assign an alpha (transparency) value to vertices on the selected face(s). The spinner value is a percentage; zero is completely transparent and 100 is completely opaque.

Edit Geometry Rollout (Mesh)

Select an editable mesh object. > Modify panel > Selection rollout > Choose any sub-object level.

Select an editable mesh object. > Modify panel > Modifier Stack display > Expand Editable Mesh. > Choose any sub-object level.

Select an editable mesh object. > Quad menu > Tools 1 quadrant > Choose any sub-object level.
The Edit Geometry rollout for Meshes contains most of the controls that let you alter the geometry of the mesh, at either the Object (top) level, or one of the sub-object levels. The controls that the rollout displays can vary, depending on which level is active; if a control is not available for the active level, it might be grayed out, or simply might not appear at all. The descriptions below indicate the levels at which controls are available.

**Editing buttons**

Create  Lets you add sub-objects to a single selected mesh object. Select an object, choose a sub-object level, click Create, and then click to add sub-objects. Available only at the Vertex, Face, Polygon, and Element levels only.

For example, at the Vertex sub-object level, Create lets you add free-floating vertices to the object. The new vertices are placed on the active construction plane.

To create faces at the Face, Polygon, or Element level, click Create. All vertices in the object are highlighted, including isolated vertices left after deleting faces. Click three existing vertices in succession to define the shape of the new face. (The cursor changes to a cross when it is over a vertex that can legally be part of the face.)

You can also create new faces at the Polygon and Element sub-object levels. At the Face and Element sub-object levels, a new face is created after every third click. At the Polygon sub-object level, you can continue clicking as many times as you like to add vertices to the new polygon. To finish drawing a new polygon, click twice, or click again on any existing vertex in the current polygon.

At the Face, Polygon, and Element levels, you can add vertices while Create is on by Shift+clicking in an empty space; these vertices are incorporated into the face or polygon you’re creating.

You can start creating faces or polygons in any viewport, but all subsequent clicks must take place in the same viewport.

---

**TIP** For best results, click vertices in counterclockwise (preferred) or clockwise order. If you use clockwise order, the new polygon will be facing away from you, and you won’t be able to see it unless you’ve turned on Force 2-Sided or are using a two-sided material.

---

Delete (sub-object levels only) Deletes selected sub-objects and any faces attached to them.

Attach  Lets you attach another object in the scene to the selected mesh. You can attach any type of object, including splines, patch objects, and NURBS surfaces. Attaching a non-mesh object converts it to a mesh. Click the object you want to attach to the currently selected mesh object.

When you attach an object, the materials of the two objects are combined in the following way:

- If the object being attached does not have a material assigned, it inherits the material of the object it is being attached to.
Handle inherits material from the cup it is being attached to.

- Likewise, if the object you're attaching to doesn't have a material, it inherits the material of the object being attached.

- If both objects have materials, the resulting new material is a multi/sub-object material on page 6120 that encompasses the input materials. A dialog appears offering three methods of combining the objects' materials and material IDs. For more information, see Attach Options Dialog on page 2233.
Attach remains active in all sub-object levels, but always applies to objects.

**Attach List (Object level only)** Lets you attach other objects in the scene to the selected mesh. Click to open the Attach List dialog, which works like Select From Scene on page 206 to let you choose multiple objects to attach.

**Detach (Vertex and Face/Polygon/Element levels only)** Detaches the selected sub-object as a separate object or element. All faces attached to the sub-object are detached as well.
A dialog appears, prompting you to enter a name for the new object. The dialog has a Detach As Clone option that copies the faces rather than moving them.

Detached faces leave a hole in the original object when you move them to a new position.

**Break (Vertex level only)** Creates a new vertex for each face attached to selected vertices, allowing the face corners to be moved away from each other where they were once joined at the original vertex. If a vertex is isolated or used by only one face, it is unaffected.

**Turn (Edge level only)** Rotates the edge within its bounding. All mesh objects in 3ds Max are composed of triangular faces, but by default, most polygons are depicted as quadrilaterals, with a hidden edge dividing each quad into two triangles. Turn lets you change the direction in which the hidden edge (or any other) runs, thus affecting how the shape changes when you transform sub-objects directly, or indirectly with a modifier.

**Divide (Face/Polygon/Element levels only)** Subdivides faces into three smaller faces. This function applies to faces even if you’re at the Polygon or Element sub-object level. Click Divide, and then select a face to be divided. Each face is subdivided where you click it. You can click as many faces as you want divided, in sequence. To stop dividing, click Divide again to turn it off, or right-click.

**Extrude, Chamfer, and Bevel group**

The Extrude controls let you extrude edges or faces. Edge extrusion works in a fashion similar to face extrusion. You can apply extrusion interactively (by dragging on sub-objects) or numerically (using spinners).
Extrude (Edge and Face/Polygon/Element levels only) Click this button and then either drag to extrude the selected edges or faces, or adjust the Extrude spinner to perform the extrusion. You can select different sub-objects to extrude while Extrude is active.

- **Extrude Amount** This spinner (to the right of the Extrude button) lets you specify the amount to extrude the edge. Select one or more edges, and then adjust the spinner.
The Chamfer controls are available only at the Vertex and Edge sub-object levels. They let you bevel object corners using a chamfer function. You can apply this effect interactively (by dragging vertices) or numerically (using the Chamfer spinner).

**Chamfer (Vertex and Edge levels only)**  Click this button, and then drag vertices or edges in the active object. The Chamfer Amount spinner updates to indicate the chamfer amount as you drag.

If you drag one or more selected vertices or edges, all selected sub-objects are chamfered identically. If you drag an unselected vertex or edge, any selected sub-objects are first deselected.

A chamfer "chops off" the selected sub-objects, creating a new face connecting new points on all visible edges leading to the original sub-object. Chamfer Amount specifies the exact distance from the original vertex along each of these edges. New chamfer faces are created with the material ID of one of the neighboring faces (picked at random) and a smoothing group that is an intersection of all neighboring smoothing groups.

For example, if you chamfer one corner of a box, the single corner vertex is replaced by three vertices moving along the three visible edges that lead to the corner. 3ds Max rearranges and splits the adjacent faces to use these three new vertices, and creates a new triangle at the corner.

- **Chamfer Amount**  Adjust this spinner (to the right of the Chamfer button) to apply a chamfer effect to selected vertices.

- **Normal (Edge and Face/Polygon/Element levels only)**  Determines how a selection of more than one edge is extruded. With Normal set to Group (the default), extrusion takes place along the averaged normal of each continuous group (line) of edges. If you extrude multiples of such groups, each group moves along its own averaged normal. If you set Normal to Local, extrusion takes place along each selected edge’s normal.

Beveling, available only at the Face/Polygon/Element levels, is a second step to extrusion: it lets you scale the faces you have just extruded.
TIP  A similar operation is Inset on page 1401, which Editable Poly has but Editable Mesh doesn’t. When you inset a polygon, you create another, smaller polygon of the same proportions inside the borders of an original polygon, in the plane of the original. Essentially, it’s a bevel with no height. You can achieve this in Editable Mesh with the following procedure:

1  Select the polygon to inset.

2  Right-click the spinner all the way to the right of the Extrude button. This performs an extrusion with no height, thus creating a new polygon plus connecting polygons in the same position as the original.

3  Set a negative Bevel value using the numeric field or the spinner. This insets the new polygon created by the extrusion without changing its height.
Extruded face beveled in two different directions

You can bevel faces by dragging or by using keyboard/spinner entry.

**Bevel (Face/Polygon/Element levels only)** Click this button, and then drag vertically on any face to extrude it. Release the mouse button and move the mouse vertically to bevel the extrusion. Click to finish.

- When over a selected face, the mouse cursor changes to a Bevel cursor.
With multiple faces selected, dragging on any one bevels all selected faces equally.

You can drag other faces in turn to bevel them while the Bevel button is active. Click Bevel again or right-click to end the operation.

**Outlining** This spinner (to the right of the Bevel button) lets you scale selected faces bigger or smaller, depending on whether the value is positive or negative. It is normally used after an extrusion for beveling the extruded faces.

**Cut and Slice group**

Lets you subdivide edges with either cut or slice tools to create new vertices, edges, and faces. For details, see Cut and Slice (Editable Mesh) on page 2235.

**NOTE** At the Vertex sub-object level, Slice is available but Cut is not.

**Weld group (Vertex level only)**

**Selected** Welds selected vertices that fall within the tolerance specified in the Weld Threshold spinner (to the button's right). All line segments become connected to the resulting single vertex.

**Target** Enters weld mode, which allows you to select vertices and move them around. While moving, the cursor changes to the Move cursor as usual, but when you position the cursor over an unselected vertex the cursor changes to a + cursor. Release the mouse at that point to weld all selected vertices to the target vertex they were dropped on.

The pixels spinner to the right of the Target button sets the maximum distance in screen pixels between the mouse cursor and the target vertex.

**Tessellate group (Face/Polygon/Element levels only)**

Use these controls to tessellate (subdivide) selected faces. Tessellation is useful for increasing local mesh density while modeling. You can subdivide any selection of faces. Two tessellation methods are available: Edge and Face-Center.

**Tessellate** Click to tessellate selected faces, based on the Edge, Face-Center, and Tension (spinner) settings.
Top: Original selection
Middle: Tessellated once
Bottom: Tessellated twice

**Tension** (Active only when Tessellate by Edge is active.) This spinner, to the right of the Tessellate button, lets you increase or decrease the Edge tension value. A negative value pulls vertices inward from their plane, resulting in a concave effect. A positive value pulls vertices outward from their plane, resulting in a rounding effect.

**By Edge/Face-Center** Edge inserts vertices in the middle of each edge and draws three lines connecting those vertices. As a result, four faces are created out of one face. (To see this at the Polygon or Element sub-object level, turn off Display panel > Display Properties rollout > Edges Only.)

Face-Center adds a vertex to the center of each face and draws three connecting lines from that vertex to the three original vertices. As a result, three faces are created out of one face.

Set of polygons showing Face-Center tessellation
Explode group (Object and Face/Polygon/Element levels only)

**Explode** Breaks up the current object into multiple elements or objects based on the angles of its edges. This function is available in Object mode as well as all sub-object levels except Vertex and Edge.

Exploded faces (white) removed from tessellated faces

The angle threshold spinner, to the right of the Explode button, lets you specify the angle between faces below which separation will not occur. For example, all sides of a box are at 90-degree angles to each other. If you set the spinner to 90 or above, exploding the box changes nothing. However, at any setting below 90, the sides all become separate objects or elements.

**To Objects/Elements** Specifies whether the exploded faces become the separate objects or elements of the current object.

---

**Remove Isolated Vertices** Deletes all isolated vertices in the object regardless of the current selection.
Select Open Edges (Edge level only) Selects all edges with only one face. In most objects, this shows you where missing faces exist.

Create Shape from Edges (Edge level only) After selecting one or more edges, click this button to create a spline shape from the selected edges. A Create Shape dialog appears, letting you name the shape, set it to Smooth or Linear, and ignore hidden edges. The new shape's pivot is placed at the center of the mesh object.

View Align Aligns all vertices in selected objects or sub-objects to the plane of the active viewport. If a sub-object level is active, this function affects only selected vertices or those belonging to selected sub-objects.

In the case of orthographic viewports on page 8668, using View Align has the same effect as aligning to the construction grid when the home grid is active. When aligning to a perspective viewport (including camera and light views), the vertices are reoriented to be aligned to a plane that is parallel to the camera's viewing plane. This plane is perpendicular to the view direction that is closest to the vertices’ average position.

Grid Align Aligns all vertices in selected objects or sub-objects to the plane of the current view. If a sub-object level is active, function aligns only selected sub-objects.

This function aligns the selected vertices to the current construction plane. The current plane is specified by the active viewport in the case of the home grid. When using a grid object, the current plane is the active grid object.

Make Planar (sub-object levels only) Forces all selected sub-objects to become coplanar. The plane's normal is the average surface normal of all faces attached to the selected sub-objects.

Collapse (sub-object levels only) Collapses selected sub-objects into an averaged vertex.

Attach Options Dialog (Editable Mesh)

Select an editable mesh object. > Modify panel > Attach button

The Attach Options dialog appears when you attach two or more objects to which materials have been assigned. It provides three different methods of combining the sub-materials and the material IDs in the two objects.
**Interface**

**Match Material IDs to Material** The number of material IDs in the attached objects are modified so they are no greater than the number of sub-materials assigned to those objects. For example, if you have a box with only two sub-materials assigned to it, and you attach it to another object, the box will have only two material IDs, instead of the six it was assigned on creation.

**Match Material to Material IDs** Maintains the original ID assignment in the attached objects by adjusting the number of sub-materials in the resulting multi/sub-object material. For example, if you attach two boxes, both assigned single materials, but with their default assignment of 6 material IDs, the result would be a multi/sub-object material with 12 sub-materials (six containing instances of one box's material, and six containing instances of the other box's material). Use this option when it's important to maintain the original material ID assignments in your geometry.

**NOTE** If you want to make the instanced sub-materials unique, select them in Track View, and click the Make Unique button on the Track View toolbar. You can also make them unique one at a time with the Make Unique button on page 5692 in the Material Editor.

**Do Not Modify Mat IDs or Material** Does not adjust the number of sub-materials in the resulting sub-object material. Note that, if the number of material IDs in an object is greater than the number of sub-materials in its multi/sub-object material, then the resulting face-material assignment might be different after the attach.

**Condense Material IDs** Affects the Match Material IDs To Material option. When this is on, duplicate sub-materials or sub-materials that aren't used in the objects are removed from the multi/sub-object material that results from the attach operation. Default=on.
Tips

- In most cases, use the first option (Match Material IDs to Material) while keeping Condense Material IDs selected. This maintains the appearance of the objects, and results in the fewest additional sub-materials or IDs.

- Use the second option (Match Material to Material IDs) when you need to maintain the original material ID assignments.

- Avoid using the third option, unless you need to repeat a 3ds Max version 1 attachment for compatibility with a previous project.

- Leave Condense Material IDs selected unless you have an unassigned sub-material that you want to keep for future assignment.

- Perform Edit menu > Hold before performing the attach.

Cut and Slice (Editable Mesh)

Select an editable mesh object. > Modify panel > Selection rollout > (Optional: Choose a sub-object level.) > Edit Geometry rollout > Cut and Slice group box

The tools available in the Cut and Slice group let you subdivide edges and faces to create new vertices, edges, and faces. You can slice an editable mesh object at any sub-object level; the Cut tool is available at every sub-object level except the Vertex sub-object level.

Procedures

To create a new face using Cut:

1. Convert the geometry to an editable mesh.

2. On the Modify panel, choose the object’s Edge (or Face, Polygon, or Element) sub-object level.

3. On the Selection rollout, turn on Ignore Backfacing.

4. On the Edit Geometry rollout, in the Cut and Slice group, click the Cut button.

5. Click the first edge you want to subdivide, and then move your cursor toward the second edge. The cursor changes to a plus sign when over an
edge, and a dotted line connects the initial point where the edge was clicked with the current cursor location.

6 Click the second edge. This edge can be anywhere, cutting across as many faces as you like. A new visible edge appears.

7 At this point, a new dotted line is connected to the mouse cursor, originating from the last point you clicked.

8 Continue clicking edges to cut. To start from a different point, right-click, and then select the new start point. To finish cutting, right-click twice. You can use Snaps on page 2807 with Cut. To divide an edge in half, set Snaps to midpoint. To start or end a cut at a vertex, set snap to vertex or endpoint.
To create multiple slices:

1. Select an editable mesh.

2. On the Modify panel, choose the object’s Edge (or Face, Polygon, or Element) sub-object level.

3. Select one or more sub-objects. Slice affects only selected sub-objects.

4. In the Cut And Slice group box, click the Slice Plane button.

5. Position and rotate the Slice Plane gizmo to where you want the first slice.

6. Click the Slice button. The object is sliced.

7. If you want, move the Slice Plane to a second position and click the Slice button again.
Click the Slice Plane button again to turn it off and see the results.

To better understand what has happened, turn off Edges Only in the Display panel.
Interface

NOTE The keyboard shortcuts listed here require that the Keyboard Shortcut Override Toggle on page 8420 be on.

Cut and Slice group

Slice Plane Creates a gizmo for a slice plane that can be positioned and rotated where you want to slice the edges. Also enables the Slice button.

Slice Performs the slice operation at the location of the slice plane. The Slice button is available only when the Slice Plane button is highlighted. This tool slices the mesh just like the Slice modifier on page 1727 in “Operate On: Face” mode.

NOTE Slice works only on a sub-object selection. Make the selection before activating Slice Plane.

Cut Lets you divide a edge at any point, then divide a second edge at any point, creating a new edge or edges between the two points. Clicking the first edge sets the first vertex. A dotted line tracks the cursor movement until you click a second edge. A new vertex is created at each edge division. Alternately, double-clicking an edge simply divides that edge at the point clicked, with invisible edges on either side.

You can use Cut to cut across any number of faces, even across an entire object. Click one edge to start the cut, and a second edge to end the cut. Use Snaps on page 2807 with Cut for precision. Cut supports Midpoint, Endpoint, and Vertex snaps.

You can also use the keyboard shortcut Alt+C to toggle Cut mode.

IMPORTANT When using the Cut tool to add new edges, you should work in a non-Perspective viewport, such as Front or User. If you use Cut while working in a Perspective viewport, you may find that the created edges appear to jump or aren't placed correctly. Using an orthographic viewport will allow the cuts to appear where you click.
**TIP** When performing a Cut, turn on Selection rollout > Ignore Backfacing to avoid accidentally selecting edges on the back side of the mesh.

**Split** When on, the Slice and Cut operations create double sets of vertices at the points where the edges are divided. This lets you easily delete the new faces to create holes, or animate the new faces as separate elements.

**Refine Ends** When on, adjacent faces at the ends of the cut are also divided by additional vertices, so that the surface stays contiguous. When Refine Ends is off, the surface will have a seam where the new vertex meets the adjacent face. For this reason, it's a good idea to keep Refine Ends turned on, unless you are sure that you don't want the extra vertices created.

Refine Ends affects only Cut. It does not affect Slice.

---

**Editable Poly Surface**

Create or select an object. > Quad menu > Transform quadrant > Convert to Editable Poly

Create or select an object. > Modify panel > Right-click the base object in the stack. > Choose Convert to: Editable Poly.

*Editable Poly* on page 8559 is an editable object with five sub-object levels: vertex, edge, border, polygon, and element. Its usage is similar to that of an *editable mesh object* on page 2192, with controls for manipulating an object as a polygon mesh at various sub-object levels. Rather than triangular faces, however, the poly object's faces are polygons with any number of vertices.

Editable Poly gives you these options:

- Transform or Shift+Clone the selection, as with any object.
- Use the options supplied on the Edit rollouts to modify the selection or object. Later topics discuss these options for each of the polymesh components.
- Pass a sub-object selection to a modifier higher in the stack. You can apply one or more standard modifiers to the selection.
- Use the options on the Subdivision Surface Rollout (Polymesh) in the *editable polysubdivision surface rollout* on page 2325 to alter surface characteristics.
You can exit most Editable Poly command modes, such as Extrude, by right-clicking in the active viewport.

**Overriding Actions with Press/Release Keyboard Shortcuts**

While working with poly objects, you can use a “press/release keyboard shortcut” to temporarily override the current operation and perform a different one. As soon as you release the keyboard shortcut, you return to the previous operation.

For example, you might be working at the Polygon sub-object level, moving polygons, and need to rotate the object to access a different part of it. Instead of having to exit the Polygon sub-object level, rotate the object and then re-enter the sub-object level, you could simply press and hold 6, rotate the object, release the key, and immediately return to moving polygons.

To see a list of press/release keyboard shortcuts, go to Customize > Customize User Interface > Keyboard panel, open the Group drop-down list, and choose Edit Poly or Editable Poly. The actions in boldface are the ones that you can assign as press/release shortcuts. Not all are assigned; for information about assigning keyboard shortcuts, see Keyboard Panel on page 8250.

The actions in boldface can function as press/release shortcuts.

**Editable Poly Workflow**

Sub-object-specific functions, such as Remove on page 1378 for edges, appear on their own rollouts in the Editable Poly user interface. This leaves the Edit...
Geometry rollout on page 1409 with functions that you can apply at most sub-object levels, as well as at the object level.

Also, many commands are accompanied by a Settings button, which gives you a second way to use the command:

- In Direct Manipulation mode, activated by clicking the command button, you apply the command by manipulating sub-objects directly in the viewport. An example of this is Extrude: You click the Extrude button, and then click and drag sub-objects in the viewports to extrude them.

  **NOTE** Some buttons, such as Tessellate, operate on the mesh immediately, with no viewport manipulation required.

- Interactive Manipulation mode is well suited to experimentation. You activate this mode by clicking the command's Settings button. This opens a non-modal settings dialog and places you in preview mode, where you can set parameters and see the results immediately in the viewport on the current sub-object selection. You can then accept the results by clicking OK, or reject them by clicking Cancel. You can also use this mode to apply the same or different settings to several different sub-object selections in a row. Make the selection, optionally change the settings, click Apply, and then repeat with a different selection.

  **IMPORTANT** When you click Apply, the settings are "baked into" the selection, and then applied again to the selection as a preview. If you then click OK to exit, you will have applied the settings twice. If your intention is to apply them only once, simply click OK the first time, or click Apply, and then Cancel.

  **NOTE** Changes implemented in Interactive Manipulation mode with editable poly objects cannot be animated. However, they can with Edit Poly objects.

See also:

- Edit Poly Modifier on page 1332
- Graphite Modeling Tools on page 2025
- Poly Select Modifier on page 1582
- Turn To Poly Modifier on page 1830
Procedures

To produce an editable poly object:

First select an object, and then do one of the following:

- If no modifiers are applied to the object, In the Modify panel, right-click in the modifier stack display and choose Editable Poly from the Convert To list on the pop-up menu.

- Right-click the object and choose Convert To Editable Poly from the Transform quadrant of the quad menu.

- Apply a modifier to a parametric object that turns the object into a poly object in the stack display, and then collapse the stack. For example, you can apply a Turn To Poly modifier on page 1830. To collapse the stack, use the Collapse utility on page 2022 and set Output Type to Modifier Stack Result, or right-click the object's modifier stack and then choose Collapse All.

Converting an object to Editable Poly format removes all parametric controls, including the creation parameters. For example, you can no longer increase the number of segments in a box, slice a circular primitive, or change the number of sides on a cylinder. Any modifiers you apply to an object are merged into the mesh as well. After conversion, the only entry left on the stack is "Editable Poly."

To maintain an object's creation parameters:

- As noted in the previous procedure, if you convert an existing object to editable poly format, 3ds Max replaces the creation parameters in the stack with "Editable Poly." The creation parameters are no longer accessible or animatable. If you want to maintain the creation parameters, you can use the Edit Poly modifier on page 1332 or the Turn To Poly modifier on page 1830.

Interface

Stack Display

For more information on the Stack Display, see Modifier Stack on page 8187.

Show End Result Normally, if you apply a modifier such as Symmetry on page 1803 to an editable poly object and then return to the Editable Poly stack entry, you cannot see the effect of the modifier on the object's geometry. But
if you turn on Show End Result while in sub-object level, you can see the final object as a white mesh, the original sub-object selection as a yellow mesh, and the original editable polymesh as an orange mesh.

**Selection rollout**

Lets you access the different sub-object levels. See Selection Rollout (Polymesh)selection rollouteditable polyeditable polyselection rolloutsub-objectselectionrolloutsselection on page 2245.

**Soft Selection rollout**

Soft Selection controls apply a smooth falloff between selected sub-objects and unselected ones. When Use Soft Selection is on, unselected sub-objects near your selection are given partial selection values. These values are shown in the viewports by means of a color gradient on the vertices, and optionally on the faces. They affect most types of sub-object deformations, such as the Move, Rotate, and Scale functions and any deformation modifiers (such as Bend) applied to the object. This provides a magnet-like effect with a sphere of influence around the selection.

For more information, see Soft Selection Rollout on page 2014.

**Edit (sub-object) rollout**

The Edit (sub-object) rollout provides sub-object-specific functions for editing an editable poly object and its sub-objects. For specific information, click any of the links below:

- Edit Vertices rollout on page 2261
- Edit Edges rollout on page 2278
- Edit Borders rollout on page 2290
- Edit Polygons/Elements rollout on page 1396

**Edit Geometry rollout**

The Edit Geometry Rollout (Polymesh and Edit Poly) on page 1409 provides global functions for editing an editable poly object and its sub-objects.

**Subdivision Surface rollout**

Controls on this rollout apply subdivision to the polymesh in the style of the MeshSmooth modifier. See Subdivision Surface Rollout (Polymesh)subdivision

---

2244 | Chapter 10  Surface Modeling
Surface rollout

The surface rollout is used to control the overall appearance of the polymesh. It includes controls for surface smoothness, lighting, and other visual effects.

Subdivision Displacement rollout

Specifies surface approximation for subdividing the polymesh. See Subdivision Displacement Rollout (Polymesh) on page 2330.

Subdivision Presets group & Subdivision Method group

The controls in these two group boxes specify how 3ds Max applies the displacement map when Subdivision Displacement is on. They are identical to the Surface Approximation controls on page 2737 used for NURBS surfaces.

Paint Deformation rollout

Paint Deformation lets you stroke elevated and indented areas directly onto object surfaces. For more information, see Paint Deformation Rollout (Polymesh) on page 2333.

Selection Rollout (Polymesh)

Create or select an editable poly object. > Modify panel > Selection rollout

The Selection rollout provides tools for accessing different sub-object levels and display settings and for creating and modifying selections, and displays information about selected entities.

When you first access the Modify panel with an editable poly selected, you're at the Object level, with access to several functions available as described in Editable Poly (Object) on page 2256. You can toggle the various sub-object levels, and access relevant functions, by clicking the buttons at the top of the Selection rollout.

Clicking a button here is the same as choosing a sub-object type in the modifier stack display. Click the button again to turn it off and return to the Object selection level.
NOTE You can convert sub-object selections in three different ways with the use of the Ctrl and Shift keys:

■ To convert the current selection to a different sub-object level, clicking a sub-object button on the Selection rollout with Ctrl held down. This selects all sub-objects at the new level that touch the previous selection. For example, if you select a vertex, and then Ctrl+click the Polygon button, all polygons that use that vertex are selected.

■ To convert the selection to only sub-objects all of whose source components are originally selected, hold down both Ctrl and Shift as you change the level. For example, if you convert a vertex selection to a polygon selection with Ctrl+Shift+click, the resultant selection includes only those polygons all of whose vertices were originally selected.

■ To convert the selection to only sub-objects that border the selection, hold down Shift as you change the level. The selection conversion is inclusive, meaning:

■ When you convert faces, the resulting selection of edges or vertices all belong to selected faces that bordered unselected faces. Only the edges or vertices that bordered unselected faces are selected.

■ When you convert vertices to faces, the resulting selection of faces had all of their vertices selected and bordered unselected faces. When you convert vertices to edges, the resulting selection contains only edges all of whose vertices were previously selected and only edges of faces that did not have all vertices selected; that is, of faces around the border of the vertex selection.
When you convert edges to faces, the resulting selection of faces had some but not all of their edges selected, and were next to faces with no edges selected. When you convert edges to vertices, the resulting vertices are on previously selected edges, but only at intersections where not all edges were selected.

Conversion commands are also available from the quad menu.

- **Vertex** Accesses the Vertex sub-object level, which lets you select a vertex beneath the cursor; region selection selects vertices within the region.

- **Edge** Accesses the Edge sub-object level, which lets you select a polygon edge beneath the cursor; region selection selects multiple edges within the region.

- **Border** Accesses the Border sub-object level, which lets you select a sequence of edges that borders a hole in the mesh. A border comprises only connected edges with faces on only one side of them, and is always a complete loop. For example, a default box primitive doesn't have a border, but the teapot object has a couple of them: one each on the lid, the body, and the spout, and two on the handle. If you create a cylinder and delete one end, the row of edges around that end forms a border.

  When Border sub-object level is active, you can't select edges that aren't on borders. Clicking a single edge on a border selects that whole border.

  You can cap a border, either with the Cap function on page 1392 or by applying the Cap Holes modifier on page 1185. You can also connect borders between objects with the Connect compound object on page 695.

**NOTE**

The Edge and Border sub-object levels are compatible, so if you go from one to the other, any existing selection is retained.
Polygon

Accesses the Polygon sub-object level, which lets you select polygons beneath the cursor. Region selection selects multiple polygons within the region.

Element

Accesses the Element sub-object level, which lets you select all contiguous polygons in an object. Region selection lets you select multiple elements.

NOTE

The Polygon and Element sub-object levels are compatible, so if you go from one to the other, any existing selection is retained.

By Vertex

When on, you can select sub-objects only by selecting a vertex that they use. When you click a vertex, all sub-objects that use the selected vertex are selected.

Not available at the Vertex sub-object level.

Ignore Backfacing

When on, selection of sub-objects affects only those facing you. When off (the default), you can select any sub-object(s) under the mouse cursor, regardless of their visibility or facing. If there are more than one sub-object under the cursor, repeated clicking cycles through them. Likewise, with Ignore Backfacing off, region selection includes all sub-objects, regardless of the direction they face.

NOTE  The state of the Backface Cull on page 166 setting on the Display panel does not affect sub-object selection. Thus, if Ignore Backfacing is off, you can still select sub-objects even if you can’t see them.

By Angle

When on, selecting a polygon also selects neighboring polygons based on the angle setting to the right of the check box. This value determines the maximum angle between neighboring polygons to select. Available only at the Polygon sub-object level.

For example, if you click a side of a box and the angle value is less than 90.0, only that side is selected, because all sides are at 90-degree angles to each other. But if the angle value is 90.0 or greater, all sides of the box are selected. This function speeds up selection of contiguous areas made up of polygons that are at similar angles to one another. You can select coplanar polygons with a single click at any angle value.
**Shrink** Reduces the sub-object selection area by deselecting the outermost sub-objects. If the selection size can no longer be reduced, the remaining sub-objects are deselected.

**Grow** Expands the selection area outward in all available directions. For this function, a border is considered to be an edge selection.

With Shrink and Grow, you can add or remove neighboring elements from the edges of your current selection. This works at any sub-object level.

**Ring** Expands an edge selection by selecting all edges parallel to the selected edges. Ring applies only to edge and border selections.
Ring selection adds to the selection all the edges that are parallel to the ones selected originally.

**TIP** After making a ring selection, you can use Connect on page 1383 to subdivide the associated polygons into new edge loops.

**[Ring Shift]** The spinner next to the Ring button lets you move the selection in either direction to other edges in the same ring; that is, to neighboring, parallel edges. If you have a loop selected, you can use this function to select a neighboring loop. Applies only to Edge and Border sub-object levels.
Left: Original loop selection

Upper right: Ring Shift up moves selection outward (from center of model).

Lower right: Ring Shift down moves selection inward (toward center of model).

To expand the selection in the chosen direction, Ctrl+click the up or down spinner button. To shrink the selection in the chosen direction, Alt+click the up or down spinner button.

**Loop** Expands the selection as far as possible, in alignment with selected edges.

Loop applies only to edge and border selections, and propagates only through four-way junctions.
Loop selection extends your current edge selection by adding all the edges aligned to the ones selected originally.

**[Loop Shift]** The spinner next to the Loop button lets you move the selection in either direction to other edges in the same loop; that is, to neighboring, aligned edges. If you have a ring selected, you can use this function to select a neighboring ring. Applies only to Edge and Border sub-object levels.
Left: Original ring selection

Upper right: Loop Shift up moves selection outward.

Lower right: Loop Shift down moves selection inward.

To expand the selection in the chosen direction, Ctrl+click the up or down spinner button. To shrink the selection in the chosen direction, Alt+click the up or down spinner button.

**Preview Selection**
This option lets you preview a sub-object selection before committing to it. You can preview at the current sub-object level, or switch sub-object levels automatically based on the mouse position. The choices are:

- **Off**  No preview is available.
- **SubObj**  Enables previewing at the current sub-object level only. As you move the mouse over the object, the sub-object under the cursor highlights in yellow. To select the highlighted object, click the mouse. To select multiple sub-objects at the current level, press and hold Ctrl, move the mouse to highlight more sub-objects, and then click to select all highlighted sub-objects.

![Polygon sub-object selection preview with Ctrl held down](image)

To deselect multiple sub-objects at the current level, press and hold Ctrl+Alt, move the mouse to highlight more sub-objects, and then click a selected sub-object. This deselects all highlighted sub-objects.

- **Multi**  Works like SubObj, but also switches among the Vertex, Edge, and Polygon sub-object levels on the fly, based on the mouse position. For example, if you position the mouse over an edge, the edge highlights, and then clicking activates the Edge sub-object level and selects the edge. To select multiple sub-objects of the same type, press and hold Ctrl after highlighting a sub-object, move the mouse to highlight more sub-objects,
and then click to activate that sub-object level and select all highlighted sub-objects.

To deselect multiple sub-objects at the current sub-object level, press and hold Ctrl+Alt, move the mouse to highlight more sub-objects, and then click a selected sub-object. This deselects all highlighted sub-objects. Note that this method does not switch sub-object levels.

**NOTE** When Ignore Backfacing on page 1350 is off, you’ll see backfacing vertices and edges highlight while previewing a sub-object selection.

**Selection Information**

At the bottom of the Selection rollout is a text display giving information about the current selection. If 0 or more than one sub-object is selected, the text gives the number and type selected; for example, “4 Polygons Selected.” If one sub-object is selected, the text gives the identification number and type of the selected item; for example, “Polygon 73 Selected.”

When using Preview Selection on page 1356, a second line gives additional information about the identity or number of highlighted sub-objects.

**Editable Poly (Object)**

Select an editable poly object. > Modify panel

Select an editable poly object. > Quad menu > Tools 1 quadrant > Top-level

Editable Poly (Object) functions are available when no sub-object levels are active. These functions are also available at all sub-object levels, and work the same in each mode, except as noted below.

Use the Selection rollout on page 2248 or modifier stack on page 8187 to access the different sub-object levels.
Interface

Edit Geometry rollout

For detailed descriptions of these controls, see Edit Geometry Rollout (Polymesh and Edit Poly) on page 1409.

Subdivision Surface rollout

For information about the Subdivision Surface rollout settings, see Subdivision Surface Rollout (Polymesh) on page 2325.
Subdivision Displacement rollout

For information about the Subdivision Displacement rollout settings, see Subdivision Displacement Rollout (Polymesh) subdivision displacement rollout editable poly editable polys subdivision displacement rollout on page 2330.

Paint Deformation rollout

Paint Deformation lets you stroke elevated and indented areas directly onto object surfaces. For more information, see Paint Deformation Rollout (Polymesh) editable polypaint deformation rollout edit polypaint deformation rollout spaint deformation paint deformation rollout on page 2333.

Editable Poly (Vertex)

Select an editable poly object. > Modify panel > Selection rollout > Vertex

Select an editable poly object. > Modify panel > Modifier Stack display > Expand Editable Poly. > Vertex

Select an editable poly object. > Quad menu > Tools 1 quadrant > Vertex

Vertices are points in space: They define the structure of other sub-objects (edges and polygons) that make up the poly object. When you move or edit vertices, the connected geometry is affected as well. Vertices can also exist independently; such isolated vertices can be used to construct other geometry but are otherwise invisible when rendering.

At the editable poly Vertex sub-object level, you can select single and multiple vertices and move them using standard methods. This topic covers the Edit Vertices and Vertex Properties rollouts and provides links to the rest.

Procedures

To weld polygon vertices:

You can use either of two methods to combine several vertices into one, also known as welding. If the vertices are very close together, use the Weld function. You can also use Weld to combine a number of vertices to the average position of all of them.
Alternatively, to combine two vertices that are far apart, resulting in a single vertex that’s in the same position as one of them, use Target Weld.

1 To use Weld:
   1 On the Selection rollout, turn on Ignore Backfacing, if necessary. This ensures that you're welding only vertices you can see.
   2 Select the vertices to weld.
   3 If the vertices are very close together, simply click Weld. If that doesn't work, proceed to the next step.

4 Click the Settings button to the right of the Weld button. This opens the Weld Vertices dialog on page 2359.

5 Increase the Weld Threshold value gradually using the spinner (click and hold on the up-down arrow buttons to the right of the numeric field and then drag upward). If you need the value to change more quickly, hold down the Ctrl key as you drag.
When the threshold equals or exceeds the distance between two or more of the vertices, the weld occurs automatically, and the resulting vertex moves to their average location.

6 If not all the vertices are welded, continue increasing the Weld Threshold value until they are.

7 Click OK to exit.

2 To use Target Weld:
   1 On the Selection rollout, turn on Ignore Backfacing, if necessary. This ensures that you're welding only vertices you can see.
   2 Find two vertices you want to weld, and determine the ultimate location of the resulting vertex. The two vertices must be contiguous; that is, they must be connected by a single edge.
For this example, we'll call the vertices A and B, and the resulting vertex will be at vertex B's location.
   3 Click the Target Weld button. The button stays highlighted, to indicate that you're now in Target Weld mode.
   4 Click vertex A and then move the mouse.
   A rubber-band line connects the vertex and the mouse cursor.
Position the cursor over vertex B, whereupon the cursor image changes from an arrow to a crosshairs. Reminder: Only vertices connected to the first vertex by a single edge qualify for target welding.

Click to weld the two.
The resulting vertex remains at vertex B's position.

Click Target Weld again to turn it off.

To select vertices by color:

1 In the Vertex Properties rollout > Select Vertices By group, click the color swatch, and specify the color of vertex you want in the Color Selector on page 371.

2 Specify ranges in the RGB Range spinners. This lets you select vertices that are close to the specified color, but don't match exactly.

3 Click the Select button.
All vertices matching the color, or within the RGB range, are selected.
You can add to the selection by holding Ctrl as you click the Select button, and subtract from the selection by holding the Alt key.

**TIP** You can select all vertices of the same color by first selecting the vertex you want matched, dragging a copy of the Edit Color swatch to the Existing Color swatch, and then clicking the Select button. (If you want an exact match, be sure to set the RGB Range spinners to 0 first.)

**Interface**

**Selection rollout**

See *Editable Poly* on page 2248 for information on the Selection rollout settings.

**Soft Selection rollout**

Soft Selection controls apply a smooth falloff between selected sub-objects and unselected ones. When Use Soft Selection is on, unselected sub-objects near your selection are given partial selection values. These values are shown in the viewports by means of a color gradient on the vertices, and optionally on the faces. They affect most types of sub-object deformations, such as the
Move, Rotate, and Scale functions, as well as any deformation modifiers (such as Bend) applied to the object. This provides a magnet-like effect with a sphere of influence around the selection.

For more information, see Soft Selection Rollout on page 2014.

**Edit Vertices rollout**

This rollout includes commands specific to vertex editing.

**NOTE** To delete vertices, select them and press the Delete key. This can create one or more holes in the mesh. To delete vertices without creating holes, use Remove (see following).

**Remove** Deletes selected vertices and combines the polygons that use them. The keyboard shortcut is Backspace.
Removing one or more vertices deletes them and retriangulates the mesh to keep the surface intact. If you use Delete instead, the polygons depending on those vertices are deleted as well, creating a hole in the mesh.

**WARNING** Use of Remove can result in mesh shape changes and non-planar polygons.

**Break** Creates a new vertex for each polygon attached to selected vertices, allowing the polygon corners to be moved away from each other where they were once joined at each original vertex. If a vertex is isolated or used by only one polygon, it is unaffected.

**Extrude** Lets you extrude vertices manually via direct manipulation in the viewport. Click this button, and then drag vertically on any vertex to extrude it.

Extruding a vertex moves it along a normal and creates new polygons that form the sides of the extrusion, connecting the vertex to the object. The extrusion has the same number of sides as the number of polygons that originally used the extruded vertex.

Following are important aspects of vertex extrusion:

- When over a selected vertex, the mouse cursor changes to an Extrude cursor.
- Drag vertically to specify the extent of the extrusion, and horizontally to set the size of the base.
- With multiple vertices selected, dragging on any one extrudes all selected vertices equally.

- You can drag other vertices in turn to extrude them while the Extrude button is active. Click Extrude again or right-click in the active viewport to end the operation.

Chamfer box showing extruded vertex

- **Extrude Settings** Opens the Extrude Vertices dialog on page 2350, which lets you perform extrusion via interactive manipulation. If you click this button after performing a manual extrusion, the same extrusion is performed on the current selection as a preview and the dialog opens with Extrusion Height set to the amount of the last manual extrusion.

- **Weld** Combines contiguous, selected vertices that fall within the tolerance specified in Weld dialog on page 2359. All edges become connected to the resulting single vertex.
Using Weld at the Vertex level

Vertices farther apart than the Threshold distance are not welded.

Weld is best suited to automatically simplifying geometry that has areas with a number of vertices that are very close together. Before using Weld, set the Weld Threshold via the Weld dialog on page 2359. To weld vertices that are relatively far apart, use Target Weld on page 1366 instead.

**Weld Settings** Opens the Weld dialog on page 2359, which lets you specify the weld threshold.

**Chamfer** Click this button and then drag vertices in the active object. To chamfer vertices numerically, click the Chamfer Settings button and use the Chamfer Amount value.

If you chamfer multiple selected vertices, all of them are chamfered identically. If you drag an unselected vertex, any selected vertices are first deselected.

Each chamfered vertex is effectively replaced by a new face that connects new points on all edges leading to the original vertex. These new points are exactly \(<\text{chamfer amount}\)> distance from the original vertex along each of these edges. New chamfer faces are created with the material ID of one of the neighboring faces (picked at random) and a smoothing group which is an intersection of all neighboring smoothing groups.

For example, if you chamfer one corner of a box, the single corner vertex is replaced by a triangular face whose vertices move along the three edges that led to the corner. Outside faces are rearranged and split to use these three new vertices, and a new triangle is created at the corner.

Alternatively, you can create open space around the chamfered vertices; for details, see Chamfer Vertices dialog on page 2344.
Top: The original vertex selection
Center: Vertices chamfered
Bottom: Vertices chamfered with Open on

Chamfer Settings Opens the Chamfer Vertices dialog on page 2344, which lets you chamfer vertices via interactive manipulation and toggle the Open option.

If you click this button after performing a manual chamfer, the same chamfer is performed on the current selection as a preview and the dialog opens with Chamfer Amount set to the amount of the last manual extrusion.

Target Weld Allows you to select a vertex and weld it to a neighboring target vertex. Target Weld works only with pairs of contiguous vertices; that is, vertices connected by a single edge.

In Target Weld mode, the mouse cursor, when positioned over a vertex, changes to a + cursor. Click and then move the mouse; a dashed, rubber-band
line connects the vertex to the mouse cursor. Position the cursor over another, neighboring vertex and when the + cursor appears again, click the mouse. The first vertex moves to the position of the second and the two are welded. Target Weld remains active until you click the button again or right-click in the viewport.

**Connect** Creates new edges between pairs of selected vertices.

Connect does not let the new edges cross. Thus, for example, if you select all four vertices of a four-sided polygon and then click Connect, only two of the vertices will be connected. In this case, to connect all four vertices with new edges, use **Cut** on page 1417.

**Remove Isolated Vertices** Deletes all vertices that don't belong to any polygons.

**Remove Unused Map Verts** Certain modeling operations can leave unused (isolated) map vertices that show up in the Unwrap UVW editor on page 1856, but cannot be used for mapping. You can use this button to automatically delete these map vertices.

**Weight** Sets the weight of selected vertices. Used by the **NURMS subdivision option** on page 2326 and by the **MeshSmooth modifier** on page 1505. Increasing a vertex weight tends to pull the smoothed result toward the vertex.

For detailed descriptions of these controls, see Edit Geometry Rollout (Polymesh and Edit Poly) [edit geometry rollout] on page 1409.
Vertex Properties rollout

Edit Vertex Colors group

Use these controls to assign the color, and illumination color (shading) of selected vertices.

**Color** Click the color swatch to change the color of selected vertices.

**Illumination** Click the color swatch to change the illumination color of selected vertices. This lets you change the illumination without changing the vertex's color.

**Alpha** Lets you set specific alpha values of selected vertices. These alpha values are maintained by the pipeline and can be used in conjunction with vertex color to provide full RGBA data for export.

Select Vertices By group

**Color/Illumination** Determines whether to select vertices by vertex color values or vertex illumination values.

**Color Swatch** Displays the Color Selector on page 371, where you can specify a color to match.

**Select** Depending on which radio button is chosen, selects all vertices whose vertex color or illumination values either match the color swatch, or are within the range specified by the RGB spinners.

**Range** Specifies a range for the color match. All three RGB values in the vertex color or illumination must either match the color specified by the color swatch.
in Select By Vertex Color, or be within plus or minus the values in the Range spinners. Default=10.

**Subdivision Surface rollout**

For information about the Subdivision Surface rollout settings, see Subdivision Surface Rollout (Polymesh) subdivsion surface rollout editable poly on page 2325.

**Subdivision Displacement rollout**

For information about the Subdivision Displacement rollout settings, see Subdivision Displacement Rollout (Polymesh) subdivsion displacement rollout editable poly on page 2330.

**Paint Deformation rollout**

Paint Deformation lets you stroke elevated and indented areas directly onto object surfaces. For more information, see Paint Deformation Rollout (Polymesh) paint deformation rollout editable poly on page 2333.

---

**Editable Poly (Edge)**

Select an editable poly object. > Modify panel > Selection rollout > Edge

Select an editable poly object. > Modify panel > Modifier Stack display > Expand Editable Poly. > Edge

Select an editable poly object. > Quad menu > Tools 1 quadrant > Edge

An edge is a line connecting two vertices that forms the side of a polygon. An edge can’t be shared by more than two polygons. Also, the normals of the two polygons should be adjacent. If they aren’t, you wind up with two edges that share vertices.

At the editable poly Edge sub-object level, you can select single and multiple edges and transform them using standard methods. This topic covers the Edit Geometry and Edit Edges rollouts; for other controls, see Editable Poly on page 2240.
NOTE Besides edges, each polygon has one or more internal diagonals that determine how the polygon is triangulated by 3ds Max. Diagonals can't be manipulated directly, but you can use the Turn on page 1387 and Edit Triangulation on page 1386 functions to change their positions.

Procedures

Example: To use the Cut and Turn features:

3ds Max provides a convenient function for turning edges, which, along with the Cut feature, streamlines the custom modeling process considerably. Specifically, cutting a new polygon into existing geometry minimizes the number of extra visible edges, typically adding none or one. And after using cut, the Turn function lets you adjust any diagonal with a single click.

1. In the Perspective viewport, add a Plane object. This object is available from the Create panel > Standard Primitives > Object Type rollout. By default, the Plane object is divided into 4 x 4 polygons. If you don't see the polygons in the Perspective viewport, press F4 to activate Edged Faces view mode.

2. Convert the Plane object to Editable Poly format. If you're not sure how, continue in this step; otherwise, skip to the next step after converting. To convert the object, right-click once in the Perspective viewport to exit create mode. This leaves the object selected. Right-click again in the Perspective viewport, and then at the bottom of the Transform quadrant,
choose Convert To > Convert To Editable Poly. Alternatively, apply the Edit Poly modifier.

The object is now an editable poly and the command panel switches to the Modify panel.

3 Cut is available at the object level as well as at every sub-object level. On the Edit Geometry rollout, find the Cut button, and then click it.

4 In the Perspective viewport, position the mouse cursor in the center of a corner polygon, such as the one closest to you, click once, and then move the mouse around the viewport.
Two or three lines appear and move as you move the mouse. One line connects the mouse cursor to the original click location, and indicates where the next cut will appear when you click the mouse button. Another connects to a corner of the polygon; this connection changes depending on the mouse position. And, if the cursor isn't over an edge or a vertex (it changes appearance if it is, depending on which), a third line connects the mouse cursor to another vertex.

This demonstrates one aspect of the new Cut functionality; in previous versions, the first click in a Cut operation connected to two corners of the polygon.

Continue cutting in a rectangular pattern, clicking once at the center of a different polygon, finish by clicking once more at the starting point, and then right-click to exit Cut mode.
The result is a rectangle across four polygons, without any connecting visible edges. In previous versions, you would have had eight connecting visible edges: two in each of the original polygons. Note that all the edges you created are selected, and ready for further transformation or editing.

6 Cut a rectangle into the center of a single polygon.
In this case you end up with a single, additional visible edge instead of seven, as in previous versions. The edge connects corner of the new polygon with a corner of the original one. This new edge is not selected, but the ones you created explicitly are.
Connecting the remaining corners are a number of diagonals on page 8551, which serve to fully triangulate the polygons. The new Turn function lets you manipulate each of these with a single click.

7 Go to the Edge sub-object level, and then, on the Edit Edges rollout, click Turn.
All diagonals, including those created from the Cut operations, appear as dashed lines.
Click a diagonal to turn it, and then click it again to return it to its original status.

In Turn mode, click a diagonal (dashed line) once to turn it.

Each diagonal has only two different available positions, given no changes in any other diagonals’ or edges’ positions.

Compare this with the Edit Triangulation tool, with which you must click two vertices to change a diagonal’s position.

This simple demonstration shows how, when manually subdividing a polygon mesh for modeling and animation purposes, you can save a good deal of time by using the Cut and Turn tools in 3ds Max.

To create a shape from one or more edges:

1. Select the edges you want to make into shapes.
2. On the Edit Edges rollout, click Create Shape From Selection.
3. Make changes, as needed, on the Create Shape dialog that appears.
   - Enter a curve name or keep the default.
   - Choose Smooth or Linear as the shape type.
4. Click OK.

The resulting shape consists of one or more splines whose vertices are coincident with the vertices in the selected edges. The Smooth option results in vertices using smooth values, while the Linear option results in linear splines with corner vertices.

If the selected edges are not continuous, or if they branch, the resulting shape will consist of more than one spline. When the Create Shape function runs into a branching 'Y' in the edges, it makes an arbitrary decision as to which edge produces which spline. If you need to control
this, select only those edges that will result in a single spline, and perform a Create Shape operation repeatedly to make the correct number of shapes. Finally, use Attach on page 655 in the Editable Spline to combine the shapes into one.

Above: Original object

Below: Object with edges selected
Above: Selected edges removed from original object

Below: Unwanted edges removed

Interface

Selection rollout

See Editable Poly on page 2248 for information on the Select rollout settings.
**Soft Selection rollout**

Soft Selection controls apply a smooth falloff between selected sub-objects and unselected ones. When Use Soft Selection is on, unselected sub-objects near your selection are given partial selection values. These values are shown in the viewports by means of a color gradient on the vertices, and optionally on the faces. They affect most types of sub-object deformations, such as the Move, Rotate, and Scale functions, as well as any deformation modifiers (such as Bend) applied to the object. This provides a magnet-like effect with a sphere of influence around the selection.

For more information, see Soft Selection Rollout on page 2014.

**Edit Edges rollout**

This rollout includes commands specific to edge editing.

**NOTE** To delete edges, select them and press the Delete key. This deletes all selected edges and attached polygons, which can create one or more holes in the mesh. To delete edges without creating holes, use Remove on page 1378.

**Insert Vertex** Lets you subdivide visible edges manually.

After turning on Insert Vertex, click an edge to add a vertex at that location. You can continue subdividing polygons as long as the command is active.

To stop inserting edges, right-click in the viewport, or click Insert Vertex again to turn it off.
**Remove** Deletes selected edges and combines the polygons that use them.

Removing one edge is like making it invisible. The mesh is affected only when all or all but one of the edges depending on one vertex are removed. At that point, the vertex itself is deleted and the surface is retriangulated.

To delete the associated vertices when you remove edges, press and hold Ctrl while executing a Remove operation, either by mouse or with the Backspace key. This option, called Clean Remove, ensures that the remaining polygons are planar.

Left: The original edge selection  
Center: Standard Remove operation leaves extra vertices.  
Right: Clean Remove with Ctrl+Remove deletes the extra vertices.
Edges with the same polygon on both sides usually can’t be removed.

**WARNING** Use of Remove can result in mesh shape changes and non-planar polygons.

**Split** Divides the mesh along the selected edges. This does nothing when applied to a single edge in the middle of a mesh. The vertices at the end of affected edges must be separable in order for this option to work. For example, it would work on a single edge that intersects an existing border, since the border vertex can be split in two. Additionally, two adjacent edges could be split in the middle of a grid or sphere, since the shared vertex can be split.

**Extrude** Lets you extrude edges manually via direct manipulation in the viewport. Click this button, and then drag vertically on any edge to extrude it.

![Extrusion Diagram]

When extruding a vertex or edge interactively in the viewport, you set the extrusion height by moving the mouse vertically and the base width by moving the mouse horizontally.

Extruding an edge moves it along a normal and creates new polygons that form the sides of the extrusion, connecting the edge to the object. The extrusion has either three or four sides; three if the edge was on a border, or four if it was shared by two polygons. As you increase the length of the extrusion, the base increases in size, to the extent of the vertices adjacent to the extruded edge’s endpoints.

Following are important aspects of edge extrusion:

- When over a selected edge, the mouse cursor changes to an Extrude cursor.
- Drag vertically to specify the extent of the extrusion, and horizontally to set the size of the base.
With multiple edges selected, dragging on any one extrudes all selected edges equally.

You can drag other edges in turn to extrude them while the Extrude button is active. Click Extrude again or right-click in the active viewport to end the operation.

Chamfer box showing extruded edge

Extrude Settings  Opens the Extrude Edges dialog on page 2350, which lets you perform extrusion via interactive manipulation.

If you click this button after performing a manual extrusion, the same extrusion is performed on the current selection as a preview and the dialog opens with Extrusion Height set to the amount of the last manual extrusion.

Weld Combines selected edges that fall within the threshold specified in Weld dialog on page 2359.

You can weld only edges that have one polygon attached; that is, edges on a border. Also, you cannot perform a weld operation that would result in illegal geometry (e.g., an edge shared by more than two polygons). For example, you cannot weld opposite edges on the border of a box that has a side removed.

Weld Settings  Opens the Weld dialog on page 2359, which lets you specify the weld threshold.
**Chamfer** Click this button and then drag edges in the active object. To chamfer edges numerically, click the Chamfer Settings button and change the Chamfer Amount value.

If you chamfer multiple selected edges, all of them are chamfered identically. If you drag an unselected edge, any selected edges are first deselected.

An edge chamfer “chops off” the selected edges, creating a new polygon connecting new points on all visible edges leading to the original vertex. The new edges are exactly <chamfer amount> distance from the original edge along each of these edges. New chamfer faces are created with the material ID of one of the neighboring faces (picked at random) and a smoothing group which is an intersection of all neighboring smoothing groups.

For example, if you chamfer one edge of a box, each corner vertex is replaced by two vertices moving along the visible edges that lead to the corner. Outside faces are rearranged and split to use these new vertices, and a new polygon is created at the corner.

![Using Chamfer at the Edge level](image)

Alternatively, you can create open space around the chamfered edges; for details, see Chamfer Edges dialog on page 2344.

**Chamfer Settings** Opens the Chamfer Edges dialog on page 2344, which lets you chamfer edges via interactive manipulation and toggle the Open option.

If you click this button after performing a manual chamfer, the same chamfer is performed on the current selection as a preview and the dialog opens with Chamfer Amount set to the amount of the last manual chamfer.
**Target Weld** Allows you to select an edge and weld it to a target edge. When positioned over an edge, the cursor changes to a + cursor. Click and move the mouse and a dashed line appears from the vertex with an arrow cursor at the other end of the line. Position the cursor over another edge and when the + cursor appears again, click the mouse. The first edge is moved to the position of the second, and the two are welded.

You can weld only edges that have one polygon attached; that is, edges on a border. Also, you cannot perform a weld operation that would result in illegal geometry (e.g., an edge shared by more than two polygons). For example, you cannot weld opposite edges on the border of a box that has a side removed.

**Bridge** Connects border edges on an object with a polygon “bridge.” Bridge connects only border edges; that is, edges that have a polygon on only one side. This tool is particularly useful when creating edge loops or profiles.

There are two ways to use Bridge in Direct Manipulation mode (that is, without opening the Bridge Edges settings dialog):

- Select two or more border edges on the object, and then click Bridge. This immediately creates the bridge between the pair of selected borders using the current Bridge settings, and then deactivates the Bridge button.

- If no qualifying selection exists (that is, two or more selected border edges), clicking Bridge activates the button and places you in Bridge mode. First click a border edge and then move the mouse; a rubber-band line connects the mouse cursor to the clicked edge. Click a second edge on a different border to bridge the two. This creates the bridge immediately using the current Bridge settings; the Bridge button remains active for connecting more edges. To exit Bridge mode, right-click the active viewport or click the Bridge button.

The new polygons that result from a Bridge operation are automatically selected; you can see this by accessing the Polygon sub-object level.
Using Bridge at the Edge level

**NOTE** Bridge always creates a straight-line connection between edges. To make the bridge connection follow a contour, apply modeling tools as appropriate after creating the bridge. For example, bridge two edges, and then use **Bend** on page 1165.

**Bridge Settings** Opens the Bridge Edges dialog on page 2341, which lets you add polygons between pairs of edges via interactive manipulation.

**Connect** Creates new edges between pairs of selected edges using the current Connect Edges dialog settings. Connect is particularly useful for creating or refining edge loops.

**NOTE** You can connect only edges on the same polygon. Also, Connect will not let the new edges cross. For example, if you select all four edges of a four-sided polygon and then click Connect, only neighboring edges are connected, resulting in a diamond pattern.
Connecting two or more edges using the Settings dialog creates equally spaced edges. The number of edges is set in the dialog. When you click the Connect button, the current dialog settings are applied to the selection.

Connect Settings Opens the Connect Edges dialog on page 2345, which lets you preview the Connect results, specify the number of edge segments created by the operation, and set spacing and placement for the new edges.

Create Shape From Selection After selecting one or more edges, click this button to create a spline shape from the selected edges. A Create Shape dialog appears, letting you name the shape and set it to Smooth or Linear. The new shape’s pivot is placed at the center of the poly object.
An edge selection (top); a smooth shape (center); a linear shape (bottom)

**Weight** Sets the weight of selected edges. Used by the NURMS subdivision option on page 2326 and by the MeshSmooth modifier on page 1505. Increasing an edge weight tends to push the smoothed result away.

**Crease** Specifies how much creasing is performed on the selected edge or edges. Used by the NURMS subdivision option on page 2326 and by the MeshSmooth modifier on page 1505.
At low settings, the edge is relatively smooth. At higher settings, the crease becomes increasingly visible. At 1.0, the highest setting, the edge becomes a hard crease.

**Edit Tri[angulation]** Lets you modify how polygons are subdivided into triangles by drawing internal edges, or diagonals on page 8551.

In **Edit Triangulation** mode, you can see the current triangulation in the viewport, and change it by clicking two vertices on the same polygon.

To edit triangulation manually, turn on this button. The hidden edges appear. Click a polygon vertex. A rubber-band line appears, attached to the cursor. Click a non-adjacent vertex to create a new triangulation for the polygon.

**TIP** For easier editing of triangulation, use the Turn command instead (see following).

**Turn** Lets you modify how polygons are subdivided into triangles by clicking diagonals. When you activate Turn, the diagonals on page 8551 become visible as dashed lines in wireframe and edged-faces views. In Turn mode, click a diagonal to change its position. To exit Turn mode, right-click in the viewport or click the Turn button again.

Each diagonal has only two available positions at any given time, so clicking a diagonal twice in succession simply returns it to its original position. But changing the position of a nearby diagonal can make a different alternate position available to a diagonal.
For more information on how to use Turn with the enhanced Cut tool, see this procedure on page 1368.

**Edit Geometry rollout**

- **Repeat Last**
- **Constraints:** None
- **Preserve UVs**
- **Create**
- **Collapse**
- **Attach**
- **Detach**
- **Slice Plane**
  - **Split**
  - **Slice**
  - **Reset Plane**
- **QuickSlice**
  - **Cut**
- **MSmooth**
- **Tessellate**
- **Make Planar**
  - X
  - Y
  - Z
- **View Align**
  - **Grid Align**
- **Relax**
- **Hide Selected**
- **Unhide All**
- **Hide Unselected**
- **Named Selections:**
  - **Copy**
  - **Paste**
  - **Delete Isolated Vertices**
  - **Full Interactivity**

For detailed descriptions of these controls, see *Edit Geometry Rollout (Polymesh and Edit Poly)* on page 1409.

**Subdivision Surface rollout**

For information about the Subdivision Surface rollout settings, see *Subdivision Surface Rollout (Polymesh)* on page 2325.
Subdivision Displacement rollout

For information about the Subdivision Displacement rollout settings, see Subdivision Displacement Rollout (Polymesh) on page 2330.

Paint Deformation rollout

Paint Deformation lets you stroke elevated and indented areas directly onto object surfaces. For more information, see Paint Deformation Rollout (Polymesh) on page 2333.

Editable Poly (Border)

Select an editable poly object. > Modify panel > Selection rollout > Border

Select an editable poly object. > Modify panel > Modifier Stack display > Expand Editable Poly. > Border

Select an editable poly object. > Quad menu > Tools 1 quadrant > Border

A border is a linear section of a mesh that can generally be described as the edge of a hole. This is usually a sequence of edges with polygons on only one side. For example, a box primitive on page 389 doesn't have a border, but the teapot on page 416 object has several: on the lid, on the body, on the spout, and two on the handle. If you create a cylinder and then delete an end polygon, the adjacent row of edges forms a border.

At the editable poly Border sub-object level, you can select single and multiple borders and transform them using standard methods. This topic covers the Edit Geometry and Edit Borders rollouts; for other controls, see Editable Poly on page 2240.

Procedures

To create a polygon that closes the surface at the selected border:

1. At the Border sub-object level, select any open edge.
   This selects the entire closed loop of continuous open edges that make up the border selection.

2. Click Cap.
Interface

Selection rollout

See Editable Poly on page 2248 for information on the Selection rollout settings.

Soft Selection rollout

Soft Selection controls apply a smooth falloff between selected sub-objects and unselected ones. When Use Soft Selection is on, unselected sub-objects near your selection are given partial selection values. These values are shown in the viewports by means of a color gradient on the vertices, and optionally on the faces. They affect most types of sub-object deformations, such as the Move, Rotate, and Scale functions, as well as any deformation modifiers (such as Bend) applied to the object. This provides a magnet-like effect with a sphere of influence around the selection.

For more information, see Soft Selection Rollout on page 2014.

Edit Borders rollout

This rollout includes commands specific to editing borders.

NOTE To delete a border, select it and press the Delete key. This deletes the border and all attached polygons.

Extrude Lets you extrude a border manually via direct manipulation in the viewport. Click this button, and then drag vertically on any border to extrude it.
Extruding a border moves it along a normal and creates new polygons that form the sides of the extrusion, connecting the border to the object. The extrusion can form a varying number of additional sides, depending on the geometry near the border. As you increase the length of the extrusion, the base increases in size, to the extent of the vertices adjacent to the extruded border's endpoints.

Following are important aspects of border extrusion:

- When the mouse cursor is over a selected border, it changes to an Extrude cursor.

- To specify the extent of the extrusion, drag vertically, and to set the size of the base, drag horizontally.

- With multiple borders selected, dragging on any one extrudes all selected borders equally.

- While the Extrude button is active, you can extrude other borders in turn by dragging them. Click Extrude again or right-click in the active viewport to end the operation.

**Extrude Settings** Opens the Extrude Edges dialog on page 2350, which lets you perform extrusion via interactive manipulation.

If you click this button after performing a manual extrusion, the same extrusion is performed on the current selection as a preview and the dialog opens with Extrusion Height set to the amount of the last manual extrusion.

**Insert Vertex** Lets you subdivide border edges manually.

After turning on Insert Vertex, click a border edge to add a vertex at that location. You can continue subdividing border edges as long as the command is active.

To stop inserting vertices, right-click in the viewport, or click Insert Vertex again to turn it off.

**Chamfer** Click this button and then drag a border in the active object. The border need not be selected first.

If you chamfer multiple selected borders, all of them are chamfered identically. If you drag an unselected border, any selected borders are first deselected.

A border chamfer essentially “frames” the border edges, creating a new set of edges paralleling the border edges, plus new diagonal edges at any corners. These new edges are exactly <chamfer amount> distance from the original edges. New chamfer faces are created with the material ID of one of the
neighboring faces (picked at random) and a smoothing group which is an
intersection of all neighboring smoothing groups.
Alternatively, you can create open space around the chamfered borders,
especially cutting away at the open edges; for details, see Chamfer Edges
dialog on page 2344.

Chamfer Settings Opens the Chamfer Edges dialog on page 2344, which
lets you chamfer borders via interactive manipulation and toggle the Open
option.
If you click this button after performing a manual chamfer, the same chamfer
is performed on the current selection as a preview and the dialog opens with
Chamfer Amount set to the amount of the last manual chamfer.

Cap Caps an entire border loop with a single polygon.
Select the border, and then click Cap.

Bridge Connects pairs of borders on an object with polygon “bridges.” There
are two ways to use Bridge in Direct Manipulation mode (that is, without
opening the Bridge Settings dialog):
■ Select an even number of borders on the object, and then click Bridge.
  This immediately creates the bridge between each pair of selected borders
  using the current Bridge settings, and then deactivates the Bridge button.
■ If no qualifying selection exists (that is, two or more selected borders),
clicking Bridge activates the button and places you in Bridge mode. First
  click a border edge and then move the mouse; a rubber-band line connects
  the mouse cursor to the clicked edge. Click a second edge on a different
  border to bridge the two. This creates the bridge immediately using the
  current Bridge settings; the Bridge button remains active for connecting
  more pairs of borders. To exit Bridge mode, right-click the active viewport
  or click the Bridge button.

The new polygons that result from a Bridge operation are automatically
selected; you can see this by accessing the Polygon sub-object level.
NOTE Bridge always creates a straight-line connection between border pairs. To make the bridge connection follow a contour, apply modeling tools as appropriate after creating the bridge. For example, bridge two borders, and then use Bend on page 1165.

Bridge Settings Opens the Bridge dialog on page 2339, which lets you connect pairs of borders via interactive manipulation.

Connect Creates new edges between pairs of selected border edges. The edges are connected from their midpoints.

You can connect only edges on the same polygon.

Connect will not let the new edges cross. Thus, for example, if you select all four edges of a four-sided polygon and then click Connect, only neighboring edges are connected, resulting in a diamond pattern.

Connect Settings Lets you preview the Connect and specify the number of edge segments created by the operation. To increase the mesh resolution around the new edge, increase the Connect Edge Segments setting.

Create Shape From Selection After selecting one or more borders, click this button to create a spline shape from the selected edges. A Create Shape dialog appears, letting you name the shape and set it to Smooth or Linear. The new shape's pivot is placed at the center of the poly object.

Weight Sets the weight of selected borders. Used by the NURMS subdivision option on page 2326.
Increasing an edge weight tends to push the smoothed result away.

**Crease** Specifies how much creasing is performed on the selected border or borders. Used by the NURMS subdivision option on page 2326. At low settings, the border is relatively smooth. At higher settings, the crease becomes increasingly visible. At 1.0, the highest setting, the border is not smoothed at all.

**Edit Tri[angulation]** Lets you modify how polygons are subdivided into triangles by drawing internal edges, or diagonals on page 8551. To edit triangulation manually, turn on this button. The hidden edges appear. Click a polygon vertex. A rubber-band line appears, attached to the cursor. Click a non-adjacent vertex to create a new triangulation for the polygon.

**TIP** For easier editing of triangulation, use the Turn command instead (see following).

**Turn** Lets you modify how polygons are subdivided into triangles by clicking diagonals. When you activate Turn, the diagonals on page 8551 become visible as dashed lines in wireframe and edged-faces views. In Turn mode, click a diagonal to change its position. To exit Turn mode, right-click in the viewport or click the Turn button again. Each diagonal has only two available positions at any given time, so clicking a diagonal twice in succession simply returns it to its original position. But changing the position of a nearby diagonal can make a different alternate position available to a diagonal.

For more information on how to use Turn with the enhanced Cut tool, see this procedure on page 1368.
Edit Geometry rollout

For detailed descriptions of these controls, see Edit Geometry Rollout (Polymesh and Edit Poly) on page 1409.

Subdivision Surface rollout

For information about the Subdivision Surface rollout settings, see Subdivision Surface Rollout (Polymesh) on page 2325.
Subdivision Displacement rollout

For information about the Subdivision Displacement rollout settings, see Subdivision Displacement Rollout (Polymesh) on page 2330.

Paint Deformation rollout

Paint Deformation lets you stroke elevated and indented areas directly onto object surfaces. For more information, see Paint Deformation Rollout (Polymesh) on page 2333.

Editable Poly (Polygon/Element)

Select an editable poly object. > Modify panel > Selection rollout > Polygon or Element

Select an editable poly object. > Modify panel > Modifier Stack display > Expand Editable Poly. > Polygon/Element

Select an editable poly object. > Quad menu > Tools 1 quadrant > Polygon or Element

A polygon is a closed sequence of three or more edges connected by a surface. Polygons provide the renderable surface of editable poly objects.

At the Editable Poly (Polygon) sub-object level, you can select single and multiple polygons and transform them using standard methods. At the Element sub-object level you can select and edit groups of contiguous polygons. For further distinctions between polygon and element, see Editable Poly > Selection rollout on page 2248. This topic covers the Edit Polygons/Elements rollout and Edit Geometry rollout functions for these sub-object types; for other controls, see Editable Poly on page 2240.

NOTE  Workflow enhancements in the Editable Poly user interface give you a choice of editing methods. See Editable Poly Workflow on page 2241 for more information.
Interface

Selection rollout

See Editable Poly > Selection rollout on page 2248 for information on the Selection rollout settings.

Soft Selection rollout

Soft Selection controls apply a smooth falloff between selected sub-objects and unselected ones. When Use Soft Selection is on, unselected sub-objects near your selection are given partial selection values. These values are shown in the viewports by means of a color gradient on the vertices, and optionally on the faces. They affect most types of sub-object deformations, such as the Move, Rotate, and Scale functions, as well as any deformation modifiers (such as Bend) applied to the object. This provides a magnet-like effect with a sphere of influence around the selection.

For more information, see Soft Selection Rollout on page 2014.

Edit Polygons/Elements rollout

At the Element sub-object level, this rollout includes commands that are common to both polygons and elements. At the Polygon level, it contains those as well as a number more that are unique to polygons. The commands available at both levels are Insert Vertex, Flip, Edit Triangulation, Retriangulate, and Turn.
NOTE To delete polygons or elements, select them and press the Delete key. If Delete Isolated Vertices on page 1422 is off, this can result in isolated vertices; that is, vertices with no associated face geometry.

**Insert Vertex** Lets you subdivide polygons manually. Applies to polygons, even if at the element sub-object level.

After turning on Insert Vertex, click a polygon to add a vertex at that location. You can continue subdividing polygons as long as the command is active. To stop inserting vertices, right-click in the viewport, or click Insert Vertex again to turn it off.

**Extrude** Lets you perform manual extrusion via direct manipulation in the viewport. Click this button, and then drag vertically on any polygon to extrude it.

Extruding polygons moves them along a normal and creates new polygons that form the sides of the extrusion, connecting the selection to the object. Following are important aspects of polygon extrusion:

- When over a selected polygon, the mouse cursor changes to an Extrude cursor.
- Drag vertically to specify the extent of the extrusion, and horizontally to set the size of the base.
- With multiple polygons selected, dragging on any one extrudes all selected polygons equally.
- You can drag other polygons in turn to extrude them while the Extrude button is active. Click Extrude again or right-click in the active viewport to end the operation.
Extrude Settings Opens the Extrude Polygons dialog on page 2349, which lets you perform extrusion via interactive manipulation.

If you click this button after performing an extrusion, the same extrusion is performed on the current selection as a preview and the dialog opens with Extrusion Height set to the amount of the last manual extrusion.

Outline Lets you increase or decrease the outside edge of each contiguous group of selected polygons.
Outline is often used after an extrusion or bevel to adjust the size of the extruded faces. It doesn’t scale the polygons; only changes the size of the outer edge. For example, in the following illustration, note that the sizes of the inner polygons remain constant.
Extruded polygons (top), outline expanded (middle), outline reduced (bottom)

Note that inner polygons do not change size.
**Outline Settings** Opens the Outline Polygons dialog, which lets you perform outlining by a numeric setting.

**Bevel** Lets you perform manual beveling via direct manipulation in the viewport. Click this button, and then drag vertically on any polygon to extrude it. Release the mouse button and then move the mouse vertically to outline the extrusion. Click to finish.

- When over a selected polygon, the mouse cursor changes to a Bevel cursor.
- With multiple polygons selected, dragging on any one bevels all selected polygons equally.
- You can drag other polygons in turn to bevel them while the Bevel button is active. Click Bevel again or right-click to end the operation.

**Bevel Settings** Opens the Bevel Polygons dialog on page 2337, which lets you perform beveling via interactive manipulation.

If you click this button after performing a bevel, the same bevel is performed on the current selection as a preview and the dialog opens with the same settings used for the previous bevel.
**Inset** Performs a bevel with no height; that is, within the plane of the polygon selection. Click this button, and then drag vertically on any polygon to inset it.

- When over a selected polygon, the mouse cursor changes to an Inset cursor.
- With multiple polygons selected, dragging on any one insets all selected polygons equally.
- While the Inset button is active, you can drag other polygons in turn to inset them. To end the operation, click Inset again or right-click.

Inset works on a selection of one or more polygons. As with Outline, only the outer edges are affected.

**Inset Settings** Opens the Inset Polygons dialog on page 2353, which lets you inset polygons via interactive manipulation.

If you click this button after performing a manual inset, the same inset is performed on the current selection as a preview and the dialog opens with Inset Amount set to the amount of the last manual inset.

**Bridge** Connects two polygons or polygon selections on an object with a polygon “bridge.” There are two ways to use Bridge in Direct Manipulation mode (that is, without opening the Bridge Settings dialog):

- Make two separate polygon selections on the object, and then click Bridge. This creates the bridge immediately using the current Bridge settings, and then deactivates the Bridge button.
If no qualifying selection exists (that is, two or more discrete polygon selections), clicking Bridge activates the button and places you in Bridge mode. First click a polygon and move the mouse; a rubber-band line connects the mouse cursor to the clicked polygon. Click a second polygon to bridge the two. This creates the bridge immediately using the current Bridge settings; the Bridge button remains active for connecting more pairs of polygons. To exit Bridge mode, right-click the active viewport or click the Bridge button.

Using Bridge at the Polygon level

NOTE Bridge always creates a straight-line connection between polygon pairs. To make the bridge connection follow a contour, apply modeling tools as appropriate after creating the bridge. For example, bridge two polygons, and then use Bend on page 1165.

Bridge Settings Opens the Bridge dialog on page 2339, which lets you connect pairs of polygon selections via interactive manipulation.

Flip Reverses the directions of the normals of selected polygons, hence their facing.

Hinge From Edge Lets you perform a manual hinge operation via direct manipulation in the viewport. Make a polygon selection, click this button, and then drag vertically on any edge to hinge the selection. The mouse cursor changes to a cross when over an edge.
The hinge edge needn't be part of the selection. It can be any edge of the mesh. Also, the selection needn't be contiguous.

Hinging polygons rotates them about an edge and creates new polygons that form the sides of the hinge, connecting the selection to the object. It's essentially an extrusion with rotation, with the exception that, if the hinge edge belongs to a selected polygon, that side is not extruded. The manual version of Hinge From Edge works only with an existing polygon selection.

**TIP** To avoid inadvertently hinging about a backfacing edge, turn on Ignore Backfacing.

- **Hinge Settings** Opens the Hinge From Edge dialog on page 2352, which lets you hinge polygons via interactive manipulation. If you click this button after performing a manual hinge, the dialog opens with Angle set to the extent of the last manual hinge.

- **Extrude Along Spline** Extrudes the current selection along a spline.
You can extrude a single polygon (1) or a selection of contiguous (2) or non-contiguous polygons (3). Extrusion 2 uses Taper Curve and Twist (available via Settings). Extrusion 3 uses Taper Amount; each extrusion has a different curve rotation.

Make a selection, click Extrude Along/On Spline, and then select a spline in the scene. The selection is extruded along the spline, using the spline's current orientation, but as though the spline's start point were moved to the center of each polygon or group.

- **Extrude Along Spline Settings** Opens the Extrude Polygons Along Spline dialog on page 2347, which lets you extrude along splines via interactive manipulation.

- **Edit Triangulation** Lets you modify how polygons are subdivided into triangles by drawing internal edges.
In Edit Triangulation mode, you can see the current triangulation in the viewport, and change it by clicking two vertices on the same polygon.

To manually edit triangulation, turn on this button. The hidden edges appear. Click a polygon vertex. A rubber-band line appears, attached to the cursor. Click a non-adjacent vertex to create a new triangulation for the polygon.

Retriangulate Lets 3ds Max automatically do its best triangulation on the polygon or polygons currently selected.

Retriangulate attempts to optimize how selected polygons are subdivided into triangles.
**Turn** Lets you modify how polygons are subdivided into triangles by clicking diagonals. When you activate Turn, the diagonals on page 8551 become visible as dashed lines in wireframe and edged-faces views. In Turn mode, click a diagonal to change its position. To exit Turn mode, right-click in the viewport or click the Turn button again.

Each diagonal has only two available positions at any given time, so clicking a diagonal twice in succession simply returns it to its original position. But changing the position of a nearby diagonal can make a different alternate position available to a diagonal.

For more information on how to use Turn with the enhanced Cut tool, see this procedure on page 1368.

**Edit Geometry rollout**
For detailed descriptions of these controls, see Edit Geometry Rollout (Polymesh and Edit Poly) on page 1409.

**Polygon: Material IDs rollout**

![Polygon: Material IDs rollout](image)

**Set ID** Lets you assign a particular material ID to selected polygons for use with multi/sub-object materials on page 6120 and other applications. Use the spinner or enter the number from the keyboard. The total number of available IDs is 65,535.

**Select ID** Selects polygons corresponding to the Material ID specified in the adjacent ID field. Type or use the spinner to specify an ID, then click the Select ID button.

**[Select By Name]** This drop-down list shows the names of sub-materials if an object has a Multi/Sub-Object material assigned to it. Click the drop arrow and choose a sub-material from the list. The sub-objects that are assigned that material are selected. If an object does not have a Multi/Sub-Object material assigned, the name list is unavailable. Likewise, if multiple objects are selected that have an Edit Patch, Edit Spline, or Edit Mesh modifier applied, the name list is inactive.

**NOTE** Sub-material names are those specified in the Name column on the material's Multi/Sub-Object Basic Parameters rollout; these are not created by default, and must be specified separately from any material names.

**Clear Selection** When on, choosing a new ID or material name deselects any previously selected sub-objects. When off, selections are cumulative, so new ID or sub-material name selections add to the existing selection set of patches or elements. Default=on.
Polygon: Smoothing Groups rollout

Use these controls to assign selected polygons to different smoothing groups on page 8724, and to select polygons by smoothing group.

To assign polygons to one or more smoothing groups, select the polygons, and then click the number(s) of the smoothing group(s) to assign them to.

Select By SG (Smoothing Group) Displays a dialog that shows the current smoothing groups. Select all polygons that belong to a group by clicking the corresponding numbered button and clicking OK.

If Clear Selection is on, any previously selected polygons are first deselected. If Clear Selection is off, the new selection is added to any existing selection.

Clear All Removes any smoothing group assignments from selected polygons.

Auto Smooth Sets the smoothing groups based on the angle between polygons. Any two adjacent polygons will be put in the same smoothing group if the angle between their normals is less than the threshold angle, set by the spinner to the right of this button.

Threshold This spinner (to the right of Auto Smooth) lets you specify the maximum angle between the normals of adjacent polygons that determines whether those polygons will be put in the same smoothing group.

Polygon: Vertex Colors rollout

Use these controls to assign selected polygons to different smoothing groups on page 8724, and to select polygons by smoothing group.

To assign polygons to one or more smoothing groups, select the polygons, and then click the number(s) of the smoothing group(s) to assign them to.

Select By SG (Smoothing Group) Displays a dialog that shows the current smoothing groups. Select all polygons that belong to a group by clicking the corresponding numbered button and clicking OK.

If Clear Selection is on, any previously selected polygons are first deselected. If Clear Selection is off, the new selection is added to any existing selection.

Clear All Removes any smoothing group assignments from selected polygons.

Auto Smooth Sets the smoothing groups based on the angle between polygons. Any two adjacent polygons will be put in the same smoothing group if the angle between their normals is less than the threshold angle, set by the spinner to the right of this button.

Threshold This spinner (to the right of Auto Smooth) lets you specify the maximum angle between the normals of adjacent polygons that determines whether those polygons will be put in the same smoothing group.

Polygon: Vertex Colors rollout

Use these controls to assign selected polygons to different smoothing groups on page 8724, and to select polygons by smoothing group.

To assign polygons to one or more smoothing groups, select the polygons, and then click the number(s) of the smoothing group(s) to assign them to.

Select By SG (Smoothing Group) Displays a dialog that shows the current smoothing groups. Select all polygons that belong to a group by clicking the corresponding numbered button and clicking OK.

If Clear Selection is on, any previously selected polygons are first deselected. If Clear Selection is off, the new selection is added to any existing selection.

Clear All Removes any smoothing group assignments from selected polygons.

Auto Smooth Sets the smoothing groups based on the angle between polygons. Any two adjacent polygons will be put in the same smoothing group if the angle between their normals is less than the threshold angle, set by the spinner to the right of this button.

Threshold This spinner (to the right of Auto Smooth) lets you specify the maximum angle between the normals of adjacent polygons that determines whether those polygons will be put in the same smoothing group.
Use these controls to assign the color, illumination color (shading), and alpha (transparency) values of vertices on selected polygons or elements.

**Color** Click the color swatch to change the color of vertices on selected polygons or elements.

**Illumination** Click the color swatch to change the illumination color of vertices on selected polygons or elements. This lets you change the illumination without changing the vertex's color.

**Alpha** Lets you assign an alpha (transparency) value to vertices on selected polygons or elements. The spinner value is a percentage; zero is completely transparent and 100 is completely opaque.

### Subdivision Surface rollout

For information about the Subdivision Surface rollout settings, see Subdivision Surface Rollout (Polymesh) on page 2325.

### Subdivision Displacement rollout

For information about the Subdivision Displacement rollout settings, see Subdivision Displacement Rollout (Polymesh) on page 2330.

### Paint Deformation rollout

Paint Deformation lets you stroke elevated and indented areas directly onto object surfaces. For more information, see Paint Deformation Rollout (Polymesh) on page 2333.

---

**Edit Geometry Rollout (Polymesh and Edit Poly)**

Create or select an editable poly or Edit Poly object. > Modify panel > Edit Geometry rollout

The Edit Geometry rollout provides global controls for changing the geometry of the poly object, at either the top (Object) level or the sub-object levels. The controls are the same at all levels, except as noted in the descriptions below.
Interface

Repeat Last

Repeats the most recently used command.

For example, if you extrude a polygon, and want to apply the same extrusion to several others, select the others, and then click Repeat Last.
You can apply a spline extrusion of a single polygon (left) repeatedly to other single polygons (1) or to multiple polygon selections, contiguous (2) or not (3).

**NOTE** Repeat Last does not repeat all operations. For example, it does not repeat transforms. To determine which command will be repeated when you click the button, check the tooltip for the Repeat Last button on the command panel, which gives the name of the last operation that can be repeated. If no tooltip appears, nothing will happen when you click the button.

**Constraints** Lets you use existing geometry to constrain sub-object transformation. Choose the constraint type:

- **None**: No constraints. This is the default option.
- **Edge**: Constrains sub-object transformations to edge boundaries.
- **Face**: Constrains sub-object transformations to individual face surfaces.
- **Normal**: Constrains each sub-object’s transformations to its normal, or the average of its normals. In most cases, this causes sub-objects to move perpendicular to the surface.

**NOTE** This constraint works like the Push modifier on page 1640, including the fact that it operates on unmodified base normals. Edited normals are unsupported.
When set to Edge, moving a vertex will slide it along one of the existing edges, depending on the direction of the transformation. If set to Face, the vertex moves only on the polygon's surface.

**NOTE** You can set constraints at the Object level, but their use pertains primarily to sub-object levels. The Constraints setting persists at all sub-object levels.

**Preserve UVs** When on, you can edit sub-objects without affecting the object’s UV mapping. You can choose any of an object’s mapping channels to preserve or not; see Preserve UVs Settings, following. Default=off.

Without Preserve UVs, there is always a direct correspondence between an object’s geometry and its UV mapping. For example, if you map an object and then move vertices, the texture moves along with the sub-objects, whether you want it to or not. If you turn on Preserve UVs, you can perform minor editing tasks without changing the mapping.

**TIP** For best results with Preserve UVs at the vertex level, use it for limited vertex editing. For example, you’ll usually have no trouble moving a vertex within edge or face constraints. Also, it’s better to perform one big move than several smaller moves, as multiple small moves can begin to distort the mapping. If, however, you need to perform extensive geometry editing while preserving mapping, use the Channel Info utility on page 6486 instead.
Preserve UVs Settings Opens the Preserve Map Channels dialog on page 2355, which lets you specify which vertex color channels and/or texture channels (map channels) to preserve. By default, all vertex color channels are off (not preserved), and all texture channels are on (preserved).

Create Lets you create new geometry. How this button behaves depends on which level is active:

- **Object, Polygon, and Element levels** Lets you add polygons in the active viewport. After you turn on Create, click three or more times in succession anywhere, including on existing vertices, to define the shape of the new polygon. To finish, right-click.

  While creating a polygon at the Polygon or Element level, you can delete the most recently added vertex by pressing Backspace. You can do this repeatedly to remove added vertices in reverse order of placement.

  You can start creating polygons in any viewport, but all subsequent clicks must take place in the same viewport.

  **TIP** For best results, click vertices in counterclockwise (preferred) or clockwise order. If you use clockwise order, the new polygon will face away from you.

- **Vertex level** Lets you add vertices to a single selected poly object. After selecting the object and clicking Create, click anywhere in space to add free-floating (isolated) vertices to the object. The new vertices are placed on the active construction plane unless object snapping is on. For example, with face snapping on, you can create vertices on object faces.

- **Edge and Border levels** Lets you create an edge between a pair of non-adjacent vertices on the same polygon. Click Create, click a vertex, and then move the mouse. A rubber-band line extends from the vertex to the mouse cursor. Click a second, non-adjacent vertex on the same polygon to connect them with an edge. Repeat, or, to exit, right-click in the viewport or click Create again.

  Edges you create separate the polygons. For example, by creating an edge inside a quadrilateral polygon, you turn it into two triangles.

Collapse (Vertex, Edge, Border, and Polygon levels only) Collapses groups of contiguous selected sub-objects by welding their vertices to a vertex at the selection center.
Using collapse on a vertex selection

Using collapse on a polygon selection

Attach  Lets you attach other objects in the scene to the selected poly object. After activating Attach, click an object to attach to the selected object. Attach remains active, so you can continue clicking objects to attach them. To exit, right-click in the active viewport or click the Attach button again.

You can attach any type of object, including splines, patch objects, and NURBS surfaces. Attaching a non-mesh object converts it to editable-poly format.

When you attach an object, the materials of the two objects are combined in the following way:

- If the object being attached does not have a material assigned, it inherits the material of the object it is being attached to.
Handle inherits material from the cup it is being attached to.

- Likewise, if the object you're attaching to doesn't have a material, it inherits the material of the object being attached.
- If both objects have materials, the resulting new material is a multi/sub-object material on page 6120 that includes the input materials. A dialog appears offering three methods of combining the objects' materials and material IDs. For more information, see Attach Options Dialog on page 2233.
  Attach remains active in all sub-object levels, but always applies to objects.

**Attach List** Lets you attach other objects in the scene to the selected mesh. Click to open the Attach List dialog, which works like Select From Scene on page 206 to let you choose multiple objects to attach.
Shaded view of model (upper left); wireframe view of model (upper right); model with objects attached (lower left); and subsequent multi/sub-object material (lower right)

**Detach (sub-object levels only)** Detaches the selected sub-objects and the polygons attached to them as a separate object or element(s).

With an Editable Poly object, when you click Detach, the software prompts you for the options specified on the Detach dialog. With an Edit Poly object, Detach on the Modify panel automatically uses those settings. To change them, click Detach Settings (see following).

**Detach Settings** Opens the Detach dialog on page 1423, which lets you set several options. Available only with Edit Poly objects; with Editable Poly, this dialog opens automatically when you click Detach.
Cut and Slice group

These knife-like tools let you subdivide the poly mesh along a plane (Slice) or in a specific area (Cut). Also see Full Interactivity on page 1422.

Slice Plane (sub-object levels only) Creates a gizmo for a slice plane that you can position and rotate to specify where to slice. Also enables the Slice and Reset Plane buttons; click Slice to create new edges where the plane intersects the geometry.

If you use Slice Plane from the modeling ribbon, the Slice, Split, and Reset Plane controls are available on the Slice Mode contextual panel on page 2098.

If snapping is off, you see a preview of the slice as you transform the slice plane. To perform the slice, click the Slice button.

NOTE At the Polygon or Element sub-object level, Slice Plane affects only selected polygons. To slice the entire object, use Slice Plane at any other sub-object level, or at the object level.

Split When on, the QuickSlice and Cut operations create double sets of vertices at the points where the edges are divided. This lets you easily delete the new polygons to create holes, or animate the new polygons as separate elements.

Slice (sub-object levels only) Performs the slice operation at the location of the slice plane. Available only when Slice Plane is on. This tool slices the poly just like the “Operate On: Polygons” mode of the Slice modifier on page 1727.

Left: Using Slice; Right: After slicing and moving the pieces apart

Reset Plane (sub-object levels only) Returns the Slice plane to its default position and orientation. Available only when Slice Plane is on.
QuickSlice Lets you quickly slice the object without having to manipulate a gizmo. Make a selection, click QuickSlice, and then click once at the slice start point and again at its endpoint. You can continue slicing the selection while the command is active.

To stop slicing, right-click in the viewport, or click QuickSlice again to turn it off.

With Quickslice on, you can draw a line across your mesh in any viewport, including Perspective and Camera views. The mesh is sliced interactively as you move the line endpoint.

**NOTE** At the Object level, QuickSlice affects the entire object. To slice only specific polygons, use QuickSlice on a polygon selection at the Poly sub-object level.

**NOTE** At the Polygon or Element sub-object level, QuickSlice affects only selected polygons. To slice the entire object, use QuickSlice at any other sub-object level, or at the object level.

Cut Lets you create edges from one polygon to another or within polygons. Click at the start point, move the mouse and click again, and continue moving and clicking to create new connected edges. Right-click once to exit the current cut, whereupon you can start a new one, or right-click again to exit Cut mode.
While cutting, the mouse cursor icon changes to show the type of sub-object it’s over, to which the cut will be made when you click. The following illustration shows the three different cursor icons.

Top: Cutting to a vertex
Center: Cutting to an edge
Bottom: Cutting to a polygon

Cut is available at the object level and all sub-object levels.
**NOTE** You can use Cut with Turn for enhanced productivity. For more information, see this procedure on page 1368.

---

**MSmooth** Smoothes the object using the current settings. This command uses subdivision functionality similar to that of the MeshSmooth modifier on page 1505 with NURMS Subdivision, but unlike NURMS subdivision, it applies the smoothing instantly to the selected area of the control mesh.

![Smoothing a low-poly object with NURMS subdivision](image)

**MSmooth Settings** Opens the MeshSmooth Selection dialog on page 2354, which lets you specify how smoothing is applied.

**Tessellate** Subdivides all polygons in the object based on the Tessellation settings on page 2358. Tessellation is useful for increasing local mesh density while modeling. You can subdivide any selection of polygons. Two tessellation methods are available: Edge and Face.

**Tessellate Settings** Opens the Tessellate Selection dialog on page 2358, which lets you specify how smoothing is applied.

**Make Planar** Forces all selected sub-objects to be coplanar. The plane's normal is the average surface normal of the selection. At the Object level, forces all vertices in the object to become coplanar.
**TIP** One application for Make Planar is making a flat side on an object. Normally, you would use a contiguous selection set. If the selection includes vertices on various parts of the object, the vertices are still made planar, but with distorting effects on the rest of the geometry.

X/Y/Z Makes all selected sub-objects planar and aligns the plane with the corresponding plane in the object’s local coordinate system. The plane used is the one to which the button axis is perpendicular; so, for example, clicking the X button aligns the object with the local YZ axis.

At the Object level, makes all vertices in the object planar.

**View Align** Aligns all vertices in the object to the plane of the active viewport. At sub-object levels, this function affects only selected vertices or those belonging to selected sub-objects.

In orthographic viewports, aligning to the view has the same effect as aligning to the construction grid when the home grid is active. Aligning to a perspective viewport (including camera and light views), reorients the vertices to a plane that is parallel to the camera’s viewing plane. This plane is perpendicular to the view direction that is closest to the vertices’ average position.
Grid Align Aligns all vertices in the selected object to the plane of the current view. At sub-object levels, aligns only selected sub-objects. This command aligns the selected vertices to the current construction plane. The current plane is specified by the active viewport in the case of the home grid. When using a grid object, the current plane is the active grid object.

Relax Applies the Relax function to the current selection, using the Relax dialog settings (see following). Relax normalizes mesh spacing by moving each vertex toward the average location of its neighbors. It works the same way as the Relax modifier on page 1643. At the object level, Relax applies to the entire object. At sub-object levels, Relax applies only to the current selection.

Relax Settings Opens the Relax dialog on page 2357, which lets you specify how the Relax function is applied.

Hide Selected (Vertex, Polygon, and Element levels only) Hides selected sub-objects.

Unhide All (Vertex, Polygon, and Element levels only) Restores hidden sub-objects to visibility.

Hide Unselected (Vertex, Polygon, and Element levels only) Hides unselected sub-objects.
Named Selections (sub-object levels only)

Lets you copy and paste named selection sets of sub-objects between objects. Start by creating one or more named selection sets, copy one, select a different object, go to the same sub-object level, and then paste the set.

**NOTE** This function uses sub-object IDs, so if the target object’s geometry differs from that of the source object, the pasted selection will probably comprise a different set of sub-objects.

For more information, see Named Selection Sets on page 185.

**Copy** Opens a dialog that lets you specify a named selection set to place into the copy buffer.

**Paste** Pastes the named selection from the copy buffer.

Delete Isolated Vertices (Edge, Border, Polygon, and Element levels only) When on, deletes isolated vertices when you delete a selection of contiguous sub-objects. When off, deleting sub-objects leaves all vertices intact. Default=on.

**Full Interactivity (editable poly only)** Toggles the level of feedback for the QuickSlice and Cut tools, as well as all settings dialogs. Available with editable poly objects, but not the Edit Poly modifier.

When on (the default), the final result is always visible as you use the mouse to manipulate the tool or change a numeric setting. With Cut and QuickSlice, when Full Interactivity is turned off, only the rubber-band line is visible until you click. Similarly, with numeric settings in dialogs, the final result is visible only when you release the mouse button after changing the setting.

The state of Full Interactivity doesn't affect changing a numeric setting from the keyboard. Whether it’s on or off, the setting takes effect only when you exit the field by pressing Tab or Enter, or by clicking a different control in the dialog.

Subdivision Surface Rollout (Polymesh)

Create or select an editable poly object. > Modify panel > Subdivision Surface rollout
Applies subdivision to the object in the style of MeshSmooth on page 1505, so you can work on a lower-resolution "cage" mesh and simultaneously see a smoother, subdivided result. This rollout is available at all sub-object levels, as well as at the object level, and always affects the entire object.

### Interface

#### Subdivision Surface

- **Smooth Result**
- **Use NURMS Subdivision**
- **Isoline Display**
- **Show Cage**

**Display**

- Iterations: 1
- Smoothness: 1.0

**Render**

- Iterations: 0
- Smoothness: 1.0

**Separate By**

- Smoothing Groups
- Materials

**Update Options**

- Always
- When Rendering
- Manually

**Update**

#### Smooth Result

Applies the same smoothing group to all polygons.

#### Use NURMS Subdivision

Applies smoothing via the NURMS method. See NURMS on page 1508. The difference between NURMS in Editable Poly and MeshSmooth is that the latter gives you access to control vertices, but the former does not.

You control the degree of smoothing with the Iterations controls in the Display and Render groups.
NOTE The remaining controls on this rollout take effect only when Use NURMS Subdivision is on.

Isoline Display When on, 3ds Max displays only isolines: the object's original edges, before smoothing. The benefit of using this option is a less cluttered display. When off, 3ds Max displays all faces added by NURMS Subdivision; thus, higher Iterations settings (see Display group on page 2328) result in a greater number of lines. Default=on.

Smoothed box with Isoline Display off (left) and Isoline Display on (right).

NOTE Applying a modifier to an Editable Poly object cancels the effect of the Isoline Display option; the wireframe display reverts to showing all polygons in the object. This is not, however, always the case with the MeshSmooth modifier. Most deformation and mapping modifiers maintain the isoline display, but others, such as the selection modifiers (except Volume Select) and the Turn To ... modifiers, cause the interior edges to be displayed.

Show Cage Toggles the display of a two-color wireframe that shows the editable poly object before modification or subdivision. The cage colors are shown as swatches to the right of the check box. The first color represents unselected sub-objects, and the second color represents selected sub-objects. Change a color by clicking its swatch.
The cage displays the original structure of the edited object.

Typically this feature is used in conjunction with the NURMS Subdivision feature, or with the MeshSmooth modifier on page 1505, because it lets you easily toggle visibility of the unsmoothed base object while simultaneously viewing the smoothed result, but it works with any modifier. When used with a modifier, turn on Show End Result to make Show Cage available.

**TIP** Show Cage is particularly helpful when used with the Symmetry modifier on page 1803.

**Display group**

**Iterations** Sets the number of iterations used to smooth the poly object. Each iteration generates all polygons using the vertices created from the previous iteration. Range=0 to 10.

When the Iterations check box in the Render group (see following) is off, this setting controls iterations both in the viewports and at render time. When the check box is on, this setting controls iterations only in the viewports.
WARNING Use caution when increasing the number of iterations. The number of vertices and polygons in an object (and thus the calculation time) can increase as much as four times for each iteration. Applying four iterations to even a moderately complex object can take a long time to calculate. To stop calculation and revert to the previous iteration setting, press Esc.

Smoothness Determines how sharp a corner must be before polygons are added to smooth it. A value of 0.0 prevents the creation of any polygons. A value of 1.0 adds polygons to all vertices even if they lie on a plane. When the Smoothness check box in the Render group (see following) is off, this setting controls smoothness both in the viewports and at render time. When the check box is on, this setting controls smoothness only in the viewports.

**Render group**

Applies a different number of smoothing iterations and/or a different Smoothness value to the object at render time.

**TIP** Use a low number of iterations and/or a lower Sharpness value for modeling, and higher values for rendering. This lets you work quickly with a low-resolution object in the viewports, while producing a smoother object for rendering.

**Iterations** Lets you choose a different number of smoothing iterations on page 2328 to be applied to the object at render time. Turn on Iterations, and then use the spinner to its right to set the number of iterations.

**Smoothness** Lets you choose a different Smoothness value to be applied to the object at render time. Turn on Smoothness, and then use the spinner to its right to set the smoothness value.

**Separate By group**

**Smoothing Groups** Prevents the creation of new polygons at edges between faces that don’t share at least one smoothing group.

**Materials** Prevents the creation of new polygons for edges between faces that do not share Material IDs.

**Update Options group**

Sets manual or render-time update options, for situations where the complexity of the smoothed object is too high for automatic updates.
You can also use the Iterations settings in the Render group to set a greater
degree of smoothing to be applied only at render time.

**Update Option** Choose how the software is to update the mesh:

- **Always** Updates the object automatically whenever you change any
  MeshSmooth settings.

- **When Rendering** Updates the viewport display of the object only at
  render time.

- **Manually** Any settings you change don't take effect until you click the
  Update button.

**Update** Updates the object in the viewport to match the current MeshSmooth
settings. Works only when you choose When Rendering or Manually.

---

### Subdivision Displacement Rollout (Polymesh)

Create or select an editable poly object. > Modify panel > Subdivision
Displacement rollout

Create or select an editable poly object. > modeling ribbon > Subdivision panel
> Activate Use Displacement. > Displacement panel

Specifies surface approximation settings for subdividing an editable poly object.
These controls work like the surface approximation settings for NURBS on
page 2416 surfaces. They are used when you apply a displacement map on page
6059 to the editable poly object.

**NOTE** These settings differ from the Subdivision Surface rollout on page 2325 settings
in that, while the latter are applied at the same modifier-stack level as the mesh,
subdivision displacement is always applied at the top of the stack, when the mesh
is used for rendering. So, for example, applying the Symmetry modifier to an
object that uses surface subdivision would affect the subdivided mesh, but would
not affect an object that uses subdivision displacement only.

**TIP** By default, subdivision displacement is visible only when the object is rendered.
To see the results of displacement in the viewports, apply the Displace Mesh
modifier on page 1068.
Interface

Subdivision Displacement Rollout (Polymesh)
Displacement panel on modeling ribbon

**Subdivision Displacement** When on, polygons are subdivided to accurately displace the poly object, using the method and settings you specify in the Subdivision Presets and Subdivision Method groups. When off, the poly is displaced by moving existing vertices, the way the Displace modifier on page 1313 does. Default=off.

**NOTE** On the modeling ribbon, this control is available as the Subdivision panel > Use Displacement on page 2148 button.

**Split Mesh** Affects the seams of displaced poly objects; also affects texture mapping. When on, the poly object is split into individual polygons before it is displaced; this helps preserve texture mapping. When off, the poly is not split and an internal method is used to assign texture mapping. Default=on.

**TIP** This parameter is required because of an architectural limitation in the way displacement mapping works. Turning Split Mesh on is usually the better technique, but it can cause problems for objects with clearly distinct faces, such as boxes, or even spheres. A box’s sides might separate as they displace outward, leaving gaps. And a sphere might split along its longitudinal edge (found in the rear for spheres created in the Top view) unless you turn off Split Mesh. However, texture mapping works unpredictably when Split Mesh is off, so you might need to add a Displace Mesh modifier on page 1068 and make a snapshot on page 950 of the poly. You would then apply a UVW Map modifier on page 1932 and then reassign mapping coordinates to the displaced snapshot poly.
Subdivision Presets group & Subdivision Method group

These settings determine how 3ds Max applies the displacement map when Subdivision Displacement is on. They are identical to the Tessellation settings on the Surface Approximation rollout on page 2737 used for NURBS surfaces.

Paint Deformation Rollout (Polymesh)

Paint Deformation lets you push, pull, or otherwise affect vertices by dragging the mouse cursor over the object surface. At the object level, Paint Deformation affects all vertices in the selected object. At sub-object levels, it affects only selected vertices (or vertices that belong to selected sub-objects), and recognizes soft selection.

By default, deformation occurs in the normal direction of each vertex. 3ds Max continues to use a vertex's original normal, but you can opt to use the altered normal direction for a more dynamic modeling process, or even deform along a specific axis.

NOTE Paint Deformation cannot be animated.

TIP You can streamline the painting process by using the Brush Presets tools on page 8044.

Procedures

To paint deformation onto a mesh object:

1. Apply an Edit Poly modifier on page 1332 to an object, or convert the object to Editable Poly on page 2240 format. Paint Deformation uses existing geometry, so the object should have enough mesh resolution for the desired deformation.

2. Do either of the following:
   - To deform anywhere on the object, remain at the object level, or work at a sub-object level with no sub-objects selected.
   - To deform only specific areas of an object, go to a sub-object level and then select the sub-objects in the area to deform.

3. On the Paint Deformation rollout, click Push/Pull.
4 Set Push/Pull value to a negative value to push into the object surface, or to a positive value to pull the surface outward. The higher the absolute value, the greater the effect.

5 Set Brush Size and Brush Strength.

6 Position the mouse cursor over the surface to be deformed. As you move the mouse, the “brush” reorients dynamically to show the normal direction of the portion of the mesh currently under the cursor. You can use the normal direction of deformed surfaces as the push/pull direction by choosing Deformed Normals.

7 Press the mouse button and drag to deform the surface. If you paint in the same spot repeatedly without lifting the mouse button, the effect is cumulative up to the maximum Push/Pull Value setting.

**Interface**

Paint Deformation has three modes of operation: Push/Pull, Relax, and Revert. Only one of these modes can be active at a time. The remaining settings control the effect of the active deformation mode.

For any mode, choose the mode, change settings as necessary, and then drag the cursor over the object to paint the deformation.
To paint deformation anywhere on the object, remain at the object level, or work at a sub-object level with no sub-objects selected. To deform only specific areas of an object, go to a sub-object level and select the sub-objects in the area to deform.

**Push/Pull** Moves vertices into the object surface (push) or out of the surface (pull). The direction and extent of pushing or pulling is determined by the Push/Pull Value setting.

**TIP** To reverse the Push/Pull direction while painting, press and hold Alt.

**NOTE** Push/Pull supports soft selection in that effective strength falls off with the selection value of soft-selected sub-objects.

**Relax** Normalizes the distances between vertices by moving each vertex to a position calculated from the average of its neighbors. Relax uses the same method as the Relax modifier on page 1643.

Use Relax to push apart vertices that are too close together, or to pull together vertices that are too far apart.

**Revert** Lets you gradually “erase” or reverse the effects of Push/Pull or Relax by painting. Affects only vertices deformed since the most recent Commit operation. If no vertices qualify for reversion, the Revert button is unavailable.

**TIP** You can switch to Revert mode temporarily by pressing and holding the Ctrl key while painting deformation in Push/Pull or Relax mode.

**Push/Pull Direction group**

This setting lets you specify whether pushing or pulling vertices occurs with respect to surface normals, original or deformed, or along a specific axis. Default=Original Normals.

Painting deformations with Original Normals typically moves vertices perpendicular to the original surface; using Deformed Normals tends to move vertices outward after their initial deformation, resulting in a “puffy” effect.

**Original Normals** When chosen, pushing or pulling a vertex moves it in the direction of its normal before deformation. Repeated applications of Paint Deformation always move each vertex in the same direction it moved originally.

**Deformed Normals** When chosen, pushing or pulling a vertex moves it in the current direction of the normal; that is, after deformation.
Transform axis X/Y/Z When chosen, pushing or pulling a vertex moves it along the specified axis, using the current reference coordinate system on page 922.

Push/Pull Value Determines the direction and maximum extent of a single application of the push/pull operation. Positive values “pull” vertices out of the object surface, and negative values “push” vertices into the surface. Default =10.0.

A single application is defined as painting (that is, dragging once or more over the same area) without lifting the mouse button.

TIP You can use Alt to switch between pushing and pulling with the same value while painting. For example, if you're pulling with a value of 8.5, press and hold Alt to start pushing with a value of -8.5.

Brush Size Sets the radius of the circular brush. Only vertices inside the brush circle are deformed. Default=20.0.

TIP To change the brush radius interactively, release the mouse button, press and hold Shift+Ctrl+left mouse button, and then drag the mouse. This also works with all other painter-interface features in 3ds Max such as Skin > Paint Weights and VertexPaint.

Brush Strength Sets the rate at which the brush applies the Push/Pull value. A low Strength value applies the effect more slowly than a high value. Range=0.0 to 1.0. Default=1.0.

TIP To change the brush strength interactively, release the mouse button, press and hold Shift+Alt+left mouse button, and then drag the mouse. This also works with all other painter-interface features in 3ds Max such as Skin > Paint Weights and VertexPaint.

Brush Options Click this button to open the Painter Options dialog on page 1989, where you can set various brush-related parameters.

Commit Makes any deformation changes permanent, “baking” them into the object geometry. After using Commit, you can no longer apply Revert to changes up to that point.

Cancel Eliminates all changes since the initial application of Paint Deformation or the most recent Commit operation.
Editable Poly Settings Dialogs

These topics describe support dialogs for tools for editing Editable Polymesh surfaces. The dialogs are used in Interactive Manipulation mode on page 1339, in which you can adjust settings parametrically and see the results immediately in the viewports.

**IMPORTANT** With the exception noted following, dialog settings persist throughout the current session and affect subsequent use of the related tool. For example, if you change the Segments value for the Bridge tool, and then use the tool subsequently in Direct Manipulation mode on page 1339, the altered Segments value is applied automatically.

The exception is where you apply a setting directly, typically by dragging on a sub-object. For example, changing the Chamfer Amount setting in a dialog doesn’t apply to chamfering a sub-object directly, because you set the amount by dragging.

**Bevel Polygons Dialog (Polymesh)**

Select an Edit Poly or editable poly object. > Modify panel > Polygon sub-object level > Edit Polygons rollout > Bevel Settings button

Select an Edit Poly or editable poly object. > Polygon sub-object level > Quad menu > tools 2 quadrant > Bevel Settings button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Polygon sub-object level > Polygons panel > Shift+click Bevel button or choose Bevel Settings from drop-down.

Beveling involves first extruding and then scaling the extruded polygon(s). Use these settings for beveling polygons in Interactive Manipulation mode.
Interface

### Bevel Polygons

**Bevel Type group**

- **Group** Beveling takes place along the average normal of each contiguous group of polygons. If you bevel multiples of such groups, each group moves along its own averaged normal.

- **Local Normal** Beveling takes place along each selected polygon's normal.

- **By Polygon** Bevels each polygon individually.

**Height** Specifies the extent of the extrusion in scene units. You can extrude selected polygons outward or inward, depending on whether the value is positive or negative.

**Outline Amount** Makes the outer border of selected polygons bigger or smaller, depending on whether the value is positive or negative.

---

**Apply** Applies the settings to the current selection, retaining them if you then make another selection.

**OK** Applies the settings to the current selection and closes the dialog.

**Cancel** Closes the dialog without applying the settings to the current selection. Does not reverse previous uses of Apply.
Bridge Borders/Polygons Dialog (Polymesh)

Select an Edit Poly or editable poly object. > Modify panel > Polygon or Border sub-object level > Edit Polygons rollout > Bridge Settings button

Select an Edit Poly or editable poly object. > Polygon or Border sub-object level > Quad menu > tools 2 quadrant > Bridge Settings button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Polygon or Border sub-object level > Polygons or Border Edges panel > Shift+click Bridge button or choose Bridge Settings from drop-down.

Use these settings for bridging pairs of polygons, polygon selections, or borders in Interactive Manipulation mode.

**NOTE** Bridge calculates which way the bridge polygons should face. If you bridge two sub-objects so that the bridge goes through the object, the bridge polygons face inward. But if you create a bridge that goes through empty space, such as when connecting sub-objects between two elements, the polygons face outward. To make the bridge polygons face differently, use the Flip function.

Examples of an internal bridge (left) and an external bridge (right), the latter connecting two elements
NOTE Bridging two elements makes them contiguous, combining them into a single element.

Interface

Bridge lets you use existing poly/border selections, or pick them from the dialog. Choose one of the following:

- **Use Specific Polygons/Borders** In this mode, use the Pick buttons to designate polygons or borders for bridging.

- **Use Polygon/Border Selection** If one or more qualifying selection pairs exist, choosing this option connects them immediately. If not, you can select pairs of sub-objects in a viewport to connect them. If you make more than two qualifying selections, Bridge connects them in increasing order of ID. For example, if you select polygon 12, 35, and 89, Bridge connects polygons 12 and 35. But if you then deselect polygon 35, Bridge then connects polygons 12 and 89.

**Polygon/Edge 1/2** Click each Pick button in turn, and then click a polygon or border edge in a viewport. At the Border sub-object level, clicking any edge on a border designates the entire border for bridging. Also, the edges you pick on each border are connected directly, and the remaining edges are connected in consecutive order. You can change the order of the edge correspondences with the Twist settings. Available only in Use Specific mode.
After clicking a sub-object, the Pick button shows its ID number. You can change the selection at any time by clicking a Pick button and picking a different sub-object.

**Twist 1/2** Rotates the order of connection between the edges of the two selections. The two controls let you set a different twist amount for each end of the bridge.

**Segments** Specifies the number of polygons along the length of the bridge connection. This setting also applies to manually bridged polygons.

**TIP** When using Taper, set Segments to a value greater than 1.

**Taper** Sets the extent to which the bridge width becomes smaller or larger toward its center. Negative settings taper the bridge center smaller; positive settings taper it larger.

**NOTE** To change the location of maximum taper, use the Bias setting.

**Bias** Determines the location of maximum taper amount. The range of the Bias value is -99.0 to 99.0. At the default value of 0.0, the taper amount is greatest at the center of the bridge. At -99.0, the taper amount is greatest near the first selected polygon or border; at 99.0, it's greatest near the second selected polygon or border.

**Smooth** Determines the maximum angle between columns across which smoothing can occur. A column is a string of polygons extending along the length of the bridge.

---

**Apply** Applies the settings to the current selection, retaining them if you then make another selection.

**OK** Applies the settings to the current selection and closes the dialog.

**Cancel** Closes the dialog without applying the settings to the current selection. Does not reverse previous uses of Apply.

### Bridge Edges Dialog (Polymesh)

Select an Edit Poly or editable poly object. > Modify panel > Polygon or Border sub-object level > Edit Polygons rollout > Bridge Settings button
Select an Edit Poly or editable poly object. > Polygon or Border sub-object level > Quad menu > tools 2 quadrant > Bridge Settings button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Edge sub-object level > Edges panel > Shift+click Bridge button or choose Bridge Settings from drop-down.

Use these settings for bridging pairs of edges in Interactive Manipulation mode.

NOTE Bridge calculates which way the bridge polygons should face. If you bridge two edges so that the bridge goes through the object, the bridge polygons face inward. But if you create a bridge that goes through empty space, such as when connecting edges between two elements, the polygons face outward, in general. To make the bridge polygons face differently, use the Flip function.

NOTE Bridging edges of two elements makes them contiguous, combining them into a single element.

Interface

![Bridge Edges Interface](image)

Bridge lets you use existing edge selections, or pick them from the dialog. Choose one of the following:

- **Bridge Specific Edges** In this mode, use the Pick buttons to designate polygons or borders for bridging.

- **Use Edge Selection** If one or more qualifying selection pairs exist, choosing this option connects them immediately. If not, you can select pairs of sub-objects in a viewport to connect them.
**Edge 1/Edge 2** Click each Pick button in turn, and then click a border edge in a viewport. Available only in Bridge Specific Edges mode.

After clicking an edge, the Pick button shows its ID number. You can change the selection at any time by clicking a Pick button and picking a different sub-object.

**Segments** Specifies the number of polygons along the length of the bridge connection. This setting also applies to manually bridged edges.

**Smooth** Specifies the maximum angle between columns across which smoothing can occur. A column is a string of polygons extending along the length of the bridge.

**Reverse Triangulation** When bridging two edge selections each of which contains different numbers of edges, two ways of triangulating the bridge polygons are possible. This check box lets you toggle between them.

![Left: Reverse Triangulation on](image1)
![Right: Reverse Triangulation off](image2)

**Bridge Adjacent** Specifies the minimum angle between adjacent edges across which bridging can occur. Edges less than this angle will not be bridged, and instead will be skipped.
Top Left: Edge selections before bridging
Top Right: Segments=2, Bridge Adjacent<83.0
Bottom Left: Bridge Adjacent=83.0
Bottom Right: Bridge Adjacent=126.5

NOTE The above illustration shows, among other things, how setting Bridge Adjacent too high can cause overlapping polygons (left side of the two bottom images), which is undesirable.

---

Apply Applies the settings to the current selection, retaining them if you then make another selection.

OK Applies the settings to the current selection and closes the dialog.

Cancel Closes the dialog without applying the settings to the current selection. Does not reverse previous uses of Apply.

Chamfer Vertices/Edges/Borders Dialog (Polymesh)

Select an Edit Poly or editable poly object. > Modify panel > Vertex/Edge/Border sub-object level > Edit Vertices/Edges/Borders rollout > Chamfer Settings button
Select an Edit Poly or editable poly object. > Vertex/Edge/Border sub-object level > Quad menu > tools 2 quadrant > Chamfer Settings button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Vertex/Edge/Border sub-object level > Vertices/Edges/Border Edges panel > Shift+click Chamfer button or choose Chamfer Settings from drop-down.

Chamfering creates new faces around the chamfered entity, along with connecting edges. Or, with the Open option, you can create an open (empty) area instead. For vertices, edges, and borders, you can use the dialog to set the chamfer amount numerically and to toggle the Open option. The Segments setting applies only to edges and borders.

**Interface**

![Chamfer Edges](image)

- **Chamfer Amount** The extent of the chamfer. Default=1.0.
- **Segments** (edges/borders only) Adds edges and polygons over the area of the chamfer, and, with single chamfered edges, rounds off the chamfer. By default, the chamfer uses a single segment, which covers the chamfered area with a new polygon positioned diagonally with respect to the original corner. The higher the Segments value you use, the more the chamfer is rounded off. If you chamfer two or more adjacent, open edges at a time, the rounding off takes place only at open ends of the edges. No rounding takes place where the edges meet.
- **Open** When on, the chamfered area is deleted, leaving open space. Default=off.

**Connect Edges Dialog (Polymesh)**

Select an Edit Poly or editable poly object. > Modify panel > Edge sub-object level > Edit Edges rollout > Connect Settings button

Select an Edit Poly or editable poly object. > Edge sub-object level > Quad menu > tools 2 quadrant > Connect Settings button
Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Edge sub-object level > Loops panel > Shift+click Connect button or choose Connect Settings from drop-down.

Connecting edges creates new edges between adjacent pairs of selected edges. The Connect Edges dialog settings let you specify the number of new edges, the amount of separation from each other, and their general location.

**TIP** Connecting edges, and in particular the Slide function, work best with ring selections on page 1351.
Interface

**Segments** The number of new edges between each adjacent pair of selected edges. Default=1.

**Pinch** The relative spacing between the new, connecting edges. Negative values move the edges closer together; positive values move them farther apart. Default=0.
If Segments=1, the Pinch setting has no effect.

**Slide** The relative positioning of the new edges. Default=0.
By default, the new edges are centered. Positive values move them in one direction, while negative values move them in the opposite direction. The new edges cannot move beyond existing edges.

**Extrude Polygons Along Spline Dialog (Polymesh)**

Select an Edit Poly or editable poly object. > Modify panel > Polygon sub-object level > Edit Polygons rollout > Extrude Along Spline Settings button

Select an Edit Poly or editable poly object. > Polygon sub-object level > Quad menu > tools 2 quadrant > Extrude Along Spline Settings button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Polygon sub-object level > Polygons panel > Shift+click Extrude On Spline button or choose Extrude On Spline Settings from drop-down.

Use these settings for extruding polygons along splines in Interactive Manipulation mode.
Interface

**Pick Spline** Click this button and then select a spline along which to extrude in the viewport. The spline object's name then appears on the button. If you open this dialog after performing a manual Extrude Along Spline, the name of the spline you used appears on the button.

**Align to face normal** Aligns the extrusion with the face normal, which, in most cases, makes it perpendicular to the extruded polygon(s). When turned off (the default), the extrusion is oriented the same as the spline.

With Align To Face Normal, the extrusion does not follow the original orientation of the spline (1); it's reoriented to match the face normals (2), or averaged normals for contiguous selections. The Rotation option is available only when Align To Face Normal is on.
**Rotation** Sets the rotation of the extrusion. Available only when Align To Face Normal is on. Default=0. Range=-360 to 360.

**Segments** Specifies the number of polygons into which each extruded side is subdivided. This setting also applies to manually extruded polygons.

**Taper Amount** Sets the extent to which the extrusion becomes smaller or larger along its length. Negative settings taper the extrusion smaller; positive settings taper it larger.

**Taper Curve** Sets the rate at which the tapering proceeds. Lower settings result in a more gradual taper; large settings result in a more abrupt taper. Taper Curve affects the thickness of the extrusion between its endpoints, but not the size of the ends.

**Twist** Applies a twist along the length of the extrusion. When using this option, increasing the number of segments will improve the smoothness of the extrusion.

---

**Apply** Applies the settings to the current selection, retaining them if you then make another selection.

**OK** Applies the settings to the current selection and closes the dialog.

**Cancel** Closes the dialog without applying the settings to the current selection. Does not reverse previous uses of Apply.

---

**Extrude Polygons Dialog (Polymesh)**

Select an Edit Poly or editable poly object. > Modify panel > Polygon sub-object level > Edit Polygons rollout > Extrude Settings button

Select an Edit Poly or editable poly object. > Polygon sub-object level > Quad menu > tools 2 quadrant > Extrude Settings button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Polygon sub-object level > Polygons panel > Shift+click Extrude button or choose Extrude Settings from drop-down.

Use these settings for extruding polygons in Interactive Manipulation mode.
Interface

Extrude Polygons

Extrusion Type group

Group Extrusion takes place along the average normal of each contiguous group of polygons. If you extrude multiples of such groups, each group moves along its own averaged normal.

Local Normal Extrusion takes place along each selected polygon’s normal.

By Polygon Extrudes or bevels each polygon individually.

Extrusion Height Specifies the amount of the extrusion in scene units. You can extrude selected polygons outward or inward, depending on whether the value is positive or negative.

Apply Applies the settings to the current selection, retaining them if you then make another selection.

OK Applies the settings to the current selection and closes the dialog.

Cancel Closes the dialog without applying the settings to the current selection. Does not reverse previous uses of Apply.

Extrude Vertices/Edges Dialog (Polymesh)

Select an Edit Poly or editable poly object. > Modify panel > Vertex/Edge/Border sub-object level > Edit Vertices/Edges/Borders rollout > Extrude Settings button
Select an Edit Poly or editable poly object. > Vertex/Edge/Border sub-object level > Quad menu > tools 2 quadrant > Extrude Settings button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Vertex/Edge sub-object level > Vertices/Edges panel > Shift+click Extrude button or choose Extrude Settings from drop-down.

Use this dialog for extruding vertices, edges, and borders in Interactive Manipulation mode.

NOTE At the Border sub-object level, this dialog is named Extrude Edges.

Interface

**Extrude Vertices**

- **Extrusion Height**: Specifies the amount of the extrusion in scene units. You can extrude sub-objects outward or inward, depending on whether the value is positive or negative.

- **Extrusion Base Width**: Specifies the size of the extrusion base in scene units. You can set this as high as you want, but the actual size cannot extend beyond the vertices adjacent to the extruded sub-object(s).

---

**Apply** Applies the settings to the current selection, retaining them if you then make another selection.

**OK** Applies the settings to the current selection and closes the dialog.

**Cancel** Closes the dialog without applying the settings to the current selection. Does not reverse previous uses of Apply.
Hinge Polygons From Edge Dialog (Polymesh)

Select an Edit Poly or editable poly object. > Modify panel > Polygon sub-object level > Edit Polygons rollout > Hinge From Edge Settings button

Select an Edit Poly or editable poly object. > Polygon sub-object level > Quad menu > tools 2 quadrant > Hinge From Edge Settings button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Polygon sub-object level > Polygons panel > Shift+click Hinge button or choose Hinge Settings from drop-down.

Use these settings for hinging polygons in Interactive Manipulation mode.

Interface

**Angle** Quantifies the rotation about the hinge. You can hinge selected polygons outward or inward, depending on whether the value is positive or negative.

**Segments** Specifies the number of polygons into which each extruded side is subdivided. This setting also applies to manually hinged polygons.

**Current Hinge** Click Pick Hinge, and then click an edge to be the hinge. After you designate a hinge, the “Pick Hinge” button text is replaced with “Edge #” where # is the ID number of the hinge edge.

All subsequent hinge operations created via the dialog will use this hinge. To hinge multiple polygons, each from one of its own sides, you must reselect the hinge each time.
Apply Applies the settings to the current selection, retaining them if you then make another selection.

OK Applies the settings to the current selection and closes the dialog.

Cancel Closes the dialog without applying the settings to the current selection. Does not reverse previous uses of Apply.

**Inset Polygons Dialog (Polymesh)**

Select an Edit Poly or editable poly object. > Modify panel > Polygon sub-object level > Edit Polygons rollout > Inset Settings button

Select an Edit Poly or editable poly object. > Polygon sub-object level > Quad menu > tools 2 quadrant > Inset Settings button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Polygon sub-object level > Polygons panel > Shift+click Inset button or choose Inset Settings from drop-down.

Use these settings for insetting polygons in Interactive Manipulation mode.

**Interface**

**Inset Type group**

This setting affects how Inset works with selections of more than one polygon.

**Group** The inset takes place across multiple, contiguous polygons.

**By Polygon** Insets each polygon individually.
Inset Amount Specifies the amount of the inset in scene units.

Apply Applies the settings to the current selection, retaining them if you then make another selection.

OK Applies the settings to the current selection and closes the dialog.

Cancel Closes the dialog without applying the settings to the current selection. Does not reverse previous uses of Apply.

MeshSmooth Selection Dialog (Polymesh)

Select an Edit Poly or editable poly object. > Modify panel > Polygon sub-object level > Edit Geometry rollout > MSmooth Settings button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Polygon sub-object level > Subdivision panel > Shift+click MSmooth (MeshSmooth) button or choose MeshSmooth Settings from drop-down.

This dialog lets you specify how mesh smoothing affects editable poly and Edit Poly objects.

Interface

![MeshSmooth Selection Dialog](image)

Smoothness Determines how sharp a corner must be before polygons are added to smooth it. Smoothness is calculated as the average angle of all edges.
connected to a vertex. A value of 0.0 prevents the creation of any polygons. A value of 1.0 adds polygons to all vertices even if they lie on a plane.

**Separate by Smoothing Groups** Prevents the creation of new polygons at edges between polygons that don’t share at least one smoothing group.

**Separate by Materials** Prevents the creation of new polygons for edges between polygons that do not share Material IDs.

---

**Apply** Applies the settings to the current selection, retaining them if you then make another selection.

**OK** Applies the settings to the current selection and closes the dialog.

**Cancel** Closes the dialog without applying the settings to the current selection. Does not reverse previous uses of Apply.

### Preserve Map Channels Dialog (Polymesh)

Select an Edit Poly or editable poly object. > Modify panel > any sub-object level > Edit Geometry rollout > Preserve UVs button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Polygon sub-object level > Edit panel > Shift+click Preserve UVs button or choose Preserve UVs Settings from drop-down.

Use these settings for specifying which map channels to preserve when editing sub-objects with the Preserve UVs option on. A preserved map channel doesn’t respond to minor editing that changes vertex locations, but a channel whose UVs aren’t preserved allows mapping to be changed by changes in vertex locations.

**Interface**

The dialog contains buttons for all available, data-containing vertex color channels and texture channels. The number and type of buttons displayed vary depending on the state of the object; they can be changed, for example, with the VertexPaint modifier on page 1959 and the Channel Info utility on page 6486.

Click a button to toggle its state. When off, a button is gray and appears higher than the dialog surface. When on, a button is orange and appears pressed in.
**Vertex Color Channels** Displays buttons for any vertex-color channels that contain data. These can be Vertex Colors, Vertex Illumination, and Vertex Alpha. By default, all vertex-color buttons are off, so that associated UVs are affected by sub-object editing. To prevent a channel from being affected by sub-object editing, click its button.

**Texture Channels** Displays buttons for any texture (mapping) channels that contain data. These are identified by number. By default these are on, so that associated UVs are not affected by sub-object editing. To allow a channel to be affected by sub-object editing, click its button.

**Reset All** Returns all channel buttons to their default states: all vertex color channels off, all texture channels on.

---

**Apply** Applies the settings to the current selection, retaining them if you then make another selection.

**OK** Applies the settings to the current selection and closes the dialog.

**Cancel** Closes the dialog without applying the settings to the current selection. Does not reverse previous uses of Apply.
Relax Dialog (Polymesh)

Select an Edit Poly or editable poly object. > Modify panel > object level or any sub-object level > Edit Geometry rollout > Relax Settings button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Polygon sub-object level > Geometry (All) panel > Shift+click Relax button or choose Relax Settings from drop-down.

Use these settings for relaxing vertices in Interactive Manipulation mode. Relax in Edit/Editable Poly works much like the Relax modifier on page 1643: It normalizes the distance between each affected vertex and its neighbors by moving the vertex toward the average position of its neighbors.

NOTE At the object level, Relax applies to the entire object. At any sub-object level, Relax applies to selected sub-objects only.

Interface

Amount Controls how far a vertex moves for each iteration. The value specifies a percentage of the distance from the original location of a vertex to the average location of its neighbors. Range=-1.0 to 1.0. Default=0.5.

Iterations Sets how many times to repeat the Relax process. For each iteration, average locations are recalculated and the Relax Value is reapplied to every vertex. Default=1.

Hold Boundary Points Controls whether vertices at the edges of open meshes are moved. Default=on.

When on, boundary vertices do not move while the rest of the object is relaxed. This option is particularly useful when working with multiple elements within a single object that share open edges.

When this check box is off, all vertices of the object are relaxed.
**Hold Outer Points** When on, preserves the original positions of vertices farthest away from the object center.

---

**Apply** Applies the settings to the current selection, retaining them if you then make another selection.

**OK** Applies the settings to the current selection and closes the dialog.

**Cancel** Closes the dialog without applying the settings to the current selection. Cancel does not reverse previous uses of Apply.

---

**Tessellate Selection Dialog (Polymesh)**

Select an Edit Poly or editable poly object. > Modify panel > Polygon sub-object level > Edit Geometry rollout > Tessellate Settings button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Polygon sub-object level > Subdivision panel > Shift+click Tessellate button or choose Tessellate Settings from drop-down.

Use this dialog to specify how Tessellate subdivides polygons.

**Interface**

![Tessellate Selection](image)

**Edge** Inserts vertices in the middle of each edge and draws lines connecting those vertices. The number of polygons created will equal the number of sides of the original polygon.

**Face** Adds a vertex to the center of each polygon and draws connecting lines from that vertex to the original vertices. The number of polygons created will equal the number of sides of the original polygon.
**Tension** Lets you increase or decrease the Edge tension value. Available only when Type: Edge is active.

A negative value pulls vertices inward from their plane, resulting in a concave effect. A positive value pulls vertices outward from their plane, resulting in a rounding effect.

---

**Apply** Applies the settings to the current selection, retaining them if you then make another selection.

**OK** Applies the settings to the current selection and closes the dialog.

**Cancel** Closes the dialog without applying the settings to the current selection. Does not reverse previous uses of Apply.

---

**Weld Vertices/Edges Dialog (Polymesh)**

Select an Edit Poly or editable poly object. > Modify panel > Vertex or Edge sub-object level > Edit Vertices/Edges rollout > Weld Settings button

Select an Edit Poly or editable poly object. > Vertex or Edge sub-object level > Quad menu > tools 2 quadrant > Weld Settings button

Select an Edit Poly or editable poly object. > Modeling ribbon > Graphite Modeling Tools tab > Polygon Modeling panel > Vertex/Edge sub-object level > Vertices/Edges panel > Shift+click Weld button or choose Weld Settings from drop-down.

Use this dialog for setting the weld threshold for vertices and edges.

**Interface**

![Weld Vertices Dialog](image)
**Weld Threshold** Specifies the maximum distance, in scene units, within which selected sub-objects will be welded. Any vertex or edge that lies outside this threshold (that is, it’s farther than this from the nearest vertex or edge) will not be welded.

**Number of Vertices** Shows the number of vertices before and after the weld. The After quantity updates dynamically as you change the setting with the spinner.

---

**Apply** Applies the settings to the current selection, retaining them if you then make another selection.

**OK** Applies the settings to the current selection and closes the dialog.

**Cancel** Closes the dialog without applying the settings to the current selection. Does not reverse previous uses of Apply.

---

### Patch Objects

With patch modeling, you can create objects that look mesh-like but whose surface curvature can be controlled with handles, like splines. You can create a patch model with built-in patch grids, and can convert most objects to patch format.

### Editable Patch Surface

Create or select an object > Modify panel > Right-click object’s entry in the stack display > Convert To: Editable Patch

Create or select an object > Right-click the object > Transform (lower-right) quadrant of the quad menu > Convert To: > Convert to Editable Patch

Editable Patch provides controls for manipulating an object as a patch object and at five sub-object levels: vertex, handle, edge, patch, and element.

Editable Patch objects provide the same basic functionality as the Edit Patch modifier on page 1329. Because working with them requires less processing and memory, we recommend you use Editable Patch objects rather than the Edit Patch modifier whenever possible.
When you convert an object to Editable Patch format or apply an Edit Patch modifier, 3ds Max converts the object’s geometry into a collection of separate Bezier patches, each patch made up of a framework of vertices and edges, plus a surface.

- The **framework** of control points and connecting tangents defines the surface. Transforming the components of this framework is the primary technique in patch modeling. The framework does not appear in scanline renderings.

- The **surface** is the Bezier patch surface, whose shape is controlled by the vertices and edges. The surface is the renderable geometry of the object.

Prior to version 3 of 3ds Max, some patch objects contained a lattice that appeared separate from the surface. This is no longer the case: The control framework conforms exactly to the surface, making it easier to visualize the results of patch modeling.

The output of the **Surface modifier** on page 1763 is a patch surface. If you are modeling with splines and are using the Surface modifier to generate a patch surface from the spline cage, you can use an **Edit Patch modifier** on page 1329 for further modeling.

**Show End Result**

- Turn on Show End Result on the Modify panel if you have modifiers above the Editable Patch modifier and want to see the result of all the modifiers in the modifier stack. This function will remain on until you turn it off.

**See also:**

- **Edit Modifiers and Editable Objects** on page 1052
- **Modifying at the Sub-Object Level** on page 1054
- **Modifier Stack Controls** on page 8187

**Procedures**

**To work at a sub-object level:**

1. In the modifier stack display, choose a selection level: Element, Patch, Edge, or Vertex.
To attach an object using Edit Patch:
1 Select an editable patch object, or an object with the Edit Patch modifier applied.
2 In the Modify panel > Geometry rollout > Topology group, click Attach.
3 Turn off Reorient, if necessary.
4 Select an object to attach.
The object takes on a patch structure and stays in its original location.
The attached object is now part of the editable patch object. The Tessellation settings for the original object affect attached objects as well.

To attach and reorient an object:
- Turn on Reorient before attaching the object.
The object is both attached and moved to align with the patch object. The pivot of the attached object matches the pivot of the Edit Patch object.

To detach a patch surface:
1 Make a selection at the Patch sub-object level.
2 If you want to reorient the detached surface, turn on Reorient.
3 Click Detach.
   A Detach dialog appears.
4 Name the detached surface.
The detached surface remains in place if you chose not to reorient it. It is deselected and assigned a different color.

To copy a patch surface:
1 Make a selection at the Patch sub-object level.
2 In the Geometry rollout > Topology group, turn on Copy.
3 If you want to reorient the copied surface, turn on Reorient.
4 Click Detach.
   A Detach dialog appears.
5 Name the patch copy.
The copied object remains in place if you chose not to reorient it.

To delete patches:
1 Make a selection at the Patch sub-object level.
2 Click Delete.
The patches disappear.

To subdivide a patch:
1 Make a selection at the Patch sub-object level.
2 Turn on Propagate to maintain surface continuity.
3 Click Subdivide.
The patch selection is subdivided, increasing the number of patches.
You can repeat this process, subdividing multiple times. Each subdivision
increases the number of patches, which become increasingly smaller. The
following figure is an example of modeling a highly subdivided surface.

To subdivide an edge:
1 At the Edge sub-object level, make an edge selection.
A single edge is indicated by its coordinate axis or transform gizmo at
the center of the edge. For multiple edges, the axis icon is at the center
of the selection set.
2 Optionally, turn on Propagate to maintain surface continuity.
3 Click Subdivide.
   The edge selection is subdivided. Each new edge is on the boundary of a
   new, smaller patch.

To add a patch:
1 At the Edge sub-object level, select an open edge (one that bounds a single
   patch, and therefore is not shared with another patch).
2 Click Add Tri or Add Quad.
   A new patch is added to the surface.

To unlock interior edges of selected patches:
1 At the Patch sub-object level, select one or more patches.
2 Right-click the selection and choose Manual Interior from the pop-up
   menu.
   The check mark moves from Auto Interior, the default, to Manual Interior.
   Interior edges and their vertices are now unlocked. If you now transform
   the patch, the interior edges remain static. To transform the interior
   vertices, see the following procedure.

To transform interior vertices:
1 At the Patch sub-object level, select one or more patches.
2 Right-click the selection and choose Manual Interior from the pop-up
   menu.
   The check mark moves from Auto Interior, the default, to Manual Interior.
3 Switch to Handle level.
   The interior vertices appear as yellow squares.
4 Transform the interior vertices of the selected patches.
To anchor a patch:

By default, the welding process shifts the geometry of both patches to a common center. You can anchor one patch so that the other patch moves to its location when the weld occurs.

1. At the Patch (Patch) level, before you begin the weld, select the patch you want anchored.

2. Return to Vertex level and weld the vertices.
   When the weld occurs, the anchor patch remains fixed while the other patch moves to make the weld.

To create a new element, do one of the following:

- Shift+drag one or more patches.
- Shift+extrude one or more patches.
- Shift+extrude one or more edges.
- Shift+drag an element.

Interface

Selection rollout

For information about these settings, see Selection Rollout (Editable Patch) on page 2366.

Soft Selection rollout

For information on the Soft Selection rollout settings, see Soft Selection Rollout on page 2014.

Geometry and Surface Properties rollouts

The Geometry rollout on page 2394 provides functions for editing a patch object and its sub-objects, and the Surface Properties controls let you modify the object's rendering characteristics. For detailed information on sub-object-specific controls, see the topics in this section.
Selection Rollout (Editable Patch)

Create or select an object > Modify panel > Right-click object's entry in the stack display > Convert To: Editable Patch > Selection rollout

Create or select an object > Right-click the object > Transform (lower-right) quadrant of the quad menu > Convert To: > Convert to Editable Patch > Selection rollout

The Selection rollout provides buttons for selecting the sub-object level, working with named selections, display and filter settings, and displays information about selected entities.

Editable Patch has five levels of sub-object editing: Vertex, Handle, Edge, Patch, and Element. The selection you make at each level appears in the viewport as a component of the patch object. Each level maintains its own sub-object selection. When you return to a level, the selection reappears.

Clicking a sub-object level button here is the same as clicking a sub-object level in the modifier stack. Click the button again to turn it off and return to the object selection level.
Vertex Lets you select vertex control points and their vector handles on a patch object. At this level, vertices can be welded and deleted. By default, a transform gizmo or axis tripod appears at the geometric center of the selected vertices. If you turn on Gizmo Preferences on page 8354 > Allow Multiple Gizmos, however, gizmos or tripods appear at all selected vertices. Vector handles appear as small green squares around selected vertices. Also, with certain objects you may see interior vertices represented as yellow squares.

Handle Lets you select vector handles associated with each vertex. This level lets you manipulate the handles without needing to deal with vertices. A Transform gizmo or axis tripod appears at the geometric center of the selected handles.
At this level, vector handles appear as small green squares around all vertices. Also, with certain objects you may see interior vertices represented as yellow squares.

**Edge** Selects a bounding edge of the patch object. At this level, edges can be subdivided, and new patches added to open edges. A Transform gizmo or axis tripod appears in the middle of a single selected edge. For multiple selected edges, the icon is at the selection center.

**Patch** Selects an entire patch. At this level, a patch can be detached, deleted, or its surface subdivided. When a patch is subdivided, the surface is broken into smaller patches, each with its own vertices and edges.

**Element** Select and edit an entire element. An element has contiguous faces.

**TIP** You can highlight selected patches in a shaded display by turning on Shade Selected Faces in the Viewport Properties dialog. Right-click over the viewport name and choose Configure in the menu to display the Viewport Properties dialog. You can also use the default keyboard shortcut, **F2**, to toggle this feature.

**Named Selections group**

These functions work with named sub-object selection sets. To create a named sub-object selection, make the selection, and then enter a name in the Named Selection Sets field on the toolbar. For more information, see Named Selection Sets on page 217.

**Copy** Places a named sub-object selection into the copy buffer. After clicking this button, choose the named sub-object selection from the Copy Named Selection dialog that appears.

**Paste** Pastes the named sub-object selection from the copy buffer.

You can use Copy and Paste to copy sub-object selections between different objects.

**Filter group**

These two check boxes, available only at the Vertex sub-object level, let you select and transform vertices, vectors (handles on the vertices), or both. When a check box is turned off, you can't select the corresponding element type.
Thus, for example, if you turn off Vertices, you can manipulate vectors without accidentally moving a vertex.

**TIP** For easier editing of vectors only, use the Handle sub-object level on page 2380.

You can't turn off both check boxes. When you turn off either check box, the other one becomes unavailable. At that point, you can manipulate the element corresponding to the check box that's on, but you can't turn it off.

**Vertices** When on, you can select and move vertices.

**Vectors** When on, you can select and move vectors.

---

**Lock Handles** Affects only Corner vertices. Locks the tangent vectors together so that when you move one, you move them all. Available only at the Vertex sub-object level.

**By Vertex** When you click a vertex, any handles, edges, or patches that use that vertex, depending on the current sub-object level, are selected. Available only at the Handle, Edge, and Patch sub-object levels.

This also works with Region Select.

**Ignore Backfacing** When on, selection of sub-objects selects only those sub-objects whose normals are visible in the viewport. When off (the default), selection includes all sub-objects, regardless of the direction of their normals. Use this on a complex patch model where you want to select only visible patches.

**NOTE** The state of the Backface Cull setting in the Display panel does not affect sub-object selection. Thus, if Ignore Backfacing is off, you can still select sub-objects, even if you can't see them.

**Shrink** Reduces the sub-object selection area by deselecting the outermost sub-objects. If the selection size can no longer be reduced, the remaining sub-objects are deselected. Unavailable at the Handle sub-object level.

**Grow** Expands the selection area outward in all available directions. Unavailable at the Handle sub-object level.

**Ring** Expands an edge selection by selecting all edges parallel to the selected edges. Available only at the Edge sub-object level.

**Loop** Expands the selection as far as possible, in alignment with selected edges. Available only at the Edge sub-object level.
Select Open Edges Selects all edges that are used by only one patch. Available only at the Edge sub-object level. You can use this to troubleshoot a surface; open edges will be highlighted.

Selection Information At the bottom of the Selection rollout is a text display giving information about the current selection. If multiple sub-objects are selected, or none is selected, the text gives the number and type selected. If one sub-object is selected, the text gives the identification number and type of the selected item.

Editable Patch (Object)

Select an editable patch > Modify panel > Editable patch (not a sub-object level) selected in the modifier stack
Select an editable patch > Right-click the patch > Tools 1 (upper-left) quadrant of the quad menu > Sub-objects > Top-level
The functions available at the editable patch object level (that is, when no sub-object level is chosen) are also available at all sub-object levels, and work exactly the same at each level.

Interface

Selection rollout

For information on these settings, see Editable Patch Surface on page 2360.
Geometry rollout

Editable Patch Surface | 2371
See Geometry Rollout (Patch) on page 2394 for detailed descriptions of these controls.

**Surface Properties rollout**

The Relax Mesh controls on the Surface Properties rollout change the apparent surface tension by moving vertices closer to, or away from, their neighbors. The typical result is that the object gets smoother and a little smaller as the vertices move toward an averaged center point. You can see the most pronounced effects on objects with sharp corners and edges.

- **Relax** Turns on the relax function for renderings.
- **Relax Viewports** Turns on the relax function for viewports.
- **Relax Value** Sets the distance a vertex moves as a percentage of the distance between a vertex and the average location of its neighbors. Range=-1.0 to 1.0. Default=0.5.
- **Iterations** Sets how many times Relax is repeated. Each iteration recalculates average vertex locations based on the result of the previous iteration. Default=1.
- **Keep Boundary Pts Fixed** Vertices at the edge of open patches do not relax. Default=on.
- **Save Outer Corners** Preserves the original positions of vertices farthest away from the object center.
A patch box with Relax off (left), and Relax Value=1.0, with 1, 2, and 3 iterations (left to right)

**Editable Patch (Vertex)**

Select an editable patch > Modify panel > Expand Editable Patch in the stack display > Vertex sub-object level
Select an editable patch > Modify panel > Selection rollout > Vertex button
Select an editable patch > Right-click the patch > Tools 1 (upper-left) quadrant of the quad menu > Sub-objects > Vertex

At the Editable Patch (Vertex) level, you can select single and multiple vertices and move them using standard methods. You can also move and rotate vector handles on page 8755, thus affecting the shapes of any patches connected to the vertex.

**Procedures**

To transform either vertices or vectors:

1. At Patch (Vertex) level, with Selection rollout > Filter group > Vertices turned on, select vertices in the patch object you want to transform. Vertices and their vectors both appear.

2. Turn off one of the filters, leaving the other on, and choose a transform.
A transform cursor appears when you move onto a vertex or vector in the selection set. You can toggle between filters to alternatively transform either component.

**To switch vertex types:**

1. Right-click a patch vertex.

2. Choose from commands on the quad menu. The Tools 1 (upper-left) quadrant includes two options specific to patch vertices:
   - **Coplanar:** If you set a patch control point's property to be coplanar, it's like locking the handle of the outgoing vector for that point. Moving a handle attached to a coplanar vertex causes the opposite vectors to adjust their positions to maintain a coplanar surface. This option is the default and gives smooth transitions between patches.
   - **Corner:** If you set a patch control point's property to be corner, it unlocks the handle of the outgoing vector, so you can create a discontinuous break in the patch surface.

**To switch vertex types from Coplanar to Corner, do one of the following:**

- Hold down Shift as you move a handle of a Coplanar vertex. This changes the vertex type to Corner.
  - If Lock Handles is off (the default), Shift+Move "breaks" the handle, allowing it to move independently.
  - If Lock Handles is on, the handles remain locked in their coplanar relationship. However, the vertex is still switched to Corner, and turning off Lock Handles lets you move the handles separately.

- Right-click the vertex and then choose Corner from the quad menu.

**To delete a vertex:**

1. At Patch (Vertex) level, select a vertex.

2. Click Delete.
   - The vertex and all patches sharing this control point are deleted.
To weld vertices:

1. At Patch (Vertex) level, select two valid vertices on different patches.
2. Set Weld Threshold to a value at least equal to the distance between the selected vertices.

3. Click Selected.
   The two vertices move together and join.
To transform interior vertices:

Using program defaults, you can select only vertices and vectors on the outer edge or boundary of a patch. This default is known as Auto Interior.

In some cases, you might want to move the interior vertices. For example, you might want to tweak a patch's curvature without having to subdivide the patch.

- At Patch level on page 2385, you can change the default on a patch-by-patch basis by right-clicking a patch and choosing Manual Interior from the shortcut menu. This lets you select and transform individual interior vertices. These vertices appear as yellow squares in the viewports.

  WARNING  If you return a patch to the default, changes due to Manual Interior are lost.

  NOTE  Certain objects are automatically set to Manual Interior when converted to patch objects. In such cases, you can see all interior vertices when you go to the Vertex sub-object level.

**Surface Properties rollout**

![Surface Properties rollout](image)

**Edit Vertex Colors group**

Use these controls to assign the color, illumination color (shading), and alpha (transparency) values of selected vertices.

**Color** Click the color swatch to change the color of selected vertices.

**Illumination** Click the color swatch to change the illumination color of selected vertices. This lets you change the color of shadows without changing the vertex colors.

**Alpha** Lets you assign an alpha (transparency) value to selected vertices. The spinner value is a percentage; zero is completely transparent and 100 is completely opaque.

**Select Vertex By group**

**Color and Illumination radio buttons** These buttons determine whether to select vertices by vertex color values or vertex illumination values.

**Color Swatch** Displays the Color Selector, where you can specify a color to match.
Select Depending on which radio button is selected, selects all vertices whose vertex color or illumination values either match the color swatch, or are within the range specified by the RGB spinners.

Range Specifies a range for the color match. All three RGB values in the vertex color or illumination must either match the color specified by the Color swatch in Select By Vertex Color, or be within plus or minus the values in the Range spinners. Default=10.

Editable Patch (Handle)

Select an editable patch > Modify panel > Expand the editable patch in the stack display > Handle sub-object level

Select an editable patch > Modify panel > Selection rollout > Handle button

Select an editable patch > Right-click the patch > Tools 1 (upper-left) quadrant of the quad menu > Sub-objects > Handle

The Handle sub-object level in Editable Patch provides direct access to vertex handles, or vectors, without going through the Vertex sub-object level. Handles are still accessible at the Vertex sub-object level, but the Handle level provides enhanced functionality as follows:

- The ability to select multiple handles for transformation and application of operations such as Patch Smooth to them.
- Usage of the transform gizmo when manipulating handles.
- Elimination of the possibility of inadvertently transforming vertices.
- Support for named selection sets of handles.
- Copying and pasting handles.
- Use the Align tool on page 967 for aligning handles.
See Geometry Rollout (Patch) on page 2394 for detailed descriptions of these controls.

**Editable Patch (Edge)**

Select an editable patch > Modify panel > Expand the editable patch in the stack display > Edge sub-object level

Select an editable patch > Modify panel > Selection rollout > Edge button

Select an editable patch > Right-click the patch > Tools 1 (upper-left) quadrant of the quad menu > Sub-objects > Edge

An edge is the portion of a patch object between two adjacent vertices. When at the Editable Patch (Edge) level, you can select single and multiple segments and move, rotate, and scale them using standard methods. You can also hold down the Shift key and drag an edge to create a new patch. Holding down the Shift key during edge extrusion creates a new element.

**Procedures**

**To unlock interior edges:**

When you move an outer or boundary edge of a patch, the adjacent interior edges are normally “locked” so that they move in parallel with the boundary edge. This is often useful, because it provides a uniform transition across the patch. This default is known as Auto Interior.

- **At Patch level** on page 2385, you can change the default on a patch-by-patch basis by right-clicking a patch and choosing Manual Interior from the Tools 1 (upper-left) quadrant of the quad menu. Thereafter, when you move a boundary edge, interior edges are affected in a nonlinear way. The interior edges are no longer locked to the boundary edge.

**WARNING** If you return a patch to the default, changes caused by Manual Interior are lost.
Interface

Selection rollout

Select Open Edges Selects all edges that are used by only one patch. You can use this to troubleshoot a surface; open edges will be highlighted.

For information on the other controls in this rollout, see Selection Rollout (Editable Patch) on page 2366.

**Editable Patch (Patch)**

Select an editable patch > Modify panel > Expand the editable patch in the stack display > Patch sub-object level

Select an editable patch > Modify panel > Selection rollout > Patch button

Select an editable patch > Right-click the patch > Tools 1 (upper-left) quadrant of the quad menu > Sub-objects > Patch

A patch is an area of a patch object, defined by three or four surrounding edges and vertices. Controls described in this topic let you manipulate a patch object at the patch level. As well as moving and rotating patches, you can create a separate element by holding down the Shift key during a move operation. This creates a separate element of the selected patches.

**Texture Mapping Patches: Interpolation in Curved Space**

Patches can now be mapped in curved space; this means simplified texture mapping for patches. A planar map on a complex patch object will not be distorted. At the Patch sub-object level there is a parameter in the right-click quad menu (Tools 1 quadrant) called Linear Mapping. If you leave Linear Mapping off, then textures are interpolated in curved space and behave much like texture mapping a mesh object, predictably.

In the old method, patch mapping is interpolated between the knot points. This works well with procedural maps but not so well with bitmaps, since each patch is linear in UV space.
A complex patch (on right) no longer deforms a bitmap

The two leftmost patches show Linear patch mapping. The top left patch is a patch with planar mapping and the bottom left shows its UVW space representation. The patch on the right is a curved projection where the vectors are used in UVW space projection. Notice the bottom right represents the UVW space and notice how the handles and knots contribute to the shape of the UVW space.

In short, leave the Linear option off for predictable planar maps. Leave the linear mapping option on for backward compatibility.

**NOTE** The Unwrap UVW modifier now supports the new patch curve mapping. Spline handles can be manipulated in the Edit dialog in the Unwrap UVW modifier.

**Surface Properties rollout**

These controls let you work with patch normals, material IDs, smoothing groups and vertex colors.

**Normals group**

**Flip** Reverses the direction of the surface normals of the selected patches.
**Unify** Flips the normals of an object so that they all point in the same direction, usually outward. This is useful for setting an object’s patches to appropriate orientations, thus eliminating apparent holes in the object surface.

**Flip Normal Mode** Flips the normal of any patch you click. To exit, click this button again or right-click anywhere in the 3ds Max interface.

**TIP** The best way to use Flip Normal Mode is to set up your viewport to display with Smooth+Highlight and Edged Faces on. If you use Flip Normal Mode with default settings, you’ll be able to flip a patch away from you, but you won’t be able to flip it back. For best results, turn off Ignore Backfacing in the Selection rollout. This lets you click any patch and flip the direction of its normal, regardless of its current direction.

**Material group**

These controls let you use multi/sub-object materials with patches.

**Set ID** Lets you assign a particular material ID number to selected patches for use with multi/sub-object materials and other applications. Use the spinner or enter the number from the keyboard. The total number of available IDs is 65,535.

**Select ID** Selects patches or elements corresponding to the Material ID specified in the adjacent ID field. Type or use the spinner to specify an ID, then click the Select ID button.

[Select By Name] This drop-down list shows the names of sub-materials if an object has a Multi/Sub-Object material assigned to it. Click the drop arrow and choose a sub-material from the list. The patches or elements that are assigned that material are selected. If an object does not have a Multi/Sub-Object material assigned, the name list is unavailable. Likewise, if multiple objects are selected that have an Edit Patch, Edit Spline, or Edit Mesh modifier applied, the name list is inactive.

**NOTE** Sub-material names are those specified in the Name column on the material’s Multi/Sub-Object Basic Parameters rollout; these are not created by default, and must be specified separately from any material names.

**Clear Selection** When on, choosing a new ID or material name deselects any previously selected patches or elements. When off, selections are cumulative, so new ID or sub-material name selections add to the existing selection set of patches or elements. Default=on.
**Smoothing Groups group**

Use these controls to assign selected patches to different smoothing groups on page 8724, and to select patches by smoothing group.

To assign patches to one or more smoothing groups, select the patches, and then click the number(s) of the smoothing group(s) to assign them to.

**Select by SG (Smoothing Group)** Displays a dialog that shows the current smoothing groups. Select a group by clicking the corresponding numbered button and clicking OK.

**Clear All** Removes any smoothing group assignments from selected patches.

**Edit Vertex Colors group**

Use these controls to assign the color, illumination color (shading), and alpha (transparency) values of vertices on the selected patch(es).

**Color** Click the color swatch to change the color of vertices on the selected patch(es).

**Illumination** Click the color swatch to change the illumination color of vertices on the selected patch(es). This lets you change the color of shadows without changing the vertex colors.

**Alpha** Lets you assign an alpha (transparency) value to vertices on the selected patch(es).

The spinner value is a percentage; zero is completely transparent and 100 is completely opaque.

---

**Editable Patch (Element)**

Select an editable patch > Modify panel > Expand the editable patch in the stack display > Element sub-object level

Select an editable patch > Modify panel > Selection rollout > Element button

Select an editable patch > Right-click the patch > Tools 1 (upper-left) quadrant of the quad menu > Sub-objects > Element

Use the Element sub-object level when you want to select and work on all contiguous faces in an element. The Element sub-object level is essential when you are Shift+cloning and Shift+extruding patches, because doing so creates separate elements. For example, if you select a patch, hold down the Shift key,
and move the patch to a new location, a new element is created separate from
the original. This also applies to extrusion. If you hold the Shift key down
while you extrude, a new element is created.

**NOTE** In some cases, you might find that moving a patch element causes parts
of it to move by differing amounts. This typically occurs because the object is set
to Manual Interior. It happens, for instance, when you convert a sphere primitive
to an editable patch object. To remedy this, select the element, and then right-click
it to display the quad menu, and in the Tools1 quadrant, choose Auto Interior.

**Interface**

**Selection rollout**

For information on the controls in this rollout, see *Selection Rollout (Editable
Patch)* on page 2366.

**Soft Selection rollout**

See *Soft Selection Rollout* on page 2014 for information on the Soft Selection
rollout settings.

**Geometry Rollout (Patch)**

Select an editable patch > Modify panel > Geometry rollout

The Geometry rollout for Patches contains most of the controls that let you alter the geometry of the patch, at either the Object (top) level, or one of the sub-object levels. The controls that the rollout displays can vary, depending on which level is active; if a control is not available for the active level, it might be grayed out, or simply might not appear at all. The descriptions below indicate the levels at which controls are available.

Subdivision group (Vertex, Edge, Patch, and Element levels only)

Bind (Vertex level only) Lets you create a seamless, gapless connection between two patch edges that have unequal numbers of vertices. The two patches must belong to the same object, and the vertex need not be selected first. Click Bind, then drag a line from an edge-based vertex (not a corner vertex) to the edge you want to bind it to. The cursor turns into a white cross when over a legal edge.

Binding patch edges

To exit Bind mode, click the Bind button again, or right-click in the active viewport.

**TIP** When connecting two patches edge-to-edge, first line up as many pairs of vertices as possible, and use Weld to connect them. Then use Bind to connect the remaining vertices. Bound vertices cannot be manipulated directly, although their handles can.

**NOTE** Bind is useful for connecting patch objects with different patch resolutions, such as a head and a neck, without the need to create additional patches in the lower-resolution object.

Unbind (Vertex level only) Disconnects a vertex connected to a patch with Bind. Select the vertex, and then click Unbind.
Subdivide (Edge, Patch, and Element levels only) Subdivides the selected sub-objects.

- **Propagate** When on, extends the subdivision to neighboring patches. Propagating the subdivisions along all contiguous patches prevents patch cracks where you have attached patches together.

**Topology group**

**Add Tri / Add Quad (Edge level only)** You can add Tri and Quad patches to any open edge of an object. On closed objects such as spheres, you can delete one or more existing patches to create open edges, and then add new patches. The new patches adapt to the existing geometry. For example, when you add a patch to a curved edge, the new patch follows that curve and seamlessly extends it.
Add Tri adds a three-sided patch to each selected edge. Select one or more edges, then click Add Tri to add the patch or patches.

Add Quad adds a four-sided patch to each selected edge. Select one or more edges, and then click Add Quad to add the patch or patches.

Create (Vertex, Patch, and Element levels only) Lets you add geometry to the patch object. Available at Vertex, Patch, and Element sub-object levels only.
At the Vertex sub-object level, turn on Create and then click anywhere to add vertices to the object.

At the Patch and Element levels, you can add three- and four-sided patches. The cursor changes to white cross hairs when over an existing patch vertex. Select an existing vertex by clicking it. Click in free space to create a new vertex at that location; this vertex is included in the sequence of vertices for the new patch.

- **To create a Tri Patch**: Click three times in free space or on existing vertices. Right-click anywhere, or left-click one of the vertices in the current sequence to complete the creation of a Tri Patch.

- **To create a Quad Patch**: Click four times in free space or on existing vertices. The Quad Patch is automatically created at the fourth click.

No operation takes place if you right-click or select a vertex in the current sequence with only one or two vertices in the sequence.

**Detach** *(Patch and Element levels only)* Let you select one or more patches or elements within the current object and then detach them (or copy them) to form a separate patch object.

- **Reorient** When on, the detached patch or element copies the position and orientation of the source object’s Local coordinate system (when the source object was created). The new detached object is moved and rotated so that its Local coordinate system is positioned and aligned with the origin of the current active grid.

- **Copy** When on, the detached patches or elements are copied to a new patch object, leaving the originals intact.

**Attach** Lets you attach an object to the currently selected patch object. Click the object you want to attach to the currently selected patch object. If you attach a non-patch object, the object is converted to a patch object.

When you attach an object, the materials of the two objects are combined in the following way:

- If the object being attached does not have a material assigned, it inherits the material of the object it is being attached to.

- Likewise if the object you're attaching to doesn’t have a material, it inherits the material of the object being attached.

- If both objects have materials, the resulting new material is a [multi/sub-object material](#) on page 6120 that encompasses the input materials. A dialog appears offering three methods of combining the objects' materials.
and material IDs. For more information, see Attach Options Dialog on page 2233.

Attach remains active in all sub-object modes, but always applies to objects.

**Top: Original patch object with rendering**

**Bottom: Rendering with another patch attached**

**Reorient** When on, reorients the attached element so that each patch’s creation local coordinate system is aligned with the creation local coordinate system of the selected patch.

**Delete (Vertex, Edge, Patch, and Element levels only)** Deletes the selected sub-objects.
WARNING Delete vertices or edges with caution. Deleting a vertex or edge also deletes the patches that share them. For example, if you delete the single vertex at the top of a spherical patch, the top four patches are also deleted.

**Break** (Vertex and Edge levels only) For vertices, breaks a vertex into multiple vertices. Use this if you need to split open an edge to add another patch or for general modeling operations. Select a vertex, and then click Break. After the break, select the individual vertices and move them to separate the edges. For edges, splits an edge. Use this if you need to split open an edge for general modeling operations. Select one or more edges, and then click Break. After the break, move the handles of adjacent vertices to create a gap in the patch.

**Hide** (Vertex, Edge, Patch, and Element levels only) Hides the selected sub-objects. For vertices and edges, Hide also hides the patches that are attached to them.

**NOTE** At least one patch in the object must remain visible.

**Unhide All** Restores any hidden sub-objects to visibility.

**Weld group** (Vertex and Edge levels only)

**Selected** Welds selected vertices that fall within the tolerance specified in the Weld Threshold spinner (to the right of the Weld button). Select the vertices you want to weld between two different patches, set the spinner to a sufficient distance, and click Selected.

At the Edge sub-object level, clicking Selected welds two edges that share vertices. You can use this to eliminate gaps on a surface.

**Target** (Vertex level only) Turn on and drag from one vertex to another to weld the vertices together. The dragged vertex fuses to the target vertex. The pixels spinner to the right of the Target button sets the maximum distance in screen pixels between the mouse cursor and the target vertex.

**Extrude & Bevel group** (Edge, Patch, and Element levels only)

These controls let you extrude and bevel edges, patches, or elements. Extruding patches moves them along a normal and creates new patches that form the sides of the extrusion, connecting the selection to the object. Beveling adds a second step that lets you scale the extruded patches. You can extrude and bevel patches by dragging or by direct entry. You can also hold down the Shift key during extrusion, which creates a separate element.
**NOTE** Sides created by beveling or extrusion are assigned to smoothing group 1.

**Extrude** Click this button, and then drag any edge, patch, or element to extrude it interactively. Hold down the Shift key during this operation to create a new element.

When the mouse cursor is over a selected patch or element, it changes to an Extrude cursor.

**Bevel (Patch and Element levels only)** Click this button, and then drag any patch or element to extrude it interactively, then click and release the mouse button, and drag again to bevel the extrusion. Hold down the Shift key during this operation to create a new element.

When the mouse cursor is over a selected element, it changes to a Bevel cursor.
NOTE In some cases, particularly with closed objects (objects with no holes or open edges), the second bevel step might not produce visible results.

**Extrusion** This spinner sets whether the extrusion is outward or inward, depending on whether the value is positive or negative.

**Outlining (Patch and Element levels only)** This spinner lets you scale selected patches or elements bigger or smaller, depending on whether the value is positive or negative. It is normally used after an extrusion for beveling the extruded patches.
Normal If Normal is set to Local (the default), extrusion takes place along the normal of each selected edge, patch, or individual patch in an element. If normal is set to Group, extrusion takes place along the averaged normal of each contiguous group in a selection. If you extrude multiples of such groups, each group moves along its own averaged normal.

Bevel Smoothing (Patch and Element levels only) These settings let you set the shape of the intersection between the surface created by a beveling operation and the neighboring patches. The shapes are determined by the handle configurations of vertices at the intersections. Start refers to the intersection between the sides and the patches surrounding the beveled patch. Finish refers to the intersection between the sides and the beveled patch or patches. The following settings are available for each:

- **Smooth**  Vertex handles are set so the angles between the new patches and their neighbors are relatively small.
- **Linear**  Vertex handles are set to create linear transitions.
- **None**  Vertex handles are not modified.

**WARNING** Set Bevel Smoothing before the bevel is performed; changing the setting has no effect on existing beveled patches.

Tangent group (Vertex and Handle levels only)

These controls let you copy orientation, and optionally length, between handles on the same object, or on different objects applied with instances of the same Edit Patch modifier. The tool doesn't support copying handles from one patch object to another, or between spline and patch objects.

**Copy**  Copies a patch handle’s transform settings to a copy buffer. When you click Copy, 3ds Max displays all handles on the selected object. When the mouse cursor is over a handle end, the cursor image changes to the one shown below. Click a handle end to copy its direction and length to the paste buffer; this also exits Copy mode.

**Paste**  Pastes orientation information from the copy buffer to a vertex handle. If Paste Length is on, it also pastes the length of the copied handle. When you click Paste, 3ds Max displays all handles on the selected object. When the mouse cursor is over a handle end, the cursor image changes to the
one shown below. Click a handle end to paste the information from the buffer to the handle. You can continue clicking other handle ends to paste the information repeatedly. To exit Paste mode, right-click in the viewport or click the Paste button.

**Copy Length / Paste Length** When on and you use Copy, the length of the handle is also copied. When on and you use Paste, the length of the originally copied handle is pasted as well as its orientation. When off, only the orientation is copied or pasted.

**Surface group**

**View Steps** Controls the grid resolution of the patch model surface as depicted in the viewports. Range=0 to 100. Default=5.

**Render Steps** Controls the grid resolution of the patch model surface when rendered. Range=0 to 100. Default=5.
**Show Interior Edges** Enables the display of the patch object's interior edges in wireframe views. When off, only the object's outline is visible. Turn on to simplify the display for faster feedback.

**Use True Patch Normals** Determines how 3ds Max smooths the edges between patches. Default=off.

When the check box is off, 3ds Max computes the surface normals from the smoothing groups of the mesh object to which the patch object is converted before rendering. These normals are not accurate, especially with a low View/Render Steps setting. When the check box is on, 3ds Max computes true patch normals directly from the patch surfaces, which can generate more accurate shading.

In the illustration below, a sphere was converted to Editable Patch format, and then a vertex was moved toward the center and rotated. The sphere on
the left has Use True Patch Normals turned off, and the one on the right has it turned on. In both cases, View Steps was set to 8.

A patch sphere with Use True Patch Normals off (left) and on (right).

**Miscellaneous group**

**Create Shape (Edge level only)** Creates splines based on the selected edges. If no edges are selected, then splines are created for all the patch edges. 3ds Max prompts you for a name: Type in a name for the new shape object, and then click OK.

Each patch edge forms an individual spline. You can use this to create a spline cage based on patch edges. This is useful for spline modeling or working with surface tools.

**Patch Smooth** At the sub-object level, adjusts the tangent handles of the vertices of selected sub-objects to smooth the surface of the patch object. At the object level, adjusts all tangent handles to smooth the surface.

Patch Smooth sets the handles to absolute positions based on the patch object geometry; repeated applications have no effect.
Patch Grids

Create panel > Geometry > Patch Grids
Create menu > Patch Grids

You can create two kinds of patch surfaces in grid form: Quad Patch and Tri Patch. Patch grids begin as flat plane objects but can be modified into arbitrary 3D surfaces by either using an Edit Patch modifier or collapsing the grid’s modifier stack down to an Editable Patch in the Modify panel.

Patch grids provide convenient "building material" for custom surfaces and objects, or for adding patch surfaces to existing patch objects.

You can animate the surface of a Patch object using various modifiers such as the Flex and Morph modifiers. Control vertices and tangent handles of a patch surface can be animated with an Editable Patch modifier.

Surface Tools

The output of the Surface modifier on page 1763 is a Patch object. Patch objects offer a flexible alternative to mesh and NURBS modeling and animation.
Editable Patches

You can convert a basic patch grid to an editable patch object on page 2360. The editable patch has a variety of controls that let you directly manipulate it and its sub-objects. For example, at the Vertex sub-object level, you can move vertices or adjust their Bezier handles. Editable patches let you create surfaces that are less regular, more free-form than the basic, rectangular patches.

When you convert a patch to an editable patch, you lose the ability to adjust or animate its creation parameters.

See also:

- Edit Modifiers and Editable Objects on page 1052
- Modifying at the Sub-Object Level on page 1054
- Modifier Stack Controls on page 8187

Procedures

To create a patch grid:

1. On the Create panel > Geometry > Patch Grids > Object Type rollout, click either Quad Patch or Tri Patch.
2. Drag over any viewport to create a patch.
Interface

AutoGrid Uses surface normals as a plane to create patches. Click a patch type and then click and drag the cursor over a face in the viewports.

Quad Patch

Create panel > Geometry > Patch Grids > Quad Patch
Create menu > Patch Grids > Quad Patch
Quad Patch creates a flat grid with a default of 36 visible rectangular facets. A hidden line divides each facet into two triangular faces for a total of 72 faces.
Procedures

To create a patch grid:

1. On the Create panel > Geometry > Patch Grids > Object Type rollout, click either Quad Patch or Tri Patch.
2. Drag over any viewport to define a length and width for the patch.

To edit a Quad Patch:

1. Select a Quad Patch.
2. On the Modify panel, right-click Quad Patch in stack view and choose Editable Patch.
   The Quad Patch collapses to an Editable Patch.
4. In any viewport, select a vertex on the patch object, and move the vertex to change the surface topology.
   Vertices and vectors can be animated with an Editable Patch modifier.

At the sub-object Edge level, you can add patches along any edge. You can create complex patch models beginning from a single patch.

An ear is created by adding patches and editing patch vertices
Interface

Name and Color rollout

The Name and Color rollout on page 8182 lets you rename objects and change their wireframe color.

Keyboard Entry rollout

X/Y/Z Sets the patch center.
Length Sets the patch length.
Width Sets the patch width.
Create Creates a patch based on the XYZ, Length, and Width values.
Parameters rollout

Length, Width Sets the grid dimensions in current units.

Length, Width Segments Determines the number of facets along the length and width of the grid. Default=1.
The density of a Quad Patch rises sharply as you increase the segments. A Quad Patch of two segments on a side contains 288 faces. The maximum is 100 segments. High segment values can slow performance.

Generate Mapping Coordinates Creates map coordinates for applying mapped materials. Default=off.

Tri Patch

Create panel > Geometry > Patch Grids > Tri Patch
Create menu > Patch Grids > Tri Patch

Tri Patch creates a flat grid with 72 triangular faces. The face count remains at 72, regardless of its size. The faces become larger to fill the area as you increase the size of the grid.
Tri Patch

Procedures

To create a Tri Patch:

1. On the Create panel > Geometry > Patch Grids > Object Type rollout, click Tri Patch.
2. Drag over any viewport to create the patch.

To edit a Tri Patch:

1. Select a Tri Patch.
2. On the Modify panel, right-click TriPatch in stack view, and choose Editable Patch.
   The Tri Patch collapses to an Editable Patch.
3. In the Editable Patch Selection rollout, click Vertex.
4. In any viewport, select a vertex on the patch object and move the vertex to change the surface topology.
You can animate vertices and vectors with an Editable Patch modifier.

**Interface**

- **Name and Color rollout**
  The Name and Color rollout on page 8182 lets you rename objects and change their wireframe color.

- **Keyboard Entry rollout**
  X/Y/Z Sets the patch center.

  X: 0.0
  Y: 0.0
  Z: 0.0

  Length: 0.0
  Width: 0.0

  Create

- **Parameters**
  Length: 0.0
  Width: 0.0

  Generate Mapping Coords.
**Length** Sets the patch length.

**Width** Sets the patch width.

**Create** Creates a patch based on the XYZ, Length, and Width values.

**Parameters rollout**

**Length**, **Width** Sets dimensions of grid in current units.

**Generate Mapping Coordinates** Creates map coordinates for applying mapped materials. Default=off.

---

**NURBS Modeling**

3ds Max provides NURBS surfaces and curves. NURBS stands for *Non-Uniform Rational B-Splines*. NURBS have become an industry standard for designing and modeling surfaces. They are especially suited for modeling surfaces with complicated curves.

The tools for modeling with NURBS do not require an understanding of the mathematics that produces these objects. NURBS are popular because they are easy to manipulate interactively, and because the algorithms that create them are both efficient and numerically stable.
You can also model surfaces using polygonal meshes or patches. Compared to NURBS surfaces, meshes and patches have these shortcomings:

- Using polygons can make it more difficult to create complicated curved surfaces.
- Because meshes are faceted, facets appear at the edge of rendered objects. You must have a large number of small faces to render a smoothly curved edge.

NURBS surfaces, on the other hand, are analytically generated. They are more efficient to calculate, and you can render a NURBS surface that appears to be seamless. (A rendered NURBS surface is actually approximated by polygons, but the NURBS approximation can be very fine grained.)

**NURBS Models: Objects and Sub-Objects**

Like Shape on page 572 objects, a NURBS model can be an assemblage of multiple NURBS sub-objects. For example, a NURBS object might contain two
surfaces that are separate in space. NURBS curves and NURBS surfaces are controlled by either point or control vertex (CV) sub-objects. Points and CVs behave somewhat like the vertices of spline objects, but there are differences.

The parent object in a NURBS model is either a NURBS surface or a NURBS curve. Sub-objects can be any of the objects listed here. A NURBS curve remains a Shape object unless you add a surface sub-object to it when you convert it to a NURBS surface (without changing its name).

**Surfaces** There are two kinds of NURBS surfaces. A point surface is controlled by points, which always lie on the surface. A CV surface is controlled by control vertices (CVs). Instead of lying on the surface, CVs form a control lattice that surrounds the surface. (This is similar to the lattice used by the FFD [free-form deformation] modifiers.)

See Creating Surface Sub-Objects on page 2603 and Editing Surface Sub-Objects on page 2530.

**Curves** There are also two kinds of NURBS curves. These correspond exactly to the two kinds of surfaces. A point curve is controlled by points, which always lie on the curve. A CV curve is controlled by CVs, which don't necessarily lie on the curve.

See Creating Surface Sub-Objects on page 2603 and Editing Curve Sub-Objects on page 2518.

**Points** Point surfaces and point curves have point sub-objects. You can also create separate point sub-objects that are not part of a surface or a curve.

See Creating and Editing Point Sub-Objects on page 2694.

**CVs** CV surfaces and CV curves have CV sub-objects. Unlike points, CVs are always part of a surface or a curve.

See Editing Curve CV Sub-Objects on page 2503 and Editing Surface CV Sub-Objects on page 2509.

**Imports** Imports are 3ds Max objects, including other NURBS objects. Within the NURBS model, they render as NURBS; but they retain their original parameters and modifiers.

See Attaching and Importing 3ds Max Objects on page 2490.

Sub-objects can be dependent on page 2433 sub-objects whose geometry is related to the geometry of other sub-objects.
Creating NURBS Models

There is a variety of ways to create NURBS models. These are various ways you can create a top-level, parent NURBS object:

- You can create a NURBS curve on page 2464 on the Shape on page 572 panel of the Create panel.
- You can create a NURBS surface on page 2454 on the Geometry on page 357 panel of the Create panel. When you use this technique, the NURBS surface is initially a flat rectangle. You can alter it using the Modify panel.
- You can turn a standard geometry primitive on page 388 into a NURBS object.
- You can turn a torus knot on page 426 into a NURBS object.
- You can turn a prism on page 458 extended primitive into a NURBS object.
- You can turn a spline on page 577 object (Bezier spline) into a NURBS object.
- You can turn a patch grid on page 2408 object (Bezier patch) into a NURBS object.
- You can turn a loft on page 742 object into a NURBS object.

To turn objects other than NURBS curves and surfaces into NURBS objects, use the Modify panel. Right-click the object’s name in the stack display (see Modifier Stack on page 8187) and choose Convert To: NURBS.

In viewports, the quad menu on page 8052 also lets you convert objects to NURBS. Select and then right-click the object, and in the Transform (lower-right) quadrant, choose Convert To: > Convert to NURBS.

- In addition, the modifiers Extrude on page 1425 and Lathe on page 1474 let you choose NURBS output, which creates a NURBS object.

Working with NURBS Models

When you work with NURBS models, usually you create one NURBS object as the “starter” object, then edit the starter object or add additional sub-objects.
Here is the two-step process in more detail:

- Create one NURBS object as the "starter" object. This can be a surface object, a curve object, or a converted geometry primitive, as described in Creating NURBS Models on page 2419. Often modelers like to identify a single, master surface as the main component of the model. Converted geometry primitives are good if you want the starter surface to become the master surface. See Creating NURBS Surfaces from Geometric Primitives on page 2483. Point and CV surfaces are good as starters for rectangular surfaces.

- On the Modify panel, you can edit the original object, or you can create additional sub-objects. See Using the NURBS Toolbox to Create Sub-Objects on page 2426. You might even choose to delete the original, starter object once you have built a model from newer sub-objects.

Going immediately to the Modify panel avoids the problem of creating additional top-level NURBS objects, which you can't use to build relational, dependent sub-objects. (The exception is using curves for loft and sweep surfaces. See U Loft Surface on page 2646, UV Loft Surface on page 2656, 1-Rail Sweep Surface on page 2663, or 2-Rail Sweep Surface on page 2673.)

**NURBS Surface Trimming**

To trim a surface is to use a curve on the surface to cut away part of the surface, or to cut a hole in the surface.

Before you trim a surface, you must create a curve on that surface. These are the kinds of curves that can trim surfaces:

- U iso and V iso curves on page 2584
- Surface-surface intersection curve on page 2578
- Normal projected curve on page 2586
- Vector projected curve on page 2589
Once you've created the curve, you trim the surface by turning on Trim in the curve sub-object's parameters. A Flip Trim control inverts the trim direction. The direction of the curve determines the initial direction of the trim. For example, a closed curve on surface created in a clockwise direction trims inward, creating a hole in the surface; while a closed curve on surface created in a counterclockwise direction trims outward, creating a curve-shaped portion of the surface.

When a surface is trimmed, its untrimmed version is still present in the 3ds Max scene. You can select it for the purposes of editing it, or replacing it as a parent to a dependent sub-object on page 2433. For details, see Sub-Object Selection on page 2428.

**Procedures**

**Example: To cut a hole in a CV surface:**

1. Create a CV surface in the Top viewport.
2. Create a closed CV curve sub-object that lies on top of (or above) the surface.
3. In the toolbox, turn on Normal Projected Curve, then in the Top viewport select first the CV curve, then the surface.
   This creates a projection of the CV curve that lies on the surface, and can trim it.
4. In the normal projected curve's parameters, click to turn on Trim.
   A hole appears in the surface. Depending on the orientation of the Normal Projected curve, you might see everything but the hole.
5. Use the Flip Trim toggle to invert the trim.

**NOTE** Trims aren't displayed in viewports if the NURBS surface's Surface Trims toggle is turned off on the General rollout's Display group box.
To select an untrimmed surface:

1 Make sure the Keyboard Shortcut Override toggle on page 8420 is on.

2 At the appropriate sub-object level or during a replace parent operation, press H. This opens the Select Sub-Objects dialog, which is a subset of the Selection Floater on page 209 that you can use during sub-object creation as well as sub-object selection.

3 If the untrimmed version is selectable at this level, the trimmed version appears as a "tree," with a plus sign next to it. Click the plus sign to expand the tree. The child is the untrimmed version. Highlight its name to select it.
Modifying NURBS Models and Creating Sub-Objects

You can edit NURBS immediately when you enter the Modify panel. You don’t have to apply a modifier, as you do for most kinds of 3ds Max objects.

While you are editing a NURBS object on the Modify panel, you can create sub-objects "on the fly," without having to go back to the Create panel. This is an exception to the way you usually use 3ds Max. The Modify panel for NURBS curve and NURBS surface objects includes rollouts that let you create new NURBS sub-objects.

Example: Rollout for creating NURBS surface sub-objects

**TIP** Another way to create curve and surface sub-objects is to use the NURBS Creation Toolbox on page 2426.
This is a summary of how to create sub-objects:

- An individual point sub-object is either an independent point or a dependent point tied to other NURBS geometry.

- Curve sub-objects are either independent point curves or CV curves, or they are dependent on page 8550 curves whose geometry is based on other curves or surfaces already present in the model. For example, a blend curve is a dependent curve sub-object that connects the endpoints of two other curves.

- Surface sub-objects are either independent point surfaces or CV surfaces, or they are dependent on page 8550 surfaces whose geometry is based on other surfaces or curves already present in the model. For example, a blend surface is a dependent surface sub-object that connects the edges of two other surfaces.

- You can attach 3ds Max objects. If the attached object is not already a NURBS object, it is converted to NURBS geometry. You can attach a NURBS curve, another NURBS surface, or a convertible 3ds Max object. The attached object becomes one or more curve or surface sub-objects.

- You can import 3ds Max objects. The imported object retains its parameters. While it is part of the NURBS object it renders as a NURBS, but you can still edit it parametrically at the Imports sub-object level. At this sub-object level, viewports display its usual geometry, not its NURBS form. A NURBS curve can import NURBS curves or spline curves. A NURBS surface can import curves, surfaces, or convertible 3ds Max objects.

**NOTE** You can detach a NURBS sub-object to make it a new, top-level NURBS object, and you can extract an imported object to create an independent, top-level object once again.

### Quad Menu for NURBS Objects

While a NURBS object is selected and the Modify panel is active, the quad menu on page 8052 displays two quadrants that are specifically for NURBS editing.
Quad menu for modifying NURBS models

**Tools 1 (upper-left) Quadrant**

These options are general display and sub-object level shortcuts.

- **Transform Degrade** Toggles Degradation Override on page 123.

- **Display Shaded Lattice, Display Lattices, Display Surfaces, and Display Curves** See Display Controls for NURBS Models on page 2486.

- **Sub-objects** Displays the sub-object choices for the selected object, as well as a Top-level choice.
Tools 2 (lower-left) Quadrant

These options are creation and editing shortcuts.

Create CV Surface, Create CV Curve, Create Point Surface, Create Point Curve These create a new NURBS sub-object.

Insert CV Row, Insert CV Column, Refine CV Curve, Refine CV Row These add CVs to a CV Surface sub-object by inserting or refining. For the difference between inserting and refining, see Editing Surface CV Sub-Objects on page 2509. See NURBS Concepts on page 2440 for more information about refining.

Using the NURBS Toolbox to Create Sub-Objects

Modify panel > Select NURBS object. > General rollout > NURBS Creation Toolbox button

Keyboard > Ctrl+T (Keyboard Shortcut Override Toggle must be on.)

Besides using rollouts at the NURBS object level, you can use the NURBS toolbox to create sub-objects.
Interface

The toolbox contains buttons for creating NURBS sub-objects. In general, the toolbox behaves like this:

- While the button is on, the toolbox is visible whenever a NURBS object or sub-object is selected and you are on the Modify panel. It disappears whenever you deselect the NURBS object or make a different panel active. When you return to the Modify panel and select a NURBS object, it reappears.

- You can use the toolbox to create sub-objects from either the top, object level, or from any NURBS sub-object level.

- When you turn on a toolbox button, you go into creation mode, and the Modify panel changes to show the parameters (if there are any) for the kind of sub-object you are creating. Other NURBS rollouts aren't displayed while you create the new sub-object. This differs from using the NURBS object’s Create rollouts or the NURBS right-click menu on page 2424.

NURBS Models: Objects and Sub-Objects | 2427
If you are at the top, object level and use the toolbox to create a sub-object, you must then go to the sub-object level to edit the new sub-object. (This is the same as using the buttons on the rollouts.)

If you are at a sub-object level and use the toolbox to create an object of the same sub-object type, you can edit it immediately after you turn off the create button (or right-click to end object creation).

If you are at a sub-object level and use the toolbox to create an object of a different sub-object type, you must change to that sub-object level before you can edit the new sub-object.

The individual creation buttons are described in these topics:

- Creating and Editing Point Sub-Objects on page 2694
- Creating Curve Sub-Objects on page 2549
- Creating Surface Sub-Objects on page 2603

**NURBS Sub-Object Selection**

When you work with NURBS models, you often work with sub-objects. While you are at the sub-object level, you use the usual selection techniques, such as clicking, dragging a region, or holding down Ctrl, to choose one or more sub-objects.

You can also select NURBS point, curve, and surface sub-objects by name. Turn on the Keyboard Shortcut Override Toggle on page 8420, go to a NURBS sub-object level, and then press the H key. This opens the Select Sub-Objects dialog, which is a subset of the Selection Floater on page 209 that lists only sub-objects at the current level. Choose one or more objects in the list, and then click Select. You can assign your own names to NURBS sub-objects (aside from CVs) that you want to edit frequently.

**TIP**

Press Ctrl+H to have the Select Sub-Objects dialog list only sub-objects directly beneath the mouse cursor.

**TIP**

The H shortcut is also a convenient way to choose parent objects while you’re creating dependent sub-objects.
Workflow Tips

When you work with NURBS, you switch frequently between the object and sub-object levels, or from one sub-object level to another. Keyboard shortcuts and pop-up menus can help you do this.

- The Sub-Object Selection Toggle (default: Ctrl+B) switches between object and sub-object levels.
- The Cycle Sub-Object Level shortcut (default: Insert) switches from one sub-object level to another.
- When you right-click in a viewport while a NURBS object is selected and the Modify panel is active, the quad menu lets you switch between various levels of the NURBS model: Top Level, Surface CV Level, Surface Level, Curve CV Level, Point Level, Curve Level, and Imports Level.
- The command panel’s right-click popup menu (available whenever the mouse cursor becomes a pan hand) helps you navigate the rollouts on the current command panel. If you have a three-button or wheel mouse, rolling the wheel scrolls the command panel.
- Sub-object selection sets are persistent. If you go to a different sub-object level, when you return to the previous level, your selection is still available. However, refining or inserting points or CVs makes the sub-object selection sets invalid for that object.
- You can move a sub-object selection set among sub-objects at the active level of the NURBS model by holding down Ctrl while you press the arrow keys.
- When you select surface CV sub-objects that are "on top of" each other in a 3D view, sometimes all the selected CVs fail to highlight. To fix this, choose Customize > Viewport Configuration on page 8374, and turn on Z-buffer Wireframe Objects.

CV Sub-Objects and Point Sub-Objects

Independent curves and independent surfaces both come in two varieties: they are either CV sub-objects or point sub-objects. This topic describes the differences between the two.
CV Curves and CV Surfaces

CV curves and CV surfaces have control vertices (CVs) as do splines. The position of the CVs controls the shape of the curve or the surface. However, unlike spline vertices, CVs don’t necessarily lie on the curve or surface they define. The CVs define a control lattice that connects the CVs and surrounds the NURBS curve or surface. The control lattice displays in lines that are yellow by default.

Cone-shaped NURBS surface with its control lattice (CVs are displayed as green squares)

**TIP** When you use Zoom Extents, the entire extents of a NURBS object are displayed, including its control lattice. Because CVs can be located some distance from an object, the curve or surface itself (the object’s renderable geometry) is sometimes hard to see. If this happens, use Zoom Region or Field of View to zoom in.

You can move a CV at the Curve CV or Surface CV sub-object level on the Modify panel. Other transforms, rotate and scale, work as well. Rotate and scale are useful mainly when you have selected multiple CVs.
Moving and rotating CVs to change a surface (selected CVs are displayed in red)

Each CV also has a weight, which you can use to adjust the CV’s effect on the curve or surface. Increasing the weight pulls the surface toward the CV. Decreasing the weight relaxes the surface away from the CV.
Weights can be a useful way to "tune" the appearance of a NURBS curve or surface.

The weight value of a CV is rational (as in a "rational number"). That is, it is relative to other CVs in the curve or surface. Changing the weight of all CVs at once has no effect, because it doesn’t change the ratio between weights.

**Points, Point Curves, and Point Surfaces**

Point curves and point surfaces are similar to CV curves and surfaces, but the points that control them are required to lie on the curve or surface. Unlike CVs, points do not have a weight.

Point curves and point surfaces can be more intuitive to create and work with. However, working with point sub-objects is slower than working with CV sub-objects. You can think of a point curve or point surface as being dependent on the points to which it fits.

Points that you create individually are the same as the points on point curves and surfaces, except that initially they aren’t part of a curve or surface. You can create a point curve by fitting it to points that you select. When you fit the new point curve, you can use points that are part of curves or surfaces, and individual point sub-objects.
Dependent Sub-Objects (NURBS)

A NURBS sub-object is either independent or dependent. A dependent sub-object is based on the geometry of other sub-objects. For example, a blend surface smoothly connects two other surfaces. Transforming or animating either of the original, parent surfaces causes the shape of the blend to change as it maintains a connection between the parents.

The immediate, interactive relation between the parent and dependent sub-objects is known as relational modeling. Relational modeling is one of the reasons NURBS models can be particularly easy to change or to animate.

IMPORTANT Dependent sub-objects must have parents that are also sub-objects of the same NURBS model. Dependent relationships can’t exist between object-level NURBS curves or surfaces. If you want to use a top-level NURBS object to create a dependent object, first you must attach or import the top-level object. See Attaching and Importing 3ds Max Objects on page 2490.

You have the option of making a dependent sub-object independent. After you do so, the sub-object is no longer related to its parents. Changes to the former parents don’t affect it, but you can edit and transform it as an independent sub-object in its own right.
At the appropriate sub-object level, dependent NURBS are displayed in green in wireframe viewports. (You can change the display color using the Colors panel of the Customize User Interface dialog on page 8249.)

Relational modeling does add computation time to a model, so when you transform or edit dependent sub-objects in other ways, often you will notice a slowdown in performance. Once a dependent surface sub-object has the shape you want, you can improve performance by making it into a rigid surface on page 2436.

**Transforming Dependent Sub-Objects**

In general, you can select and transform dependent sub-objects, but the effect of the transform depends on the sub-object type. Some dependent objects have a gizmo, similar to the gizmo used with modifiers. Sub-objects that don’t have gizmos can’t change relative to their parent objects. For these kinds of sub-objects, transforms apply equally to the sub-object and its parents. For example, moving a blend sub-object moves its parents as well. Sub-objects that have gizmos can change relative to their parent objects. In this case, as with modifiers that use gizmos, you are really transforming the gizmo. For example, rotating a mirror sub-object changes the mirror axis, and therefore the mirror’s position relative to its parent curve or surface.

When you Shift+Clone on page 2734 a dependent NURBS sub-object, by default the parent objects are also cloned. For example, if you Shift+Clone a UV loft, all the lofting curves are copied as well. This means that the new object has the same type as the original object. The cloned object keeps its parents, so you can edit it just as you do the original. When you Shift+Clone a NURBS sub-object, you can also choose to remove dependencies in order to improve performance.

**Error Condition for Dependent Sub-Objects**

Sometimes changes you make to the parent objects make it no longer possible to correctly update the dependent object’s geometry. For example, a fillet between two curves requires the curves to be coplanar. If you move one curve (or its CVs or points) so that the curves are no longer coplanar, the fillet cannot update correctly. In this case, the dependent object’s geometry reverts to a default position, and it is displayed in orange to indicate an error condition. (You can change the error color using the Colors panel on page 8272 of the Customize User Interface dialog on page 8249.)
The arrow points to the segment indicating an error condition.

Seed Values

Some kinds of dependent sub-objects depend on geometry that might have more than one solution. For example, if you want to create a surface-curve intersection point, and the curve intersects the surface more than once, 3ds Max must decide which intersection is to be the location of the point.

For these kinds of objects, seed value on page 8713 parameters control the decision. The seed location is on a parent object, and 3ds Max chooses the location nearest to the seed value that satisfies the creation condition. You can alter the seed value when you edit these dependent sub-objects. The seed location is displayed as a yellow square.

For example, the seed location for a surface-curve intersection point is a U position along the length of the parent curve. The surface-curve intersection closest to the seed is chosen as the location of the dependent point.

The seed location for a surface is a pair of UV coordinates in the surface's parameter space on page 8674.
Replacing Parent Sub-Objects

Dependent sub-objects have controls that let you replace the object or objects on which they depend. For example, Offset Surface has a button called Replace Base Surface. You can click this button and then click a different surface to act as the base of the offset.

This capability lets you replace a trimmed surface with its untrimmed version, or vice versa. To do so, you need to use the Select Sub-Objects dialog, which is a subset of the Selection Floater on page 209 that you can use during sub-object creation as well as sub-object selection. For example, select the trimmed surface sub-object and turn on the Keyboard Shortcuts Override toggle on page 8420. Click the replacement button, press the H key, expand the surface's tree, and then highlight the name of the untrimmed version.

Rigid NURBS Surfaces

To improve performance, you can make any kind of surface sub-object into a rigid surface. The only editing allowed on a rigid surface is to transform it at the Surface sub-object level. You can't move a rigid surface's points or CVs, or change the number of points or CVs.

Rigid surfaces reduce the amount of memory used by the NURBS model. Making surfaces rigid improves performance, especially for large and complex models.

When a surface is rigid, you can't see its points or CVs when you are at the Point or Surface CV sub-object levels. If the model has only rigid surfaces and no point curves, the Point and Surface CV sub-object levels aren't available at all.

To make a rigid surface editable again, click Make Point, Make Independent, Make Loft, or Convert Surface.

NURBS and Modifiers

In general, you can apply modifiers to NURBS models as you do to other objects.

You can apply Edit Patch on page 1329 and Edit Mesh on page 1321 modifiers to NURBS surface objects.
**TIP** To improve performance while you animate your scene, make the surfaces in your NURBS model *nonrelational surfaces* on page 2484. Modifiers treat nonrelational surfaces as if they were independent CV surfaces: you can animate the scene more efficiently, and then turn relational modeling back on before you render.

---

### Deforming NURBS Objects

Deform modifiers such as *Bend* on page 1165 and *Twist* on page 1833 operate on CV and point sub-objects. They don't change the NURBS model into an editable mesh object. This means that you can use a deform modifier, collapse the stack, and still have a NURBS object that you can edit further. However, because the deform modifiers directly affect CVs and points (and not the mesh approximation of the NURBS model), they can produce unexpected results. For example, a *Ripple* on page 1650 modifier does not ripple the surface if the CVs are farther apart than the wavelength of the ripples. If you want the modifier to affect the mesh approximation instead of the CVs, you can apply a *Mesh Select* on page 1500 modifier first. Then when you collapse the stack, you get an editable mesh, not a NURBS object.

These are the deform modifiers that collapse to NURBS:

- Modifiers in the Parametric Deformers set, except for Lattice (which collapses to an editable mesh) and Slice (which collapses to an editable poly or an editable mesh).

- Modifiers in the Animation Modifiers set, except for the world-space modifier (WSM) versions of PatchDeform, PathDeform, and SurfDeform, which don't collapse.

**TIP** While the Morpher and Skin modifiers collapse to a NURBS object, they are meant to be used with their own controls, and lose their usefulness when you collapse them.

The modifiers with Soft Selection controls treat NURBS models the same way they treat editable meshes. As with editable mesh vertices, CVs are colored proportionally according to how much the region affects them.

If Relational Stack is turned off (see *Nonrelational NURBS Surfaces* on page 2484), the Affect Neighbors toggle can affect all surface CVs, curve CVs, and points in neighboring sub-objects. If Relational Stack is on, Soft Selection affects neighboring sub-objects only if they are at the same sub-object level. Soft Selection works with Scale and Rotate as well as with the Move transform.
NURBS Objects and the UVW Map Modifier

When you apply a UVW Map on page 1932 modifier, it affects the NURBS object the same way it affects a mesh. If you then collapse the stack, UVW mapping is still in effect. However, you can override the mapper for individual surface sub-objects. To do so, turn on the surface's Generate Mapping Coords check box, if necessary. When the check box is on, you get the natural mapping of the surface; when it is off, you get the mapping from the collapsed UVW modifier.

**TIP** Don't use UVW Map to assign a texture to an animated surface. The texture will shift as the surface animates.

NURBS Selection Modifier

The NURBS Surface Selection (NSurf Sel) on page 1555 lets you place a NURBS sub-object selection on the modifier stack. This lets you modify only the selected sub-objects. Also, selected curve sub-objects are Shape on page 572 objects that you can use as paths and motion trajectories.

NSurf Sel can select any kind of NURBS sub-object except imports. Each sub-object selection is of one sub-object level only.

Procedures

To use a NURBS select modifier:

1. With a NURBS object selected, go to the Modify panel and apply NSurf Sel.
   The selection modifier has no controls at the object level.

2. Click to open the modifier's hierarchy, and choose a sub-object level.
   The selection modifier has the same selection controls you see for the corresponding sub-object type.

   While applying the modifier, you can also select NURBS sub-objects by name. Turn on the Keyboard Shortcut Override Toggle button on the status bar, and then press the H key. This open the Select Sub-Objects dialog, which is a subset of the Selection Floater on page 209 that you can use during sub-object creation as well as sub-object selection. Choose one or more objects in the list, and then click Select. Press Ctrl+H to have the Select Sub-Objects dialog list only sub-objects (for example, points) directly under the mouse cursor.
3 Use the selection controls to create a selection set of the chosen sub-object type.

With the NSurf Sel modifier, you can select NURBS sub-objects at any level except imports.

**NOTE** To select point, curve, or curve CV sub-objects, you must go to the NURBS object and turn on Relational Stack.

Once you have used the modifier to create the selection, you can apply other modifiers to it. If the selected sub-object is a curve, you can also use it as a path or trajectory.

**NOTE** NSurf Sel doesn't support copy and paste of selections as Mesh Select does. Copying and pasting mesh selections is based on vertex indexes. NURBS selections are based on object IDs, which are unique to each model.

**NURBS and Animation**

In general, you animate NURBS curves and NURBS surfaces by turning on the Auto Key button and transforming sub-object attributes such as CV or point positions, by animating the parameters that control dependent NURBS objects, and so on.

You can't animate NURBS object creation or creation parameters, or fundamental changes to NURBS geometry such as adding or deleting CVs or points, attaching objects, and so on.

**TIP** To improve performance while you animate your scene, make the surfaces in your NURBS model nonrelational surfaces on page 2484. Modifiers treat nonrelational surfaces as if they were independent CV surfaces: you can animate the scene more efficiently, and then turn relational modeling back on before you render.

Some NURBS editing operations remove animation controllers.

**Operations that Remove Animation**

The following operations remove animation from a NURBS object or sub-object:

- Make Independent
  
  This operation removes the animation of anything directly dependent on the object.
Break, Extend, Join and Zip, Refine, Delete, Rebuild, Reparameterize, Close, Make Loft, Convert Curve, and Convert Surface
Any operation that changes the number of points or CVs in a curve or surface removes the animation of all points or CVs that are lost.

Fuse
The animation of the point or CV being fused to the other point or CV (the second one chosen) is lost. The first point or CV acquires the animation of the second.

NURBS Concepts

NURBS curves and surfaces did not exist in the traditional drafting world. They were created specifically for 3D modeling using computers. Curves and surfaces represent contours or shapes within a 3D modeling space. They are constructed mathematically.

NURBS mathematics is complex, and this section is simply an introduction to some NURBS concepts that might help you understand what you are creating, and why NURBS objects behave as they do. For a comprehensive description of the mathematics and algorithms involved in NURBS modeling, see *The NURBS Book* by Les Piegl and Wayne Tiller (New York: Springer, second edition 1997).

Definition and Parameter Space

The term NURBS stands for Non-Uniform Rational B-Splines. Specifically:

- **Non-Uniform** means that the extent of a control vertex's influence can vary. This is useful when modeling irregular surfaces.

- **Rational** means that the equation used to represent the curve or surface is expressed as a ratio of two polynomials, rather than a single summed polynomial. The rational equation provides a better model of some important curves and surfaces, especially conic sections, cones, spheres, and so on.

- A **B-spline** (for basis spline) is a way to construct a curve that is interpolated between three or more points. Shape curves such as the Line tool and other Shape tools are Bezier curves, which are a special case of B-splines.
The non-uniform property of NURBS brings up an important point. Because they are generated mathematically, NURBS objects have a parameter space on page 8674 in addition to the 3D geometric space in which they are displayed. Specifically, an array of values called knots on page 8617 specifies the extent of influence of each control vertex (CV) on the curve or surface. Knots are invisible in 3D space and you can't manipulate them directly, but occasionally their behavior affects the visible appearance of the NURBS object. This topic mentions those situations. Parameter space is one-dimensional for curves, which have only a single U dimension topologically, even though they exist geometrically in 3D space. Surfaces have two dimensions in parameter space, called U and V.

NURBS curves and surfaces have the important properties of not changing under the standard geometric affine transformations (Transforms), or under perspective projections. The CVs have local control of the object: moving a CV or changing its weight does not affect any part of the object beyond the neighboring CVs. (You can override this property by using the Soft Selection on page 2541 controls.) Also, the control lattice that connects CVs surrounds the surface. This is known as the convex hull on page 8540 property.

**Degree and Continuity**

All curves have a degree on page 8549. The degree of a curve is the highest exponent in the equation used to represent it. A linear equation is degree 1; a quadratic equation is degree 2. NURBS curves typically are represented by cubic equations and have a degree of 3. Higher degrees are possible, but usually unnecessary.

Curves also have continuity on page 8537. A continuous curve is unbroken. There are different levels of continuity on page 8537. A curve with an angle or cusp is C0 continuous: that is, the curve is continuous but has no derivative at the cusp. A curve with no such cusp but whose curvature changes is C1 continuous. Its derivative is also continuous, but its second derivative is not. A curve with uninterrupted, unchanging curvature is C2 continuous. Both its first and second derivatives are also continuous.
Levels of curve continuity:

Left: C0, because of the angle at the top

Middle: C1, at the top a semicircle joins a semicircle of smaller radius

Right: C2, the difference is subtle but the right side is not semicircular and blends with the left

A curve can have still higher levels of continuity, but for computer modeling these three are adequate. Usually the eye can't distinguish between a C2 continuous curve and one with higher continuity.

Continuity and degree are related. A degree 3 equation can generate a C2 continuous curve. This is why higher-degree curves aren't generally needed in NURBS modeling. Higher-degree curves are also less stable numerically, so using them isn't recommended.

Different segments of a NURBS curve can have different levels of continuity. In particular, by placing CVs at the same location or very close together, you reduce the continuity level. Two coincident CVs sharpen the curvature. Three coincident CVs create an angular cusp in the curve. This property of NURBS curves is known as multiplicity on page 8649. In effect, the additional one or two CVs combine their influence in that vicinity of the curve.

Effects of multiplicity: there are three CVs at the apex on the left, two CVs at the apex on the right.
By moving one CV away from the other, you increase the curve's continuity level again. Multiplicity also applies when you fuse CVs. Fused CVs create a sharper curvature or a cusp in the curve. Again, the effect goes away if you unfuse the CVs and move one away from the other.

Degree, continuity, and multiplicity apply to NURBS surfaces as well as to curves.

**Refining Curves and Surfaces**

*Refining* a NURBS curve means adding more CVs. Refining gives you finer control over the shape of the curve. When you refine a NURBS curve, 3ds Max preserves the original curvature. In other words, the shape of the curve doesn't change, but the neighboring CVs *move away from* the CV you add. This is because of multiplicity: if the neighboring CVs didn't move, the increased presence of CVs would sharpen the curve. To avoid this effect, first refine the curve, and then change it by transforming the newly added CVs, or adjusting their weights.

![Refining a NURBS curve.](image)

NURBS surfaces have essentially the same properties as NURBS curves, extended from a one-dimensional parameter space to two dimensions.

**Reparameterizing CV Curves and Surfaces**

When you refine a NURBS curve or surface, it is a good idea to reparameterize it. Reparameterizing adjusts the parameter space so the curve or surface will behave well when you edit it in viewports. There are two ways to reparameterize:

- Chord-length
  Chord-length reparameterization spaces knots in parameter space based on the square root of the length of each curve segment.

- Uniform
Uniform reparameterization spaces knots uniformly. A uniform knot vector has the advantage that the curve or surface changes only locally when you edit it.

CV curve and surface sub-objects give you the option of reparameterizing automatically whenever you edit the curve or surface.

**Point Curve and Surface Concepts**

You can work with point curves and point surfaces as well as with CV curves and surfaces. The points that control these objects are constrained to lie on the curve or surface. There is no control lattice, and no weight control. This is a simpler interface that you might find easier to work with. Also, point-based objects give you the ability to construct curves based on dependent (constrained) points, and then use these to construct dependent surfaces.

You can think of point curves and surfaces as an interface to CV curves and surfaces, which are the fully defined NURBS objects. The underlying representation of the curve or surface is still constructed using CVs.

You can also think of a point curve or surface as dependent on its points. You can use the Convert Curve button to convert a point curve or surface to the CV form, or vice versa.

**NURBS Tips and Techniques**

These topics contain suggestions on how to work with NURBS. They include tips collected from various NURBS modeling users.

**How to Make Objects with NURBS Modeling**

These are tips on using NURBS to create models.

**Objects and Sub-Objects**

- In 3ds Max, a NURBS model is a single, top-level NURBS object that can contain a variety of sub-objects. Get in the habit of creating a single object at the top level, then going immediately to the Modify panel and adding sub-objects by using rollouts or the NURBS Creation Toolbox on page 2426.
Sub-objects are either independent or dependent. Dependent sub-objects on page 2433 use relational modeling to build NURBS geometry that is related to other geometry. However, understand that the more dependencies a model has, the slower interactive performance becomes.

In general, point curves and surfaces are slower than CV curves and surfaces. Trims are the slowest kind of dependency, and texture surfaces are the slowest kind of dependent sub-object.

If a dependent sub-object doesn't change during animation, you can improve performance by making the sub-object independent after you finish creating it.

You can use NSurf Sel on page 1555 to apply modifiers to a sub-object selection. However, before you do so make sure that Relational Stack is on; Relational Stack on page 2484 is on the General rollout for NURBS models. Otherwise, NSurf Sel can select only the Surface and Surface CV sub-object levels.

Converting Other Objects to NURBS

Remember that you can collapse splines on page 577 to NURBS objects. A spline Shape or a NURBS curve can be a good starter object for a NURBS model.

Shapes with sharp angles collapse to multiple NURBS curves. You can control this before NURBS conversion by first converting the Shape to an editable spline on page 620. Modify the editable spline so that all its vertices are Bezier or Smooth vertices. Then when you collapse the spline to a NURBS curve, you obtain a single curve.

If you want a single NURBS curve, don't change vertices to Bezier Corner vertices. These always convert to a junction between two different NURBS curves.

Collapsing a primitive on page 388 into a NURBS object is one of the quickest ways to start building a NURBS model. After collapsing the primitive, you can select various CVs and transform them. Other objects you can convert to NURBS are prisms on page 458, torus knots on page 426, lofts on page 742, and patch grids on page 2408.

You can also change the NURBS surface by applying modifiers. The modifiers act on the points or CVs of the surface, and not on the surface itself. After applying the modifiers, collapse the modifier stack on page 8187.
This removes the modifiers from the stack without changing the position of the modified points or CVs, making for a simpler and quicker model.

- Another way to create a NURBS surface object is to apply a Lathe on page 1474 or Extrude on page 1425 modifier to a NURBS curve. Set the modifier's Output Type to NURBS, and then collapse when you're done adjusting the parameters. (There are also NURBS lathe and extrude surface sub-object types, which you can apply to curve sub-objects.)

### Shortcuts, Snaps, and User Interface Tips

- Remember to turn on the Plug-In Keyboard Shortcut Toggle on page 8420. While it is on, you can use all the NURBS keyboard shortcuts.

- One of the most useful NURBS keyboard shortcuts is H, which opens the Select Sub-Objects dialog. This is a subset of the Selection Floater on page 209 that you can use during sub-object creation as well as sub-object selection. This is handy when sub-objects are crowded or hard to see. A variant is Ctrl+H, which also displays the Select Sub-Objects dialog, but lists only those NURBS sub-objects beneath the mouse cursor position.

- There are special NURBS Snaps in the Grid and Snap Settings dialog on page 2819 (right-click the 3D Snap toggle to display this). When you use NURBS snaps, turn off Options/Axis Constraints; otherwise, snaps work only in the current axis. Also, remember that snaps work in a viewport only when you have made the viewport active. And choosing your snap settings does not turn on snaps. You must also turn on the 3D Snap Toggle button on page 2807 (on the status bar).

  Snaps are especially important when you create the curves for building 1-rail on page 2663 and 2-rail on page 2673 sweep surfaces.

- Remember that without leaving the viewport, you can right-click to display a quad menu on page 8052 with shortcuts for changing the sub-object level, creating some sub-objects, and using some other edit commands.

- When you work with NURBS, there are a lot of rollouts in the Modify panel. Minimize the rollouts you don't need. For example, minimizing the Modifiers rollout helps unless you're applying Modifiers, and minimizing the Surface Common rollout is useful when you're creating U loft, UV loft, and 1-rail or 2-rail sweep surfaces.

- Don't set viewports to display edged faces. Displaying edges is almost twice as slow as displaying a simple shaded viewport.
Creating Curves

■ When drawing a CV curve, click three times to get a sharp corner. Be aware, however, that multiple CVs increase the amount of calculation and therefore reduce the performance and stability of your model. However, if you want to use the curve to construct a U Loft, and so on, this is the best technique.

■ You can also create sharp corners by fusing the ends of two separate NURBS curve sub-objects. This is the recommended method if you aren't using the curves to construct a surface.

■ While creating curves, you can turn on the Draw in All Viewports toggle. This lets you draw curves in 3D. Begin drawing a curve in one viewport, go to another viewport, and continue drawing. If your mouse has a middle mouse button, Alt+middle mouse button lets you use Orbit on page 8152 to change a viewport's orientation while you are creating the curve.

■ To create a transform curve along a specific axis, turn on the appropriate axis constraints, and then Shift+move a copy of the transform curve.

Curves and Direction

■ NURBS curves show their direction in viewports. A small circle indicates the first vertex. If the curve is closed, a plus sign (+) indicates the direction of the curve. Be aware of curve direction when you use curves to construct blend surfaces on page 2614, U loft on page 2646 and UV loft on page 2656 surfaces, and 1-rail on page 2663 and 2-rail on page 2673 sweeps. If the curves don't have the same direction, you can get strange twisting. Make sure curves have the same direction before you construct the surface. On the Curve Common rollout, the controls Reverse and Make First let you control the direction of the curve, and where its starting point or CV is located. Another good way to make sure curves are aligned is to draw one curve and then use Shift+Clone to create the others. After creating the aligned curves, you can transform CVs to vary the curves on which the surface will be based.

Curves for Sweeps

■ Besides expecting cross-section curves to be all in the same direction, 1-rail on page 2663 and 2-rail on page 2663 sweep surfaces work best if the cross
sections intersect the rail or rails. To achieve this, draw the rails first, then draw the cross sections using the NURBS Snaps on page 2819 Curve End and Curve Edge turned on.

- 2-rail sweeps have the additional requirement that the endpoints of the first cross section intersect the endpoints of the rails. Again, NURBS Snaps help you do this. If the endpoints of the first cross-section don't coincide with the rail endpoints, the resulting surface might not follow the rails.

- While you're editing a sweep, the Edit Curve button lets you directly transform the CVs of a rail or cross section, without changing the sub-object level. Edit Curve also gives you access to all the rollouts that control the curve. You can use Refine or Make First, for example, without changing levels.

Curves on Surfaces and Projected Curves

- You can use a viewport to draw a curve on a surface on page 2593 (COS), but this works only for visible portions of the surface. To see the entire surface and the curve or curves on it projected into a flat plane, use Edit Curve. If your mouse has a middle mouse button, Alt+middle mouse button lets you use Orbit on page 8152 to change a viewport’s orientation while you draw the curve on surface.

- Neither curves on surfaces nor projected curves can cross the edge of a surface. This includes the seam on surfaces with fused CVs. If you try to project across the seam, only part of the curve’s projection is created.

Creating Blend Surfaces

- You can blend between curves or between surface edges. (You can't blend from a trimmed edge. In that situation, you are blending from the curve that trimmed the surface.)

- If you want a controllable tangent or tension, you must blend to a surface edge or a curve on a surface. Adjusting tension changes the flatness or "bulginess" of that end of the blend. When a curve and a surface (or two surfaces) are near each other, sometimes it can be hard to tell which edge you are selecting. To assist you, the currently selected surface turns yellow, and the edge that will be used for the blend turns blue. Make sure you have selected the right surface before you choose the edge.
- If the edges you are blending have different numbers of points (usually due to different surface approximation settings), then sometimes rendering shows gaps between the blend and the original surface. If this happens, go to the Surface Approximation rollout on page 2737 and increase the value of Merge until the gaps disappear when you render. The Merge setting affects only the production renderer. It has no effect on viewport display.

**Lofts**

- If you need a surface between only two curves, use a ruled surface on page 2640 instead of a U loft. This is faster.

- If loft creation seems slow, make sure the Display While Creating check box (in the U Loft Surface rollout on page 2646) is turned off.

- If the U loft doesn’t come out as you expected, try reparameterizing the curves. Click Reparam. at the Curve sub-object level. This button is on the CV Curve rollout. In the Reparameterize dialog on page 2733, choose Chord Length reparameterization. If a curve is dependent or a point curve, first you will have to make it independent (this also improves performance). Curves that are made of two joined curves have this problem more often than others. If you have a joined curve as one of the curves to construct the loft, reparameterize it before you create the loft, or set the curves to reparameterize automatically.

- The Edit Curve button lets you directly transform the CVs of a curve within a U loft or UV loft on page 2656, without changing the sub-object level. Edit Curve also gives you access to all the rollouts that control the curve. You can use Refine or Make First, for example, without changing levels.

- To close a UV loft, you can pick the first V curve again to make it the last curve in the loft. Sometimes a seam is visible at this location in the UV loft.

**Multisided Blend Surfaces**

- If 3ds Max doesn’t create the multisided blend on page 2683, fuse the CVs at the three or four corners. Snapping CVs to each other doesn’t always succeed, because of rounding off.
Multicurve Trimmed Surfaces

- Multicurve trimmed surfaces are the only way to create a trimmed hole that contains sharp angles.

Displacement Mapping

- In general, the default tessellation settings aren't suitable for displaced surfaces. With these default settings, displacement mapping can create an extremely high face count, which performs very slowly. Change the surface approximation to the lowest necessary resolution. A good rule of thumb is to start with Spatial approximation and an Edge value of 20. If that is too low, reduce the Edge value until the model looks as it should.

- Use the Displace NURBS world space modifier on page 1071 to convert the displacement map into an actual displaced mesh so you can see the effect of displacement in viewports. To make a displaced mesh copy of the NURBS model, use Snapshot on page 950.

Connecting an Arm to a Shoulder

- The easiest approach is to create a CV curve on surface on page 2593 or normal projected curve on page 2586 on the shoulder. Then create the arm as a U loft on page 2646. For the last curve of the U loft, select the CV curve on surface or the normal projected curve. Then turn on Use COS Tangents, which makes the loft surface tangent to the other surface where the arm joins the shoulder.

- If the blend appears twisted, use the Start Point spinner to change the location of the first point of the curves that make up the U loft surface.

- Another way to connect a U loft to another surface is to project the last curve in the U loft onto the other surface. Click Make COS to convert the projected curve into a curve on surface, and then on the U Loft Surface rollout click Insert to make the new curve on surface the last curve in the U loft. You can scale the curve on surface or move its CVs to get the curvature and blending you want.
How to Fix NURBS Objects

These are tips on fixing problems with NURBS models.

- If you create a surface but it isn't visible in viewports, click Flip Normals. Flip Normals is available on the surface's creation rollout, or at the Surface sub-object level on the Surface Common rollout.

- If you create a blend surface on page 2614 and it looks like a bow tie, use Flip End 1 or Flip End 2 to correct the twist.

- If a CV curve gives you unexpected or incorrect results, try reparameterizing it. Click Reparam. at the Curve sub-object level. This button is on the CV Curve rollout. In the Reparameterize dialog on page 2733, choose Chord Length reparameterization.
  If the curve still gives you trouble, try rebuilding it. The Rebuild button is on the same rollout.

- If a blend between a surface and a curve gives you unexpected or incorrect results, try reparameterizing the parent surface. Click Reparam. at the Surface sub-object level. This button is on the CV Surface rollout. In the Reparameterize dialog on page 2733, choose Chord Length reparameterization.

- If you see a seam in a shaded viewport, render the viewport first before you try to fix the seam. What you see in viewports might not be what you get in a render, and the viewport shader is less accurate than the production renderer. Seams in viewports can also result from different surface approximation settings on page 2737 for the viewport and the renderer, so check these as well.

- If you see gaps between faces in the rendered model, increase the Merge value for the renderer in the surface approximation settings.

- Sometimes gaps between faces appear after you convert a NURBS model into a mesh. (For example, by using Mesh Select on page 1500.) If this happens, increase the Merge value for the renderer in the surface approximation on page 2737 settings.

- If you see odd twists in a 1-rail on page 2663 or 2-rail on page 2673 sweep, add more cross sections at the areas of change in the surface. For example, if your rail looks like a box with rounded corners, placing cross sections at the corners helps to control the shape of the sweep. On the other hand, you don't need more cross sections for a rail shaped like an 'S', because the curvature is more constant.
If a U loft or UV loft doubles back on itself unexpectedly, make sure that all the curves are going in the same direction. Click Reverse to change a curve's direction. Use the Start Point spinner to align the curve's initial points.

How to Improve NURBS Performance

These are tips on improving the performance of your NURBS models.

- Avoid using point curves and point surfaces. These are slower than CV curves and CV surfaces. Use the point forms only when you need them for construction; for example, when you use Curve Fit to create a curve that interpolates specific points.

- Use the nonrelational stack on page 2484 feature in conjunction with the Shaded Lattice toggle to improve performance while you animate your NURBS model.

- Use Transform Degrade to hide surfaces while you are moving, rotating, and scaling NURBS sub-objects. The shortcut Ctrl+X toggles this option. You can use Ctrl+X in the middle of a transform, to turn on degradation if things are happening slowly.

- Turn off the display of dependent surfaces while you are creating new dependent surfaces or moving, rotating, or scaling NURBS sub-objects. The shortcut Ctrl+D toggles dependent surface display.

- Trim holes only when you need to. For example, when you connect an arm to a torso, you don't need to create a hole beneath the arm, as it won't be visible anyway. You can also speed up performance by turning off the Display Trims toggle. The shortcut Shift+Ctrl+T toggles trim display. The trims still appear in renderings.

- For symmetrical models, create only half the geometry, and then mirror it. You can then use a blend on page 2614 surface or ruled on page 2640 surface to connect the two halves.

- Restart 3ds Max when performance begins to slow down. If your NURBS model needs to page, then working with it for a long time causes performance to slow. If you notice this, save your work, close 3ds Max, and then restart.

- Convert point surfaces to CV surfaces whenever possible.
When you use texture surfaces, use the Edit Texture Surface dialog on page 2719 (click Edit Texture Surface on the Material Properties rollout on page 2544) to rebuild the texture surface with the minimum necessary number of UV rows and columns.

- U lofts are faster than UV lofts.
- Every type of surface is faster if you can make it independent.
- Set the surface approximation on page 2737 for viewports to use the lowest possible resolution. Set the renderer to use higher resolution, and turn on View Dependent for the renderer so objects far from the camera render more quickly.
- You can customize and save surface approximation on page 2737 presets by using the Surface Approximation utility on page 2748. This utility also lets you set surface approximation values for a selection set of multiple NURBS models.

**NURBS Animation, Textures, and Rendering**

These are tips about animating NURBS models and using textures with animated NURBS models.

- An easy way to animate a growing surface is to put a curve point on page 2698 with trimming on a curve, then animate the U position of the curve point, and then use this curve as the rail of a 1-rail sweep on page 2663. As the trimmed rail grows, so does the sweep surface. (You must trim the curve before you create the sweep surface.)

- If you see gaps between surfaces in rendered images, increase the value of Merge for the renderer in the surface approximation on page 2737 settings.

- If a texture slides around on the surface during animation, this is because you are using the default Chord-Length parameterization of the texture surface. Select the surface, then on the Material Properties rollout on page 2544 change the parameterization to User Defined. Now the texture should stick to the surface better.

- Don't use the UVW Map modifier on page 1932 to apply a texture to an animated NURBS surface.

- If a surface seems to glitter or jump around as you move toward it in an animation, this is because View Dependent tessellation is on (on the Surface
If a surface seems to glitter or jump around while it changes during animation, this is because the tessellation is changing as the surface animates. Changing surface approximation (on the Surface Approximation rollout) to Regular fixes this in all cases. Parametric tessellation also solves this problem for every kind of surface except U lofts on page 2646 and UV lofts on page 2656.

If the View Dependent setting doesn’t seem to be doing much, change the tessellation (on the Surface Approximation rollout) from Curvature to Spatial. You will then get a much more drastic change in face count.

To get a map to smoothly cover two or more surface without tiling, create another surface whose shape covers and roughly conforms to the original surfaces. Apply the texture to the larger surface. In the Material Properties rollout on page 2544 for the original surfaces, set Texture Surface to Projected, click Pick Source Surface, and pick the larger surface. Adjust the larger surface to fine-tune the map projection. Hide the larger surface before you render.

To have different maps on a surface sub-object, use different mapping coordinates on page 8628, and multiple map channels on page 8627. On the Material Properties rollout on page 2544, change the Map Channel value and then turn on Generate Mapping Coordinates. (Each map channel requires its own set of mapping coordinates.) NURBS surface sub-objects let you set the map channel directly, and don’t require you to apply UVW Map modifiers as other objects do.

If a map doesn’t align to a surface sub-object the way you want it to, on the Material Properties rollout on page 2544 choose User Defined as the Texture Surface, and then use Edit Texture Points or the Edit Texture Surface dialog to move the points of the texture surface.

To adjust how the map aligns to the edges of a surface sub-object, use the Texture Corner settings on the Material Properties rollout on page 2544.

**NURBS Surfaces**

Create panel > Geometry > NURBS Surfaces

Create menu > NURBS > CV Surface/Point Surface
NURBS on page 8655 surface objects are the basis of NURBS models. The initial surface you create using the Create panel is a planar segment with points or CVs. It is meant simply to be "raw material" for creating a NURBS model. Once you have created the initial surface, you can modify it on the Modify panel by moving CVs or NURBS points, attaching other objects, creating sub-objects, and so on.

There are two kinds of NURBS surfaces:

**Point Surface** on page 2456

**CV Surface** on page 2460

You can also create a NURBS surface from a geometric primitive on page 2483.

NURBS surfaces can contain multiple sub-objects, including NURBS points, NURBS curves, and other NURBS surfaces. These sub-objects are either dependent or independent.

**Creating Curve Sub-Objects** on page 2549

**Creating Surface Sub-Objects** on page 2603

**Creating and Editing Point Sub-Objects** on page 2694

**Common Sub-Object Controls** on page 2494

**Editing Point Sub-Objects** on page 2496

**Editing Curve CV Sub-Objects** on page 2503

**Editing Surface CV Sub-Objects** on page 2509

**Editing Curve Sub-Objects** on page 2518

**Editing Surface Sub-Objects** on page 2530

You can also create NURBS surface sub-objects by attaching or importing other 3ds Max objects on page 2490.

Both NURBS curves and NURBS surfaces have a Display area in the General rollout on the Modify panel. These controls affect which portions of the NURBS geometry are displayed. Next to the Display area is the button that turns on the toolbox for creating sub-objects.

**Display Controls for NURBS Models** on page 2486
WARNING When you move CV sub-objects, the effect must be calculated over a region of the surface. Although the calculations are optimized, this is a more involved process than simply moving vertices in an editable mesh. Because of this, if you manipulate large numbers of a NURBS surface’s CVs by transforming, animating, applying modifiers, and so on, you will notice a drop in interactive performance.

You can use MAXScript to control NURBS objects. See "Working with NURBS in MAXScript" in the MAXScript help file. Choose Help > Additional Help, and then choose MAXScript from the list of additional help files.

Point Surface

Create panel > Geometry > NURBS Surfaces > Point Surf
Create menu > NURBS > Point Surface
Point surfaces are NURBS surfaces on page 2454 whose points are constrained to lie on the surface.

Points shape the surface they lie on.
Because an initial NURBS surface is meant to be edited, the surface creation parameters do not appear on the Modify panel. In this respect, NURBS surface objects are different from other objects. The Modify panel provides other ways to change the values you set in the Create panel.

**Procedures**

**To create a point surface:**

1. Go to the Create panel.
2. Turn on Geometry, and choose NURBS Surfaces from the drop-down list.
3. Turn on Point Surf.
4. In a viewport, drag to specify the area of the planar segment.
5. Adjust the surface’s creation parameters.

**Interface**

The creation parameters are the same for both point surfaces and CV surfaces, except that the labels indicate which kind of basic NURBS surface you are creating.

**Keyboard Entry rollout**

The Keyboard Entry rollout lets you create a point surface by typing. Use the Tab key to move between the controls on this rollout. To click the Create button from the keyboard, press Enter while the button is active.
X, Y, and Z Let you enter the coordinates of the center of the surface.

Length and Width Let you enter the dimensions of the surface in current 3ds Max units.

Length Points Lets you enter the number of points along the length of the surface (this is the initial number of point columns).

Width Points Lets you enter the number of points along the width of the surface (this is the initial number of point rows).

Create Creates the surface object.
Create Parameters rollout

**Length** The length of the surface in current 3ds Max units.

**Width** The width of the surface in current 3ds Max units.

On the Modify panel, the Length and Width spinners are no longer available. You can change the length or width of the surface by scaling the surface at the Surface sub-object level. Moving point sub-objects also alters the length and width of the surface.

**Length Points** The number of points along the length of the surface. In other words, the initial number of point columns in the surface. Range=2 to 50. Default=4.

**Width Points** The number of points along the width of the surface. In other words, the initial number of point rows in the surface. Range=2 to 50. Default=4.

On the Modify panel, the point Length and Width spinners are no longer available. You can change the number of rows and columns by deleting existing rows and columns, or by adding new rows and columns using the Refine controls at the Point sub-object level.

**Generate Mapping Coordinates** Generates mapping coordinates so you can apply mapped materials to the surface.

The Generate Mapping Coordinates control is present on the Modify panel. It is at the Surface sub-object level.

**Flip Normals** Turn on to reverse the direction of the surface normals.
The Flip Normals control is present on the Modify panel. It is at the Surface sub-object level.

When you modify a point surface, a rollout lets you change its surface approximation settings on page 2737.

**CV Surface**

Create panel > Geometry > NURBS Surfaces > CV Surf

Create menu > NURBS > CV Surface

CV surfaces are NURBS surfaces on page 2454 controlled by control vertices (CVs on page 8543). The CVs don't lie on the surface. They define a control lattice on page 8538 that encloses the surface. Each CV has a weight that you can adjust to change the shape of the surface.

![CV Surface](image)

The CVs in a control lattice shape the surface it defines.

Because an initial NURBS surface is meant to be edited, the surface creation parameters do not appear on the Modify panel. In this respect, NURBS surface objects are different from other objects. The Modify panel provides other ways to change the values you set in the Create panel.
Procedures

To create a CV surface:

1. Go to the Create panel.
2. Turn on Geometry, and choose NURBS Surfaces from the drop-down list.
3. Turn on CV Surf.
4. In a viewport, drag to specify the area of the planar segment.
5. Adjust the surface’s creation parameters.

**NOTE** When you edit a CV surface you can add or move CVs so that more than one CV is at the same location (or close to it) to increase the influence of the CVs in that region of the surface. Two coincident CVs sharpen the curvature. Three coincident CVs create an angular peak in the surface. This technique can help you shape the surface. However, if you later move the CVs individually, you lose this effect. (You can also obtain the influence of multiple CVs by fusing on page 8588 CVs.)

Interface

The creation parameters are the same for both point surfaces and CV surfaces, except that the labels indicate which kind of basic NURBS surface you are creating.

**Keyboard Entry rollout**

The Keyboard Entry rollout lets you create a CV surface by typing. Use the Tab key to move between the controls on this rollout. To click the Create button from the keyboard, press Enter while the button is active.
X, Y, and Z Let you enter the coordinates of the center of the surface.

Length and Width Let you enter the dimensions of the surface, in current 3ds Max units.

Length CVs Lets you enter the number of CVs along the length of the surface (this is the initial number of CV columns).

Width CVs Lets you enter the number of CVs along the width of the surface (this is the initial number of CV rows).

Create Creates the surface object.
Create Parameters rollout

Length  The length of the surface in current 3ds Max units.

Width  The width of the surface in current 3ds Max units.

On the Modify panel, the Length and Width spinners are no longer available. You can change the length or width of the surface by scaling the surface at the Surface sub-object level. Moving CV sub-objects also alters the length and width of the surface.

Length CVs  The number of CVs along the length of the surface. In other words, the initial number of CV columns in the surface. Can range from 4 to 50.

Width CVs  The number of CVs along the width of the surface. In other words, the initial number of CV rows in the surface. Can range from 4 to 50.

On the Modify panel, the CV Length and Width spinners are no longer available. You can change the number of rows and columns by deleting existing rows and columns, or by adding new rows and columns using the Refine controls at the Surface CV sub-object level.
**Generate Mapping Coordinates** Generates mapping coordinates so you can apply mapped materials to the surface. The Generate Mapping Coordinates control is present on the Modify panel. It is at the Surface sub-object level.

**Flip Normals** Turn on to reverse the direction of the surface normals. The Flip Normals control is present on the Modify panel. It is at the Surface sub-object level. When you modify a CV surface, a rollout lets you change its surface approximation settings on page 2737.

**Automatic Reparameterization group**

The radio buttons in this group box let you choose automatic reparameterization. With reparameterization, the surface maintains its parameterization as you edit it. Without reparameterization, the surface's parameterization doesn't change as you edit it, and can become irregular.

**None** Do not reparameterize.

**Chord Length** Chooses the chord-length algorithm for reparameterization. Chord-length reparameterization spaces knots (in parameter space on page 8674) based on the square root of the length of each curve segment. Chord-length reparameterization is usually the best choice.

**Uniform** Spaces the knots uniformly. A uniform knot vector has the advantage that the surface will change only locally when you edit it. With the other two forms of parameterization, moving any CV can change the entire surface.

**NURBS Curves**

Create panel > Shapes button > NURBS Curves

NURBS on page 8655 curves are Shape objects on page 572, and you can use them as you do splines. You can use the Extrude or Lathe modifiers to generate a 3D surface based on a NURBS curve. You can use NURBS curves as the path or the shape of a loft. (Lofts created using NURBS curves are loft objects, not NURBS objects.)

You can also use NURBS curves as Path Constraint and Path Deform paths or as motion trajectories.
You can assign thickness to a NURBS curve so it renders as a cylindrical object. (The thickened curve renders as a polygonal mesh, not as a NURBS surface.)

A curve and the same curve rendered with thickness

There are two kinds of NURBS curve objects:
- Point Curve on page 2466
- CV Curve on page 2473

Like other Shape objects, NURBS curves can contain multiple sub-objects, which are either dependent or independent.
- Creating Curve Sub-Objects on page 2549
- Creating Surface Sub-Objects on page 2603
- Creating and Editing Point Sub-Objects on page 2694
- Common Sub-Object Controls on page 2494
- Editing Point Sub-Objects on page 2496
- Editing Curve CV Sub-Objects on page 2503
- Editing Surface CV Sub-Objects on page 2509
- Editing Curve Sub-Objects on page 2518
- Editing Surface Sub-Objects on page 2530

**NOTE** Like an object-level NURBS surface on page 2454, an object-level NURBS curve is a top-level NURBS model on page 8656 that can contain NURBS curve, NURBS surface, and NURBS point sub-objects. A NURBS curve remains a Shape object unless you add a surface sub-object to it; if you do, it converts to a NURBS surface (without changing its name).
Creating Independent Surfaces from NURBS Curve Objects on page 2480

You can also create NURBS curve sub-objects by attaching or importing other objects such as other NURBS curves or spline shapes.

Attaching and Importing 3ds Max Objects on page 2490

Display Controls for NURBS Models on page 2486

Both NURBS curves and NURBS surfaces have a Display area in the Modify panel. These controls affect which portions of the NURBS geometry are displayed. Next to the Display area is the button that turns on the toolbox for creating sub-objects.

**Point Curve**

Create panel > Shapes button > NURBS Curves > Point Curve button

Create menu > NURBS > Point Curve

Point curves are NURBS curves on page 2464 whose points are constrained to lie on the curve.

A point curve can be the basis of a full NURBS model on page 8656.
Points lie on the curve they define.

**Drawing Three-Dimensional Curves**

When you create a point curve, you can draw it in three dimensions. There are two ways to do this:

- **Draw In All Viewports:** This toggle lets you use any viewport to draw the curve, enabling you to draw three dimensionally.

- **Using Ctrl to drag points:** While you draw a curve, you can use the Ctrl key to drag a point off of the construction plane.

With the Ctrl-key method, further mouse movement lifts the latest point off the construction plane. There are two ways to use this:

- **Click-drag.** If you hold down Ctrl and also hold down the mouse button, you can drag to change the height of the point. The point's location is set when you release the mouse button. This method is probably more intuitive.
Click-click. If you Ctrl+click and then release the mouse button, the height changes as you drag the mouse. Clicking the mouse a second time sets the point's location. This method is less prone to repetitive stress injury.

While you are offsetting the point, a red dotted line is drawn between the original point on the construction plane and the actual point offset from the plane. You can move the mouse into an inactive viewport, in which case 3ds Max sets the height of the point using the point's Z axis in the inactive viewport. This lets you set the height of the point with accuracy.

Snaps on page 2819 also work when you change the height of a point. For example, if you turn on Point snapping, you can set a point to have the same height as another point by snapping to that other point in an inactive viewport.

Procedures

To create a NURBS point curve:

1. Go to the Create panel.
2. Turn on Shapes, and choose NURBS Curves from the drop-down list.
3. Turn on Point Curve.
4. In a viewport, click and drag to create the first point, as well as the first curve segment. Release the mouse button to add the second point. Each subsequent location you click adds a new point to the curve. Right-click to end curve creation.

**NOTE** If you begin the curve by clicking without dragging, this also creates the curve's first point. However, if you release the mouse button more than five pixels away from where you initially pressed it, this creates an additional point.

While you are creating a point curve, you can press Backspace to remove the last point you created, and then previous points in reverse order. If Draw In All Viewports is on, you can draw in any viewport, creating a 3D curve.
To lift a point off the construction plane, use the Ctrl key as described earlier in this topic under "Drawing Three-Dimensional Curves."

As with splines, if you click over the curve's initial point, a **Close Curve dialog** on page 2730 is displayed. This dialog asks whether you want the curve to be closed. Click No to keep the curve open or Yes to close the curve. (You can also close a curve when you edit it at the Curve sub-object level.) When a closed curve is displayed at the Curve sub-object level, the initial point is displayed as a green circle, and a green tick mark indicates the curve's direction.

5  Adjust the curve's creation parameters.

6  (Optional.) To add a new NURBS curve sub-object, you can turn off the Start New Shape check box, and then repeat the preceding steps.

**Interface**

The creation parameters are the same for both point curves and CV curves.
Rendering rollout

Lets you turn on and off the renderability of the curve, specify its thickness in the rendered scene, and apply mapping coordinates.

Render parameters can be animated. For example, you can animate the number of sides.

Enable In Renderer When on, the shape is rendered as a 3D mesh using the Radial or Rectangular parameters set for Renderer.

Enable In Viewport When on, the shape is displayed in the viewport as a 3D mesh using the Radial or Rectangular parameters set for Renderer.

Use Viewport settings Lets you set different rendering parameters, and displays the mesh generated by the Viewport settings. Available only when Enable in Viewport is turned on.

Generate Mapping Coords Turn this on to apply mapping coordinates. Default=off.
The U coordinate wraps once around the thickness of the spline; the V coordinate is mapped once along the length of the spline. Tiling is achieved using the Tiling parameters in the material itself.

**Real-World Map Size** Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=on.

**Viewport** Turn this on to specify Radial or Rectangular parameters for the shape as it will display in the viewport when Enable in Viewport is turned on.

**Renderer** Turn this on to specify Radial or Rectangular parameters for the shape as it will display when rendered or viewed in the viewport when Enable in Viewport is turned on.

**Radial** Displays the 3D mesh as a cylindrical object.

**Thickness** Specifies the diameter of the viewport or rendered spline mesh. Default=1.0. Range=0.0 to 100,000,000.0.

Splines rendered at thickness of 1.0 and 5.0, respectively

**Sides** Sets the number of sides (or facets) for the spline mesh in the viewport or renderer. For example, a value of 4 results in a square cross section.

**Angle** Adjusts the rotational position of the cross-section in the viewport or renderer. For example, if the spline mesh has a square cross section you can use Angle to position a "flat" side down.

**Rectangular** Displays the spline's mesh shape as rectangular.

**Aspect** Sets the aspect ratio for rectangular cross-sections. The Lock check box lets you lock the aspect ratio. When Lock is turned on, Width is locked to Depth that results in a constant ratio of Width to Depth.
Length Specifies the size of the cross-section along the local \( Y \) axis.

Width Specifies the size of the cross-section along the local \( X \) axis.

Angle Adjusts the rotational position of the cross-section in the viewport or renderer. For example, if you have a square cross-section you can use Angle to position a "flat" side down.

Auto Smooth If Auto Smooth is turned on, the spline is auto-smoothed using the threshold specified by the Threshold setting below it. Auto Smooth sets the smoothing based on the angle between spline segments. Any two adjacent segments are put in the same smoothing group if the angle between them is less than the threshold angle.

Threshold Specifies the threshold angle in degrees. Any two adjacent spline segments are put in the same smoothing group if the angle between them is less than the threshold angle.

Keyboard Entry rollout

The Keyboard Entry rollout lets you create a NURBS curve by typing. Use the Tab key to move between the controls in this rollout. To click a button from the keyboard, press Enter while the button is active.

<table>
<thead>
<tr>
<th>X</th>
<th>Y</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.1</td>
<td>0.3</td>
<td>0.3</td>
</tr>
</tbody>
</table>

Add Point Adds the point to the curve.

Close Ends creation of the curve and creates a segment between the last point and the initial point to close the curve.

Finish Ends creation of the curve, leaving it open.
Create Point Curve rollout

This rollout contains the controls for curve approximation.

Interpolation group

The controls in this group box change the accuracy and type of curve approximation on page 2736 used to generate and display the curve.

Draw In All Viewports  Lets you use any viewport while you are drawing the curve. This is one way to create a 3D curve. When off, you must finish drawing the curve in the viewport where you began it. Default=on.

While Draw In All Viewports is on, you can also use snaps on page 2819 in any viewport.

CV Curve

Create panel > Shapes button > NURBS Curves > CV Curve button
Create menu > NURBS > CV Curve

CV curves are NURBS curves on page 2464 controlled by control vertices (CVs on page 8543). The CVs don't lie on the curve. They define a control lattice on page 8538 that encloses the curve. Each CV has a weight that you can adjust to change the curve.

While you're creating a CV curve you can click to create more than one CV at the same location (or close to it), increasing the influence of the CVs in that region of the curve. Creating two coincident CVs sharpens the curvature. Creating three coincident CVs creates an angular corner in the curve. This technique can help you shape the curve; however, if you later move the CVs individually, you lose this effect. (You can also obtain the influence of multiple CVs by fusing on page 8588 CVs.)

A CV curve can be the basis of a full NURBS model on page 8656.
CVs shape the control lattice that defines the curve.

**Drawing Three-Dimensional Curves**

When you create a CV curve, you can draw it in three dimensions. There are two ways to do this:

- **Draw In All Viewports:** This toggle lets you use any viewport to draw the curve, enabling you to draw three dimensionally.

- **Using Ctrl to drag CVs:** While you draw a curve, you can use the Ctrl key to drag a CV off of the construction plane.

With the Ctrl–key method, further mouse movement lifts the latest CV off the construction plane. There are two ways to use this:

- **Click-drag:** If you hold down Ctrl and also hold down the mouse button, you can drag to change the height of the CV. The CV’s location is set when you release the mouse button. This method is probably more intuitive.
Click-click. If you Ctrl+click and then release the mouse button, the height changes as you drag the mouse. Clicking the mouse a second time sets the CV's location. This method is less prone to repetitive stress injury.

While you are offsetting the CV, a red dotted line is drawn between the original CV on the construction plane and the actual CV offset from the plane. You can move the mouse into an inactive viewport, in which case 3ds Max sets the height of the CV using the CV's Z axis in the inactive viewport. This lets you set the height of the CV with accuracy.

Snaps on page 2819 also work when you change the height of a CV. For example, if you turn on CV snapping, you can set a CV to have the same height as another CV by snapping to that other CV in an inactive viewport.

Procedures

To create a NURBS CV curve:

1. Go to the Create panel.
2. Turn on Shapes, and choose NURBS Curves from the drop-down list.
3. Turn on CV Curve.
4. In a viewport, click and drag to create the first CV, as well as the first curve segment. Release the mouse to add the second CV. Each subsequent location you click adds a new CV to the curve. Right-click to end curve creation.

**NOTE** If you begin the curve by clicking without dragging, this also creates the curve's first CV. However, if you release the mouse more than five pixels away from where you initially pressed it, this creates an additional CV.

While you are creating a CV curve, you can press Backspace to remove the last CV you created, and then previous CVs in reverse order.

If Draw In All Viewports is on, you can draw in any viewport, creating a 3D curve.

To lift a CV off the construction plane, use the Ctrl key as described earlier in this topic under "Drawing Three-Dimensional Curves."
As with splines, if you click over the curve's initial CV, a Close Curve dialog on page 2714 is displayed. This dialog asks whether you want the curve to be closed. Click No to keep the curve open or Yes to close the curve. (You can also close a curve when you edit it at the Curve sub-object level.) When a closed curve is displayed at the Curve sub-object level, the initial CV is displayed as a green circle, and a green tick mark indicates the curve's direction.

5 Adjust the curve's creation parameters.

6 (Optional) To add a new NURBS curve sub-object, you can turn off the Start New Shape check box, and then repeat the preceding steps.

Interface

The creation parameters are the same for both point curves and CV curves.

Rendering rollout
Enable In Renderer When on, the shape is rendered as a 3D mesh using the Radial or Rectangular parameters set for Renderer.

Enable In Viewport When on, the shape is displayed in the viewport as a 3D mesh using the Radial or Rectangular parameters set for Renderer.

Use Viewport settings Lets you set different rendering parameters, and displays the mesh generated by the Viewport settings. Available only when Enable in Viewport is turned on.

Generate Mapping Coords Turn this on to apply mapping coordinates. Default=off.

The U coordinate wraps once around the thickness of the spline; the V coordinate is mapped once along the length of the spline. Tiling is achieved using the Tiling parameters in the material itself.

Real-World Map Size Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found in the applied material's Coordinates rollout on page 6201. Default=on.

Viewport Turn this on to specify Radial or Rectangular parameters for the shape as it will display in the viewport when Enable in Viewport is turned on.

Renderer Turn this on to specify Radial or Rectangular parameters for the shape as it will display when rendered or viewed in the viewport when Enable in Viewport is turned on.

Radial Displays the 3D mesh as a cylindrical object.

Thickness Specifies the diameter of the viewport or rendered spline mesh. Default=1.0. Range=0.0 to 100,000,000.0.

Splines rendered at thickness of 1.0 and 5.0, respectively
**Sides** Sets the number of sides (or facets) for the spline mesh in the viewport or renderer. For example, a value of 4 results in a square cross section.

**Angle** Adjusts the rotational position of the cross-section in the viewport or renderer. For example, if the spline mesh has a square cross section you can use Angle to position a "flat" side down.

**Rectangular** Displays the spline's mesh shape as rectangular.

**Aspect** Sets the aspect ratio for rectangular cross-sections. The Lock check box lets you lock the aspect ratio. When Lock is turned on, Width is locked to Depth that results in a constant ratio of Width to Depth.

**Length** Specifies the size of the cross-section along the local Y axis.

**Width** Specifies the size of the cross-section along the local X axis.

**Angle** Adjusts the rotational position of the cross-section in the viewport or renderer. For example, if you have a square cross-section you can use Angle to position a "flat" side down.

**Auto Smooth** If Auto Smooth is turned on, the spline is auto-smoothed using the threshold specified by the Threshold setting below it. Auto Smooth sets the smoothing based on the angle between spline segments. Any two adjacent segments are put in the same smoothing group if the angle between them is less than the threshold angle.

**Threshold** Specifies the threshold angle in degrees. Any two adjacent spline segments are put in the same smoothing group if the angle between them is less than the threshold angle.

---

A curve and the same curve rendered with thickness
Keyboard Entry rollout

The Keyboard Entry rollout lets you create a NURBS curve by typing. Use the Tab key to move between the controls in this rollout. To click a button from the keyboard, press Enter while the button is active.

<table>
<thead>

</tr>
<tr>
<td>Z: 0.0</td>
</tr>
<tr>
<td>Weight: 1.0</td>
</tr>
</tbody>
</table>

**Add Point** Adds the CV to the curve.

**Weight** Enter a weight for the CV.

**Close** Ends creation of the curve and creates a segment between the last CV and the initial CV, to make the curve a closed curve.

**Finish** Ends creation of the curve, leaving it open ended.

Create CV Curve rollout

This rollout contains the controls for curve approximation.
Interpolation group

The controls in this group box change the accuracy and kind of curve approximation on page 2736 used to generate and display the curve.

Draw In All Viewports Lets you use any viewport while you are drawing the curve. This is one way to create a 3D curve. When off, you must finish drawing the curve in the viewport where you began it. Default=On.
While Draw In All Viewports is on, you can also use snaps on page 2819 in any viewport.

Automatic Reparameterization group

The controls in this group box let you specify automatic reparameterization. They are similar to the controls in the Reparameterize dialog on page 2733, with one addition: all choices except for None tell 3ds Max to reparameterize the curve automatically; that is, whenever you edit it by moving CVs, refining, and so on.

None Do not reparameterize automatically.

Chord Length Chooses the chord-length algorithm for reparameterization.
Chord-length reparameterization spaces knots (in parameter space on page 8674) based on the square root of the length of each curve segment.
Chord-length reparameterization is usually the best choice.

Uniform Spaces the knots uniformly.
A uniform knot vector has the advantage that the curve or surface changes only locally when you edit it. With the other two forms of parameterization, moving any CV can change the entire sub-object.

Creating NURBS Curve and Surface Objects

These topics describe how to create top-level, “starter” NURBS objects.

Creating Independent Surfaces from NURBS Curve Objects

To create independent surfaces from top-level NURBS curve objects, use the Extrude on page 1425 and Lathe on page 1474 modifiers. Extrude adds height to
the curve, creating a shape by sweeping it along the curve's local Z axis. Lathe
creates a surface of rotation, revolving the shape along a specified axis. You
can also use the Bevel on page 1169 and Bevel Profile on page 1176 modifiers on
NURBS curves.

These modifiers treat NURBS curves the same way they treat shapes on page
572. The advantage of using NURBS curves instead of shapes is in the different
possible shapes that NURBS geometry and editing provide.

**TIP** When you create a complicated surface, especially with the Lathe modifier,
you often want to render both sides of the surface. To see both sides of the
extruded or lathed surface in rendered output, turn on Force 2-Sided on the Render
Setup dialog. To see both sides in viewports, turn on Force 2-Sided on the Viewport
Configuration dialog.

By default, an object with Extrude or Lathe collapses to an editable mesh on
page 2192 object. To have Extrude or Lathe output collapse to a NURBS object,
change the setting to NURBS in the Output group box of the Extrude or Lathe
rollout, and then collapse the modifier stack on page 8187.

**Creating NURBS Curves from Splines**

Select Spline object. > Modify panel > Right-click the spline name. > Convert
To: NURBS

You can turn a spline on page 577 into a NURBS object formed of CV curves
on page 2464. Once converted, you can no longer edit the spline shape
parametrically, but you can edit it as a NURBS object, moving CVs and so on.
Splines become NURBS curves that then become NURBS surfaces.

When you convert a spline circle on page 590 to a NURBS curve, the direction of the curve is reversed. This facilitates using the curve to trim a surface: if the direction weren't reversed, usually the circle would trim outward instead of inward.

Procedures

To turn a spline into NURBS curves:

1. Create the spline.

2. Go to the Modify panel.

3. In the stack display, right-click the name of the spline.

4. On the pop-up menu, choose Convert To: NURBS.
   The spline is converted to one or more CV curves.
   Smoothly curved splines, such as circles and arcs, convert to a single CV curve.
Splines with sharp angles, such as rectangles and stars, convert to multiple CV curves whose endpoints are at the angles in the original spline. These endpoints are fused except for the initial CV in the spline (for a star, the initial segment is unfused at both ends).

"Sharp angles" doesn't apply to smooth splines to which you have given angles by changing vertex tangents using the Edit Spline on page 1424 modifier. These still convert to a single NURBS curve.

Creating NURBS Surfaces from Geometric Primitives

You can turn a standard primitive on page 388 into a NURBS object formed of CV surfaces on page 2606. Once converted, you can no longer edit the object parametrically, but you can edit it as a NURBS object, moving CVs and so on.

Primitive objects become NURBS surfaces that you can then edit in various ways.

You can't convert most extended primitive objects in this way, but you can convert the torus knot on page 426 and prism on page 458 extended primitives to NURBS objects.
You can also convert patch on page 2408 objects and loft on page 742 compound objects.

**Tips**

- Geospheres are good for creating rounded models with no sharp edges.
- Boxes are good for creating models that have sharp edges.
- Flattened cones work well for models whose contours are roughly triangular.

If the primitive is closed, the converted surface is a closed CV surface, which has no visible seams. Also, relational cap surfaces on page 2643 are used to cap surfaces that aren’t closed.

**Procedures**

To turn a primitive into a NURBS object:

1. Create the primitive object.
2. Go to the Modify panel.
3. In the stack display, right-click the name of the object.
4. On the pop-up menu, choose Convert To: NURBS.
   The object is converted to one or more CV surfaces. The surfaces can be independent surface sub-objects, or dependent surface sub-objects such as Lathe.

**Nonrelational NURBS Surfaces**

Select NURBS object. > Modify panel > General rollout > Relational Stack toggle
Nonrelational NURBS surfaces provide a way to improve the performance of NURBS with modifiers. These are controlled by the Relational Stack toggle on the General rollout for NURBS objects.
When Relational Stack is on, NURBS maintain full relational modeling on the modifier stack on page 8187. When this toggle is off (the default), then using the modifier stack converts surfaces into independent CV surfaces before applying modifiers. Surfaces on the stack behave in a nonrelational way. If your NURBS model contains no dependent surfaces, then it behaves the same on the stack regardless of the Relational Stack setting. However, the results are still faster if Relational Stack is turned off.

When Relational Stack is off, there is no overhead of copying the data from the relational model, and no need to compute the relational surfaces, so performance is faster.

**TIP** To improve performance still further, display surfaces as shaded lattices (see Display Controls for NURBS Models on page 2486). With Relational Stack off and Shaded Lattice chosen, NURBS objects perform on the stack about as well as mesh objects do.
Procedures

To use nonrelational NURBS surfaces:

1. Make sure Relational Stack is off and Shaded Lattice is chosen.

2. Set up your modifiers and animation.

3. If your model has only independent CV surfaces, you can render it now. If it has relational surfaces such as blends or lofts, then before you render, choose the NURBS model at the bottom of the stack, and turn on Relational Stack.

   When you return to the top of the modifier stack, performance is slower but dependent surfaces are accurate. The modified NURBS model looks different than it did with the nonrelational stack. Usually the difference in appearance isn't great, but the nonrelational stack can show anomalies such as cracks between Blend surfaces.

Display Controls for NURBS Models

Modify panel > Select NURBS object. > General rollout > Display group, Surface Display group, and NURBS Creation Toolbox button

Modify panel > Select NURBS object. > Right-click in viewport. > Display commands on the Tools 1 (upper-left) quadrant of the quad menu

The check boxes on the General rollout for a NURBS curve or surface control how the object is displayed in viewports. If all check boxes are turned off, the NURBS object is invisible (except for the white bounding-box indicators displayed in shaded viewports when the object is selected).

An additional rollout, Display Line Parameters on page 2489, contains controls for how surfaces display in viewports.
### Interface

![Interface Display Group](image)

#### Display group

**Lattices** When on, displays control lattices in yellow lines. (You can change the lattice color using the Colors panel on page 8272 of the Customize User Interface dialog.) The Curve CV and Surface CV sub-object levels also have a local Display Lattice toggle, which overrides this global setting at the sub-object level. The Curve CV and Surface CV settings are independent. In other words, at the sub-object level you can turn on the lattice for an object’s curves but not its surfaces, or vice versa.

Keyboard shortcut (while Keyboard Shortcut Override Toggle is on): Ctrl+L

At the object level, this shortcut is equivalent to turning Lattice on or off. At the sub-object level, Ctrl+L overrides the setting of Lattice, toggling the local Display Lattice setting.

**Curves** When on, displays curves.

Keyboard shortcut (while Keyboard Shortcut Override Toggle is on): Ctrl+Shift+C

**Surfaces** When on, displays surfaces.

Keyboard shortcut (while Keyboard Shortcut Override Toggle is on): Ctrl+Shift+S

**Dependents** When on, displays dependent sub-objects.

Keyboard shortcut (while Keyboard Shortcut Override Toggle is on): Ctrl+D

**Surface Trims** When on, displays surface trimming on page 2420. When turned off, displays the entire surface, even if it’s trimmed.

Keyboard shortcut (while Keyboard Shortcut Override Toggle is on): Ctrl+Shift+T

**Transform Degrade** When on, transforming a NURBS surface can degrade its display in shaded viewports, to save time. This is similar to the Degradation Override on page 123 button for playing animations. You can turn off this...
toggle so surfaces are always shaded while you transform them, but transforms can take longer.
Keyboard shortcut (while Keyboard Shortcut Override Toggle is on): Ctrl+X

**TIP** You can toggle Ctrl+X during a transform, as well as before you begin the transform.

NURBS Creation Toolbox
Turn on to display the NURBS sub-object creation toolbox. See Using the NURBS Toolbox to Create Sub-Objects on page 2426.
Keyboard shortcut (while Keyboard Shortcut Override Toggle is on): Ctrl+T

**Surface Display group**

![Surface Display]

This group box, for surfaces only, lets you choose how to display surfaces in viewports.

**Tessellated Mesh** When chosen, NURBS surfaces display as fairly accurate tessellated meshes in shaded viewports. In wireframe viewports, they appear as either iso curves or wire meshes, depending on the settings you've chosen on the Display Line Parameters rollout on page 2489.

**Shaded Lattice** When chosen, NURBS surfaces appear as shaded lattices in shaded viewports. Wireframe viewports display the surface's lattice without shading. A shaded lattice shades the CV control lattice on page 8538 of the NURBS surface. This displays more quickly than a tessellated mesh. The shading is not accurate. It gives you a fairly good idea of loft's, but is less accurate for free-form surfaces. The shading is always as large or larger than the actual surface, because of the convex hull property on page 8540.

Shaded lattice display doesn't show surface trimming on page 2420 or texture mapping.

**TIP** Shaded Lattice is a good option to choose when you use the modifier stack with nonrelational NURBS surfaces on page 2484.

Keyboard shortcut: Alt+L
(You can use this keyboard shortcut without having to turn on the Keyboard Shortcut Override Toggle.)

**Display Line Parameters for NURBS Surfaces**

Select NURBS object. > Modify panel > Display Line Parameters rollout
These parameters are contained on a single rollout at the top level of a NURBS object.

**Interface**

![Display Line Parameters Rollout]

**U Lines and V Lines** The number of lines used to approximate the NURBS surface in viewports, along the surface's local U and V dimensions, respectively. Reducing these values can speed up the display of the surface, but reduce accuracy of the display. Increasing these values increases accuracy at the expense of time. Setting one of these values to 0 displays only the edge of the object in the corresponding dimension.
Iso and mesh displays of a NURBS teapot

**Iso Only** When chosen, all viewports display iso line representations of the surface. Iso(parametric) lines are similar to contour lines. The lines show where the NURBS surface has a constant U value or V value or both. Iso line representations can be less crowded and easier to visualize than wire mesh representations.

**Iso and Mesh** (The default.) When chosen, wireframe viewports display iso line representations of the surface, and shaded viewports display the shaded surface.

**Mesh Only** When chosen, wireframe viewports display the surface as a wire mesh, and shaded viewports display the shaded surface. In wireframe viewports, this option lets you see the surface approximation on page 2737 used for viewports.

### Creating and Editing NURBS Sub-Objects

These topics describe how to create and edit lower-level, sub-object NURBS.

#### Attaching and Importing 3ds Max Objects

Modify panel > Select NURBS object > General rollout > Attach button, Import button, and related controls
You can bring other 3ds Max objects into a NURBS model.

There are two ways to bring other 3ds Max objects into a NURBS object:

- **Attach**, which works like Attach for meshes and splines. It converts the attached object to NURBS format. Once the object is attached, you can edit it as a NURBS surface or curve. However, the attached object's history is lost.

  **NOTE** For NURBS surfaces, you can attach other NURBS objects, standard primitive on page 388 objects, or quad patch on page 2410 and tri patch on page 2413 surfaces. The patch is converted to a NURBS surface. Quad patches convert more successfully than Tri Patches. A converted Tri Patch has a collapsed internal edge, which gives irregular results when you manipulate its mesh.

  When you convert a spline circle on page 590 to a NURBS curve, the direction of the curve is reversed. This facilitates using the curve to trim a surface: if the direction weren't reversed, usually the circle would trim outward instead of inward.

- **Import**, which works somewhat like the operand of a Boolean on page 713. The object is brought into the NURBS object without losing its history. You can select the imported object as a sub-object.

**Using Imports**

Here are reasons to use Import instead of Attach:

- To maintain parametric control over primitives. For example, if you import a sphere, you can change its radius directly, which you can't do after using Attach.

- To use Bezier splines as NURBS curves. For example, if you want to use a Bezier spline as a curve in a NURBS model, import it. This allows you to edit it as a Bezier spline, and not as a NURBS curve.

Surfaces and curves created by an import are available in the NURBS model. For example, if you import a box, you can create a blend surface between one of its polygons and another surface in your NURBS object.

Once you have imported an object, the NURBS object has an Imports sub-object level. When you select an import, it is highlighted in red.

It is an error to apply a modifier to an import when the modifier converts the import into something that can't be converted to a NURBS object. For example,
if you import a sphere and apply a Bend on page 1165 to it, the sphere converts to an editable mesh, which can't automatically convert to a NURBS surface. In this case, the import sub-object is in an error state, and it is displayed in the error color (orange by default).

Imports are displayed in two different ways. While you work at the NURBS object level or at a sub-object level other than Imports, imports are displayed as NURBS curves or surfaces, and use the NURBS object's mesh tessellation (see Surface Approximation on page 2737). However, at the Imports sub-object level, the selected import is displayed using its native display format. In other words, it displays as it would if it were a top-level object. This is because the display must let you edit the imported object. For example, an imported Bezier spline needs to display its tangent handles. This wouldn't be possible if it were displayed as a converted NURBS curve. Leaving the Imports sub-object level returns to NURBS-style display.

You can extract an imported object. This creates an independent, top-level object again.

![Extract](image)

**Procedures**

**To attach or import an object to a NURBS object:**

1. Select the NURBS object and go to the Modify panel.

2. (Optional.) Turn on Reorient if you want to reorient and align the import with the center of the NURBS object.

3. Turn on Attach or Import.

   **NOTE** At this step, you can click Attach Multiple or Import Multiple instead. These buttons open a Select From Scene dialog on page 206 so you can choose multiple objects to attach or import.

4. Click the object to attach or import.

   The mouse cursor changes shape to indicate a valid object. You can attach curves, NURBS surfaces, or objects convertible to NURBS.
To extract an imported object:

1. Go to the Imports sub-object level and select the object to extract.
2. Click Extract Import on the Import sub-object rollout.

If Copy is set (the default), the extracted object is a top-level copy of the imported object. If Instance is set, the extracted object is an instance of the imported object. Initially the extracted object occupies the same space as the imported object; you must move either the extracted object, the import sub-object, or the whole NURBS model before you can see the extracted object.

**Interface**

![Attach, Attach Multiple, Reorient, Import, Import Multiple buttons]

**Attach and Import controls**

**Attach** Lets you attach another object to the NURBS object. Click to turn on Attach, and then click the object to attach. If the object you're attaching isn't already a NURBS object, it is converted to one or more NURBS curves or surfaces that are sub-objects of the object you're modifying.

**Attach Multiple** Lets you attach multiple objects to the NURBS surface. Opens a version of the Select From Scene dialog on page 206, listing the objects that can be attached. Use the dialog controls to select one or more objects by name, and then click Attach.

**Reorient** Moves and reorients the object you are attaching or importing so its creation local coordinate system is aligned with the creation local coordinate system of the NURBS object.

**Import** Lets you import another object to the NURBS object. Works the same way Attach does, but the imported object retains its parameters and modifiers.

**Import Multiple** Lets you import multiple objects. Works the same way Attach Multiple does, but the imported objects retain their parameters and modifiers.
Common Sub-Object Controls

Many controls are common to the various kinds of sub-objects in NURBS models (with the exception of Imports on page 2490). This topic introduces the controls that are common to most NURBS sub-objects.

See also:
- Editing Point Sub-Objects on page 2496
- Editing Curve CV Sub-Objects on page 2503
- Editing Surface CV Sub-Objects on page 2509
- Editing Curve Sub-Objects on page 2518
- Editing Surface Sub-Objects on page 2530

Transforming Sub-Objects

One way to alter a NURBS model is to transform its sub-objects. Transforming lets you interactively change the model's curvature and shape. Transforming points or CVs is especially useful for adjusting the shape of a NURBS curve or surface.

You can also Shift+Clone most kinds of sub-objects, except CVs. For curves and surfaces, Shift+Cloning displays a Sub-Object Clone Options dialog on page 2734, which lets you reduce relational dependencies to improve performance.

Selection Controls

There is a Selection group box on the rollout for all NURBS sub-objects except Imports. The buttons in this group let you control which sub-objects to select. The selection buttons let you select sub-objects individually, or multiple sub-objects at once. For example, Surface CV selection buttons give you the option of selecting individual CVs, or selecting a row of CVs on the surface, and so on.

NOTE There is no delete modifier for NURBS curves as there is for splines. There is a NURBS selection modifier, NSurf Sel on page 1555. See NURBS and Modifiers on page 2436.
Selection controls also include a Name field that lets you customize the name of individual NURBS sub-objects other than CVs. (The Name field is the only selection control for Import sub-objects.)

**Visibility**

You can hide or unhide NURBS sub-objects as you do other objects. Hidden sub-objects are invisible in viewports, but remain renderable. (At the sub-object level, hiding doesn’t affect the renderer.) You can’t select hidden sub-objects. Hide and unhide by name is available for curve and surface sub-objects.

**Make Independent**

You can make a dependent point, curve, or surface sub-object independent.

**WARNING** When you make an object independent, you lose the animation controllers for all objects that depend on it in turn. When you make point objects independent, you lose the animation controllers for all points on the curve or surface. Also, if you make a curve that trims a surface independent, you lose the trimming of the surface.

**Remove Animation**

All sub-object rollouts have a Remove Animation button. This removes animation controllers from the selected sub-objects.

**Detach and Copy**

You can create a new curve or surface object by detaching a curve or surface sub-object from a NURBS model. To do so, select the curve or surface and then click Detach. A dialog is displayed, which lets you enter a name for the new NURBS object. The new object is no longer part of the original NURBS object.

You can also use the Detach button to create a new NURBS object that is a copy of a curve or surface sub-object. To do so, select the curve or surface, and click to turn on Copy before you click Detach. A dialog is displayed, which lets you enter a name for the new object. The original curve or surface sub-object remains part of the NURBS object you were editing, but the copied curve or surface is now a NURBS object of its own.

**Relational** This toggle affects dependent objects. When off, detaching a dependent sub-object makes it an independent object. For example, detaching a U loft converts it to a CV surface. When on, detaching a dependent sub-object
also detaches the objects it depends on, so the object remains dependent. For example, detaching a U loft also detaches the curves that define it.

**Editing Point Sub-Objects**

Modify panel > Select NURBS object or sub-object > Point sub-object level > Select point sub-objects.

Modify panel > Select NURBS object or sub-object > Right-click > Tools 1 (upper-left) quadrant > Sub-objects > Point > Select point sub-objects.

This topic describes the controls for point sub-objects. A rollout labeled Point contains the point sub-object controls for NURBS models. In addition to the Point rollout described here, the Point sub-object level displays the Soft Selection rollout on page 2541.

**Procedures**

To transform point sub-objects:

1. At the Point sub-object level, select one or more points.
   The sub-object selection tools are the same as for other kinds of sub-objects. You can also use the H key while the Keyboard Shortcut Override toggle on page 8420 is on. See Sub-Object Selection on page 2428.
   The Selection group box, described under "Interface" later in this topic, provides some additional options for selecting Point sub-objects.

2. Turn on Move or another transform and then drag in a viewport to transform the selection.
   The shape of the model changes as you interactively transform the points. Rotate and Scale are useful only when you've selected multiple points.

**Tips**

- The Lock Selection Set button is useful when you transform NURBS point sub-objects. You can make a selection in one viewport, click Lock Selection Set (or press the Spacebar), and then transform the selection in a different viewport.

- When you move point sub-objects, move them as systematically as possible to avoid "getting lost."
On surfaces, avoid moving points so they cross over or under adjacent points. This can create odd-looking warps or overlaps in the surface.

**To Shift+Clone a point sub-object:**
- Hold down Shift while you transform the point.
  This works only for points that lie on curves or surfaces, independent point on page 2695 sub-objects, and curve point on page 2698 or surface point on page 2701 sub-objects that lie on the curve or surface (that is, that aren't displaced).

**To use the keyboard to select point sub-objects:**
You can select point sub-objects using the Ctrl key and the arrow keys. The arrows traverse the sub-objects in the order they were created. To do so, follow these steps:

1. Turn on the Keyboard Shortcut Override Toggle.
2. Click or drag to select points.
3. Hold down Ctrl and use the arrow keys to move among the point sub-objects.
   For points on curves, the arrow keys traverse the point selection along the length of the curve. The arrow keys don’t move between curve sub-objects.
   For points on surfaces, the left and right arrow keys traverse the U dimension of a surface, while the up and down arrow keys traverse the V dimension of the surface. The arrow keys don’t move between surface sub-objects.
   The arrow keys don’t traverse individually created points that aren’t part of a curve or surface.

You can also use the H keyboard shortcut (while the Keyboard Shortcut Override Toggle is on) to display a dialog and select points by name. Ctrl+H displays only the names of points directly beneath the mouse cursor.

**To remove a point from a curve:**
1. Select a point.
2 In the Delete group box, click Point.
   Keyboard shortcut: Delete
   The point is deleted and the shape of the curve is updated.

   **NOTE** An open point curve must have at least two endpoints.

**To remove points from a surface:**
1 Select a point, row, or column.
   The appropriate Delete buttons are enabled.
2 In the Delete group box, click Point, Row, or Col.
   The point, row, or column is deleted. Deleting a "single" point actually
   deletes both the row and column to which the point belongs.

**To add a point to a curve:**
1 In the Refine group box, turn on Curve.
2 Click the curve where you want to add the point.
   A point is added at the location you clicked. The curvature can change.

**To add a point and extend the length of a curve:**
1 Click to turn on Extend.
2 Move the mouse over a point curve. The curve is highlighted in blue,
   and one of the curve's ends displays a box to show where the curve will
   be extended.
3 Drag from the highlighted end point, and then release the mouse button.
   A new point is added beyond the original length of the curve.

**To add points to a point surface:**
1 In the Refine group box, click Surf Row, Surf Col., or Surf Row & Col.
2 Click the surface.
   A row, a column, or both are added close to the point where you clicked
   the surface. The new points are placed on the surface so they preserve
   the surface's curvature. The curvature can change, but only slightly.
To fuse two points:

1. Turn on Fuse.
2. Click a point without releasing the mouse button. Drag to another point, and then release the mouse button.

   The first point you choose acquires the position of the second point, and becomes dependent to it. If the first point has an animation controller, the controller is discarded. If the second point has an animation controller, the first point acquires it too.

   Fused points display in purple by default.

To unfuse fused points:

1. Select the fused point.
2. Click Unfuse.
   - Now you can move and edit the two points independently.

To transform a region:

1. Using sub-object selection, select one or more points for the center of transformation.
2. Turn on Soft Selection.
3. Transform the point.
   - A region around the selected point is transformed accordingly.

Move is the most common transform to use. Rotate and Scale can be used with a non-local transform center.

**TIP** If Soft Selection appears not to be working, the Falloff value might be too small for the size of your surface. On the Soft Selection rollout on page 2541, increase the value of Falloff so it encompasses other points.

**Interface**

In addition to the Point rollout described here, the Point sub-object level also displays the Soft Selection rollout on page 2541.
Selection group

Point sub-object selection controls

- **Single Point** (The default.) When on, you can select individual points by clicking, or groups of points by dragging a region.

- **Row of Points** When on, clicking a point selects the entire row the point belongs to. Dragging selects all rows in the region.
  If the point is on a curve, Row of Points selects all points in the curve.

- **Column of Points** When on, clicking a point selects the entire column the point belongs to. Dragging selects all columns in the region.
  If the point is on a curve, Column of Points selects only a single point.

- **Row and Column of Points** When on, clicking a point selects both the row and column the point belongs to. Dragging selects all rows and columns in the region.

- **All Points** When on, clicking or dragging selects all the points in the curve or surface.

**TIP** Rows and columns are easily visible when the NURBS surface is planar, or nearly so. When the surface has a complicated curvature, rows and columns can be more difficult to see. The Row, Column, and Row/Column buttons can be especially useful in this situation.

**Name** Shows the name of the currently selected point. It is disabled if you have selected multiple points.
By default, the name is "Point" followed by a sequence number. You can use this field to give the point a name that you choose.

**Hide** Click to hide the currently selected points.

**Unhide All** Click to unhide all hidden points.

**Fuse** Fuses a point to another point. (You can't fuse a CV to a point, or vice versa.) This is one way to connect two curves or surfaces. It is also a way to change the shape of curves and surfaces.

Fusing points does **not** combine the two point sub-objects. They are connected but remain distinct sub-objects that you can unFuse later.

Fused points behave as a single point until you unFuse them.

Fused points are displayed in a distinct color. The default is purple. (You can change this color using the Colors panel on page 8272 of the Customize User Interface dialog on page 8249.)

**Unfuse** Unfuses the fused points.

**Extend** Extends a point curve. Drag from the end of a curve to add a new point and extend the curve.

**WARNING** When you add points with Extend, you lose the animation controllers for all points on the curve or surface.

**Make Independent** Disabled if the point is independent. If the point is dependent, clicking this button makes it independent.

**WARNING** When you make a point independent, you lose the animation controllers for all objects that depend on it in turn.

**Remove Animation** Removes animation controllers from the selected points.

**Delete group**

The buttons in this group box delete one or more points.

**Point** Deletes a single point (on a curve) or a row and column of points (on a surface).

**Row** Deletes a row from a surface.

**Col.** Deletes a column from a surface.

**WARNING** When you delete points, you lose the animation controllers for all points on the curve or surface.
Refine group

The buttons in this box refine point curves or surfaces by adding points to them.

**Curve** Adds points to a point curve.

**Surf Row** Adds a row of points to a point surface.

**Surf Col.** Adds a column of points to a point surface.

**Surf Row & Col.** Adds both a row and a column to a point surface; their intersection is where you click the surface.

---

**WARNING** When you add points, you lose the animation controllers for all points on the curve or surface.

---

**Points Selected** This text field shows how many points are currently selected.

---

Editing Curve CV Sub-Objects

Modify panel > Select NURBS object or sub-object. > Stack display > Curve CV sub-object level > Select CV sub-objects.

Modify panel > Select NURBS object or sub-object. > Right-click. > Tools 1 (upper-left) quadrant > Sub-objects > Curve CV > Select CV sub-objects.

This topic describes the controls for CV sub-objects that lie on curves. A rollout labeled CV contains the CV sub-object controls for NURBS models. In addition to the CV rollout described here, the Curve CV sub-object level displays the Soft Selection rollout on page 2541.

In you can edit the CVs in **CV curves on surfaces** on page 2593 as you edit other kinds of curve CVs. You can transform CVs in CV curves on surfaces, but you can't move the CVs off the surface. Using the Curve CV sub-object level is an alternative to editing these CVs by using the **Edit Curve on Surface** on page 2716 dialog.

---

Procedures

**To transform curve CV sub-objects:**

1. At the Curve CV sub-object level, select one or more CVs.
The sub-object selection tools are the same as for other kinds of sub-objects. You can also use the H key while the Keyboard Shortcut Override toggle on page 8420 is on. See Sub-Object Selection on page 2428.

The Selection group box, described under "Interface" later in this topic, provides some additional options for selecting CV sub-objects.

2 Turn on Move or another transform and then drag in a viewport to transform the selection.

The shape of the model changes as you interactively transform the CVs. Rotate and Scale are useful only when you've selected multiple CVs.

**Tips**

- When you transform NURBS CV sub-objects, the Lock Selection Set button can be useful. You can make a selection in one viewport, click Lock Selection Set (or press the Spacebar), and then transform the selection in a different viewport.

- When you move CV sub-objects, move them as systematically as possible to avoid "getting lost."

**To use the keyboard to select curve CV sub-objects:**

You can select curve CV sub-objects using the Ctrl key and the arrow keys. The arrows traverse the sub-objects in the order they were created. To do so, follow these steps:

1. Turn on the Keyboard Shortcut Override Toggle.

2. Click or drag to select CVs.

3. Hold down Ctrl and use the arrow keys to move among the CV sub-objects. For CVs on curves, the arrow keys traverse the CV selection along the length of the curve. The arrow keys don't move between curve sub-objects.

You can also use the H keyboard shortcut (while the Keyboard Shortcut Override Toggle button is on) to display a dialog and select CVs by name. Ctrl+H displays only the names of CVs directly beneath the mouse cursor.
To remove a CV from a curve:

1 Select a CV.

2 Click Delete.
   - Keyboard shortcut: Delete
   - The CV is deleted and the shape of the curve is updated.

   **NOTE** A CV curve must have at least one more CV than the degree on page 8549 of the curve.

To add a CV to a curve:

1 Turn on Refine.

2 Click the curve where you want to add the CV.
   - A CV is added at the location you clicked. Neighboring CVs move away from the new CV in order to preserve the original curvature.

To add CVs and extend the length of a curve:

1 Click to turn on Extend.

2 Move the mouse over a CV curve. The curve is highlighted in blue, and one of the curve's ends displays a box to show where the curve will be extended.

3 Drag from the highlighted end CV, and then release the mouse button.
   - New CVs are added beyond the original length of the curve.

To fuse two CVs:

1 Turn on Fuse.

2 Click a CV without releasing the mouse button. Drag to another CV, and then release the mouse button.
   - The first CV you choose acquires the position of the second CV, and becomes dependent to it. If the first CV has an animation controller, the controller is discarded. If the second CV has an animation controller, the first CV acquires it too.
   - Fused CVs display in purple by default.
To unfuse fused CVs:

1. Select the fused CV.
2. Click Unfuse.
   Now you can move and edit the two CVs independently.

To transform a region:

1. Using sub-object selection, select one or more CVs for the center of transformation.
2. Turn on Soft Selection.
3. Transform the CV.
   A region around the selected CV is transformed accordingly.

Move is the most common transform to use. Rotate and Scale can be used with a non-local transform center.

**TIP** If Soft Selection appears not to be working, the Falloff value might be too small for the size of your surface. On the Soft Selection rollout on page 2541, increase the value of Falloff so it encompasses other points or CVs.

**Interface**

In addition to the CV rollout described here, the Curve CV sub-object level also displays the Soft Selection rollout on page 2541.
Selection group

Curve sub-object selection controls

- **Single CV** (The default.) When on, you can select individual CVs by clicking, or groups of CVs by dragging a region.

- **All CVs** When on, clicking or dragging selects all the CVs in the curve.
Name  Shows either "No CVs selected", "Multiple CVs selected", or "CurveName(index)", where "CurveName" is the name of the CV's parent curve, and "index" is the CV's U location along the length of the curve. You can't edit the Name field to customize the names of CVs. If CVs are fused, the Name field shows the name of the first CV.

Weight  Adjusts the weight of the selected CVs. You can use a CV's weight to adjust the CV's effect on the curve. Increasing the weight pulls the curve toward the CV. Decreasing the weight relaxes the curve away from the CV. Increasing weight is a way to harden a curve; that is, to sharpen its curvature at a particular location.

By default, the weight is 1.0 for the CVs of NURBS objects that you create on the Create panel or the NURBS sub-object creation rollouts. The weight of CVs in geometry that you convert to NURBS can vary, depending on the object's original shape.

You can change the weight when multiple CVs are selected. Using the Weight field or spinner while multiple CVs are selected assigns all of them the value you choose. Because weights are relative to each other (rational), using the Weight control when all CVs are selected has no visible effect.

Hide  Click to hide the currently selected CVs.

Unhide All  Click to unhide all hidden CVs.

Fuse  Fuses a CV to another CV. (You can't fuse a CV to a point, or vice versa.) This is one way to connect two curves. It is also a way to change the shape of curves.

Fusing CVs does not combine the two CV sub-objects. They are connected but remain distinct sub-objects that you can unfuse later.

Fused CVs behave as a single CV until you unfuse them. Fused CVs behave similar to a single point, but the property of multiplicity for coincident CVs also applies. (See NURBS Concepts on page 2440 and CV Curve on page 2473.) The fused CVs have proportionally more influence on the curve. The curve can become sharper in the fused CVs' vicinity, or even angular if more than two CVs are fused together.

Fused CVs are displayed in a distinct color. The default is purple. (You can change this color using the Colors panel on page 8272 of the Customize User Interface dialog on page 8249.)

Unfuse  Unfuses the fused CVs.

Refine  Refines the curve by adding CVs.
WARNING  When you add CVs with Refine, you lose the animation controllers for all CVs on the curve.

As you move the mouse over the CV curve, a preview of the CVs that will be added, and their locations, is displayed in blue.

TIP  It is a good idea to reparameterize after you have added CVs to a curve by refining. See Editing Curve Sub-Objects on page 2518.

Delete  Deletes the selected CVs.

Insert  Inserts CVs into the curve. Click Insert and then click the curve where you want to insert the new CV. Inserting CVs is similar to refining with CVs, except that other CVs in the curve do not move. This means that the shape of the curve changes when you insert.

Inserting CVs does not remove animation from the curve, as refining does.

TIP  It is a good idea to reparameterize after you have added CVs to a curve by inserting. See Editing Curve Sub-Objects on page 2518.

Extend  Extends a CV curve. Drag from the end of a curve to add a new CV and extend the curve.

WARNING  When you add points with Extend, you lose the animation controllers for all points on the curve.

Remove Animation  Removes animation controllers from the selected CVs.

Display Lattice  When on, displays the control lattice on page 8538 that surrounds CV curves. When off, the control lattice isn’t shown in viewports. Default=on.

CVs Selected  This text field shows how many CVs are currently selected.

Editing Surface CV Sub-Objects

Modify panel > Select NURBS object or sub-object. > Stack display > Surface CV sub-object level > Select CV sub-objects.

Modify panel > Select NURBS object or sub-object. > Right-click a viewport. > Tools 1 (upper-left) quadrant > Sub-objects > Surface CV > Select CV sub-objects.

Procedures  on page 2510
This topic describes the controls for CV sub-objects that lie on surfaces. A rollout labeled CV contains the CV sub-object controls for NURBS models. In addition to the CV rollout described here, the Curve CV sub-object level displays the Soft Selection rollout on page 2541.

Transforming CVs changes the shape of the surface.

Procedures

To transform surface CV sub-objects:

1. At the Surface CV sub-object level, select one or more CVs.
   The sub-object selection tools are the same as for other kinds of sub-objects. You can also use the H key while the Keyboard Shortcut Override Toggle on page 8420 button is on. See Sub-Object Selection on page 2428.
   The Selection group box, described under "Interface" later in this topic, provides additional options for selecting CV sub-objects.

2. Turn on Move or another transform and then drag in a viewport to transform the selection.
The shape of the model changes as you interactively transform the CVs. Rotate and Scale are useful only when you've selected multiple CVs.

**Tips**

- The Lock Selection Set button is useful when you transform NURBS CV sub-objects. You can make a selection in one viewport, click Lock Selection Set (or press the Spacebar), and then transform the selection in a different viewport.
- When you move CV sub-objects, move them as systematically as possible to avoid "getting lost."
- On surfaces, avoid moving CVs so they cross over or under adjacent points. This can create odd-looking warps or overlaps in the surface.

To **Shift+clone surface sub-objects:**

- Hold down Shift while you transform the surface selection. The Sub-Object Clone Options on page 2734 dialog appears. This dialog provides various ways to clone the surfaces, some of which reduce relational dependencies to improve performance.

To **use the keyboard to select surface CV sub-objects:**

You can select surface CV sub-objects using the Ctrl key and the arrow keys. The arrows traverse the sub-objects in the order they were created. To do so, follow these steps:

1. Turn on the Keyboard Shortcut Override Toggle.
2. Click or drag to select CVs.
3. Hold down Ctrl and use the arrow keys to move among the CV sub-objects. For CVs on surfaces, the left and right arrow keys traverse the U dimension of a surface, while the up and down arrow keys traverse the V dimension of the surface. The arrow keys don’t move between surface sub-objects.
You can also use the H keyboard shortcut (while the Keyboard Shortcut Override Toggle button is on) to display a dialog and select CVs by name. Ctrl+H displays only the names of CVs directly beneath the mouse cursor.

To remove CVs from a surface:

1. Select a row, column, or a row and column.
   The appropriate Delete buttons are enabled.
2. In the Delete group box, click Row, Col., or Both.
   The row, the column, or both are deleted.

   **NOTE** You can't delete a single CV from a CV surface. Nor can you delete a row or column if that would make the surface have fewer than four rows or columns.

To add CVs to a CV Surface:

1. In the Refine group box, click Row, Col., or Both.
2. Click the surface.
   A row, a column, or both are added close to the point where you clicked the surface. Neighboring CVs move away from the new CVs in order to preserve the surface's original curvature.

To fuse two CVs:

1. Turn on Fuse.
2. Click a CV without releasing the mouse button. Drag to another CV, and then release the mouse button.
   The first CV you choose acquires the position of the second CV, and becomes dependent to it. If the first CV has an animation controller, the controller is discarded. If the second CV has an animation controller, the first CV acquires it too.

   **NOTE** Fused CVs display in purple by default.

To unfuse fused CVs

1. Select the fused CV.
2. Click Unfuse.
Now you can move and edit the two CVs independently.

**To transform a region:**

1. Using sub-object selection, select one or more CVs for the center of transformation.
2. Turn on Soft Selection.
3. Transform the CV.
   A region around the selected CV is transformed accordingly.

Move is the most common transform to use. Rotate and Scale can be used with a non-local transform center.

**TIP** If Soft Selection appears not to be working, the Falloff value might be too small for the size of your surface. On the Soft Selection on page 2541 rollout, increase the value of Falloff so it encompasses other CVs.

**Interface**

In addition to the CV rollout described here, the Surface CV sub-object level also displays the Soft Selection rollout on page 2541.
CV rollout

Surface CV sub-object rollout
Selection group

Surface CV sub-object selection controls

- **Single CV** (The default.) When on, you can select individual CVs by clicking, or groups of CVs by dragging a region.

- **Row of CVs** When on, clicking a CV selects the entire row the CV belongs to. Dragging selects all rows in the region.

- **Column of CVs** When on, clicking a CV selects the entire column the CV belongs to. Dragging selects all columns in the region.

- **Row and Column of CVs** When on, clicking a CV selects both the row and column the CV belongs to. Dragging selects all rows and columns in the region.

- **All CVs** When on, clicking or dragging selects all the CVs in the surface.

**Name** Shows either "No CVs selected", "Multiple CVs selected", or "SurfaceName(uIndex,vIndex)", where "SurfaceName" is the name of the CV's parent surface, and "uIndex,vIndex" is the CV's UV location on the surface. You can't edit the Name field to customize the names of CVs. If CVs are fused, the Name field shows the name of the first CV.

**Weight** Adjusts the weight of the selected CVs. You can use a CV's weight to adjust the CV's effect on the surface. Increasing the weight pulls the surface toward the CV. Decreasing the weight relaxes the surface away from the CV. Increasing weight is a way to harden a surface: that is, to sharpen its curvature at a particular location.
By default, the weight is 1.0 for the CVs of NURBS objects that you create on the Create panel or the NURBS sub-object creation rollouts. The weight of CVs in geometry that you convert to NURBS can vary, depending on the object's original shape.

You can change the weight when multiple CVs are selected. Using the Weight field or spinner while multiple CVs are selected assigns all of them the value you choose. Because weights are relative to each other (rational), using the Weight control when all CVs are selected has no visible effect.

**TIP** You can increase the curvature of an indentation in a surface by increasing the weight of the CVs surrounding the indented area. This is easier and often more effective than moving the indented area's CVs.

**Hide** Click to hide the currently selected CVs.

**Unhide All** Click to unhide all hidden CVs.

**Fuse** Fuses a CV to another CV. (You can't fuse a CV to a point, or vice versa.) This is one way to connect two surfaces. It is also a way to change the shape of surfaces.

Fusing CVs does not combine the two CV sub-objects. They are connected but remain distinct sub-objects that you can unfuse later.

Fused CVs behave as a single CV until you unfuse them. Fused CVs behave similar to a single point, but the property of multiplicity for coincident CVs also applies. (See NURBS Concepts on page 2440 and CV Curve on page 2473.) The fused CVs have proportionally more influence on the curve, which can become sharper in the fused CVs' vicinity, or even angular if more than two CVs are fused together.

Fused CVs are displayed in a distinct color. The default is purple. (You can change this color using the Colors panel on page 8272 of the Customize User Interface dialog on page 8249.)

**Unfuse** Unfuses the fused CVs.

**Remove Animation** Removes animation controllers from the selected CVs.

**Constrained Motion group**

These buttons constrain CV motion. They are enabled when you select one or more CVs. When you finish dragging the CV selection, the active constraint button turns off.

**U** Constrains the CV selection to move in the surface's U dimension.

Keyboard shortcut (Keyboard Shortcut Override Toggle must be on): Alt+U
V Constrains the CV selection to move in the surface's V dimension.  
Keyboard shortcut (Keyboard Shortcut Override Toggle must be on): Alt+V

**Normal** Constrains the CV selection to move normal to the original surface.  
Keyboard shortcut (Keyboard Shortcut Override Toggle must be on): Alt+N

**Delete group**

These buttons delete CVs from the surface. Select one or more CVs, and then click Row, Col., or Both.

You can't delete surface CVs if the deletion would give the surface fewer than four rows or fewer than four columns. Aside from that restriction, these buttons delete all rows, columns, or rows and columns that contain selected CVs. This means that you can't delete after you make a selection using the Row and Column or All selection buttons: that would imply deleting the entire CV surface.

These buttons are unavailable unless the deletion is possible.

---

**WARNING** When you delete CVs, you lose the animation controllers for all CVs on the surface.

**Row** Deletes rows of CVs from the surface.

**Col.** Deletes columns of CVs from the surface.

**Both** Deletes both rows and columns of CVs from the surface.

**Refine group**

These buttons refine the surface by adding CVs. As you move the mouse over the surface, a preview of the CVs that will be added, and their locations, is displayed in blue.

---

**WARNING** When you add CVs with Refine, you lose the animation controllers for all CVs on the surface.

**Row** Adds a row of CVs to the surface.

**Col.** Adds a column of CVs to the surface.

**Both** Adds both a row and a column of CVs to the surface.

---

**TIP** It is a good idea to reparameterize after you have added CVs to a surface by refining. See Editing Surface Sub-Objects on page 2530.
**Insert group**

These buttons insert CVs into the curve. Click to turn on one of these buttons and then click the surface where you want to insert the new CVs. Inserting CVs is similar to refining with CVs, except that other CVs in the surface do not move. This means that the shape of the surface can change when you insert.

Inserting CVs does not remove animation from the surface the way refining does.

- **Row** Inserts a row of CVs into the surface.
- **Col.** Inserts a column of CVs into the surface.
- **Both** Inserts both a row and a column of CVs into the surface.

**TIP** It is a good idea to reparameterize after you have added CVs to a surface by inserting. See *Editing Surface Sub-Objects* on page 2530.

**Display Lattice** When on, displays the control lattice that surrounds CV surfaces. When off, the control lattice isn't shown in viewports. Default=on.

**CVs Selected** This text field shows how many CVs are currently selected.

---

**Editing Curve Sub-Objects**

Modify panel > Stack display > Open the NURBS object's hierarchy. > Curve sub-object level > Select curve sub-objects.

This topic describes the controls that are common to point and CV curves. A rollout labeled Curve Common contains the curve sub-object controls for NURBS models.

**Procedures**

To transform curves:

1. At the Curve sub-object level, select one or more curves.

   The sub-object selection tools are the same as for other kinds of sub-objects. You can also press the H key when the Keyboard Shortcut Override toggle on page 8420 is on. See *Sub-Object Selection* on page 2428.
The Selection group box, described under "Interface" later in this topic, provides additional options for selecting curves.

2 Turn on Move or another transform and then drag in a viewport to transform the selection.
   The shape of the model changes as you interactively transform the curves.

   **TIP** The Lock Selection Set button is useful when you transform NURBS curve sub-objects. You can make a selection in one viewport, click Lock Selection Set (or press the Spacebar), and then transform the selection in a different viewport.

**To Shift+Clone curve sub-objects:**

- Hold down Shift while you transform the curve selection.
  The Sub-Object Clone Options on page 2734 dialog is displayed. This dialog provides various ways to clone the curves, some of which reduce relational dependencies to improve performance.

**To use the keyboard to select curve sub-objects:**

You can select curve sub-objects using the Ctrl key and the arrow keys. The arrows traverse the sub-objects in the order they were created. To do so, follow these steps:

1 Turn on the Keyboard Shortcut Override Toggle.

2 At the Curve sub-object level, set the selection controls to select curves individually.

3 Click or drag to select curves.

4 Hold down Ctrl and use the arrow keys to move among the curves in the current model.
   At the Curve sub-object level, the left and right arrow keys move forward and backward through individual curves in the order they were created. The up and down arrows are equivalent to left and right.
You can also use the H keyboard shortcut (while the Keyboard Shortcut Override Toggle is on) to display a dialog and select curves by name. Ctrl+H displays only the names of curves directly beneath the mouse cursor.

To delete a curve:

- Select the curve and then click Delete.
  Keyboard shortcut: Delete

To turn a CV curve into a point curve:

1 Select the curve sub-object, and then click Make Fit.
   The Make Point Curve on page 2730 dialog is displayed. This dialog asks how many points the new point curve should have.

2 Change the number of points, and then click OK.
   Reducing the number of points can change the shape of the curve.

If the selected curve is already a point curve, you can use Make Fit to change the number of points it has.

To select a first vertex on the curve:

- Select the curve sub-object, turn on Make First, and then click a location on the curve.
  If the curve is closed and there is a vertex where you click, this vertex becomes the first vertex. If the curve is closed and there is no vertex where you click, a new vertex is created at the location you click. It becomes the new first vertex, and the curve's points or CVs adapt to maintain the curvature.
  If the curve is open, clicking it has no effect.

**WARNING** Using Make First discards any animation controllers for the points or CVs in the curve.

If the curve is open, the first vertex must be one of the endpoints (by default, it is the first you created). The Make First button has no effect, but you can use Reverse to change the curve's direction.
The small circle indicates the first vertex.

To turn a curve that lies on a surface into a Point Curve on Surface:

1. Select the curve sub-object, and then click Make COS. Make COS is unavailable unless the curve already lies on a surface; for example, it is a U Iso curve.

2. The Convert Curve on Surface dialog on page 2710 is displayed.
Choose CV Curve on Surface to create a CV curve, or Point Curve on Surface to create a point curve. The Number of CVs or Number of Points values let you specify the complexity and accuracy of the new curve on surface. If Preview is on, the new curve is previewed in viewports. This can help you choose the number.

**To reverse a curve:**

- Select a curve sub-object and then click Reverse.
Reversing a curve affects the blend surface that depends on it.

**To join two curves:**

1. In a NURBS object that contains two curve sub-objects, turn on Join.

2. Click one curve near the end that you want to connect. Drag to near the end of the other curve, and then release the mouse.
   
   The Join Curve dialog on page 2723 is displayed. This dialog gives you a choice of methods for joining the curves. Whichever method you choose, the two original curves are replaced by a single curve.

3. If the gap between the curves is small (less than about 30 units), use the Join Curve dialog to set the Tolerance value greater than the distance of the gap.

**To break a curve:**

- Turn on Break and then click a curve.
The curve is split into two independent curve sub-objects. Two coincident (but independent) points or CVs are created at the location you clicked: each is the endpoint of one part of the original curve.

If the curve is a closed curve, Break creates a single curve object, with its new start and end points at the location you clicked. The new start and end points are coincident but independent.

**To close a curve:**

- Select the curve and then click Close.
  3ds Max closes the curve by adding a segment between the curve's endpoints. The curvature of the new segment blends the curvature of the previous end segments.

Closing a curve does not add points or CVs. The curve retains its original number of points or CVs, and increases its number of segments by one.
Interface

Curve Common rollout
The controls on this rollout apply to all curve types. Depending on the type of curve, an additional rollout is displayed with controls specific to that type of curve.

**Selection group**

The selection buttons for curve sub-objects let you select either individual curves, or curves that are connected in space.

**Curve sub-object selection controls**

**Single Curve** Clicking or transforming a curve selects only a single independent curve sub-object.

**All Connected Curves** Clicking or transforming a curve selects all curve sub-objects that are connected within the NURBS object. To be connected, two curves must have fused points, or one curve must be a connected dependent (a blend, fillet, or chamfer) of the other.

**Name** Shows the name of the currently selected curve. It is disabled if you have selected multiple curves.

By default, the name is the name of the curve type ("CV Curve" or "Point Curve") followed by a sequence number. You can use this field to give the curve a name that you choose.

**Hide** Click to hide the currently selected curves.

**Unhide All** Click to unhide all hidden curves.

**Hide by Name** Click to display a Select Sub-Objects dialog that lists curves by name. Select the curves to hide, then click Hide.

**Unhide by Name** Disabled unless there are hidden curves. Click to display a Select Sub-Objects dialog that lists curves by name. Select the curves to make visible, then click Unhide.

**Delete** Deletes the selected curve sub-objects.
Make Fit  Turns a CV curve into a point curve. This displays the Make Point Curve dialog on page 2730, which lets you set the number of points. For a point curve, this button lets you change the number of points in the curve.

Reverse  Reverses the order of the CVs or points in a curve, so that the first vertex becomes the last, and the last becomes the first.

The first point or CV is significant when you use the NURBS curve like a spline: as a loft on page 742 path or shape, as a path constraint on page 3596 path, or as a motion trajectory on page 3411. For these purposes, the first vertex of the curve is significant. If the curve is a closed curve, you can use Make First to set the curve's first vertex.

The direction of the curve also determines the initial direction of normals on surfaces based on this curve.

Make COS  This button is enabled only for the following kinds of curves:

- U iso curves on page 2584
- V iso curves on page 2584
- Normal projected curves on page 2586
- Vector projected curves on page 2589
- Surface-surface intersection curves on page 2578
- Surface edge curves on page 2601
- CV curves on surfaces on page 2593
- Point curves on surfaces on page 2597

This displays a Make Curve on Surface dialog on page 2710, which turns the selected curve into a CV or point curve on surface. Once converted, you can edit the new curve on surface using the curve on surface controls, including the Edit Curve on Surface dialog on page 2716.

If the curve is already a curve on surface, this button lets you change it from a point to CV curve on surface, or vice versa.

The new Curve on Surface preserves the trimming of the original curve.

Convert Curve  Click to display the Convert Curve dialog on page 2708. This dialog provides a more general way to convert a CV curve to a point curve, or a point curve to a CV curve. It also lets you adjust a number of other curve parameters.
**Make Independent** Disabled if the curve is independent. If the curve is dependent, clicking this button makes it independent.

**WARNING** When you make a curve independent, you lose the animation controllers for all objects that depend on it in turn. If you make a curve that trims a surface independent, you lose the trimming of the surface.

**Remove Animation** Removes animation controllers from the selected curves.

**Detach** Detaches the selected curve sub-object from the NURBS model, making it a new top-level NURBS curve on page 2464 object. The Detach dialog on page 2715 is displayed, which lets you name the new curve. The new object is no longer part of the original NURBS model.
To create a new top-level NURBS curve that is a copy of the selected curve, turn on Copy before you click Detach.

**Copy** When on, clicking Detach creates a copy of the selected curve instead of detaching it from the NURBS model. Default=off.

**Make First** For a closed curve, lets you choose a position that becomes the first vertex of the curve.
The first point or CV is significant when you use the NURBS curve like a spline: as a loft on page 742 path or shape, as a path constraint on page 3596 path, or as a motion trajectory on page 3411. For these purposes, the first vertex of the curve is significant. If the curve is a closed curve, you can use Make First to set the curve’s first vertex.

**Break** Breaks a single curve into two curves. Click in a viewport to choose the location to break the curve.

**WARNING** When you break a curve sub-object, you lose the animation controllers for all points or CVs on the curve.

**Join** Joins two curve sub-objects together. After you have joined the curves in a viewport, the Join Curves dialog on page 2723 is displayed. This dialog lets you choose the method for joining the two curves.

**WARNING** When you join two curve sub-objects, you lose the animation controllers for all points or CVs on both curves.

**Material ID** Lets you assign a material ID value to the curve. If the curve is renderable, material IDs let you assign a material to the curve using a Multi/Sub-Object on page 6120 material. In addition, the Select by ID button lets you select a curve or multiple curves by specifying a material ID number. Can range from 1 to 100. Default=1.
Select by ID Displays a Select by Material ID on page 2736 dialog.

**CV Curve rollout**

This additional rollout is displayed when a CV curve is selected.

![CV Curve rollout](image)

**Degree** Sets the degree of the curve. The higher the degree value, the greater the continuity. The lower the degree, the more discontinuous the curve segments become. The degree can't be less than one or greater than the number allowed by the number of CVs in the curve. Degree 3 curves are adequate to represent continuous curves, and are stable and well behaved. Default=3.

Setting the degree greater than 3 isn't recommended because higher-degree curves are slower to calculate and less stable numerically. Higher-degree curves are supported primarily to be compatible with models created using other surface modeling programs.

The number of CVs in a CV curve must be at least one greater than the curve's degree.

**Automatic Reparameterization group**

The controls in this group box let you specify automatic reparameterization. They are similar to the controls in the Reparameterize dialog on page 2733, with the addition that all choices except for None tell 3ds Max to reparameterize the curve automatically; that is, whenever you edit it by moving CVs, refining, and so on.

**None** Do not reparameterize automatically.
Chord Length  Chooses the chord-length algorithm for reparameterization. Chord-length reparameterization spaces knots (in parameter space on page 8674) based on the square root of the length of each curve segment. Chord-length reparameterization is usually the best choice.

Uniform  Spacing the knots uniformly. A uniform knot vector has the advantage that the curve or surface changes only locally when you edit it. With chord-length parameterization, moving any CV can potentially change the entire curve.

Close  Closes the curve. Disabled if the curve is already closed.

Rebuild  Displays the Rebuild CV Curve dialog on page 2731, which lets you specify how to rebuild the curve. Rebuilding the curve can change its appearance.

Reparam.  Displays the Reparameterize dialog on page 2733. Reparameterizing a curve changes the curve’s parameter space on page 8674 to provide a better relation between control point locations and the shape of the curve.

TIP  It is a good idea to reparameterize after you have added CVs to the curve by refining or inserting.

**Point Curve rollout**

This additional rollout appears when a point curve is selected.

![Point Curve](image)

Close  Closes the curve. Disabled if the curve is already closed.

**Editing Surface Sub-Objects**

Modify panel > Stack display > Open the NURBS object’s hierarchy. > Surface sub-object level > Select surface sub-objects.

This topic describes controls that are common to point surfaces, CV surfaces, and the various dependent surface types. A rollout labeled Surface Common contains the surface sub-object controls for NURBS surfaces. Another rollout,
Material Properties on page 2544, controls mapping on surface sub-objects, and is described in its own topic. See Surface Approximation on page 2737 for a description of that rollout. The final rollout for surface sub-objects depends on the type of surface selected.

Procedures

To transform surface sub-objects:

1. At the Surface sub-object level, select one or more surface sub-objects. The sub-object selection tools are the same as for other kinds of sub-objects. In addition, you can use the H key when the Keyboard Shortcut Override toggle on page 8420 is on. See Sub-Object Selection on page 2428.

   The Selection group box, described under "Interface" later in this topic, provides additional options for selecting surfaces.

2. Turn on Move or another transform and then drag in a viewport to transform the selection.

   The shape of the model changes as you interactively transform the surfaces.

   TIP The Lock Selection Set button is useful when you transform NURBS sub-objects. You can make a selection in one viewport, click Lock Selection Set (or press the Spacebar), and then transform the selection in a different viewport.

To use the keyboard to select surface sub-objects:

You can select surface sub-objects using the Ctrl key and the arrow keys. The arrows traverse the sub-objects in the order they were created. To do so, follow these steps:

1. Turn on the Keyboard Shortcut Override Toggle.

2. At the Surface sub-object level, set the selection controls to select surfaces individually.
3 Click or drag to select surfaces.

4 Hold down Ctrl and use the arrow keys to move among surfaces in the current model.

At the Surface sub-object level, the left and right arrow keys move forward and backward through individual surfaces in the order they were created. The up and down arrows are equivalent to left and right.

You can also use the H keyboard shortcut (while the Keyboard Shortcut Override Toggle is on) to display a dialog and select surfaces by name. Ctrl+H displays only the names of surfaces directly beneath the mouse cursor.

To delete a surface:

- Select the surface and then click Delete.
  Keyboard shortcut: Delete

To make a surface a loft:

1 Select the surface and then click Make Loft. A Make Loft dialog on page 2727 is displayed.
2 Use the Make Loft dialog controls to choose the settings for the new surface, and then click OK.

To break a surface:

1 Turn on Break Row, Break Col., or Break Both, and then drag over the surface.
   One or two blue curves appear on the surface to indicate where the break will occur.

2 When you have dragged to the location you want to break, click the surface.

   **NOTE** If you break a dependent surface, the new "broken" surfaces are made independent.

You cannot break a trimmed surface.
To extend a surface:

1. Turn on Extend.
2. Move the mouse over the surface without depressing the mouse button. The edge that will be extended is highlighted in blue.
3. When the edge you want to extend is highlighted, press the mouse button, and then drag vertically to increase the length of the surface.

The surface extension is invalid and disappears if it would cause the surface to intersect itself or if the edge of the surface touches itself but is not closed. For example, you can’t extend the top of a cylinder.

To join two surfaces:

1. In a NURBS object that contains two surface sub-objects, turn on Join.
2. If the gap between the surfaces is small (less than about 30 units), set the Tolerance value greater than the distance of the gap.
3. Click one surface near the edge that you want to connect. The edge that will be connected is highlighted in blue. Drag to choose the edge you want to connect. Without releasing the mouse button, drag to the other surface. The edge of the other surface is also highlighted in blue. Drag on the other surface to choose the edge to connect, and then release the mouse button.

The surface that owns the highlighted edge is highlighted in yellow, to help you distinguish which edge you are choosing when two surfaces have coincident edges.

The Join Surfaces dialog on page 2725 is displayed, which gives you a choice of methods for how to join the surfaces. Whichever method you choose, 3ds Max creates a single surface that replaces the two original surfaces.

To close a surface:

- Select the surface sub-object and then click Close Rows or Close Cols.

Surface sub-object rollout

The controls on this rollout apply to all surface types. Depending on the type of surface, an additional rollout is displayed with controls specific to that type of surface.

Selection group

The selection buttons for surface sub-objects let you select either individual surfaces, or surfaces that are connected in space.
Surface sub-object selection controls

Single Surface Clicking or transforming a surface selects only a single surface sub-object.

All Connected Surfaces Clicking or transforming a surface selects all surface sub-objects that are connected within the NURBS object. To be connected, two surfaces must have all the CVs on a shared edge fused between them, or one surface must be a connected dependent of the other (for example, a blend or a cap).

Name Shows the name of the currently selected surface. It is disabled if you have selected multiple surfaces.

By default, the name is the name of the surface type ("CV Surface," "Point Surface," "Blend Surface," and so on) followed by a sequence number. You can use this field to give the surface a name that you choose.

Hide Click to hide the currently selected surface.

Unhide All Click to unhide all hidden surfaces.

Hide by Name Click to display a Select Sub-Objects dialog that lists surfaces by name. Select the surfaces to hide, then click Hide.

Unhide by Name Disabled unless there are hidden surfaces. Click to display a Select Sub-Objects dialog that lists surfaces by name. Select the surfaces to make visible, then click Unhide.

Delete Deletes the selected surface sub-objects.

Make Rigid Makes the surface rigid. The only editing allowed on a rigid surface is to transform it at the Surface sub-object level. You can't move a rigid surface's points or CVs, or change the number of points or CVs.

Rigid surfaces reduce the amount of memory used by the NURBS model. Making surfaces rigid improves performance, especially for large and complex models.

When a surface is rigid, you can't see its points or CVs when you are at the Point or Surface CV sub-object levels. If the model has no nonrigid surfaces...
and no point curves, the Point and Surface CV sub-object levels aren't available at all.

To make a surface no longer rigid, click Make Point or Make Independent. Editing the surface with Break, Join, and so on also makes it no longer rigid.

**Make Loft** Displays a Make Loft dialog on page 2727 to convert the surface sub-object to a (dependent) U loft or UV loft surface. Can also change the dimension used to construct a U loft surface.

You can't use Make Loft if the surface sub-object is in an error condition.

**TIP** Make Loft creates a loft with uniformly spaced curves. To make a loft with adaptively spaced iso curves, manually create the curves and then loft them with U Iso Lines, V Iso Lines, or U and V Iso Lines.

**Make Point** Displays a Make Point dialog on page 2729 to convert any kind of surface to a point surface. You can also use Make Point to change the number of rows and columns if the surface is already a point surface.

**Convert Surface** Click to display the Convert Surface dialog on page 2711. This dialog provides a general way to convert a surface to a different type of surface. You can convert between lofts, point ("fit") surfaces, and CV surfaces. The dialog also lets you adjust a number of other surface parameters.

**Make Independent** Disabled if the surface is independent. If the surface is dependent, clicking this button makes it independent.

**WARNING** When you make a surface independent, you lose the animation controllers for all objects that depend on it in turn.

**Remove Animation** Removes animation controllers from the selected surfaces.

**Detach** Detaches the selected surface sub-object from the NURBS model, making it a new top-level NURBS surface object on page 2454. The Detach dialog on page 2715 is displayed, which lets you name the new surface. The new object is no longer part of the original NURBS model.

To create a new top-level NURBS surface that is a copy of the selected surface, turn on Copy before you click Detach.

**Copy** When on, clicking Detach creates a copy of the selected surface instead of detaching it from the NURBS model. Default=off.

**Renderable** When on, the surface renders. Turn off to make the surface invisible in renderings. Default=on.

**Display Normals** When on, the normal for each selected surface is displayed. There is one normal per surface sub-object. The normal is displayed at the
surface's UV origin, so displaying normals can help you see how materials will be mapped. On the other hand, the normal can be hard to see if you are zoomed out. Default=off.

**Flip Normals** Turn on to reverse the direction of the surface normals. Default=off.

---

**TIP** The Flip Normals control is useful for viewing a surface that is mostly concave or mostly convex. With more complicated NURBS surfaces, you often want to render both sides of the surface. To see both sides of the surface, turn on Force 2-Sided on the Render Setup dialog on page 6506. To see both sides of the surfaces in viewports, turn on Force 2-Sided on the Rendering Method panel of the Viewport Configuration dialog on page 8374, or assign a Double-Sided Material on page 6113.

**Break Row** Breaks the surface into two surfaces in the direction of a row (the surface's U axis).

**Break Col.** Breaks the surface into two surfaces in the direction of a column (the surface's V axis).

**Break Both** Breaks the surface into four surfaces in both directions. You cannot break a trimmed surface.

**Extend** Extends the surface by changing its length.

---

**WARNING** Extending a surface loses all animation controllers for the surface and its points or CVs.

**Join** Joins two surface sub-objects together. After you have joined the surfaces in a viewport, the Join Surfaces dialog on page 2725 is displayed. This dialog lets you choose the method for joining the two surfaces. You can join only original edges of surfaces; you cannot join edges created by trimming.

---

**WARNING** When you join two surface sub-objects, you lose the animation controllers for all point or CVs on both surfaces.

**CV Surface rollout**

This additional rollout is displayed when a CV surface is selected.
U Degree and V Degree  Let you set the degree of the surface in either the U or V dimension. The higher the degree value, the greater the continuity. The lower the degree, the more discontinuous the surface segments become. The degree can't be less than one or greater than the number allowed by the number of CVs in the specified dimension. Degree 3 is adequate to represent continuous surfaces, and is stable and well behaved. Default=3.

Setting the degree greater than 3 isn't recommended because higher-degrees are slower to calculate and less stable numerically. Higher-degrees are supported primarily to be compatible with models created using other surface modeling programs.

The number of CVs in a given dimension must be at least one greater than that dimension's degree.

Automatic Reparameterization group

The controls in this group box let you specify automatic reparameterization. They are similar to the controls in the Reparameterize dialog on page 2733, with the addition that all choices except for None tell 3ds Max to reparameterize the curve automatically; that is, whenever you edit it by moving CVs, refining, and so on.

None  Do not reparameterize automatically.

Chord Length  Chooses the chord-length algorithm for reparameterization. Chord-length reparameterization spaces knots (in parameter space on page 8674) based on the square root of the length of each curve segment. Chord-length reparameterization is usually the best choice.

Uniform  Spaces the knots uniformly.
A uniform knot vector has the advantage that the curve or surface changes only locally when you edit it. With chord-length parameterization, moving any CV can potentially change the entire surface.

The close controls let you close a surface. They are displayed on the CV Surface rollout while an independent CV surface sub-object is selected. They are disabled if the surface is already closed in that direction.

**Close Rows** Closes the surface by joining the ends of its rows.

**Close Cols.** Closes the surface by joining the ends of its columns.

**Rebuild** Displays the Rebuild CV Surface dialog on page 2732, which lets you specify how to rebuild the surface. Rebuilding the surface can change its appearance.

**WARNING** When you rebuild a surface, you lose the animation controllers for all CVs on the surface.

**Reparam.** Displays the Reparameterize dialog on page 2733. Reparameterizing a surface changes the surface's parameter space on page 8674 to provide a better relation between control point locations and the shape of the surface.

**TIP** It is a good idea to reparameterize after you have added CVs to the surface by refining or inserting.

**WARNING** When you reparameterize a surface, you lose the animation controllers for all CVs on the surface.

**Point Surface rollout**

This additional rollout appears when a point surface is selected.

The close controls let you close a surface. They appear on the Point Surface rollout while an independent point surface sub-object is selected. They have no effect if the surface is already closed in that direction.

**Close Rows** Closes the surface by joining the ends of its rows.

**Close Cols.** Closes the surface by joining the ends of its columns.
Soft Selection Rollout (NURBS)

Modify panel > Select NURBS point or CV sub-objects. > Soft Selection rollout

The soft selection controls for NURBS models are like the soft selection controls for editable mesh on page 2192 objects. Soft selection controls make a point or CV behave as if surrounded by a "magnetic field." Unselected points or CVs within the field are drawn along smoothly while you move the selected one.

With this feature, you can sculpt the points or CVs of a curve or surface. For example, you can draw a sphere into an egg, or gently curve a flat surface into hills and valleys.

The Soft Selection rollout for point and CV sub-objects contains the controls for this feature. The Soft Selection check box is turned off by default.

Before you begin, you might need to increase the number of CVs or points on the surface. This allows smoother and more complex reshaping effects.

A single point or CV works well for many purposes. Moving a point or CV along a single axis is the most useful for smoothly raising and lowering surfaces. For multiple points or CVs, you can also use Rotate or Scale.
**Interface**

**Soft Selection** When on, point or CV transforms affect a region of the curve or surface.

**Affect Neighbors** When on, the transform affects points or CVs not only on this curve or surface but within the entire Falloff region of the NURBS object.

**Same Type Only** (for point curves and surfaces only) When on, the transform affects only neighboring points of the same type; that is, either curve points, surface points, or independent points.

**Soft Selection Curve** This curve display shows how Soft Selection will work. You can experiment with a curve setting, undo it, and try another setting with the same selection.

**Falloff** Distance in current units from the center to the edge of a sphere defining the region. Use higher falloff settings to achieve more gradual slopes, depending on the scale of your geometry. Default=20.
Falloff=20 (the default)  
Right: Falloff=40

Pinch Raises and lowers the top point of the curve along the vertical axis. Sets the relative "pointedness" of the region. When negative, a crater is produced instead of a point. At a setting of 0, Pinch produces a smooth transition across this axis. Default=0.

Left: Pinch=.5  
Right: Pinch=2  
Falloff and Bubble have their default values.

Bubble Expands and contracts the curve along the vertical axis. Sets the relative "fullness" of the region. Limited by Pinch, which sets a fixed starting point for Bubble. A setting of 0 for Pinch and 1.0 for Bubble produces a maximum smooth bulge. Negative values for Bubble move the bottom of the curve below the surface, creating a "valley" around the base of the region. Default=0.
Material Properties Rollout (NURBS)

Modify panel > Select NURBS object. > Stack display > Surface sub-object level > Material Properties rollout

This rollout controls material mapping onto a NURBS surface sub-object.

Procedures

To apply a mapped material to a surface sub-object:
2. Use the Material Editor on page 5641 to assign a mapped material to the surface.

To use multiple map channels on a single surface sub-object (example):
2. Change the Map Channel value to 2, and turn on Gen. Mapping Coordinates.
3. Change the U and V tiling values for map channel 2.
Now when you assign a mapped material, maps on map channel 1 use the default UV tiling, while maps on map channel 2 use the channel 2 tiling. An easy way to see this is to create a checker on page 6227 map on channel 1, and make one checker color another checker map on channel 2.
Interface

Material Properties rollout

- Material ID: [1]
- Select By ID

Texture Channels
- Map Channel: [1]
- Gen. Mapping Coords.
  - Offset: U: 0.0, V: 0.0
  - Tiling: U: 1.0, V: 1.0
- Rotation Angle: 0.0

Texture Corners
- U: 0.0, V: 0.0

Texture Surface
- Default
- User Defined
  - Edit Texture Surface
  - Edit Texture Points
- Projected
  - Pick Source Surface
- Source: None
**Material ID** Use this to change the surface's material ID number. Multiple material IDs in a single NURBS object let you assign a multi/sub-object material on page 6120 to the NURBS object.

**Select by ID** Displays a Select by Material ID dialog on page 2736.

**Texture Channels group**

The controls in this group box support materials, including tiling and positioning mapping coordinates on the surface.

**Map Channel** Chooses a UV coordinates map channel on page 8627. Range=1 to 99. A single surface can use up to 99 texture channels. Default=1.

**Gen. Mapping Coordinates** Generates mapping coordinates so you can apply mapped materials to the surface. Each surface in a NURBS object has its own set of mapping coordinates. Default=off.

**U and V Offset** Offset mapping coordinates along the surface's local U axis or V axis. That is, at 0.0 (the default), the map begins at the U or V origin. Increasing an Offset value moves the map forward along that axis, and decreasing it moves it backward. These parameters are animatable.

**U and V Tiling** Control the tiling of UV mapping coordinates; that is, the number of times a mapped material's map is repeated in the surface's local U axis or V axis. Default=1.0 for both axes (no tiling). These parameters are animatable.

**Rotation Angle** Lets you specify a rotation angle for the texture. This parameter is animatable.

**Texture Corners group**

The controls in this group box let you explicitly set which texture surface UV values to use at the corners of a surface. These controls are especially useful when you are matching the textures of adjacent surfaces.

These controls are disabled unless Generate Mapping Coordinates is on.

**Corners radio buttons** The four buttons correspond to the four corners of the currently selected surface. When you choose a button, the corresponding corner is highlighted with a blue box in 3D viewports, and the U and V spinners are enabled.

**U and V** Unavailable unless you've chosen one of the Corners radio buttons. When available, you use these spinners to set the U and V texture values for the chosen corner.
By default, the U and V values for most surfaces range from 0.0 to 1.0. For some kinds of geometry converted to a NURBS surface, these ranges can vary.

**Texture Surface group**

The controls in this group box let you choose a method for mapping texture to the currently selected NURBS surface sub-object, and to adjust the parameters for some of the chosen methods.

These controls are available when Generate Mapping Coordinates is on.

A texture surface is a surface associated with the surface sub-object. The texture surface controls how materials are mapped. In effect, changing the texture surface stretches or otherwise changes the UV coordinates for the surface, altering the mapping.

Maps can shift with certain surface approximation methods. This effect is especially noticeable when the surface has animated CVs. You can reduce or eliminate map shifting by changing the mapping method to User Defined.

**TIP** Don’t use the UVW Map modifier to apply a texture to an animated NURBS surface.

**Default** Automatically generates a texture surface. This method evenly distributes the texture and attempts to compensate for stretching of the surface. The default texture surface method has no additional controls.

**User Defined** Generates a texture surface that you can edit. You edit the user-defined texture surface either by using an Edit Texture Surface dialog (as you did in 3ds Max prior to v3), or by editing texture points directly in viewports.

**Edit Texture Surface** Click to display the Edit Texture Surface dialog on page 2719, which lets you control UV mapping on this surface. This button is available when you’ve chosen User Defined as the texture surface method.

**Edit Texture Points** Click to edit texture surface points directly in viewports. This button available when you’ve chosen User Defined as the texture surface method.

While Edit Texture Points is on, the points of the texture surface are displayed in viewports, where you can adjust their positions by using the selection and transform tools.

**Projected** Generates the texture surface by projecting the texture of another NURBS surface sub-object in the NURBS model. The projection travels along the direction of the normals of the source surface.
Projected texture surfaces are relational: if you update the source surface, the texture updates on all the surfaces it projects onto.
If you use the same source surface to project a texture onto several other connected surfaces, the textures will match along the boundaries where the mapped surfaces touch.

**Pick Source Surface** This button is available when you've chosen Projected as the texture surface method. To choose a source (projector) surface, choose Projected, click to turn on this button, and then click in a viewport to select another surface sub-object in the same NURBS model.

**Source text field** If Projected is the chosen texture surface method and you have picked a surface to project, this field displays the name of the projector (source) surface. Otherwise, this field says "None."

### Creating Curve Sub-Objects

Select NURBS object. > Modify panel > Create Curves rollout
Select NURBS object. > Modify panel > NURBS toolbox
Keyboard > Ctrl+T to toggle NURBS toolbox display (Keyboard Shortcut Override Toggle must be on)

Curve sub-objects are either independent point and CV curves (similar to the top-level point and CV curves described in Point Curve on page 2466 and CV Curve on page 2473), or they are dependent curves. Dependent curves are curve sub-objects whose geometry depends on other curves, points, or surfaces in the NURBS object. When you change the geometry of the original, parent sub-objects, the dependent curve changes as well.

You create curve sub-objects using the Create Curves rollout on the Modify command panel for a NURBS curve.
Tip: Lathe and extrude surface sub-objects can be based on only a single curve; see Creating Dependent Surfaces on page 2603. If you create dependent curves and then want to use the set of curves (for example, two parents and a fillet between them) as the basis of an extrude or loft surface, first go to the Curve sub-object level and use Join to connect the curves.

Creation operations for dependent sub-objects require you to select one or more parent objects. In general, you can click and drag, or click and then click again. You can also use the H keyboard shortcut to display the Select Sub-Objects dialog. This is a subset of the Selection Floater on page 209 for choosing the parent. (The Keyboard Shortcut Override Toggle on page 8420 must be on for H to work this way.)

Toolbox Buttons for Creating Curves

These are the toolbox on page 2426 buttons for creating curve sub-objects:

Create an independent CV curve sub-object on page 2552.
Create an independent point curve sub-object on page 2556.

Create a dependent fit curve (as with the Curve Fit on page 2558 button).

Create a dependent transform curve on page 2560.

Create a dependent blend curve on page 2562.

Create a dependent offset curve on page 2564.

Create a dependent mirror curve on page 2566.

Create a dependent chamfer curve on page 2569.

Create a dependent fillet curve on page 2574.

Create a dependent surface-surface intersection curve on page 2578.

Create a dependent U iso curve on page 2584.

Create a dependent V iso curve on page 2584.

Create a dependent normal projected curve on page 2586.

Create a dependent vector projected curve on page 2589.

Create a dependent CV curve on surface on page 2593.

Create a dependent point curve on surface on page 2597.

Create a dependent surface offset curve on page 2582.
Create a dependent surface edge curve on page 2601.

**CV Curve Sub-Object**

Select NURBS object. > Modify panel > Create Curves rollout > CV Curve button

Select NURBS object. > Modify panel > NURBS toolbox > Create CV Curve button

CV curve sub-objects are similar to object-level CV curves on page 2473. The main difference is that you can't give CV curves a renderable thickness at the sub-object level.

**Drawing Three-Dimensional Curves**

When you create a CV curve, you can draw it in three dimensions. There are two ways to do this:

- **Draw In All Viewports:** This toggle lets you use any viewport to draw the curve, enabling you to draw three dimensionally.
- **Using Ctrl to drag CVs:** While you draw a curve, you can use the Ctrl key to drag a CV off of the construction plane.

With the Ctrl-key method, further mouse movement lifts the latest point off the construction plane. There are two ways to use this:

- **Click-drag:** If you hold down Ctrl and also hold down the mouse button, you can drag to change the height of the CV. The CV’s location is set when you release the mouse button. This method is probably more intuitive.
- **Click-click:** If you Ctrl+click and then release the mouse button, the height changes as you drag the mouse. Clicking the mouse a second time sets the CV's location. This method is less prone to repetitive stress injury.

While you are offsetting the CV, a red dotted line is drawn between the original CV on the construction plane and the actual CV offset from the plane. You can move the mouse into an inactive viewport, in which case 3ds Max sets
the height of the CV using the CV's Z axis in the inactive viewport. This lets you set the height of the CV with accuracy.

**Snaps** on page 2819 also work when you change the height of a CV. For example, if you turn on CV snapping, you can set a CV to have the same height as another CV by snapping to that other CV in an inactive viewport.

**Procedures**

**To create a CV curve sub-object:**

1. Turn on CV Curve.
2. In a viewport, click and drag to create the first CV, as well as the first curve segment. Release the mouse button to add the second CV. Each subsequent location you click adds a new CV to the curve. Right-click to end curve creation.

**NOTE** If you begin the curve by clicking without dragging, this also creates the curve's first CV. However, if you release the mouse button more than five pixels away from where you initially pressed it, this creates an additional CV.

While you are creating a CV curve, you can press Backspace to remove the last CV you created, and then previous CVs in reverse order.

If Draw In All Viewports is on, you can draw in any viewport, creating a 3D curve.

To lift a CV off the construction plane, use the Ctrl key as described earlier in this topic under "Drawing Three-Dimensional Curves."

As with splines, if you click over the curve's initial CV, a Close Curve dialog on page 2714 is displayed. This dialog asks whether you want the curve to be closed. Click No to keep the curve open or Yes to close the curve. (You can also close a curve when you edit it at the Curve sub-object level.) When a closed curve is displayed at the Curve sub-object level, the initial CV is displayed as a green circle, and a green tick mark indicates the curve's direction.
Interface

CV Curve rollout (creation time)

Draw In All Viewports Lets you use any viewport while you are drawing the curve. This is one way to create a 3D curve. When off, you must finish drawing the curve in the viewport where you began it. Default=on. While Draw In All Viewports is on, you can also use snaps on page 2819 in any viewport.

Automatic Reparameterization group

The controls in this group box let you specify automatic reparameterization. They are similar to the controls in the Reparameterize dialog on page 2733, with one addition: all choices except for None tell 3ds Max to reparameterize the curve automatically; that is, whenever you edit it by moving CVs, refining, and so on.

None Do not reparameterize automatically.

Chord Length Chooses the chord-length algorithm for reparameterization. Chord-length reparameterization spaces knots (in parameter space on page 8674) based on the square root of the length of each curve segment. Chord-length reparameterization is usually the best choice.

Uniform Spaces the knots uniformly.
A uniform knot vector has the advantage that the curve or surface changes only locally when you edit it. With the other two forms of parameterization, moving any CV can change the entire sub-object.
CV Curve rollout (modification time)

**Degree** Sets the degree of the curve. The higher the degree value, the greater the continuity. The lower the degree, the more discontinuous the curve segments become. The degree can't be less than one or greater than the number allowed by the number of CVs in the curve. Degree 3 curves are adequate to represent continuous curves, and are stable and well behaved. Default=3.

Setting the degree greater than 3 isn’t recommended, because higher-degree curves are slower to calculate and less stable numerically. Higher-degree curves are supported primarily to be compatible with models created using other surface modeling programs.

The number of CVs in a CV curve must be at least one greater than the curve's degree.

**Automatic Reparameterization group**

The controls in this group box let you specify automatic reparameterization. They are similar to the controls in the Reparameterize dialog on page 2733, with one addition: all choices except for None tell 3ds Max to reparameterize the curve automatically; that is, whenever you edit it by moving CVs, refining, and so on.

**None** Do not reparameterize automatically.

**Chord Length** Chooses the chord-length algorithm for reparameterization. Chord-length reparameterization spaces knots (in parameter space on page 8674) based on the square root of the length of each curve segment.
Chord-length reparameterization is usually the best choice.

**Uniform** Spaces the knots uniformly. A uniform knot vector has the advantage that the curve or surface changes only locally when you edit it. With the other two forms of parameterization, moving any CV can change the entire sub-object.

**Close** Closes the curve. Disabled if the curve is already closed.

**Rebuild** Displays the Rebuild CV Curve dialog on page 2731 to let you rebuild the CV curve.

**Reparam** Displays the Reparameterize dialog on page 2733 to let you reparameterize the CV.

### Point Curve Sub-Object

Select NURBS object. > Modify panel > Create Curves rollout > Point Curve button

Select NURBS object. > Modify panel > NURBS toolbox > Create Point Curve button

Point curve sub-objects are similar to object-level point curves on page 2466. Points are constrained to lie on the curve. The main difference is that you can’t give point curves a renderable thickness at the sub-object level.

### Drawing Three-Dimensional Curves

When you create a point curve, you can draw it in three dimensions. There are two ways to do this:

- **Draw In All Viewports:** This toggle lets you use any viewport to draw the curve, enabling you to draw three dimensionally.

- **Using Ctrl to drag points:** While you draw a curve, you can use the Ctrl key to drag a point off of the construction plane.

With the Ctrl key method, further mouse movement lifts the latest point off the construction plane. There are two ways to use this:

- **Click-drag:** If you hold down Ctrl and also hold down the mouse button, you can drag to change the height of the point. The point’s location is set when you release the mouse button.
This method is probably more intuitive.

- Click-click. If you Ctrl+click and then release the mouse button, the height changes as you drag the mouse. Clicking the mouse a second time sets the point’s location.
  This method is less prone to repetitive stress injury.

While you are offsetting the point, a red dotted line is drawn between the original point on the construction plane and the actual point offset from the plane. You can move the mouse into an inactive viewport, in which case 3ds Max sets the height of the point using the point’s Z axis in the inactive viewport. This lets you set the height of the point with accuracy.

**Snaps** on page 2819 also work when you change the height of a point. For example, if you turn on Point snapping, you can set a point to have the same height as another point by snapping to that other point in an inactive viewport.

**Procedures**

**To create a point curve sub-object:**

1. Turn on Point Curve.

2. In a viewport, click and drag to create the first point, as well as the first curve segment. Release the mouse button to add the second point. Each subsequent location you click adds a new point to the curve. Right-click to end curve creation.

**NOTE** If you begin the curve by clicking without dragging, this also creates the curve’s first point. However, if you release the mouse button more than five pixels away from where you initially pressed it, this creates an additional point.

While you are creating a point curve, you can press Backspace to remove the last point you created, and then previous points in reverse order.

If Draw In All Viewports is on, you can draw in any viewport, creating a 3D curve.

To lift a point off the construction plane, use the Ctrl key as described earlier in this topic under **Drawing Three-Dimensional Curves** on page 2556.
As with splines, if you click over the curve's initial point, a Close Curve dialog on page 2730 is displayed. This dialog asks whether you want the curve to be closed. Click No to keep the curve open or Yes to close the curve. (You can also close a curve when you edit it at the Curve sub-object level.) When a closed curve is displayed at the Curve sub-object level, the initial point is displayed as a green circle, and a green tick mark indicates the curve's direction.

**Interface**

**Point Curve rollout (creation time)**

![Point Curve rollout (creation time)](image)

**Draw In All Viewports** Lets you use any viewport while you are drawing the curve. This is one way to create a 3D curve. When off, you must finish drawing the curve in the viewport where you began it. Default=on.

While Draw In All Viewports is on, you can also use snaps on page 2819 in any viewport.

**Point Curve rollout (modification time)**

![Point Curve rollout (modification time)](image)

**Close** Closes the curve. Disabled if the curve is already closed.

**Curve Fit**

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > Curve Fit button

---

**Chapter 10   Surface Modeling**
Select NURBS object. > Modify panel > NURBS toolbox > Create Fit Curve button

This command creates a point curve fitted to points you select. The points can be part of previously created point curve and point surface objects, or they can be point sub-objects you created explicitly. They can't be CVs.

Fitting a curve to selected points

Procedures

To create a point curve with Curve Fit:

1. Turn on Curve Fit.
2. Click to select two or more points.
   A point curve is created. It runs through the points you select, in the order you select them.
   You can use Backspace to undo point selection in reverse order.
3. Right-click to end creation.
Interface

There are no parameters for a point curve created with Curve Fit.

Transform Curve

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > Transform button

Select NURBS object. > Modify panel > NURBS toolbox > Create Transform Curve button

A transform curve is a copy of the original curve with a different position, rotation, or scale.

Curve used to create a transform curve
Procedures

To create a transform curve:

- In a NURBS object that contains at least one curve, turn on Transform.
  To move the transform curve, click and drag the curve you want to duplicate. To rotate or scale the transform curve, click the parent curve, go to the Curve sub-object level in the modifier stack, and then rotate or scale the transform curve.

  When you use Move to create the transform curve, it simply copies the parent. (It doesn't exaggerate curvature as an offset curve does.)

  Axis constraints don't apply to the creation of transform curves. You can click to create the curve in place; then once it is created, transform it using constraints.

  **TIP** You can also use axis constraints by using Shift+Clone at the Curve sub-object level.

Interface

Creation time

At creation time, transform curves have no parameters.

Transform Curve rollout (modification time)

At modification time, you can transform the transform curve as a curve sub-object, and you can animate curve sub-object transforms. Transform curves also have one control in the Modify panel.

Replace Base Curve Lets you replace the parent curve. Click the button, then click the curve to replace the original curve.
Blend Curve

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > Blend button

Select NURBS object. > Modify panel > NURBS toolbox > Create Blend Curve button

A blend curve connects the end of one curve to the end of another, blending the curvature of the parents to create a smooth curve between them. You can blend curves of the same type, a point curve with a CV curve (and vice versa), an independent curve with a dependent curve, and so on.

Blend curves connecting original curves

Procedures

To create a blend curve:

1. In a NURBS object that contains two curves, turn on Blend.
2 Click one curve near the end that you want to connect. The end that will be connected is highlighted. Without releasing the mouse button, drag to the end of the other curve that you want to connect. The other end is highlighted as well. When the end that you want to connect is highlighted, release the mouse button.

After the blend curve is created, changing the position or the curvature of either parent curve changes the blend curve as well.

3 Adjust the blend parameters.

Interface

Blend Curve rollout (creation time)

"Tension" affects the tangent between a parent curve and the blend curve. The greater the tension value, the more closely the tangent parallels the parent curve, and the smoother the transition. The lower the tension, the greater the tangent angle and the sharper the transition between parent and blend.

Tension 1 Controls tension at the edge of the first curve you clicked.

Tension 2 Controls tension at the edge of the second curve you clicked.
Blend Curve rollout (modification time)

"Tension" affects the tangent between a parent curve and the blend curve. The greater the tension value, the more closely the tangent parallels the parent curve, and the smoother the transition. The lower the tension, the greater the tangent angle and the sharper the transition between parent and blend.

**Tension 1** Controls tension at the edge of the first curve you clicked.

**Tension 2** Controls tension at the edge of the second curve you clicked.

**Replace First Curve and Replace Second Curve** Let you replace the parent curves. Click the button, then click the curve to replace the original first or second curve.

**Offset Curve**

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > Offset button

Select NURBS object. > Modify panel > NURBS toolbox > Create Offset Curve button

An Offset curve is offset from the original, parent curve. It is normal to the original. You can offset both planar and 3D curves.
Curve used to create an offset curve

Procedures

To create an offset curve:

1. In a NURBS object that contains at least one curve, turn on Offset.
2. Click the curve you want to offset, and drag to set the initial distance. An offset curve is created.
3. Adjust the Offset parameter.
   If the parent curve is not linear, increasing the distance increasingly exaggerates the curvature of the offset curve.
**Interface**

**Offset Curve rollout (creation time)**

![Offset Curve rollout](image)

**Offset** The distance between the parent curve and the offset curve, in 3ds Max units.

This parameter is animatable.

**Offset Curve rollout (modification time)**

![Offset Curve rollout](image)

**Offset** The distance between the parent curve and the offset curve, in 3ds Max units.

**Replace Base Curve** Lets you replace the parent curve. Click the button, then click the curve to replace the original curve.

**Mirror Curve**

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > Mirror button

Select NURBS object. > Modify panel > NURBS toolbox > Create Mirror Curve button

A mirror curve is a mirror image of the original curve.
Curve used to create a mirror curve

Procedures

To create a mirror curve:

1. In a NURBS object that contains at least one curve, turn on Mirror.
2. On the Mirror Curve rollout, choose the axis or plane you want to use.
3. Click the curve you want to mirror, and drag to set the initial distance. A mirror curve is created. A gizmo (yellow by default) indicates the direction of mirroring. Transforming the mirror curve’s gizmo changes the orientation of the mirror, letting you mirror along an axis that isn’t aligned with a local coordinate axis.
4. Adjust the mirror parameters.

Interface

In viewports a gizmo (yellow by default) indicates the mirror axis.
Mirror Curve rollout (creation time)

Mirror Axis group

The Mirror Axis buttons control the direction in which the original curve is mirrored.

You can't transform the mirror curve directly (that would simply transform the mirror curve and its parent curve at the same time). You transform it by transforming its gizmo. By using transforms you can mirror about an arbitrary axis, rather than using one of the Mirror Axis presets. When you transform a mirror curve, you are actually transforming the mirror plane, so Rotate has the effect of rotating the plane about which the curve is mirrored. (This is like rotating the mirror gizmo in the Mirror modifier.)

Offset Controls the mirror's distance from the original curve. This parameter is animatable.
**Mirror Curve rollout (modification time)**

![Mirror Curve rollout](image)

**Mirror Axis group**

The Mirror Axis buttons control the direction in which the original curve is mirrored.

You can't transform the mirror curve directly (that would simply transform the mirror curve and its parent curve at the same time). You transform it by transforming its gizmo. By using transforms you can mirror about an arbitrary axis, rather than using one of the Mirror Axis presets. When you transform a mirror curve, you are actually transforming the mirror plane, so Rotate has the effect of rotating the plane about which the curve is mirrored. (This is like rotating the mirror gizmo in the Mirror modifier.)

**Offset** Controls the mirror's distance from the original curve. This parameter is animatable.

**Replace Base Curve** Lets you replace the parent curve. Click the button, then click the curve to replace the original curve.

**Chamfer Curve**

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > Chamfer button
Select NURBS object. > Modify panel > NURBS toolbox > Create Chamfer Curve button

Chamfer creates a curve that is a straight bevel between two parent curves.

Creating chamfers between two original curves

Procedures

To create a chamfer curve:

1. In a NURBS object that contains at least two curves, turn on Chamfer.

   **TIP** Make sure the curves intersect before you begin to create the chamfer.

2. Click one curve near the end that you want to connect. The end that will be connected is highlighted. Without releasing the mouse button, drag to the end of the other curve that you want to connect. When the end that will be connected is highlighted, release the mouse button.
A chamfer curve is created. Changing the position or the curvature of either parent curve can change the chamfer as well.

The parent curves must be coplanar. The chamfer is not necessarily connected at the endpoints of the parent curves: you can adjust its position with the chamfer’s Length parameters.

3 Adjust the chamfer parameters.

Interface

Chamfer Curve rollout (creation time)

![Chamfer Curve rollout](image)

The lengths are the distances from the intersection (or apparent intersection) at which the chamfer segment is drawn.

**Length 1** The distance along the first curve you click.

This parameter is animatable.

**Length 2** The distance along the second curve you click.
This parameter is animatable.
Some length values make it impossible to construct the chamfer. If you set
the length to an invalid value, the chamfer returns to a default position and
is displayed in the error color (orange by default).

**Trim First Curve and Trim Second Curve groups**

These two group boxes let you control how the parent curves are trimmed.
The controls are the same in each. "First" and "second" refer to the order in
which you picked the parent curves.

Flipping the direction of a trim

**Trim Curve** When on (the default), trims the parent curve against the fillet
curve. When off, the parent isn't trimmed.

**Flip Trim** When on, trims in the opposite direction.

**Seed 1 and Seed 2** Change the U location of the seed value on the first and
second curves. If there is a choice of directions, the direction indicated by the
seed points is the one used to create the chamfer.
Chamfer Curve rollout (modification time)

The lengths are the distances from the intersection (or apparent intersection) at which the chamfer segment is drawn.

**Length 1** The distance along the first curve you click.

**Length 2** The distance along the second curve you click.

Some length values make it impossible to construct the chamfer. If you set the length to an invalid value, the chamfer returns to a default position and is displayed in the error color (orange by default).
**Trim First Curve and Trim Second Curve groups**

These two group boxes let you control how the parent curves are trimmed. The controls are the same in each. "First" and "second" refer to the order in which you picked the parent curves.

**Flipping the direction of a trim**

**Trim Curve** When on (the default), trims the parent curve against the fillet curve. When off, the parent isn’t trimmed.

**Flip Trim** When on, trims in the opposite direction.

**Seed 1 and Seed 2** Change the U location of the seed value on the first and second curves. If there is a choice of directions, the direction indicated by the seed points is the one used to create the chamfer.

**Replace First Curve and Replace Second Curve** Let you replace the parent curves. Click the button, then click the curve to replace the original first or second curve.

**Fillet Curve**

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > Fillet button

Select NURBS object. > Modify panel > NURBS toolbox > Create Fillet Curve button

Fillet creates a curve that is a rounded corner between two parent curves.
Above: Two simple fillets
Below: Flip Trim changes the direction of trimming and the shape the fillet.

Procedures

To create a fillet curve:

1. In a NURBS object that contains at least two curves, turn on Fillet.
2. Click one curve near the end that you want to connect. The end that will be connected is highlighted. Without releasing the mouse button, drag to the end of the other curve that you want to connect. When the end that you want to connect is highlighted, release the mouse button.

A fillet curve is created. It trims the ends of the parent curve to match the fillet. The fillet is not necessarily placed at the endpoints of the parent curves: placement depends on the value of the Radius parameter.

Changing the position or the curvature of either parent curve can change the fillet as well.

The parent curves must be coplanar.

3. Adjust the fillet parameters.
Interface

Fillet Curve rollout (creation time)

Radius The radius of the fillet arc in the current 3ds Max units. Default=10.0. This parameter is animatable.

TIP If the fillet you initially create is in an error state, often this is because the radius is not large enough to bridge the distance between the two curves. Increasing the Radius value gives you a correct fillet. The fillet becomes an arc displayed in the dependent object color (green by default). When the fillet is in an error state it is displayed as a straight line in the error color (orange by default).

Trim First Curve and Trim Second Curve groups

These two group boxes let you control how the parent curves are trimmed. The controls are the same in each. "First" and "second" refer to the order in which you picked the parent curves.

Trim Curve When on (the default), trims the parent curve against the fillet curve. When off, the parent isn't trimmed.
Flip Trim When on, trims in the opposite direction.

Seed 1 and Seed 2 Change the U location of the seed value on the first and second curves. If there is a choice of directions, the direction indicated by the seed points is the one used to create the fillet.

Fillet Curve rollout (modification time)

Radius
The radius of the fillet arc in the current 3ds Max units. Default=10.0.

TIP If the fillet you initially create is in an error state, often this is because the radius is not large enough to bridge the distance between the two curves. Increasing the Radius value gives you a correct fillet. The fillet becomes an arc displayed in the dependent object color (green by default). When the fillet is in an error state it is displayed as a straight line in the error color (orange by default).
**Trim First Curve and Trim Second Curve groups**

These two group boxes let you control how the parent curves are trimmed. The controls are the same in each. "First" and "second" refer to the order in which you picked the parent curves.

**Trim Curve** When on (the default), trims the parent curve against the fillet curve. When off, the parent isn't trimmed.

**Flip Trim** When on, trims in the opposite direction.

**Seed 1 and Seed 2** Change the U location of the seed value on the first and second curves. If there is a choice of directions, the direction indicated by the seed points is the one used to create the fillet.

**Replace First Curve and Replace Second Curve** Let you replace the parent curves. Click the button, then click the curve to replace the original first or second curve.

---

**Surface-Surface Intersection Curve**

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > Surf x Surf button

Select NURBS object. > Modify panel > NURBS toolbox > Create Surface-Surface Intersection Curve button

This command creates a curve that is defined by the intersection of two surfaces. You can use surface-surface intersection curves for trimming on page 2420.
If the surfaces intersect at two or more locations, the intersection closest to the seed point is the one that creates the curve.

Procedures

To create a surface-surface intersection curve:

1. Turn on Create Surface-Surface Intersection Curve in the NURBS toolbox, or Surf x Surf on the Create Curves rollout.
2. Click the first surface, then the second. If the two surfaces intersect, a curve that lies along their intersection is created.
Interface

Surf-Surf Intersection Curve rollout (creation time)

Trim Controls group

Trim 1 and Trim 2 When on, trim a surface against the intersection curve. When off, the surface isn’t trimmed. Trim 1 trims the first parent surface you clicked, and Trim 2 trims the second parent surface.

If the intersection curve does not pass completely across a surface, trimming is impossible, and the affected surface is displayed in the error color (orange by default).

Flip Trim 1 and Flip Trim 2 When on, trim the associated surface in the opposite direction.

U Seed and V Seed Change the UV location of the seed value on surface 1, the first surface you clicked. If there is a choice of intersections, the intersection closest to the seed point is the one used to create the curve.
**Trim Controls group**

**Trim 1 and Trim 2** When on, trim a surface against the intersection curve. When off, the surface isn’t trimmed. Trim 1 trims the first parent surface you clicked, and Trim 2 trims the second parent surface.

If the intersection curve does not pass completely across a surface, trimming is impossible, and the affected surface is displayed in the error color (orange by default).

**Flip Trim 1 and Flip Trim 2** When on, trim the associated surface in the opposite direction.

**U Seed and V Seed** Change the UV location of the seed value on surface 1, the first surface you clicked. If there is a choice of intersections, the intersection closest to the seed point is the one used to create the curve.

**Replace First Surface and Replace Second Surface** Let you replace the parent surfaces. Click a button, then click the surface to replace the original first or second surface.
Surface Offset Curve

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > Surf Offset button

Select NURBS object. > Modify panel > NURBS toolbox > Create Surface Offset Curve button

This command creates a curve that is offset from a curve that lies on a surface. In other words, the parent curve must have one of the following types: surface-surface intersection, U iso, V iso, normal projected, vector projected, CV curve on surface, or point curve on surface. The offset is normal to the surface. That is, the new curve is either above or below the surface by the offset amount.
Procedures

To create a surface offset curve:

1. In a NURBS object that contains at least one NURBS surface with a curve on it, turn on Create Surface Offset Curve in the NURBS toolbox, or Surf Offset on the Create Curves rollout.

2. Put the cursor over a curve that lies on a surface, and drag to set the offset amount. Release the mouse button to end curve creation.

Interface

Surface Offset Curve rollout (creation time)

- Offset: The amount by which the curve is offset from the surface on which the parent curve lies.

Surface Offset Curve rollout (modification time)

- Offset: The amount by which the curve is offset from the surface on which the parent curve lies.
  This parameter is animatable.

- Replace Curve: Lets you replace the parent curve. Click the button, then click the curve to replace the original parent curve.
U and V Iso Curves

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > U Iso Curve button or V Iso Curve button

Select NURBS object. > Modify panel > NURBS toolbox > Create U Iso Curve button or Create V Iso Curve button

U and V iso curves are dependent curves created from the iso (isoparametric) lines of a NURBS surface. You can use U and V iso curves to trim surfaces on page 2420.

Iso curves in the U and V dimensions

Procedures

To create an iso curve:

- Turn on U Iso Curve or V Iso Curve, then drag over the surface. The iso lines are highlighted in blue as you drag.
Click to create the curve from the highlighted iso line.

**Interface**

**Iso Curve rollout (creation time)**

- **Position** Sets the iso curve's position along the U or V axis of the surface. This parameter is animatable.

**Trim Controls group**

- **Trim** When on, trims the surface against the iso curve.
- **Flip Trim** When on, flips the direction of the trim.
**Iso Curve rollout (modification time)**

![Iso Curve rollout](image)

**Position**
Sets the iso curve's position along the U or V axis of the surface. This parameter is animatable.

**Trim Controls group**

**Trim**
When on, trims the surface against the iso curve.

**Flip Trim**
When on, flips the direction of the trim.

**Replace Base Surface**
Lets you replace the parent surface. Click the button, then click the new surface on which to base the iso curve.

**Normal Projected Curve**

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > Normal Proj. button

Select NURBS object. > Modify panel > NURBS toolbox > Create Normal Projected Curve button

A normal projected curve lies on a surface. It is based on an original curve, which is projected onto the surface in the direction of the surface's normals.

You can use normal projected curves for **trimming** on page 2420.
Trimming a surface with a normal projected curve

If the projection intersects the surface in two or more locations, the intersection closest to the seed point is the one that creates the curve.

Procedures

To create a normal projected curve:

1. In a NURBS object that contains at least one surface and one curve sub-object, turn on NormalProjected Curve in the NURBS toolbox or Normal Proj. on the Create Curves rollout.

2. Click the curve, then click the surface where you want the normal projected curve to lie.
   If the curve can be projected onto the surface in the surface's normal direction, the projected curve is created. The original, parent curve can go "off the edge of the surface." The projected curve is created only where the projection and the surface intersect.
Interface

Normal Projected Curve rollout (creation time)

Trim Controls group

Trim When on, trims the surface against the curve. When off, the surface isn’t trimmed.
If it’s impossible to trim with this curve, the surface is displayed in the error color (orange by default). For example, the curve is unusable for trimming if it neither crosses the edge of the surface nor forms a closed loop.

Flip Trim When on, trims the surface in the opposite direction.

U Seed and V Seed Change the UV location of the seed value on the surface. If there is a choice of projections, the projection closest to the seed point is the one used to create the curve.
Normal Projected Curve rollout (modification time)

Trim Controls group

Trim When on, trims the surface against the curve. When off, the surface isn’t trimmed.

If it’s impossible to trim with this curve, the surface is displayed in the error color (orange by default). For example, the curve is unusable for trimming if it neither crosses the edge of the surface nor forms a closed loop.

Flip Trim When on, trims the surface in the opposite direction.

U Seed and V Seed Change the UV location of the seed value on the surface. If there is a choice of projections, the projection closest to the seed point is the one used to create the curve.

Replace Curve and Replace Surface Let you replace the parent sub-objects. Click a button, then click a curve or surface to replace the original parent object.

Vector Projected Curve

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > Vector Proj. button
Select NURBS object. > Modify panel > NURBS toolbox > Create Vector Projected Curve button

A Vector Projected curve lies on a surface. This is almost the same as a Normal Projected curve, except that the projection from the original curve to the surface is in the direction of a vector that you can control.

You can use vector projected curves for trimming on page 2420.

![Trimming a surface with a vector projected curve](image)

**Trimming a surface with a vector projected curve**

If the projection intersects the surface in two or more locations, the intersection closest to the seed point is the one that creates the curve.

**Procedures**

**To create a vector projected curve:**

1. In a NURBS object that contains at least one surface and one curve sub-object, click to turn on Vector Projected Curve in the NURBS toolbox or Vector Proj. in the Create Curves rollout.
2 Click the curve, then the surface where you want the vector projection curve to lie.

The initial vector direction is in the view direction. That is, the vector points away from you as you look at the viewport. If the curve can be projected onto the surface in this direction, the projection curve is created. The original, parent curve can go "off the edge of the surface." The projection curve is created only where the projection and the surface intersect.

Interface

In viewports a gizmo (yellow by default) indicates the projection axis. Transforming the gizmo changes the projection onto the surface. Rotating the gizmo is the most useful transform. You can use rotation to adjust the distortion caused by projection.

Vector Projected Curve rollout (creation time)

Trim Controls group

Trim When on, trims the surface against the curve. When off, the surface isn't trimmed.

If it's impossible to trim with this curve, the surface is displayed in the error color (orange by default). For example, the curve is unusable for trimming if it neither crosses the edge of the surface nor forms a closed loop.

Flip Trim When on, trims the surface in the opposite direction.
U Seed and V Seed Change the UV location of the seed value on the surface. If there is a choice of projections, the projection closest to the seed point is the one used to create the curve.

Vector Projected Curve rollout (modification time)

Trim Controls group

Trim When on, trims the surface against the curve. When off, the surface isn’t trimmed.

If it’s impossible to trim with this curve, the surface is displayed in the error color (orange by default). For example, the curve is unusable for trimming if it neither crosses the edge of the surface nor forms a closed loop.

Flip Trim When on, trims the surface in the opposite direction.

U Seed and V Seed Change the UV location of the seed value on the surface. If there is a choice of projections, the projection closest to the seed point is the one used to create the curve.

Replace Curve and Replace Surface Let you replace the parent sub-objects. Click a button, then click a curve or surface to replace the original parent object.
CV Curve on Surface

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > CV on Surf button

Select NURBS object. > Modify panel > NURBS toolbox > Create CV Curve on Surface button

A CV curve on surface is similar to a plain CV curve, but it lies on a surface. You create it by drawing rather than projecting from a different curve. You can use this curve type for trimming on page 2420 the surface on which it lies.

Trimming a surface with a CV curve on surface

There are two methods for drawing and editing curves on surfaces: drawing in a viewport, or using the Edit Curve on Surface dialog. The choice is useful because you draw in two dimensions, with a mouse or other pointing device, while the curve on a surface can exist in three dimensions. The more complex the 3D surface, the more effort it can require to create and edit a curve on a surface.

Visual feedback can help you draw the curve. The point whose surface you first click is shown as a blue square, and the surface's minimum UV point is shown as a plus sign (+). As you draw the curve, it is displayed interactively in viewports.
**Drawing in a Viewport**

When you click to position a CV, the click is projected in the viewport's Z dimension. That is, your click is projected "through the screen" and onto the surface. This is a straightforward way to create a curve on a surface if the portion of the surface where the curve will lie is clearly visible in the viewport. However, this method doesn't let you place CVs on surface locations that are not visible in the viewport (they are on back faces, lie behind other geometry, and so on).

**Using the Edit Curve on Surface Dialog**

The Edit Curve on Surface dialog on page 2716 lets you edit curves on surfaces as you edit regular curves in a viewport. The main part of the dialog is a two-dimensional view of the surface. The controls provide typical curve editing functions. While you are creating a CV curve on surface, the 2D View toggle controls display of the Edit Curve on Surface dialog.

You can edit the CVs in CV curves on surfaces at the Curve CV sub-object level on page 2503, as you edit other kinds of curve CVs. You can transform CVs in CV curves on surfaces, but you can't move the CVs off the surface. Using the Curve CV sub-object level is an alternative to editing these CVs by using the Edit Curve on Surface dialog.

**Procedures**

To create a CV curve on surface:

1. In a NURBS object that contains at least one surface, turn on Create CV Curve on Surface in the NURBS toolbox, or CV on Surf on the Create Curves rollout.

2. Do one of the following:
   - Draw the curve in the viewport, using the mouse above the surface.
   - Turn on 2D View. This displays an Edit Curve on Surface dialog, which lets you create the curve in a two-dimensional (UV) representation of the surface.

3. Right-click to end curve creation.
Interface

CV Curve on Surface rollout (creation time)

Trim Controls group

Trim When on, trims the surface against the curve. When off, the surface isn't trimmed.

If it's impossible to trim with this curve, the surface is displayed in the error color (orange by default). For example, the curve is unusable for trimming if it doesn't form a closed loop.

Flip Trim When on, trims the surface in the opposite direction.

Automatic Reparameterization group

The radio buttons in this group box let you choose automatic reparameterization. With reparameterization, the curve maintains its parameterization as you edit it. Without reparameterization, the curve's parameterization doesn't change as you edit it, and can become irregular.

None Do not reparameterize.

Chord Length Chooses the chord-length algorithm for reparameterization. Chord-length reparameterization spaces knots (in parameter space on page 8674) based on the square root of the length of each curve segment. Chord-length reparameterization is usually the best choice.
Uniform  Spaces the knots uniformly. A uniform knot vector has the advantage that the curve will change only locally when you edit it. With the other two forms of parameterization, moving any CV can change the entire curve.

2D View  When on, displays the Edit Curve on Surface dialog on page 2716, which lets you create the curve in a two-dimensional (UV) representation of the surface.

CV Curve on Surface rollout (modification time)

Trim Controls group

Trim  When on, trims the surface against the curve. When off, the surface isn’t trimmed.

If it's impossible to trim with this curve, the surface is displayed in the error color (orange by default). For example, the curve is unusable for trimming if it doesn't form a closed loop.

Flip Trim  When on, trims the surface in the opposite direction.
**Automatic Reparameterization group**

The radio buttons in this group box let you choose automatic reparameterization. With reparameterization, the curve maintains its parameterization as you edit it. Without reparameterization, the curve's parameterization doesn't change as you edit it, and can become irregular.

**None** Do not reparameterize.

**Chord Length** Chooses the chord-length algorithm for reparameterization. Chord-length reparameterization spaces knots (in parameter space on page 8674) based on the square root of the length of each curve segment. Chord-length reparameterization is usually the best choice.

**Uniform** Spaces the knots uniformly. A uniform knot vector has the advantage that the curve will change only locally when you edit it. With the other two forms of parameterization, moving any CV can change the entire curve.

**Replace Surface** Lets you replace the parent surface. Click a button, then click a surface to replace the original parent surface.

**Edit** Click to display the *Edit Curve on Surface dialog* on page 2716, which lets you edit the curve in a two-dimensional (UV) representation of the surface. To edit multiple curves on a surface, select more than one CV curve sub-object on the same surface, then click Edit.

**Rebuild** Displays the *Rebuild CV Curve dialog* on page 2731 to let you rebuild the CV curve on surface.

**Reparam** Displays the *Reparameterize dialog* on page 2733 to let you reparameterize the CV curve on surface.

**Point Curve on Surface**

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > Point on Surf button

Select NURBS object. > Modify panel > NURBS toolbox > Create Point Curve on Surface button

A point curve on surface is similar to a plain point curve, but it lies on a surface. You create it by drawing rather than projecting from a different curve. You can use this curve type for *trimming* on page 2420 the surface on which it lies.
Trimming a surface with a point curve on surface

There are two methods for drawing and editing curves on surfaces: drawing in a viewport, or using the Edit Curve on Surface dialog. The choice is useful because you draw in two dimensions, with a mouse or other pointing device, while the curve on a surface can exist in three dimensions. The more complex the 3D surface, the more effort it can require to create and edit a curve on a surface.
Visual feedback can help you draw the curve. The point whose surface you first click is shown as a blue square, and the surface's minimum UV point is shown as a plus sign (+). As you draw the curve, it is displayed interactively in viewports.

**Drawing in a Viewport**

When you click to position a point, the click is projected in the viewport's Z dimension. That is, your click is projected "through the screen" and onto the surface. This is a straightforward way to create a curve on a surface if the portion of the surface where the curve will lie is clearly visible in the viewport. However, this method doesn't let you place points on surface locations that are not visible in the viewport (they are on back faces, lie behind other geometry, and so on).

**Using the Edit Curve on Surface Dialog**

The *Edit Curve on Surface dialog* on page 2716 lets you edit curves on surfaces as you edit regular curves in a viewport. The main part of the dialog is a two-dimensional view of the surface. The controls provide typical curve editing functions. While you are creating a point curve on surface, the 2D View toggle controls display of the Edit Curve on Surface dialog.

You can edit the points in point curves on surfaces at the *Point sub-object level* on page 2496, as you edit other kinds of points. You can transform points in point curves on surfaces, but you can't move the points off the surface. Using the Point sub-object level is an alternative to editing these points by using the Edit Curve on Surface dialog.

**Procedures**

**To create a point curve on surface:**

1. In a NURBS object that contains at least one surface, turn on Create Point Curve on Surface in the NURBS toolbox, or Point on Surf on the Create Curves rollout.

2. Do one of the following:
   - Draw the curve in the viewport, using the mouse above the surface.
   - Turn on 2D View. This displays an Edit Curve on Surface dialog, which lets you create the curve in a two-dimensional (UV) representation of the surface.
Right-click to end curve creation.

**Interface**

Point curves on surfaces have point sub-objects that you can transform and edit in viewports as you do with plain point curves.

**Point Curve on Surface rollout (creation time)**

![Point Curve On Surface Rollout](image)

**Trim Controls group**

*Trim* When on, trims the surface against the curve. When off, the surface isn’t trimmed.

If it’s impossible to trim with this curve, the surface is displayed in the error color (orange by default). For example, the curve is unusable for trimming if it doesn’t form a closed loop.

*Flip Trim* When on, trims the surface in the opposite direction.

*2D View* When on, displays the Edit Curve on Surface dialog on page 2716, which lets you create the curve in a two-dimensional (UV) representation of the surface.
Point Curve on Surface rollout (modification time)

Trim Controls group

Trim When on, trims the surface against the curve. When off, the surface isn’t trimmed.

If it’s impossible to trim with this curve, the surface is displayed in the error color (orange by default). For example, the curve is unusable for trimming if it doesn’t form a closed loop.

Flip Trim When on, trims the surface in the opposite direction.

Replace Surface Lets you replace the parent surface. Click a button, then click a surface to replace the original parent surface.

Edit Click to display the Edit Curve on Surface dialog on page 2716, which lets you edit the curve in a two-dimensional (UV) representation of the surface. To edit multiple curves on a surface, select more than one point curve sub-object on the same surface, then click Edit.

Surface Edge Curve

Select NURBS object. > Modify panel > Create Curves rollout > Dependent Curves group box > Surf Edge button

Select NURBS object. > Modify panel > NURBS toolbox > Create Surface Edge Curve button

A surface edge curve is a dependent curve type that lies on the boundary of the surface. It can be the original boundary of the surface, or a trim edge.
Creating a curve from a surface edge

**Procedures**

To create a surface edge curve:

1. Turn on Surf Edge.
2. As you move the mouse in the scene, NURBS surface edges are highlighted in blue. Click the edge where you want to create the curve.
Interface

Surface Edge Curve rollout (creation time)

Seed 1 and Seed 2 The curve resides on the edge closest to the two seed values. Adjust the seed values to change the edge on which the curve resides.

Surface Edge Curve rollout (modification time)

Seed 1 and Seed 2 The curve resides on the edge closest to the two seed values. Adjust the seed values to change the edge on which the curve resides.

Replace Surface This lets you replace the parent surface. Click a button, then click a surface to replace the original parent surface.

Creating Surface Sub-Objects

Select NURBS object. > Modify panel > Create Surfaces rollout
Select NURBS object. > NURBS toolbox
Keyboard > Ctrl+T to toggle NURBS toolbox display (Keyboard Shortcut Override Toggle must be on.)
Surface sub-objects are either independent point and CV surfaces (like the top-level point and CV surfaces described in Point Surface and CV Surface), or they are dependent surfaces. Dependent surfaces are surface sub-objects whose geometry depends on other surfaces or curves in the NURBS model. When you change the geometry of the original, parent surface or curve, the dependent surface changes as well.

You create surface sub-objects using the Create Surfaces rollout on the Modify panel for a NURBS surface, or using the NURBS toolbox on page 2426.
**TIP** Lathe and extrude surface sub-objects can be based on only a single curve. If you have dependent curves and want to use the set of curves (for example, two parents and a fillet between them) as the basis of an extrude or lathe surface, first go to the Curve sub-object level and use Join to connect the curves.

Creation operations for dependent sub-objects require that you select one or more parent objects. In general, you can click and drag, or click and then click again. You can also use the H keyboard shortcut to open a Pick Object version of the Selection Floater on page 209 for choosing the parent. (The Keyboard Shortcut Override Toggle on page 8420 must be on for H to work this way.)

**Toolbox Buttons for Creating Surfaces**

These are the toolbox buttons for creating surface sub-objects:

- ![Create an independent CV surface sub-object on page 2606.](image)
- Create an independent point surface sub-object on page 2610.
- ![Create a dependent transform surface on page 2612.](image)
- Create a dependent blend surface on page 2614.
- ![Create a dependent offset surface on page 2621.](image)
- Create a dependent mirror surface on page 2624.
- ![Create a dependent extrude surface on page 2628.](image)
- Create a dependent lathe surface on page 2631.
- ![Create a dependent ruled surface on page 2640.](image)
- Create a dependent cap surface on page 2643.
- ![Create a dependent U loft surface on page 2646.](image)
Create a dependent UV loft surface on page 2656.

Create a dependent 1-rail sweep surface on page 2663.

Create a dependent 2-rail sweep surface on page 2673.

Create a dependent multisided blend surface on page 2683.

Create a dependent multicurve trimmed surface on page 2684.

Create a dependent fillet surface on page 2689.

CV Surface Sub-Object

Select NURBS object. > Modify panel > Create Surfaces rollout > CV Surf
Select NURBS object. > Modify panel > NURBS toolbox > Create CV Surface button
Select NURBS object. > Modify panel > Right-click a viewport. > Tools 2 (lower-left) quadrant > Create CV Surface
CV surface sub-objects are similar to object-level CV surfaces on page 2460.

See also:
- Editing Surface Sub-Objects on page 2530
- NURBS Surface Approximation on page 2737

Procedures

To create a CV surface sub-object:

1. In a NURBS object, turn on CV Surf on the Create Surfaces rollout or Create CV Surface in the toolbox.

2. In a viewport, drag to specify the initial area of the CV surface.
3. Adjust the CV surface's creation parameters.

**Interface**

The parameters that appear when you create a CV surface sub-object differ from those you see when you modify it as a sub-object.

**CV Surface rollout (creation time)**

![Image of CV Surface rollout]

- **Length** The length of the surface in current 3ds Max units.
- **Width** The width of the surface in current 3ds Max units.
- **Length Points** The number of points along the length of the surface. In other words, the initial number of point columns in the surface. Range=2 to 50. Default=4.
- **Width Points** The number of points along the width of the surface. In other words, the initial number of point rows in the surface. Range=2 to 50. Default=4.
Generate Mapping Coordinates Generates mapping coordinates so you can apply mapped materials to the surface.

Flip Normals Turn on to reverse the direction of the surface normals.

**Automatic Reparameterization group**

The radio buttons in this group box let you choose automatic reparameterization. With reparameterization, the surface maintains its parameterization as you edit it. Without reparameterization, the surface's parameterization doesn't change as you edit it, and can become irregular.

None Do not reparameterize.

Chord Length Chooses the chord-length algorithm for reparameterization. Chord-length reparameterization spaces knots (in parameter space on page 8674) based on the square root of the length of each curve segment. Chord-length reparameterization is usually the best choice.

Uniform Spaces the knots uniformly.
A uniform knot vector has the advantage that the surface will change only locally when you edit it. With the other two forms of parameterization, moving any CV can change the entire surface.

**CV Surface rollout (modification time)**
U Degree and V Degree

Let you set the degree of the surface in either the U or V dimension. The higher the degree value, the greater the continuity. The lower the degree, the more discontinuous the surface segments become. The degree can’t be less than one or greater than the number allowed by the number of CVs in the specified dimension. Degree 3 is adequate to represent continuous surfaces, and is stable and well behaved. Default=3.

Setting the degree greater than 3 isn’t recommended, because higher degrees are slower to calculate and less stable numerically. Higher degrees are supported primarily to be compatible with models created using other surface modeling programs.

The number of CVs in a given dimension must be at least one greater than that dimension’s degree.

Automatic Reparameterization group

The radio buttons in this group box let you choose automatic reparameterization. With reparameterization, the surface maintains its parameterization as you edit it. Without reparameterization, the surface’s parameterization doesn’t change as you edit it, and can become irregular.

None

Do not reparameterize.

Chord Length

Chooses the chord-length algorithm for reparameterization. Chord-length reparameterization spaces knots (in parameter space on page 8674) based on the square root of the length of each curve segment. Chord-length reparameterization is usually the best choice.

Uniform

Spaces the knots uniformly.

A uniform knot vector has the advantage that the surface will change only locally when you edit it. With the other two forms of parameterization, moving any CV can change the entire surface.

The close controls let you close a surface. They appear on the Point Surface rollout while an independent point surface sub-object is selected. They have no effect if the surface is already closed in that direction.

Close Rows

Closes the surface by joining the ends of its rows.

Close Cols.

Closes the surface by joining the ends of its columns.

Rebuild

Displays the Rebuild CV Surface dialog on page 2732, which lets you specify how to rebuild the surface. Rebuilding the surface can change its appearance.

Reparameterize

Displays the Reparameterize dialog on page 2733. Reparameterizing a surface changes the surface’s parameter space on page 8674.
to provide a better relation between control point locations and the shape of the surface.

**TIP** It is a good idea to reparameterize after you have added CVs to the surface by refining or inserting.

---

**Point Surface Sub-Object**

Select NURBS object. > Modify panel > Create Surfaces rollout > Point Surf
Select NURBS object. > Modify panel > NURBS toolbox > Create Point Surface button
Select NURBS object. > Modify panel > Right-click a viewport. > Tools 2 (lower-left) quadrant > Create Point Surface

Point surface sub-objects are similar to object-level point surfaces on page 2456. The points are constrained to lie on the surface.

**See also:**
- Editing Surface Sub-Objects on page 2530
- NURBS Surface Approximation on page 2737

**Procedures**

**To create a point surface sub-object:**

1. In a NURBS object, turn on Point Surf on the Create Surfaces rollout or Create Point Surface in the toolbox.
2. In a viewport, drag to specify the initial area of the point surface.
3. Adjust the point surface’s creation parameters.

**Interface**

The parameters that appear when you create a point surface sub-object differ from those you see when you modify it as a sub-object.
Point Surface rollout (creation time)

Length The length of the surface in current 3ds Max units.

Width The width of the surface in current 3ds Max units.

Length Points The number of points along the length of the surface. In other words, the initial number of point columns in the surface. Range=2 to 50. Default=4.

Width Points The number of points along the width of the surface. In other words, the initial number of point rows in the surface. Range=2 to 50. Default=4.

Generate Mapping Coordinates Generates mapping coordinates so you can apply mapped materials to the surface.

Flip Normals Turn on to reverse the direction of the surface normals.

Point Surface rollout (modification time)
The close controls let you close a surface. They appear on the Point Surface rollout while an independent point surface sub-object is selected. They have no effect if the surface is already closed in that direction.

**Close Rows** Closes the surface by joining the ends of its rows.

**Close Cols.** Closes the surface by joining the ends of its columns.

## Transform Surface

Select NURBS object. > Modify panel > Create Surfaces rollout Dependent Surfaces group box > Transform

Select NURBS object. > Modify panel > NURBS toolbox > Create Transform Surface button

A transform surface is a copy of the original surface with a different position, rotation, or scale.

![Surface created as a transform](image)
Procedures

To create a transform surface:

- In a NURBS object that contains at least one surface, turn on Transform.
  To move the transform surface, click and drag the surface you want to duplicate. To rotate or scale the transform surface, click the parent surface, go to the Surface sub-object level in the modifier stack, and then rotate or scale the transform surface.
  When you use Move to create the transform surface, it simply copies the parent. (It doesn’t exaggerate curvature as an offset surface does.) Axis constraints don’t apply to the creation of transform surfaces. You can click to create the surface in place; then once it is created, transform it using constraints.

You can later transform the transform surface as a surface sub-object, and you can animate surface sub-object transforms.

Interface

Creation time

At creation time, there is only one parameter.

Flip Normals Flips the surface normals
After creation, you can flip normals using controls on the Surface Common rollout.
**Transform Surface rollout (modification time)**

[Image]

**Replace Base Surface** Lets you replace the parent surface. Click the button, then click the surface to replace the original surface.

**Blend Surface**

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > Blend

Select NURBS object. > Modify panel > NURBS toolbox > Create Blend Surface button

A blend surface connects one surface to another, blending the curvature of the parent surfaces to create a smooth surface between them. You can also blend from a surface to a curve, or from a curve to a curve.
Blend surface connecting two other surfaces

Procedures

To create a blend surface:

1. In a NURBS object that contains two surfaces, two curves, or a surface and a curve, turn on Blend.

2. Click one surface near the edge that you want to connect. The edge that will be connected is highlighted in blue. Drag to choose the other edge you want to connect. When the edge you want is highlighted, click and then drag to the other surface. The edge of the other surface is also highlighted in blue. Drag on the other surface to choose the edge to connect, and then release the mouse button to create the blend surface. The surface that owns the highlighted edge is highlighted in yellow, to help you distinguish which edge you are choosing when two surfaces have coincident edges.

The blend surface is created. Changing the position or the curvature of either parent surface will change the blend surface as well.
3. Adjust the blend parameters.

**Interface**

While a blend surface sub-object is selected, a rollout with the blend parameters is displayed at the bottom of the Modify panel.

**Blend Surface rollout (creation time)**

![Blend Surface rollout](image)

"Tension" affects the tangent between a parent surface and the blend surface. The greater the tension value, the more closely the tangent parallels the parent surface, and the smoother the transition. The lower the tension, the greater the tangent angle and the sharper the transition between parent and blend.

**Tension 1** Controls tension at the edge of the first surface you clicked. This value has no effect if the edge is a curve.

**Tension 2** Controls tension at the edge of the second surface you clicked. This value has no effect if the edge is a curve.
A. Tension 1=0, Tension 2=10
B. Tension 1=1, Tension 2=1
C. Tension 1=10, Tension 2=0
D. Tension 1=0, Tension 2=0

Flip End 1 and Flip End 2 Flip one of the normals used to construct the blend. A blend surface is created using the normals of the parent surfaces. If the two parents have opposing normals, or if a curve has the opposite direction, the blend surface can be shaped like a bow tie. To correct the situation, use Flip End 1 or Flip End 2 to construct the blend using a normal opposite the corresponding parent surface’s normal.
A. No flipping
B. End 2 is flipped.

**Flip Tangent 1 and Flip Tangent 2** Flip the tangent at the edge of the first or second curve or surface. Flipping the tangent reverses the direction in which the blend surface approaches the parent sub-object at that edge.
Flipping the tangent has no effect if the edge is a curve, unless the curve is a curve on surface.
When you blend to a CV or point curve on surface, the new blend surface is tangent to the surface on which the curve on surface lies. The Flip Tangent controls are especially useful in this situation.
A. Tangent 1 flipped
B. Tangent 2 flipped

**Start Point 1 and Start Point 2** Adjust the position of the start point at the two edges of the blend. Adjusting the start points can help eliminate unwanted twists or "buckles" in the surface.

These spinners are unavailable if the edges or curves are not closed.

While you're adjusting start points, a dotted blue line is displayed between them, to show the alignment. The surface is not displayed, so it doesn't slow down adjustment. When you release the mouse button, the surface reappears.

**Flip Normals** Turn on to reverse the direction of the blend surface normals.
Blend Surface rollout (modification time)

"Tension" affects the tangent between a parent surface and the blend surface. The greater the tension value, the more closely the tangent parallels the parent surface, and the smoother the transition. The lower the tension, the greater the tangent angle and the sharper the transition between parent and blend.

**Tension 1** Controls tension at the edge of the first surface you clicked. This value has no effect if the edge is a curve.

**Tension 2** Controls tension at the edge of the second surface you clicked. This value has no effect if the edge is a curve.

**Flip End 1 and Flip End 2** Flip one of the normals used to construct the blend. A blend surface is created using the normals of the parent surfaces. If the two parents have opposing normals, or if a curve has the opposite direction, the blend surface can be shaped like a bow tie. To correct the situation, use Flip End 1 or Flip End 2 to construct the blend using a normal opposite the corresponding parent surface's normal.

**Flip Tangent 1 and Flip Tangent 2** Flip the tangent at the edge of the first or second curve or surface. Flipping the tangent reverses the direction in which the blend surface approaches the parent sub-object at that edge.
Flipping the tangent has no effect if the edge is a curve, unless the curve is a curve on surface.

When you blend to a CV or point curve on surface, the new blend surface is tangent to the surface on which the curve on surface lies. The Flip Tangent controls are especially useful in this situation.

**Start Point 1 and Start Point 2** Adjust the position of the start point at the two edges of the blend. Adjusting the start points can help eliminate unwanted twists or "buckles" in the surface.

These spinners are unavailable if the edges or curves are not closed.

While you're adjusting start points, a dotted blue line is displayed between them, to show the alignment. The surface is not displayed, so it doesn't slow down adjustment. When you release the mouse button, the surface reappears.

**Replace First Edge and Replace Second Edge** Let you replace the parent edges or curves. Click a button, then click the edge to replace the original first or second edge. The edge can be on the same surface as the original edge, or on a different surface.

---

### Offset Surface

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > Offset

Select NURBS object. > Modify panel > NURBS toolbox > Create Offset Surface button

An Offset surface is offset a specified distance from the original along the parent surface's normals.
Surface created as an offset

Procedures

To create an offset surface:

1. In a NURBS object that contains at least one surface, turn on Offset.

2. Click the surface you want to offset, and drag to set the initial distance of the offset surface.
   The offset surface is created.

3. Adjust the Offset parameter.

Interface

While an offset surface sub-object is selected, a rollout with the offset Distance parameter is displayed at the bottom of the Modify panel.
**Offset Surface rollout (creation time)**

**Offset** The distance between the parent surface and the offset surface, in 3ds Max units.

If the parent surface is planar, the appearance of the offset surface doesn't change with distance. If the parent surface is curved, increasing the offset value increasingly exaggerates the curvature of the offset surface.

**Flip Normals** Lets you flip the surface normals at creation time. (After creation, you can flip normals using controls on the Surface Common rollout.)

**Cap** When on, eight boundary curves are generated (four at the four edges of each surface), and then generates four ruled surfaces to connect the two original surfaces. While they are present, cap surfaces are maintained so they match the dimensions of the offset and its parent.

The Cap check box appears only on the creation rollout. If you want to remove the caps later, simply select them as surface sub-objects and delete them. Think of offset capping as a workflow shortcut rather than a property (or parameter) of offset surfaces.

To flip the normal of an offset cap, select it as a surface sub-object and use the Flip Normals toggle on the Surface Common rollout.

**NOTE** If you trim the original surface, or make the offset surface independent and then trim it, the capping surfaces will look strange.
Offset Surface rollout (modification time)

**Offset** The distance between the parent surface and the offset surface in 3ds Max units.
If the parent surface is planar, the appearance of the offset surface doesn't change with distance. If the parent surface is curved, increasing the offset value increasingly exaggerates the curvature of the offset surface.

**Replace Base Surface** Lets you replace the parent surface. Click the button, then click the new surface on which to base the offset.

Mirror Surface

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > Mirror

Select NURBS object. > Modify panel > NURBS toolbox > Create Mirror Surface button

A mirror surface is a mirror image of the original surface.
Surface created as a mirror

Procedures

To create a mirror surface:

1. In a NURBS object that contains at least one surface, turn on Mirror.
2. On the Mirror Surface rollout, choose the axis or plane you want to use.
3. Click the surface you want to mirror, and drag to set the initial distance of the mirror surface.
   The mirror surface is created. A gizmo (yellow by default) indicates the direction of mirroring. Transforming the mirror surface's gizmo changes the orientation of the mirror, letting you mirror along an axis that isn't aligned with a local coordinate axis.
   The Flip Normals control lets you flip the surface normals at creation time. (After creation, you can flip normals using controls on the Surface Common rollout.)
4. Adjust the Offset parameter.
Interface

While a mirror surface sub-object is selected, the Mirror Surface rollout appears at the bottom of the Modify panel. Also, a gizmo (yellow by default) indicates the mirror axis.

Mirror Surface rollout (creation time)

Mirror Axis group

The Mirror Axis buttons control the direction in which the original surface is mirrored.

You can't transform the mirror surface directly (that would simply transform the mirror surface and its parent surface at the same time). You transform it by transforming its gizmo. By using transforms you can mirror about an arbitrary axis, rather than using one of the Mirror Axis presets. When you transform a mirror surface, you are actually transforming the mirror plane, so Rotate has the effect of rotating the plane about which the surface is mirrored. (This is like rotating the mirror gizmo in the Mirror modifier.)

**TIP** A convenient way to guarantee that a surface is symmetrical is to create one side of the surface, mirror that surface, and then create a blend between the two sides.

Offset Controls the mirror's distance from the original surface. This parameter is animatable.

Flip Normals Lets you flip the surface normals.
Mirror Surface rollout (modification time)

Mirror Axis group

The Mirror Axis buttons control the direction in which the original surface is mirrored.

You can't transform the mirror surface directly (that would simply transform the mirror surface and its parent surface at the same time). You transform it by transforming its gizmo. By using transforms you can mirror about an arbitrary axis, rather than using one of the Mirror Axis presets. When you transform a mirror surface, you are actually transforming the mirror plane, so Rotate has the effect of rotating the plane about which the surface is mirrored. (This is like rotating the mirror gizmo in the Mirror modifier.)

TIP A convenient way to guarantee that a surface is symmetrical is to create one side of the surface, mirror that surface, and then create a blend between the two sides.

Offset Controls the mirror’s distance from the original surface. This parameter is animatable.

Replace Base Surface Lets you replace the parent surface. Click the button, then click the new surface on which to base the mirror.
Extrude Surface

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > Extrude

Select NURBS object. > Modify panel > NURBS toolbox > Create Extrude Surface button

An extrude surface is extruded from a curve sub-object. It is similar to a surface created with the Extrude modifier. The advantage is that an extrude sub-object is part of the NURBS model, so you can use it to construct other curve and surface sub-objects.

Procedures

To create an extrude surface:

1. In a NURBS object that contains at least one curve, turn on Extrude.
2 Move the cursor over the curve to extrude, and drag to set the initial amount.

By default, the surface extrudes along the NURBS model's local Z axis. A gizmo (yellow by default) indicates the direction of extrusion. Transforming the extrude surface's gizmo changes the direction of the extrude, letting you extrude along an axis that isn't aligned with a local coordinate axis.

The Flip Normals control lets you flip the surface normals at creation time. (After creation, you can flip normals using controls on the Surface Common rollout.)

3 Adjust the extrusion parameters.

**Interface**

While an extrude sub-object is selected, a rollout with the extrusion parameters is displayed at the bottom of the Modify panel.

**Extrude Surface rollout (creation time)**

```
- Extrude Surface

Amount: 0.0

Direction

X, Y and Z

Start Point: 0.0

Flip Normals

Cap
```

**Amount** The distance the surface is extruded from the parent curve in current 3ds Max units.

This parameter is animatable.

**Direction group**

X, Y and Z Choose the axis of extrusion. Default=Z.
**Start Point** Adjusts the position of the curve's start point. This can help eliminate unwanted twists or "buckles" in the surface. This control is disabled if the curve is not a closed curve. The start point is displayed as a blue circle.

**Flip Normals** Lets you flip the surface normals at creation time. (After creation, you can flip normals using controls in the Surface Common rollout.)

**Cap** When on, two surfaces are generated to close the ends of the extrusion. While they are present, the cap surfaces are maintained so they match the dimensions of the extrude surface. The parent curve must be a closed curve. The Cap check box appears only on the creation rollout. If you want to remove the caps later, simply select them as surface sub-objects and delete them. Think of extrude capping as a workflow shortcut rather than a property (or parameter) of extrude surfaces.

To flip the normal of an extrude cap, select it as a Surface sub-object and use the Flip Normals toggle on the Surface Common rollout.

**Extrude Surface rollout (modification time)**

![Extrude Surface Rollout](image)

**Amount** The distance the surface is extruded from the parent curve in current 3ds Max units.

**Direction group**

**X, Y and Z** Choose the axis of extrusion. Default=Z.
Start Point Adjusts the position of the curve's start point. This can help eliminate unwanted twists or "buckles" in the surface. This control is disabled if the curve is not a closed curve. The start point is displayed as a blue circle.

Replace Base Curve Lets you replace the parent curve. Click the button, then click the new curve on which to base the extruded surface.

Lathe Surface

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > Lathe
Select NURBS object. > Modify panel > NURBS toolbox > Create Lathe Surface button

A lathe surface is generated from a curve sub-object. It is similar to a surface created with the Lathe modifier. The advantage is that a lathe sub-object is part of the NURBS model, so you can use it to construct other curve and surface sub-objects.
To create a lathe surface:

1. In a NURBS object that contains at least one curve, turn on Lathe.

2. Click the curve to lathe.
   The lathe surface rotates about the NURBS model's local Y axis. The initial lathe amount is 360 degrees. A gizmo (yellow by default) indicates the axis of the lathe. Transforming the lathe surface's gizmo changes the shape of the lathe, and lets you lathe around an axis that isn't aligned with a local coordinate axis.
The Flip Normals control lets you flip the surface normals at creation time. (After creation, you can flip normals using controls on the Surface Common rollout.)

3 Adjust the lathe parameters.

**Interface**

While a lathe sub-object is selected, a rollout with the lathe parameters is displayed at the bottom of the Modify panel.
Lathe Surface rollout (creation time)

**Degrees** Sets the angle of rotation. At 360 degrees (the default), the surface completely surrounds the axis. At lower values, the surface is a partial rotation.
A partial lathe (degrees=225)

Direction group

X, Y, and Z Choose the axis of rotation. Default=Y.
X, Y, and Z rotations of the same curve

**Align group**

These buttons position the axis of rotation relative to the curve.

**Min** (The default.) Locates the lathe axis at the curve's negative local X-axis boundary.

**Center** Locates the lathe axis at the curve's center.

**Max** Locates the lathe axis at the curve's positive local X-axis boundary.
Min, Center, and Max lathes of the same curve

**Start Point** Adjusts the position of the curve's start point. This can help eliminate unwanted twists or "buckles" in the surface. This control is disabled if the curve is not a closed curve. The start point is displayed as a blue circle.

**Flip Normals** Lets you flip the surface normals at creation time. (After creation, you can flip normals using controls on the Surface Common rollout.)

**Cap** When on, two surfaces are generated to close the ends of the lathe. While they are present, the cap surfaces are maintained so they match the dimensions of the lathe surface. The lathe must be a 360-degree lathe. The Cap check box appears *only* on the creation rollout. If you want to remove the caps later, simply select them as surface sub-objects and delete them. Think of lathe capping as a workflow shortcut rather than a property (or parameter) of lathe surfaces.

To flip the normal of a lathe cap, select it as a Surface sub-object and use the Flip Normals toggle on the Surface Common rollout.
Adding a cap to a partial lathe
Lathe Surface rollout (modification time)

 Degrees  Sets the angle of rotation. At 360 degrees (the default), the surface completely surrounds the axis. At lower values, the surface is a partial rotation.

**Direction group**

 X  Y  Z  Choose the axis of rotation. Default=Y.

**Align group**

 These buttons position the axis of rotation relative to the curve.

 Min  (The default.) Locates the lathe axis at the curve's negative local X-axis boundary.

 Center  Locates the lathe axis at the curve's center.

 Max  Locates the lathe axis at the curve's positive local X-axis boundary.

 Start Point  Adjusts the position of the curve's start point. This can help eliminate unwanted twists or "buckles" in the surface.

 This control is disabled if the curve is not a closed curve.

 The start point is displayed as a blue circle.
Replace Base Curve  Lets you replace the parent curve. Click the button, then click the new surface on which to base the lathed surface.

Ruled Surface

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > Ruled

Select NURBS object. > Modify panel > NURBS toolbox > Create Ruled Surface button

A ruled surface is generated from two curve sub-objects. It lets you use curves to design the two opposite borders of a surface.

Using two curves to create a ruled surface

You can animate the parent curves or their CVs to change the ruled surface.
Automatic Curve Attachment

When you create a ruled surface, you can select curves that are not already sub-objects of the active NURBS model. You can select another curve or spline Splines object in the scene. When you select that curve, it attaches to the current object as if you had used the Attach button on page 2490.

**WARNING** If the curve you attach is a sub-object of another NURBS model, the entire model (that is, the curve's parent NURBS object) is attached as well.

As you move the mouse over a curve that is not part of the active NURBS object, the cursor changes shape to indicate that you can pick the curve, but the curve is not highlighted in blue.

Procedures

**To create a ruled surface:**

1. In a NURBS object that contains at least two curves, turn on Ruled.
2. Drag from one curve to the other.
   You can also click first one curve, then the other.
   A dependent surface is generated, using the two curves as the surface's opposite edges. The perpendicular edges are generated automatically.

The Flip Normals control lets you flip the surface normals at creation time. (After creation, you can flip normals using controls on the Surface Common rollout.)
Interface

When you turn on the Ruled button, and while a ruled surface sub-object is selected, a rollout with the ruled surface parameters is displayed at the bottom of the Modify panel.

Ruled Surf rollout (creation time)

![Ruled Surf rollout](image)

**Flip Beginning and Flip End** Flip one of the curve directions used to construct the ruled surface. A ruled surface is created using the directions of the parent curves. If the two parents have opposing directions, the ruled surface can be shaped like a bow tie. To correct the situation, use Flip Beginning or Flip End to construct the ruled surface using a direction opposite the corresponding parent curve’s direction. These controls eliminate the need to reverse the curve.

**Start Point 1 and Start Point 2** Adjust the position of the start point at the two curves that specify the ruled surface. Adjusting the start points can help eliminate unwanted twists or “buckles” in the surface.

These spinners are disabled if the edges or curves are not closed.

While you’re adjusting start points, a dotted blue line is displayed between them, to show the alignment. The surface is not displayed, so it doesn’t slow down adjustment. When you release the mouse button, the surface reappears.

**Flip Normals** Turn on to reverse the direction of the ruled surface’s normals.
Ruled Surf rollout (modification time)

Flip Beginning and Flip End  Flip one of the curve directions used to construct the ruled surface. A ruled surface is created using the directions of the parent curves. If the two parents have opposing directions, the ruled surface can be shaped like a bow tie. To correct the situation, use Flip Beginning or Flip End to construct the ruled surface using a direction opposite the corresponding parent curve's direction. These controls eliminate the need to reverse the curve.

Start Point 1 and Start Point 2  Adjust the position of the start point at the two curves that specify the ruled surface. Adjusting the start points can help eliminate unwanted twists or "buckles" in the surface.

These spinners are disabled if the edges or curves are not closed.

While you're adjusting start points, a dotted blue line is displayed between them, to show the alignment. The surface is not displayed, so it doesn't slow down adjustment. When you release the mouse button, the surface reappears.

Replace First Curve and Replace Second Curve  Let you replace the parent curves. Click a button, then click the curve to replace the original first or second curve.

Cap Surface

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > Cap
Select NURBS object. > Modify panel > NURBS toolbox > Create Cap Surface button

This command creates a surface that caps a closed curve or the edge of a closed surface. Caps are especially useful with extruded surfaces.

Capping an extrude surface

Procedures

To create a cap surface:

1. In a NURBS object, turn on Cap.

2. Move the mouse over the closed curve or the closed edge of a closed surface.
   If the cap can be created, the curve or edge is highlighted in blue.

3. Click the highlighted curve or edge.
The Flip Normals control lets you flip the surface normals at creation time. (After creation, you can flip normals using controls on the Surface Common rollout.)

**Interface**

While a cap surface sub-object is selected, a rollout with cap surface controls is displayed at the bottom of the Modify panel.

**Cap Surface rollout (creation time)**

- **Flip Normals** Turn on to reverse the direction of the cap surface's normals.
- **Start Point** Adjusts the position of the edge or curve's start point. The start point is displayed as a blue circle.

**Cap Surface rollout (modification time)**
**Replace Curve** Lets you replace the parent curve or edge. Click the button, then click the new curve or edge on which to base the cap.

**Start Point** Adjusts the position of the edge or curve's start point. The start point is displayed as a blue circle.

**U Loft Surface**

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > U Loft

Select NURBS object. > Modify panel > NURBS toolbox > Create U Loft Surface button

A U loft surface interpolates a surface across multiple curve sub-objects. The curves become U-axis contours of the surface.

*Using multiple curves to create a U Loft surface*
Tips

- A U loft can be an extremely dense surface. To improve performance while working with viewports, set the surface approximation on page 2737 for viewports to Curvature Dependent.

- You can speed up U loft creation by making sure that the curves you loft have the same number of CVs in the same order (that is, the curves point in the same direction). Also, CV curves have a performance advantage over point curves.

- Turning off display of dependent sub-objects, including the U loft itself, also speeds up interactive performance when you create a U loft. The default keyboard toggle for dependent sub-object display is Ctrl+D (the Keyboard Shortcut Override Toggle on page 8420 button must be on.)

Closed U lofts

Automatic Curve Attachment

When you create a U loft, you can select curves that are not already sub-objects of the active NURBS model. You can select another curve or spline on page
577 object in the scene. When you select that curve, it is automatically attached to the current object as if you had used the Attach button.

**WARNING** If the curve you attach is a sub-object of another NURBS model, the entire model (that is, the curve's parent NURBS object) is attached as well.

As you move the mouse over a curve that is not part of the active NURBS object, the cursor changes shape to indicate you can pick the curve, but the curve is not highlighted in blue.

**Procedures**

To **create a U loft surface**:

1. In a NURBS object that contains at least two curves, turn on U Loft.
2. Click the first curve.
3. Click additional curves in succession.
The U loft is created. It is "stretched" across the curves you click. The order in which you click the curves can affect the shape of the U loft surface. The names of the curves appear in the U Loft Surface creation rollout.

While creating a U loft, you can press Backspace to remove the last curve you clicked from the list of U loft curves.
The Flip Normals control lets you flip the surface normals at creation time. (After creation, you can flip normals using controls on the Surface Common rollout.)

4 Right-click to end U loft creation.

To create a U loft with automatic attach (example):

1 From the Create panel, create three or more independent CV or Point NURBS curves.

2 Go to the Modify panel, and click to turn on U Loft in the NURBS toolbox.

3 Select the curves in the appropriate order for the loft.
   
   The U loft is created. You don't have to collapse the curves to a NURBS surface, or attach them to an existing NURBS model on page 2490.

   As you move the mouse over a curve that is not part of the active NURBS object, the cursor changes shape to indicate you can pick the curve, but the curve is not highlighted in blue.

Interface

While a U loft sub-object is selected, a rollout with the U loft parameters is displayed at the bottom of the Modify panel. This rollout appears only when one U loft sub-object is selected. It isn't possible to edit more than one U loft at a time, so unlike some other NURBS sub-objects, the rollout doesn't appear when multiple U loft sub-objects are selected.

When you create lofted and swept surfaces, you have access to all the parameters, and some of the editing operations, of the surface. You can reverse and set start points on curves while you create the surface. You can also use the arrow buttons to change the order of the curves, and you can remove a curve with the Remove button.

TIP When you edit a U loft sub-object, close the Surface Common rollout to see the U Loft Surface rollout more easily.
U Loft Surface rollout (creation time)

**U Curves** This list shows the name of the curves you click in the order you click them. You can select curves by clicking their names. Viewports display the selected curve in blue. Initially the first curve is the one selected. You can also select more than one curve at a time. This is useful when you use the Edit Curves button.
Arrow Buttons Use these to change the order of curves used to construct the U loft. Select a curve in the list, and then use the arrows to move the selection up or down.
These buttons are available at creation time.

Curve Properties group

These controls affect individual curves you select in the U Curves list, as opposed to properties of the loft surface in general. They are enabled only when you have selected a curve in the U Curves list.

Reverse When set, reverses the direction of the selected curve.

Start Point Adjusts the position of the curve's start point.
This control is disabled if the curve is not a closed curve.
While you’re adjusting start points, a dotted blue line is displayed between them, to show the alignment. The surface is not displayed, so it doesn’t slow down adjustment. When you release the mouse button, the surface reappears.

Tension Adjusts the tension of the loft where it intersects that curve.

Use COS Tangents If the curve is a curve on surface, turning on this toggle causes the U loft to use the tangency of the surface. This can help you blend a loft smoothly onto a surface. Default=off.
This toggle is disabled unless the curve is a point or CV curve on surface.

Flip Tangents Reverses the direction of the tangents for that curve.
This toggle is disabled unless the curve is a point or CV curve on surface and Use COS Tangents is on.

Auto Align Curve Starts (Disabled.)

Close Loft (Disabled.)

Insert (Disabled.)

Remove Removes a curve from the U loft surface. Select the curve in the list, and then click Remove.
This button is available at creation time.

Refine (Disabled.)

Replace (Disabled.)

Display While Creating When on, the U loft surface is displayed while you create it. When off, the loft is created more quickly. Default=off.
**Flip Normals** Reverses the direction of the U loft's normals.

**U Loft Surface rollout (modification time)**

**U Curves** This list shows the name of the curves you click, in the order you click them. You can select curves by clicking their names in this list. Viewports display the selected curve in blue. Initially the first curve is the one selected.
You can also select more than one curve at a time. This is useful when you use the Edit Curves button.

**Arrow Buttons** Use these to change the order of curves used to construct the U loft. Select a curve in the list, and then use the arrows to move the selection up or down.

These buttons are available at creation time.

**Curve Properties group**

These controls affect individual curves you select in the U Curves list, as opposed to properties of the loft surface in general. They are enabled only when you have selected a curve in the U Curves list.

**Reverse** When set, reverses the direction of the selected curve.

**Start Point** Adjusts the position of the curve's start point.

This control is disabled if the curve is not a closed curve.

While you're adjusting start points, a dotted blue line is displayed between them, to show the alignment. The surface is not displayed, so it doesn't slow down adjustment. When you release the mouse button, the surface reappears.

**Tension** Adjusts the tension of the loft where it intersects that curve.

**Use COS Tangents** If the curve is a curve on surface, turning on this toggle causes the U loft to use the tangency of the surface. This can help you blend a loft smoothly onto a surface. Default=off.

This toggle is disabled unless the curve is a point or CV curve on surface.

**Flip Tangents** Reverses the direction of the tangents for that curve.

This toggle is disabled unless the curve is a point or CV curve on surface and Use COS Tangents is on.

**Auto Align Curve Starts** When on, aligns the start points of all curves in the U loft. 3ds Max chooses the location of the start points. Using automatic alignment minimizes the amount of twisting in the loft surface. Default=off.

**Close Loft** If the loft was initially an open surface, turning on this toggle closes it by adding a new segment to connect the first curve and the last curve. Default=off.

**Insert** Adds a curve to the U loft surface. Click to turn on Insert, then click the curve. The curve is inserted before the selected curve. To insert a curve at the end, first highlight the "----End-----" marker in the list.
**Remove** Removes a curve from the U loft surface. Select the curve in the list, and then click Remove.

This button is available at creation time.

**Refine** Refines the U loft surface. Click to turn on Refine, then click a U-axis iso curve on the surface. (As you drag the mouse over the surface, the available curves are highlighted.) The curve you click is converted to a CV curve and inserted into the loft and the U Curves list. As when you refine a point curve, refining a U loft can change the curvature of the surface slightly. Once you've refined the surface by adding a U curve, you can use Edit Curve to change the curve.

**Replace** Replaces a U curve with a different curve. Select a U curve, click to turn on Replace, then click the new curve in a viewport. Available curves are highlighted as you drag the mouse.

This button is enabled only when you've selected a single curve in the U Curves list.

**Display Iso Curves** When set, the U loft's V-axis iso curves are displayed as well as the U-axis curves used to construct the loft. The V-axis curves are only for display. You can't use them for surface construction.

**Edit Curve** Lets you edit the currently selected curve without switching to another sub-object level. Click to turn on Edit Curve. The points or CVs of the curve are displayed, as well as the control lattice if the curve is a CV curve. You can now transform or otherwise change the points or CVs as if you were at the Point or Curve CV sub-object level. To finish editing the curve, click to turn off Edit Curve.

When you turn on Edit Curves, all applicable rollouts for the selected curves are displayed, including the Curve Common rollout, the CV or Point rollout (depending on the curve type), and the CV Curve or Point Curve rollout. These rollouts appear beneath the U Loft rollout. They let you edit the loft curves and their points or CVs without having to switch sub-object levels.

**TIP** When you edit curves in a U loft, turning off display of the U loft itself can make the curves easier to see and improve performance. Use Ctrl+D (while the Keyboard Shortcut Override Toggle button on page 8420 is on) to toggle display of dependent sub-objects, including U Lofts.
UV Loft Surface

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > UV Loft

Select NURBS object. > Modify panel > NURBS toolbox > Create UV Loft Surface button

A UV loft surface is similar to a U loft surface, but has a set of curves in the V dimension as well as in the U dimension. This can give you finer control over the lofted shape, and require fewer curves to achieve the result you want.

Using perpendicular curves to create a UV loft surface

If the U and V curves intersect, the UV loft surface interpolates all the curves. If the curves don't intersect, the lofted surface lies somewhere between the U and V curves. In general, UV loft works best if the ends of all the curves in one direction lie on the two end curves in the other direction, as in the illustration. UV loft does not work well if the curves in both directions are closed.
**NOTE** The Make Loft on page 2727 dialog (displayed by the Make Loft button on the Surface Common rollout for surface sub-objects) now lets you convert a surface to a UV loft as well as a U loft. In addition, you can use point curves instead of CV curves for the new loft lattice. If you use point curves for a UV loft, turning on the Fuse Points option guarantees that the U and V curves intersect.

**Automatic Curve Attachment**

When you create a UV loft, you can select curves that are not already sub-objects of the active NURBS model. You can select another curve or spline on page 577 object in the scene. When you select that curve, it attaches to the current object as if you had used the Attach button on page 2490.

**WARNING** If the curve you attach is a sub-object of another NURBS model, the entire model (that is, the curve’s parent NURBS object) is attached as well.

As you move the mouse over a curve that is not part of the active NURBS object, the cursor changes shape to indicate that you can pick the curve, but the curve is not highlighted in blue.

**Procedures**

**To create a UV loft:**

1. Create the curves that outline the surface you want to create.
2. Click to turn on UV Loft in the toolbox or on the Create Surfaces rollout.
3. Click each of the curves in the U dimension, then right-click. Click each of the curves in the V dimension, then right-click again to end creation. As you click curves, their names appear in the lists on the UV Loft Surface creation rollout. The order in which you click the curves can affect the shape of the UV loft surface. In either dimension, you can click the same curve more than once. This can help you create a closed UV loft.

**To create a UV loft with automatic attach (example):**

1. From the Create panel, create three or more independent CV or point NURBS curves.
2. Go to the Modify panel, and click to turn on UV Loft in the NURBS toolbox.
3 Select the curves in the appropriate order for the loft.

The UV loft is created. You don’t need to collapse the curves to a NURBS surface or Attach them to an existing NURBS model.

As you move the mouse over a curve that is not part of the active NURBS object, the cursor changes shape to indicate that you can pick the curve, but the curve is not highlighted in blue.

**Interface**

While a UV Loft sub-object is selected, a rollout with the UV loft parameters appears. This rollout appears only when one UV loft sub-object is selected. It isn’t possible to edit more than one UV loft at a time, so unlike some other NURBS sub-objects, the rollout doesn’t appear when multiple UV loft sub-objects are selected.

**TIP** When you edit a UV loft sub-object, close the Surface Common rollout to see the U Loft Surface rollout more easily.
UV Loft Surface rollout (creation time)

Creating and Editing NURBS Sub-Objects | 2659
U Curves and V Curves These lists show the names of the curves you click, in the order you click them. You can select a curve by clicking its name in a list. Viewports display the selected curve in blue.

The two buttons above and the four below each list are identical for both lists. While you create the loft, in either dimension you can click the same curve more than once. This can help you create a closed UV loft.

Arrow Buttons Use these to change the order of curves in the U Curve or V Curve list. Select a curve in the list, and then use the arrows to move the selection up or down.

Insert (Disabled.)

Remove Removes a curve from the U list or V list. Select the curve in the list, and then click Remove.

Refine (Disabled.)

Replace (Disabled.)

Display While Creating When on, the UV loft surface is displayed while you create it. When off, the loft can be created more quickly. Default=off.

Flip Normals Reverses the direction of the UV loft's normals.
UV Loft Surface rollout (modification time)

Creating and Editing NURBS Sub-Objects | 2661
**U Curves and V Curves** These lists show the names of the curves you click, in the order you click them. You can select a curve by clicking its name in a list. Viewports display the selected curve in blue.

The two buttons above and the four below each list are identical for both lists.

**Arrow Buttons** Use these to change the order of curves in the U Curve or V Curve list. Select a curve in the list, and then use the arrows to move the selection up or down.

**Insert** Adds a curve to the U list or V list. Click to turn on Insert, then click the curve. The curve is inserted *before* the selected curve. To insert a curve at the end, first highlight the "----End-----" marker in the list.

**Remove** Removes a curve from the U list or V list. Select the curve in the list, and then click Remove.

**Refine** Refines the UV loft surface. Click to turn on Refine, then click an iso curve on the surface. (As you drag the mouse over the surface, the available curves are highlighted.) The curve you click is converted to a CV curve and inserted into the loft and the U Curves or V Curves list. As when you refine a point curve, refining a UV loft can change the curvature of the surface slightly. Once you’ve refined the surface by adding a U curve or V curve, you can use Edit Curves to change the curve.

**Replace** Lets you replace the selected curve. Select a curve in the list, click this button, then select the new curve.

**Display Iso Curves** When set, the UV loft’s iso curves are displayed as well as the U-axis and V-axis curves used to construct the loft. The iso curves are only for display. You can’t use them for surface construction.

**Edit Curves** Lets you edit the currently selected curve without switching to another sub-object level. Click to turn on Edit Curve. The points or CVs of the curve are displayed, as well as the control lattice if the curve is a CV curve. You can now transform or otherwise change the points or CVs as if you were at the Point or Curve CV sub-object level. To finish editing the curve, click to turn off Edit Curves.

When you turn on Edit Curves, all applicable rollouts for the selected curves are displayed, including the Curve Common rollout, the CV or Point rollout (depending on the curve type), and the CV Curve or Point Curve rollout. These rollouts appear beneath the U Loft rollout. They let you edit the loft curves and their points or CVs without having to switch sub-object levels.
TIP When you edit curves in a UV loft, turning off display of the UV loft itself can make the curves easier to see and improve performance. Use Ctrl+D (while the Keyboard Shortcut Override Toggle button on page 8420 is on) to toggle display of dependent sub-objects, including UV lofts.

The UV loft surface can deviate from the curve if you edit a curve in a UV loft by increasing the weight of the curve CVs. You can work around this by refining the curve at the point where the surface deviates.

1-Rail Sweep Surface

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > 1-Rail

Select NURBS object. > Modify panel > NURBS toolbox > Create 1-Rail Sweep button

Sweep surfaces are constructed from curves. A 1-rail sweep surface uses at least two curves. One curve, the "rail," defines one edge of the surface. The other curves define the surface's cross sections.
1-rail sweep surface

Changing the position of the rail can change the shape of the surface.

The cross-section curves should intersect the rail curve. If the cross-sections don't intersect the rail, the resulting surface is unpredictable. In addition, the initial point of the rail and the initial point of the first cross-section curve must be coincident. Use NURBS Snaps on page 2819 to accomplish this.

Automatic Curve Attachment

When you create a 1-rail sweep, you can select curves that are not already sub-objects of the active NURBS model. You can select another curve or spline on page 577 object in the scene. When you select that curve, it attaches to the current object as if you had used the Attach button on page 2490.

WARNING If the curve you attach is a sub-object of another NURBS model, the entire model (that is, the curve's parent NURBS object) is attached as well.

As you move the mouse over a curve that is not part of the active NURBS object, the cursor changes shape to indicate that you can pick the curve, but the curve is not highlighted in blue.
Procedures

To create a 1-rail sweep:

1. Create the curves that define the surface you want to create.

2. Click to turn on 1 Rail Sweep in the toolbox or on the Create Surfaces rollout.

3. Click the curve to use as the rail, then click each of the cross-section curves. Right-click to end creation. The sweep is interpolated smoothly between the cross sections, following the outline defined by the rail.
As you click curves, their names appear in the lists on the 1 Rail Sweep Surface creation rollout. The order in which you click the curves can affect the shape of the sweep surface.
Example: To create a 1-rail sweep with automatic attach:

1 From the Create panel, create two independent CV or Point NURBS curves.

2 Go to the Modify panel, and click to turn on 1-Rail Sweep in the NURBS toolbox.

3 Select the curves in the appropriate order for the sweep.
   The sweep is created. You don’t need to collapse the curves to a NURBS surface or Attach them to an existing NURBS model.
   As you move the mouse over a curve that is not part of the active NURBS object, the cursor changes shape to indicate that you can pick the curve, but the curve is not highlighted in blue.

Interface

While a 1-rail sweep sub-object is selected, a rollout with the 1-rail sweep parameters appears. This rollout appears only when one 1-rail sweep sub-object is selected. It isn’t possible to edit more than one 1-rail sweep at a time, so unlike some other NURBS sub-objects, the rollout doesn’t appear when multiple 1-rail sweep sub-objects are selected.

TIP When you edit a 1-rail sweep sub-object, close the Surface Common rollout to see the 1-rail sweep Surface rollout more easily.
1-Rail Sweep Surface rollout (creation time)

Rail Curve Shows the name of the curve you chose to be the rail.

Replace Rail (Disabled.)
Section Curves  This list shows the names of the cross-section curves, in the order you click them. You can select a curve by clicking its name in the list. Viewports display the selected curve in blue.

Arrow Buttons  Use these to change the order of section curves in the list. Select a curve in the list, and then use the arrows to move the selection up or down.

Curve Properties group

These controls affect individual curves you select in the Section Curves list, as opposed to properties of the sweep surface in general. They are enabled only when you have selected a curve in the Section Curves list.

Reverse  When set, reverses the direction of the selected curve.

Start Point  Adjusts the position of the curve's start point. This can help eliminate unwanted twists or "buckles" in the surface.

This control is disabled if the curve is not a closed curve.

While you're adjusting start points, a dotted blue line is displayed between them, to show the alignment. The surface is not displayed, so it doesn't slow down adjustment. When you release the mouse button, the surface reappears.

Insert  (Disabled.)

Remove  Removes a curve from the list. Select the curve in the list, and then click Remove.

Refine  (Disabled.)

Replace  (Disabled.)

Sweep Parallel  When on, ensures that the sweep surface's normal is parallel to the rail.

Snap Cross-Sections  When on, cross-section curves are translated so they intersect the rail. The first cross section is translated to the start of the rail, and the last to the end of the rail. The cross sections in the middle are translated to touch the rail at the closest point to the end of the cross-section curves.

When Snap Cross-Sections is on, the sweep follows the rail curve exactly. This makes it easier to construct 1-rail sweep surfaces.

Road-Like  When on, the sweep uses a constant up-vector so the cross sections twist uniformly as they travel along the rail. In other words, the cross sections bank like a car following a road, or a camera following a path constraint on page 3596. Default=off.
When you edit the surface, you can control the angle of banking. The up-vector is displayed as a yellow gizmo (similar to the gizmo that lathe surfaces on page 2631 use for the center of rotation). To change the up-vector angle, use Rotate on page 915 to change the gizmo's angle.

**Display While Creating** When on, the sweep surface is displayed while you create it. When off, the sweep can be created more quickly. Default=off.

**Flip Normals** Reverses the direction of the sweep's normals.
**1-Rail Sweep Surface rollout (modification time)**

![1-Rail Sweep Surface rollout](image)

**Rail Curve** Shows the name of the curve you chose to be the rail.

Creating and Editing NURBS Sub-Objects | 2671
**Replace Rail** Lets you replace the rail curve. Click this button, then in a viewport click the curve to use as the new rail.

**Section Curves** This list shows the names of the cross-section curves, in the order you click them. You can select a curve by clicking its name in the list. Viewports display the selected curve in blue.

**Arrow Buttons** Use these to change the order of section curves in the list. Select a curve in the list, and then use the arrows to move the selection up or down.

**Curve Properties group**

These controls affect individual curves you select in the Section Curves list, as opposed to properties of the sweep surface in general. They are enabled only when you have selected a curve in the Section Curves list.

- **Reverse** When set, reverses the direction of the selected curve.
- **Start Point** Adjusts the position of the curve's start point. This can help eliminate unwanted twists or "buckles" in the surface.
  This control is disabled if the curve is not a closed curve.
  While you're adjusting start points, a dotted blue line is displayed between them, to show the alignment. The surface is not displayed, so it doesn't slow down adjustment. When you release the mouse button, the surface reappears.

- **Insert** Adds a curve to the section list. Click to turn on Insert, then click the curve. The curve is inserted before the selected curve. To insert a curve at the end, first highlight the "----End-----" marker in the list.

- **Remove** Removes a curve from the list. Select the curve in the list, and then click Remove.

- **Refine** Refines the 1-rail sweep surface. Click to turn on Refine, then click an iso curve on the surface. (As you drag the mouse over the surface, the available section curves are highlighted.) The curve you click is converted to a CV curve and inserted into the sweep and the section list. As when you refine a point curve, refining a sweep can change the curvature of the surface slightly. Once you've refined the surface by adding a cross-section curve, you can use Edit Curves to change the curve.

- **Replace** Lets you replace the selected curve. Select a curve in the list, click this button, and then select the new curve.

- **Sweep Parallel** When on, ensures that the sweep surface's normal is parallel to the rail.
**Snap Cross-Sections** When on, cross-section curves are translated so they intersect the rail. The first cross section is translated to the start of the rail, and the last to the end of the rail. The cross sections in the middle are translated to touch the rail at the closest point to the end of the cross-section curves.

When Snap Cross-Sections is on, the sweep follows the rail curve exactly. This makes it easier to construct 1-rail sweep surfaces.

**Road-Like** When on, the sweep uses a constant up-vector so the cross sections twist uniformly as they travel along the rail. In other words, the cross sections bank like a car following a road, or a camera following a path constraint on page 3596. Default=off.

When you edit the surface, you can control the angle of banking. The up-vector is displayed as a yellow gizmo (similar to the gizmo that lathe surfaces on page 2631 use for the center of rotation). To change the up-vector angle, use Rotate on page 915 to change the gizmo's angle.

**Display Iso Curves** When set, the 1-rail sweep's V-axis iso curves are displayed as well as the U-axis curves used to construct the loft. The V-axis curves are only for display. You can’t use them for surface construction.

**Edit Curves** Lets you edit the currently selected curve without switching to another sub-object level. Click to turn on Edit Curve. The points or CVs of the curve are displayed, as well as the control lattice if the curve is a CV curve. You can now transform or otherwise change the points or CVs as if you were at the Point or Curve CV sub-object level. To finish editing the curve, click to turn off Edit Curves.

**TIP** When you edit curves in a 1-rail sweep, turning off display of the sweep itself can make the curves easier to see and improve performance. Use Ctrl+D (while the Keyboard Shortcut Override Toggle on page 8420 is on) to toggle display of dependent sub-objects, including sweeps.

The sweep surface can deviate from the curve if you edit a curve in a sweep by increasing the weight of the curve CVs. You can work around this by refining the curve at the point where the surface deviates.

### 2-Rail Sweep Surface

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > 2-Rail
Select NURBS object. > Modify panel > NURBS toolbox > Create 2-Rail Sweep button

Sweep surfaces are constructed from curves. A 2-rail sweep surface uses at least three curves. Two curves, the "rails," define the two edges of the surface. The other curves define the surface's cross sections. A 2-rail sweep surface is similar to a 1-rail sweep. The additional rail gives you more control over the shape of the surface.

The cross-section curves should intersect the rail curves. If the cross sections don't intersect the rails, the resulting surface is unpredictable. In addition, the initial points of the rails and the endpoints of the first cross-section curve must be coincident. Use NURBS Snaps to accomplish this.

**Automatic Curve Attachment**

When you create a 2-rail sweep, you can select curves that are not already sub-objects of the active NURBS model. You can select another curve or spline object on page 577 in the scene. When you select that curve, it attaches to the current object as if you had used the Attach button on page 2490.
WARNING If the curve you attach is a sub-object of another NURBS model, the entire model (that is, the curve’s parent NURBS object) is attached as well.

As you move the mouse over a curve that is not part of the active NURBS object, the cursor changes shape to indicate that you can pick the curve, but the curve is not highlighted in blue.

Procedures

To create a 2-rail sweep:

1  Create the curves that define the surface you want to create.

2  Click to turn on 2 Rail Sweep in the toolbox or on the Create Surfaces rollout.

3  Click the curve to use as the first rail, then click the curve to use as the second rail. Click each of the cross-section curves, and then right-click to end creation.

   The sweep is interpolated smoothly between the cross sections, following the outlines defined by the two rails.

   As you click curves, their names appear in the lists on the 2 Rail Sweep Surface creation rollout. The order in which you click the curves can affect the shape of the sweep surface.

Example: To create a 2-rail sweep with automatic attach:

1  From the Create panel, create three independent CV or Point NURBS curves.

2  Go to the Modify panel, and click to turn on 2-Rail Sweep in the NURBS toolbox.

3  Select the curves in the appropriate order for the sweep.

   The sweep is created. You don’t need to collapse the curves to a NURBS surface or Attach them to an existing NURBS model.

   As you move the mouse over a curve that is not part of the active NURBS object, the cursor changes shape to indicate that you can pick the curve, but the curve is not highlighted in blue.
Interface

While a 2-rail sweep sub-object is selected, a rollout with the 2-rail sweep parameters appears. This rollout appears only and when one 2-rail sweep sub-object is selected. It isn’t possible to edit more than one 2-rail sweep at a time, so unlike some other NURBS sub-objects, the rollout doesn’t appear when multiple 2-rail sweep sub-objects are selected.

**TIP** When you edit a 2-rail sweep sub-object, close the Surface Common rollout to see the 2-rail sweep surface rollout more easily.
2-Rail Sweep Surface rollout (creation time)

Rail Curves
- Shows the names of the two curves you chose to be the rails.

Rail Curves
- Point Curve 01
- Point Curve 02

Section Curves:
- Point Curve 03
- End

Curve Properties
- Reverse
- Start Point: 0.0

Buttons:
- Insert
- Remove
- Refine
- Replace

Options:
- Sweep Parallel
- Sweep Scale
- Snap Cross-Sections
- Display While Creating
- Flip Normals
Section Curves This list shows the names of the cross-section curves, in the order you click them. You can select a curve by clicking its name in the list. Viewports display the selected curve in blue.

Arrow Buttons Use these to change the order of section curves in the list. Select a curve in the list, and then use the arrows to move the selection up or down.

Curve Properties group

These controls affect individual curves you select in the Section Curves list, as opposed to properties of the sweep surface in general. They are enabled only when you have selected a curve in the Section Curves list.

Reverse When set, reverses the direction of the selected curve.

Start Point Adjusts the position of the curve's start point. This can help eliminate unwanted twists or 'buckles' in the surface.

This control is disabled if the curve is not a closed curve.

While you're adjusting start points, a dotted blue line is displayed between them, to show the alignment. The surface is not displayed, so it doesn't slow down adjustment. When you release the mouse button, the surface reappears.

Insert (Disabled.)

Remove Removes a curve from the list. Select the curve in the list, and then click Remove.

Refine (Disabled.)

Replace (Disabled.)

Sweep Parallel When off, the rail curves define a ruled surface, and the cross sections describe lofting from this base ruled surface. When on, each cross section is associated with its best fitting plane. This plane moves along the rails and parallel to them. If the rails are curved, the plane can rotate. If the spacing between the rails changes, the section scales or stretches. In either case, the surface is blended from section to section along its entire length. Default=off.

Sweep Scale When off, the size of the plane is scaled only in the direction across the rails. When on, the plane is scaled uniformly in all directions. Default=off.

Snap Cross-Sections When on, cross-section curves are translated and scaled so they intersect both rails. The first cross section is translated to the start of the rails, and the last to the end of the rails. The cross sections in the middle
are translated to touch the rails at the closest point to the ends of the cross-section curves. Default=off.
When Snap Cross-Sections is on, the sweep follows the rail curves exactly. This makes it easier to construct 2-rail sweep surfaces.

**Display While Creating** When on, the sweep surface is displayed while you create it. When off, the sweep can be created more quickly. Default=off.

**Flip Normals** Reverses the direction of the sweep's normals.
2-Rail Sweep Surface rollout (Modification time)

![2-Rail Sweep Surface rollout](image)
Rail Curves Shows the names of the two curves you chose to be the rails.

Replace Rail 1 and Replace Rail 2 Let you replace the rail curves. Click one of these buttons, then in a viewport click the curve to use as the new rail.

Section Curves This list shows the names of the cross-section curves, in the order you click them. You can select a curve by clicking its name in the list. Viewports display the selected curve in blue.

Arrow Buttons Use these to change the order of section curves in the list. Select a curve in the list, and then use the arrows to move the selection up or down.

Curve Properties group

These controls affect individual curves you select in the Section Curves list, as opposed to properties of the sweep surface in general. They are enabled only when you have selected a curve in the Section Curves list.

Reverse When set, reverses the direction of the selected curve.

Start Point Adjusts the position of the curve's start point. This can help eliminate unwanted twists or "buckles" in the surface. This control is disabled if the curve is not a closed curve.

While you're adjusting start points, a dotted blue line is displayed between them, to show the alignment. The surface is not displayed, so it doesn't slow down adjustment. When you release the mouse button, the surface reappears.

Insert Adds a curve to the section list. Click to turn on Insert, then click the curve. The curve is inserted before the selected curve. To insert a curve at the end, first highlight the "----End-----" marker in the list.

Remove Removes a curve from the list. Select the curve in the list, and then click Remove.

Refine Refines the 2-rail sweep surface. Click to turn on Refine, then click an iso curve on the surface. (As you drag the mouse over the surface, the available section curves are highlighted.) The curve you click is converted to a CV curve and inserted into the sweep and the section list. As when you refine a point curve, refining a sweep can change the curvature of the surface slightly. Once you've refined the surface by adding a cross-section curve, you can use Edit Curves to change the curve.

Replace Lets you replace the selected curve. Select a curve in the list, click this button, then select the new curve.
Sweep Parallel  When off, the rail curves define a ruled surface, and the cross sections describe lofting from this base ruled surface. When on, each cross section is associated with its best fitting plane. This plane moves along the rails and parallel to them. If the rails are curved, the plane can rotate. If the spacing between the rails changes, the section scales or stretches. In either case, the surface is blended from section to section along its entire length. Default=off.

Sweep Scale  When off, the size of the plane is scaled only in the direction across the rails. When on, the plane is scaled uniformly in all directions. Default=off.

Snap Cross-Sections  When on, cross-section curves are translated and scaled so they intersect both rails. The first cross section is translated to the start of the rails, and the last to the end of the rails. The cross sections in the middle are translated to touch the rails at the closest point to the ends of the cross-section curves. Default=off.

When Snap Cross-Sections is on, the sweep follows the rail curves exactly. This makes it easier to construct 2-rail sweep surfaces.

Display Iso Curves  When set, the 2-Rail Sweep's V-axis iso curves are displayed as well as the U-axis curves used to construct the sweep. The V-axis curves are only for display. You can’t use them for surface construction.

Edit Curves  Lets you edit the currently selected curve without switching to another sub-object level. Click to turn on Edit Curve. The points or CVs of the curve are displayed, as well as the control lattice if the curve is a CV curve. You can now transform or otherwise change the points or CVs as if you were at the Point or Curve CV sub-object level. To finish editing the curve, click to turn off Edit Curves.

TIP  When you edit curves in a 2-rail sweep, turning off display of the sweep itself can make the curves easier to see and improve performance as well. Use Ctrl+D (while the Keyboard Shortcut Override Toggle on page 8420 is on) to toggle display of dependent sub-objects, including sweeps.

The sweep surface can deviate from the curve if you edit a curve in a sweep by increasing the weight of the curve CVs. You can work around this by refining the curve at the point where the surface deviates.
Multisided Blend Surface

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > N Blend

Select NURBS object. > Modify panel > NURBS toolbox > Create a Multisided Blend Surface button

A multisided blend surface "fills in" the edges defined by three or four other curve or surface sub-objects. Unlike a regular, two-sided blend surface, the curves’ or surfaces’ edges must form a closed loop; that is, they must completely surround the opening that the multisided blend will cover.

Multisided blend between three other surfaces

TIP If the multisided blend surface can't be created, fuse the points or CVs at the corners where the surfaces meet. Sometimes snapping the corners doesn't work, because of round-off error.
Procedures

To create a multisided blend:

1. Click to turn on Multisided Blend in the toolbox or N Blend on the Create Surfaces rollout.

2. In turn, click the three or four surface sides or curves that surround the opening.

3. Right-click to end creation.

A new surface is created. It covers the opening.

You can flip normals on the multisided blend while creating it.

Interface

Multisided Blend surfaces have no parameters other than those on the Surface Common rollout on page 2530.

Multicurve Trimmed Surface

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > Multi-Trim
Select NURBS object. > Modify panel > NURBS toolbox > Create a Multicurve Trimmed Surface button
A multicurve trimmed surface is an existing surface trimmed by multiple curves that form a loop.
Creating a multicurve trimmed surface

When you create a multicurve trimmed surface, you create only one trimmed hole. If you want to create multiple holes, first create holes in the surface using other techniques, and as the final step create the multicurve trim.

You can't trim across the edge between two surfaces, or across a "seam" where a surface touches itself, as at the back of a spherical surface created by converting a Sphere primitive.

Procedures

To create a multicurve trim:

1. Create a loop out of multiple curve sub-objects.
2. At the Curve CV or Point sub-object level, use Fuse to connect the ends of the curves.
   The curves must form a single closed loop, or completely traverse the surface.
3. Project the curves onto the surface by creating a normal or vector projected curve for each curve in the loop.
4 Turn on Multicurve Trimmed Surface in the toolbox or Multi-Trim on the Create Surfaces rollout.

5 Click the surface to trim, then click each of the curves in the loop. Right-click to end creation.

The Trim list shows the names of the curves you select. Flip Trim inverts the direction of trimming. Flip Normals lets you flip the surface normals at creation time. (After you have created the surface, you can flip normals using controls on the Surface Common rollout.)

**Interface**

While a multicurve trimmed sub-object is selected, a rollout with the multicurve trim parameters appears. This rollout appears only when one multicurve trimmed sub-object is selected. It isn’t possible to edit more than one multicurve trimmed object at a time, so unlike some other NURBS sub-objects, the rollout doesn’t appear when multiple multicurve trimmed sub-objects are selected.

**TIP** When you edit a multicurve trimmed sub-object, close the Surface Common rollout to see the Multicurve Trim Surface rollout more easily.
**Multicurve Trimmed Surface rollout (creation time)**

**Trim Curves** This list shows the names of the curves used to trim the surface. You can select a curve by clicking its name. Viewports display the selected curve in blue.

**Insert** (Disabled.)

**Remove** Removes a curve from the list. Select the curve in the list, and then click Remove.

**Replace** (Disabled.)

**Flip Trim** Reverses the direction of the trim.

**Flip Normals** Turn on to reverse the direction of the trimmed surface's normals.
Multicurve Trimmed Surface rollout (modification time)

**Trim Curves** This list shows the names of the curves used to trim the surface. You can select a curve by clicking its name. Viewports display the selected curve in blue.

**Insert** Adds a curve to the Trim Curves list. Click to turn on Insert, then click the curve. The curve is inserted before the selected curve. To insert a curve at the end, first highlight the "----End-----" marker in the list.

**Remove** Removes a curve from the list. Select the curve in the list, and then click Remove.

**Edit Curves** Lets you edit the currently selected curve without switching to another sub-object level. Click to turn on Edit Curve. The points or CVs of the curve are displayed, as well as the control lattice if the curve is a CV curve. You can now transform or otherwise change the points or CVs as if you were at the Point or Curve CV sub-object level. To finish editing the curve, click to turn off Edit Curves.

Don’t edit the curve so you break the loop. If you do, the surface goes into an error condition.
**Replace** Lets you replace the selected curve. Select a curve in the list, click this button, and then select the new curve.

**Flip Trim** Reverses the direction of the trim. Along with Edit Curves, the Insert, Remove, and Replace buttons let you alter the curves that trim the surface. While you are making changes, the surface will go into an error condition (orange display by default) until the curves you are working on once again form a closed loop.

**Fillet Surface**

Select NURBS object. > Modify panel > Create Surfaces rollout > Dependent Surfaces group box > Fillet Surf

Select NURBS object. > Modify panel > NURBS toolbox > Create Fillet Surface button

A fillet surface is a rounded corner connecting the edges of two other surfaces.

_Fillet surface created from two parent surfaces_
Usually you use both edges of the fillet surface to trim the parent surfaces, creating a transition between the fillet and its parents.

**Procedures**

To create a fillet surface:

1. In a NURBS object, turn on Fillet on the Create Surfaces rollout or Create Fillet Surface in the toolbox.
2. Click to choose the first parent surface, then click to choose the second parent surface. Potential parent surfaces are highlighted in blue as you move the mouse in a viewport.
   
The fillet surface is created. If the fillet surface can't be created, a default error surface is displayed (by default, the error surface displays as orange).
Interface

Fillet Surface rollout (creation time)

Start Radius and End Radius Set the radius used to define the fillet at the first surface you chose and the second surface you chose, respectively. The radiuses control the size of the fillet surface. Default=1.0.

Lock Locks the Start and End radius values so they are identical. When on, the End Radius setting is unavailable. Default=on.
**Radius Interpolation group**

This group box controls the radius of the fillet. The Radius Interpolation setting has no effect unless one or both surfaces that define the fillet have curvature to them.

**Linear** When chosen (the default), the radius is linear.

**Cubic** When chosen, the radius is treated as a cubic function, allowing it to change based on the parent surface's geometry.

**Seeds group**

These spinners adjust the seed values for the fillet surface. If there is more than one way to construct the fillet, 3ds Max uses the seed values to choose the nearest edge for that surface.

**Surface 1 X** Sets the local X coordinate of the seed on the first surface you chose.

**Surface 1 Y** Sets the local Y coordinate of the seed on the first surface you chose.

**Surface 2 X** Sets the local X coordinate of the seed on the second surface you chose.

**Surface 2 Y** Sets the local Y coordinate of the seed on the second surface you chose.

**Trim First Surface and Trim Second Surface groups**

For each of the parent surfaces, these controls affect trimming.

**Trim Surface** Trims the parent surface at the edge of the fillet.

**Flip Trim** Reverses the direction of the trim.

**Flip Normals** Turn on to reverse the direction of the fillet surface's normals.
Fillet Surface rollout (modification time)

Start Radius and End Radius Set the radius used to define the fillet at the first surface you chose and the second surface you chose, respectively. The radiiuses control the size of the fillet surface. Default=10.0.

Lock Locks the Start and End radius values so they are identical. When on, the End Radius setting is unavailable. Default=on.
**Radius Interpolation group**

This group box controls the radius of the fillet. The Radius Interpolation setting has no effect unless one or both surfaces that define the fillet have curvature to them.

**Linear** When chosen (the default), the radius is always linear.

**Cubic** When chosen, the radius is treated as a cubic function, allowing it to change based on the parent surface's geometry.

**Seeds group**

These spinners adjust the seed values for the fillet surface. If there is more than one way to construct the fillet, 3ds Max uses the seed values to choose the nearest edge for that surface.

**Surface 1 X** Sets the local X coordinate of the seed on the first surface you chose.

**Surface 1 Y** Sets the local Y coordinate of the seed on the first surface you chose.

**Surface 2 X** Sets the local X coordinate of the seed on the second surface you chose.

**Surface 2 Y** Sets the local Y coordinate of the seed on the second surface you chose.

**Trim First Surface and Trim Second Surface groups**

For each of the parent surfaces, these controls affect trimming.

**Trim Surface** Trims the parent surface at the edge of the fillet.

**Flip Trim** Reverses the direction of the trim.

**Replace First Surface and Replace Second Surface** Let you replace the parent surfaces. Click a button, then click the surface to replace the original first or second surface.

**Creating and Editing Point Sub-Objects**

Select NURBS object. > Modify panel > Create Points rollout

Select NURBS object. > Modify panel > NURBS toolbox
Keyboard > Ctrl+T to toggle NURBS toolbox display (Keyboard Shortcut Override Toggle must be on.)

In addition to the points that are an integral part of point curve on page 2466 and point surface on page 2456 objects, you can create "freestanding" points. Such points can help you construct point curves by using the Curve Fit on page 2558 button. You also use dependent points to trim curves.

You create individual points as NURBS sub-objects while you are modifying NURBS. To create points individually, use the Create Points rollout or the NURBS toolbox on page 2426.

**Toolbox Buttons for Creating Points**

These are the toolbox buttons for creating point sub-objects:

- Create an independent point on page 2695.
- Create a dependent offset point on page 2696.
- Create a dependent curve point on page 2698.
- Create a dependent curve-curve intersection point on page 2704.
- Create a dependent surface point on page 2701.
- Create a dependent surface-curve intersection point on page 2707.

**Point (NURBS)**

Select NURBS object. > Modify panel > Create Points rollout > Point button
Select NURBS object. > Modify panel > NURBS toolbox > Create Point button
This command creates an independent, freestanding point.
Procedures

To create a freestanding point:

1. Select a NURBS object.
2. In the Modify > Create Points rollout, turn on Point.
3. Click a viewport to position the point.

Independent point sub-objects have no additional parameters. You can use Curve Fit in the Create Curves rollout to create a curve from multiple freestanding points.

Interface

There are no additional controls for independent points.

Offset Point

Select NURBS object. > Modify panel > Create Points rollout > Dependent Points group box > Offset Point button
Select NURBS object. > Modify panel > NURBS toolbox > Create Offset Point button

This command creates a dependent point that is coincident to an existing point or at a relative distance from an existing point.

Procedures

To create a dependent offset point:

1. Select a NURBS object
2. On the Modify > Create Points rollout, turn on Offset Point.
3. In a viewport, click an existing point.
4. In the Modify > Offset Points rollout, use the Offset spinners to adjust the point’s position relative to the original point.
Interface

While an offset point sub-object is selected, the Offset Point rollout appears.

**At Point** When chosen, the dependent point has the same location as the original, parent point.

**Offset** Enables point offset. Use the X,Y,Z Offset spinners to set offset values (in object space coordinates).

**Replace Base Point** (Only at modification time.) Lets you replace the parent point. Click the button, then click the new point on which to base the offset point.
Curve Point

Select NURBS object. > Modify panel > Create Points rollout > Dependent Points group box > Curve Point button

Select NURBS object. > Modify panel > NURBS toolbox > Create Curve Point button

This command creates a dependent point that lies on a curve or relative to it. The point can be either on the curve or off the curve. If it is on the curve, the U Position is the only control of its location. The U Position specifies a location along the curve (based on the curve’s local U axis). There are three ways to displace the point’s location relative to the U position.

Procedures

To create a dependent curve point:

1. Turn on Curve Point and then click along a curve to position the point.
2. The curve and cursor position are highlighted during this operation.
3. At the Point sub-object level, adjust the point’s position relative to the curve by adjusting the curve point parameters on the Curve Point rollout.
4 Right-click to end operation.

**Interface**

While a curve point sub-object is selected, the Curve Point rollout appears.
**U Position** Specifies the point's location on the curve or relative to the curve.

**On Curve** When on, the point lies on the curve at the U Position.

**Offset** Moves the point according to a relative (object space) X,Y,Z location. This is relative to the U Position.

**X Offset, Y Offset, and Z Offset** Specify the object space location of the offset curve point.

**Normal** Moves the point along the direction of the curve's normal at the U Position.

**Distance** Specifies the distance along the curve's normal. Negative values move the point opposite to the normal.
**Tangent** Moves the point along the tangent at the U Position.

**U Tangent** Specifies the distance from the curve along the tangent.

---

**Trimming group box**

Controls in this group box let you trim the parent curve.

**Trim Curve** When on, trims the parent curve against the curve point's U position. When off (the default), the parent isn't trimmed.

**Flip Trim** When on, trims in the opposite direction.

**Replace Base Curve** (Only at modification time.) Lets you replace the parent curve. Click the button, then click the new curve on which to base the curve point.

---

**Surface Point**

Select NURBS object. > Modify panel > Create Points rollout > Dependent Points group box > Surface Point button

Select NURBS object. > Modify panel > NURBS toolbox > Create Surf Point button

This command creates a dependent point that lies on a surface or relative to it. This is enabled with a NURBS object that contains a surface.
Procedures

To create a dependent surface point:

1. Turn on Surf Point and then click over a NURBS surface to position the point.
2. The surface cross-section and cursor are highlighted during this operation.
3. Right-click to end the create operation.
4. At the Point sub-object level, adjust the point’s position relative to the surface by adjusting the surface point parameters in the Surface Point rollout.

Interface

While a surface point sub-object is selected, the Surface Point rollout appears. These controls are similar to the curve point controls.
U Position and V Position If the point is on the surface, these coordinates specify the point's location, based on the surface's local UV coordinates.

On Surface Specifies that the point lies on the surface, at the location specified by U Position and V Position.

If the point lies on the surface, you can move it using the Move transform. You can also move it using the Move Surface Point button. See Editing Point Sub-Objects on page 2496. Either way, this updates the U Position and V Position values.

Offset Moves the point according to a relative (object space) X,Y,Z location.

X Offset, Y Offset, and Z Offset Specify the object space location of the offset surface point.

Normal Moves the point along the direction of the surface's normal.
**Distance** Specifies the distance from the surface, along the normal. Negative values move the point opposite to the normal.

**Tangent** Moves the point along the tangent of the UV position.

**U Tangent and V Tangent** Specify the distance from the surface along the tangents at U and V.

**Replace Base Surface** (Only at modification time.) Lets you replace the parent surface. Click the button, then click the new surface on which to base the surface point.

---

**Curve-Curve Intersection Point**

Select NURBS object. > Modify panel > Create Points rollout Dependent Points group box > Curve-Curve button

Select NURBS object. > Modify panel > NURBS toolbox > Create Curve-Curve Point button

This command creates a dependent point at the intersection of two curves.

**Procedures**

**To create a dependent curve-curve point:**

1. Turn on Curve-Curve, then drag from the first curve to the second.

   If the curves do not intersect, the point is orange, an invalid dependent point.

   The point is created at the nearest intersection between the two curves. You can use the curve-curve parameters to trim the parent curves.

2. Right-click to end the create operation.
Interface

While a curve-curve point sub-object is selected, the Curve-Curve Intersection rollout appears.
Trim First Curve and Trim Second Curve groups

These two groups let you control how the parent curves are trimmed. The controls are the same in each. "First" and "second" refer to the order in which you picked the parent curves.

Trim Curve When on, the parent curve is trimmed against the curve-curve point. When off (the default), the parent isn't trimmed.

Flip Trim When on, trims in the opposite direction.

Seed 1 and Seed 2 Change the U location of the seed value on the first and second curves. If there is a choice of intersections, the intersection closest to the seed points is the one used to create the point.

Replace First Curve and Replace Second Curve (Only at modification time.) Let you replace the parent curves. Click a button, then click the curve to replace the original first or second curve.
Surface-Curve Intersection Point

Select NURBS object. > Modify panel > Create Points rollout > Dependent Points group box > Surf-Curve button

Select NURBS object. > Modify panel > NURBS toolbox > Create Surface-Curve Point button

This command creates a dependent point at the intersection of a surface and a curve.

Procedures

To create a dependent surface-curve point:

1. In a NURBS object that has a curve that passes through a surface, click to turn on Create Surface Curve Point in the NURBS toolbox or Surf-Curve on the Create Points rollout.

2. Click the curve, then click the surface.

The point is created at the intersection between the curve and the surface that is nearest the seed point. You can use the surface-curve parameters to trim the parent curve.

Interface

While a surface-curve intersection point sub-object is selected, a rollout with its parameters appears.
Trim Curve group

Trim When on, trims the curve from the surface. When off, the curve isn’t trimmed.

Flip Trim When on, trims the curve in the opposite direction.

Seed Changes the U location of the seed value on the curve. If there is a choice of intersections, the intersection closest to the seed point is the one used to create the point.

Replace Curve and Replace Surface (Only at modification time.) Let you replace the parent sub-objects. Click a button, then click a curve or surface to replace the original parent object.

NURBS Editing Dialogs

This section describes dialogs that support creating and editing NURBS models.

Convert Curve Dialog (NURBS)

Modify panel > Select NURBS curve sub-object. > Curve Common rollout > Convert Curve button

This dialog is a general way to convert one kind of a curve to another or to adjust a curve’s parameters.
Interface

Point Curve and CV Curve Choose whether to convert to a point curve or a CV curve. If the curve is already of the type you chose, the settings in this dialog don’t convert it, but do change its properties. Default=CV Curve.

CV Curve options

These are the options when you choose CV Curve.

Number When chosen, the spinner sets the number of CVs in the CV curve.

Tolerance When chosen, 3ds Max calculates the number of CVs. This option rebuilds the curve according to accuracy. The lower the Tolerance value, the more accurate the rebuild. Increasing Tolerance enables the curve to be rebuilt using fewer CVs.

Reparameterization group

These controls let you reparameterize the CV curve and turn on automatic reparameterization.

Chord Length Chooses the chord-length algorithm for reparameterization.
Chord-length reparameterization spaces knots (in parameter space on page 8674) based on the square root of the length of each curve segment. Chord-length reparameterization is usually the best choice.

**Uniform** Spacing the knots uniformly.

A uniform knot vector has the advantage that the curve changes only locally when you edit it. With chord-length parameterization, moving any CV can potentially change the entire sub-object.

**Maintain Parameterization** When on, the curve is automatically reparameterized as you edit it, using the currently active method of reparameterization. When off, no reparameterization happens unless you use a dialog to specifically request it. Default=on.

**Point Curve options:**

These are the options when you choose Point Curve.

**Number** Sets the number of points in the point curve.

**Tolerance** When chosen, 3ds Max calculates the number of points. This option rebuilds the curve according to accuracy. The lower the Tolerance value, the more accurate the rebuild. Increasing Tolerance enables the curve to be rebuilt using fewer points.

**Preview** When on, the effect of the conversion is previewed in viewports. Default=on.

---

**Convert Curve On Surface Dialog (NURBS)**

Modify panel > Select NURBS object. > Stack display > Curve sub-object level > Select curve sub-object. > Curve Common rollout > Make COS button

This dialog converts a curve to a point curve on surface on page 2597 or CV curve on surface on page 2593.

The Make COS button that displays it is enabled only for the following types of curves:

- **U iso curves** on page 2584
- **V iso curves** on page 2584
- **Normal projected curves** on page 2586
- **Vector projected curves** on page 2589
If the curve is already a curve on surface, this dialog lets you change its type.

Interface

**Convert Curve On Surface**

- **CV Curve On Surface** Converts the curve to a CV curve on surface.
- **Point Curve On Surface** Converts the curve to a point curve on surface.

**Number of CVs/Points** Specifies the number of CVs/points in the new curve.

**Preview** When on, previews the effect of the conversion in viewports. Default=on.

**Convert Surface Dialog (NURBS)**

Modify panel > Select NURBS surface sub-object. > Surface Common rollout > Convert Surface button
This dialog provides a general way to convert one kind of a surface to another or to adjust a surface's parameters.

**Interface**

![Convert Surface dialog]

**Loft tab**

If the surface isn't already a loft, this tab converts it to the kind of loft you indicate.

The controls are comparable to those in the [Make Loft dialog](#) on page 2727.

**From U Iso Lines** Uses curves along the surface's U dimension to construct a U loft.

**From V Iso Lines** Uses curves along the surface's V dimension to construct a U loft. If the surface was already a U loft, set this to change the lofting dimension.

**From U and V Iso Lines** Uses curves from both the U and V dimensions to construct a UV loft.
U Curves Sets the number of curves in U.

V Curves Sets the number of curves in V.

Use Point Curves When on, constructs the loft from point curves instead of the default CV curves. Default=off.

Extra Points per Segment This control is available only for UV lofts (From U and V Iso Lines). Lets you increase the number of points in each segment.

Fuse Points This control is available only for UV lofts (From U and V Iso Lines). When on, fuses points at curve intersections to ensure that the U and V curves continue to intersect when you edit the surface, and that the surface remains coincident with its parent curves. UV lofts constructed from intersecting curves behave more predictably. Default=on.

Fit Point tab
If the surface isn't already a point surface, this tab converts it to a point surface.

In U Sets the number of point rows (in the surface’s U axis).

In V Sets the number of point columns (in the surface’s V axis).

Tolerance When chosen, 3ds Max calculates the number of points. This option rebuilds the surface according to accuracy. The lower the Tolerance value, the more accurate the rebuild. Increasing Tolerance enables the surface to be rebuilt using fewer points.

CV Surface tab
If the surface isn't already a CV surface, this tab converts it to a CV surface. This tab is the default.

Number When chosen, the spinners set the number of CVs in the CV surface.

In U Sets the number of CV rows (in the surface’s U axis).

In V Sets the number of CV columns (in the surface’s V axis).

Tolerance When chosen, 3ds Max calculates the number of CVs. This option rebuilds the surface according to accuracy. The lower the Tolerance value, the more accurate the rebuild. Increasing Tolerance enables the surface to be rebuilt using fewer CVs.
Reparameterization group

These controls let you reparameterize the CV surface and turn on automatic reparameterization.

Chord Length Chooses the chord-length algorithm for reparameterization. Chord-length reparameterization spaces knots (in parameter space on page 8674) based on the square root of the length of each segment. Chord-length reparameterization is usually the best choice.

Uniform Spaces the knots uniformly. A uniform knot vector has the advantage that the surface changes only locally when you edit it. With chord-length parameterization, moving any CV can potentially change the entire surface.

Maintain Parameterization When on, the surface is automatically reparameterized as you edit it, using the currently active method of reparameterization. When off, no reparameterization happens unless you use a dialog to specifically request it. Default=on.

Preview When on, viewports display a preview of the conversion. Turning off this toggle can speed up conversion, especially to lofts.

Delete Original Curves This is available only if the surface was already a U loft or UV loft. When on, Convert Surface deletes the original loft curves when you click OK. When off, the original curves remain where they are. Default=off.

CV Curve: Close Curve Dialog (NURBS)

Create panel > Shapes button > CV Curve button > In viewports, draw a CV curve and click to create a CV in the same location as the first CV in the curve.

Modify panel > Select NURBS object. > NURBS toolbox > Create CV Curve > In viewports, draw a CV curve sub-object and click to create a CV in the same location as the first CV in the curve.

This dialog lets you create a closed CV curve when you click to create a CV in the same location as the curve’s first CV.
Interface

Yes Closes the curve and ends curve creation.

No Keeps the curve open and does not end curve creation.

Detach Dialog (NURBS)

Modify panel > Select a NURBS sub-object. > Curve Common or Surface Common rollout > (optional) Copy toggle > Detach button

This dialog appears when you use Detach to create a new top-level NURBS curve or surface sub-object.

Interface

Detach as Lets you assign a name to the new object. By default, the name is "Curve" or "Surface" followed by a sequence number.

This option is unavailable when Detach To Element is on.
Relational  This toggle affects dependent objects. When off, detaching a dependent sub-object makes it an independent object. For example, detaching a U loft converts it to a CV surface. When on, detaching a dependent sub-object also detaches the objects on which it depends, so the object remains dependent. For example, detaching a U loft also detaches the curves that define it. Default=on.

Edit Curve On Surface Dialog (NURBS)

Select NURBS object. > Modify panel > Stack display > Curve sub-object level > Select NURBS curve on surface sub-object. > CV Curve On Surface or Point Curve On Surface rollout > Edit button

This dialog lets you edit curves on surfaces as you edit regular curves in a viewport. The main part of the dialog is a two-dimensional view of the surface. The controls provide typical curve editing functions.

This is a modeless dialog. You can use the main 3ds Max window while Edit Curve On Surface remains open. However, if you select a different kind of curve or a sub-object that isn’t a curve, the dialog closes.

You can edit multiple CV on surface on page 2593 or Point on surface on page 2597 curves, but you can’t edit both types of curves at the same time.

The point whose surface you first click is shown as a blue square in the dialog as well as in viewports. As you draw the curve, it appears interactively in viewports and a blue asterisk (*) shows the current mouse location on the surface.

While you are creating a curve, you can press Backspace to remove the last point or CV you created, and then previous points or CVs in reverse order.
Interface

The toolbar above the surface image provides selection, transform and viewing controls. These controls work the way their analogs do in the main 3ds Max viewports. The toolbar is disabled while you create a new curve on surface.

**Toolbar**

The toolbar above the surface image provides selection, transform and viewing controls. These controls work the way their analogs do in the main 3ds Max viewports. The toolbar is disabled while you create a new curve on surface.

**Select** Selects one or more points. Drag a window to select multiple points.
Move Moves the selected points.
Move is a flyout. The alternative buttons constrain texture points to move either vertically or horizontally.

Rotate Rotates the selected points.

Scale Scales the selected points. This is a flyout that lets you choose between uniform scale, nonuniform scale in the surface's U dimension, or nonuniform scale in the surface's V dimension.

Pan Pans the surface view.

Zoom Zooms in or out on the surface view.

Zoom Window Zooms to a window you drag on the surface view.

Zoom Extents Zooms to the extents of the surface.

Lock Selection Locks the active selection set. You can turn this on to keep from accidentally selecting other points or CVs while you’re transforming a selection set.

Preview When on (the default), edits you make in the dialog are also shown in viewports.

Curve on Surface Image

Below the toolbar is a 2D image of the curve. This image shows the points or CVs of the curve, allowing you to edit it as you edit sub-objects in viewports.
If you right-click while in the image, a pop-up menu lets you switch between Select, Move, Rotate, and Scale. This is an alternative to using the toolbar. If your mouse has a middle button, you can use it to pan in this window.

**Buttons and Weight**

These controls are comparable to editing controls on the rollouts for point sub-objects. (The Open button works differently.) These controls are disabled while you create a new curve on surface.

**Refine** Adds points to the curve. This does not change curvature. For point curves, the curvature can change, but only slightly.

**Insert** (Not available for point curves on surfaces.)

**Close** Closes the curve.

**Fuse** Fuses two points.

**Weight** (Not available for point curves on surfaces.)

**Delete** Deletes the selected points.

**Open** Opens the curve by unfusing the points where the curve was originally closed.

**Unfuse** Unfuses the selected points.

**Remove Animation** Removes animation controllers from the selected points or CVs.

**Edit Texture Surface Dialog (NURBS)**

Modify panel > Select NURBS surface sub-object. > Material Properties rollout > Texture Channels group box > Turn on Gen. Mapping Coords. > Texture Surface group box > Choose User-Defined. > Edit Texture Surface button

This dialog lets you edit the texture surface for a surface sub-object. It is available when you have chosen User Defined as the sub-object’s texture surface method.

A texture surface is associated with the surface sub-object. The texture surface is used to control how materials are mapped. In effect, changing the texture surface stretches or otherwise changes the UV coordinates for the surface, altering the mapping.
The Edit Texture Surface dialog shows a 2D view of the texture surface. You can also edit user-defined texture surfaces directly in 3D viewports, using the Edit Texture Points button. See Material Properties Rollout on page 2544.

Maps can shift with certain surface approximation methods. This effect is especially noticeable when the surface has animated CVs. You can reduce or eliminate map shifting by changing the mapping method to User Defined.

**TIP** Don't use the UVW Map modifier to apply a texture to an animated NURBS surface.
Interface

The toolbar above the surface image provides selection, transform and viewing controls. These controls work the way their analogs do in viewports.

NOTE You can animate transforms to the texture surface points.

Toolbar

The toolbar above the surface image provides selection, transform and viewing controls. These controls work the way their analogs do in viewports.

NOTE You can animate transforms to the texture surface points.
Select  Selects one or more points. Drag a window to select multiple points or CVs.

Move  Moves the selected points. Move is a flyout. The alternative buttons constrain texture points to move either vertically or horizontally.

Rotate  Rotates the selected points.

Scale  Scales the selected points. This is a flyout that lets you choose between uniform scale, nonuniform scale in the surface's U dimension, or nonuniform scale in the surface's V dimension.

Pan  Pans the surface view.

Zoom  Zooms in or out on the surface view.

Zoom Window  Zooms to a window you drag on the surface view.

Zoom Extents  Zooms to the extents of the surface.

Lock Selection  Locks the active selection set. You can turn this on so you don't accidentally select other points while you're transforming a selection set.

Preview  When on (the default), your edits are also shown in viewports. In viewports, selected texture points are displayed in red, and the others are displayed in green.
Texture Surface Image

Below the toolbar is a 2D image showing the points of the texture surface. You can edit the texture surface as you edit sub-objects in viewports.

If you right-click while in the image, the popup menu lets you switch between Select, Move, Rotate, and Scale. This is an alternative to using the toolbar.

If your mouse has a middle button, you can use it to pan in this window.

Texture Surface Controls

The controls below the surface image edit the texture surface.

Remove Animation Removes animation controllers from the selected texture points.

Reset to Defaults Resets user-defined mapping to the default.

Rebuild Displays the Rebuild Texture Surface dialog on page 2733, which rebuilds the texture surface and lets you change the number of CV rows or columns.

Insert Row, Insert Col., Insert Both Click one of these buttons to insert a row or column of points, or both at once, into the surface. Insertion adds points without moving other rows and columns.

While you refine the surface, the operation is previewed the same way Insert is previewed in 3D viewports.

Delete Row, Delete Col., Delete Both Click one of these buttons to delete a row or column of points, or both at once.

Join Curves Dialog (NURBS)

Modify panel > Select NURBS curve sub-object. > Curve Common rollout > Join button > Join two curves in a viewport.

This dialog lets you choose the way to join two curves.
Interface

ZIP tab

This tab chooses the zip algorithm. Zipping concatenates the CV lattices of the two original curves. Zipping can change the shape of the original curves, but usually it produces a better result than joining.

By default, the ZIP tab is active.

If both curves are untrimmed point curves, the result of zipping is a point curve. In all other cases, the result is a CV curve.

Tolerance A distance in 3ds Max units. If the ends of the two original curves are closer than this distance, zipping deletes one of the points or CVs in order to avoid creating coincident points or CVs in the new zipped curve.

Tension 1 (Disabled.)

Tension 2 (Disabled.)

Join tab

This tab chooses the join algorithm. Joining first creates a blend curve between the two original curves, and then makes all three into a single curve. Joining does not change the shape of the two original curves.
If both curves are point curves, the result is a point curve. If one or both curves are CV curves, the result is a CV curve.

**Tolerance** A distance in 3ds Max units. If the gap between the curves you are joining is greater than this value, the join is created by first creating a blend curve and then joining the three parts. If the gap is less than this value, or if the curves are overlapping or coincident, 3ds Max doesn’t create the blend. Creating a blend and then joining the three curves into a single curve is the better technique. The result matches the parent curves well. Without the blend step, the resulting curve can deviate from the parent curves, in order to maintain smoothness. (The amount of deviation depends on how far from tangent the two input curves were at the join.)

A problem arises when the gap is too small. In this case, 3ds Max generates the blend but because there isn’t enough room for it, the resulting curve has a loop. To avoid having this loop, set the Tolerance higher than the gap distance.

If you set the tolerance to 0.0, 3ds Max chooses a value to use for the Tolerance.

**Tension 1** Adjusts the tension of the new curve at the end of the first curve you picked.

**Tension 2** Adjusts the tension of the new curve at the end of the second curve you picked.

**Preview** When on, the effect of the zip or join is previewed in viewports. Default=on.

---

**Join Surfaces Dialog (NURBS)**

Modify panel > Select NURBS surface sub-object. > Surface Common rollout > Join button > Join two surfaces in a viewport.

This dialog lets you choose the way to join two surfaces.
Interface

ZIP tab

This tab chooses the zip algorithm. Zipping concatenates the CV lattices of the two original surfaces. Zipping can change the shape of the original surfaces, but compared to joining it usually produces a simpler surface that is easier to edit.

By default, the ZIP tab is active.

If both curves are untrimmed point surfaces, the result of zipping is a point surface. In all other cases, the result is a CV surface.

Tolerance A distance in 3ds Max units. If the edges of the two original surfaces are closer than this distance, zipping deletes one row (or column) of the points or CVs in order to avoid creating a coincident point or CV row (or column) in the new zipped surface.

Tension 1 (Disabled.)
Tension 2 (Disabled.)

Join tab

This tabChoose the join algorithm. Joining first creates a blend surface between the two original surfaces, and then makes all three into a single surface. Joining does not change the shape of the two original surfaces.
If both surfaces are point surfaces, the result is a point surface. If one or both surfaces are CV surfaces, the result is a CV surface.

**Tolerance** A distance in 3ds Max units. If the gap between the surfaces you are joining is greater than this value, the join is created by first creating a blend surface and then joining the three parts. If the gap is less than this value, or if the surfaces are overlapping or coincident, 3ds Max doesn’t create the blend. Creating a blend and then joining the three surfaces into a single surface is the better technique. The result matches the parent surfaces well. Without the blend step, the resulting surface can deviate from the parent surfaces, in order to maintain smoothness. (The amount of deviation depends on how far from tangent the two input surfaces were at the join.)

A problem arises when the gap is too small. In this case, 3ds Max generates the blend but because there isn’t enough room for it, the resulting surface has a loop. To avoid having this loop, set the Tolerance higher than the gap distance.

If you set the tolerance to 0.0, 3ds Max chooses a value to use for the Tolerance.

**Tension 1** Adjusts the tension of the new surface at the edge of the first surface you picked.

**Tension 2** Adjusts the tension of the new surface at the end of the second surface you picked.

**Preview** When on, the effect of the zip or join is previewed in viewports.

**Make Loft Dialog (NURBS)**

Modify panel > Select NURBS surface sub-object. > Surface Common rollout > Make Loft button

This dialog converts a surface sub-object to a (dependent) U loft or UV loft surface. You can also change the dimension used to construct a U loft surface.
**Interface**

From **U Iso Lines** uses curves along the surface's U dimension to construct a U loft.

From **V Iso Lines** uses curves along the surface's V dimension to construct a U loft. If the surface was already a U loft, set this to change the lofting dimension.

From **U and V Iso Lines** uses curves from both the U and V dimensions to construct a UV loft.

**U Curves** sets the number of curves in U.

**V Curves** sets the number of curves in V.

**Use Point Curves** when on, constructs the loft from point curves instead of the default CV curves. Default=off.

**Extra Points per Segment** this control is enabled only for UV lofts (From U and V Iso Lines). Lets you increase the number of points in each segment.
**Fuse Points** This control is enabled only for UV lofts (From U and V Iso Lines). When on, fuses points at curve intersections to ensure that the U and V curves continue to intersect when you edit the surface, and that the surface remains coincident with its parent curves. UV lofts constructed from intersecting curves behave more predictably. Default=on.

**Delete Original Loft Curves** This is available only if the surface was already a U loft or UV loft. When on, Make Loft deletes the original loft curves when you click OK. When off, the original curves remain where they are. Default=off.

**Preview** When on, displays a preview of the new loft surface. Loft creation is faster when Preview is off. Default=off.

### Make Point Dialog (NURBS)

Modify panel > Select NURBS surface sub-object. > Surface Common rollout > Make Point button

This dialog converts a CV surface sub-object to a point surface sub-object.

**Interface**

![Make Point Surface Dialog](image)

**Number in U** Sets the number of columns.

**Number in V** Sets the number of rows.

**Preview** When on, your changes are previewed in viewports. Point surface conversion is faster when Preview is off. Default=off.
Make Point Curve Dialog (NURBS)

Modify panel > Select NURBS curve sub-object. > Curve Common rollout > Make Fit button

The Make Fit button for a NURBS curve sub-object turns a CV curve into a point curve. For point curves, it lets you change the number of points. It displays this dialog.

Interface

![Make Point Curve Dialog]

Number of Points  Sets the number of points in the point curve.

Point Curve: Close Curve Dialog (NURBS)

Create panel > Shapes button > Point Curve button > In viewports, draw a point curve and click to create a point in the same location as the first point in the curve.

Modify panel > Select NURBS object. > NURBS toolbox > Create Point Curve > In viewports, draw a point curve sub-object and click to create a point in the same location as the first point in the curve.

This dialog lets you create a closed point curve when you click to create a point in the same location as the curve's first point.
Interface

Yes Closes the curve and ends curve creation.

No Keeps the curve open and does not end curve creation.

Rebuild CV Curve Dialog (NURBS)

Modify panel > Select NURBS object. > Stack display > Curve sub-object level > Select an independent CV curve sub-object. > CV Curve rollout > Rebuild button

The Rebuild button for CV curves displays this dialog. It lets you specify how to rebuild the curve. Rebuilding the curve can change its appearance.

Interface

Tolerance Rebuilds the curve according to accuracy. The lower the Tolerance value, the more accurate the rebuild. Increasing Tolerance enables the curve to be rebuilt using fewer CVs.

Number (The default.) Lets you alter the number of CVs in the curve.
Preview When on (the default), your changes are previewed in viewports.

Rebuild CV Surface Dialog (NURBS)

Modify panel > Select NURBS object. > Stack display > Surface sub-object level > Select an independent CV surface sub-object. > CV Surface rollout > Rebuild button

The Rebuild button for CV surfaces displays this dialog. It lets you specify how to rebuild the surface. Rebuilding the surface can change its appearance.

Interface

![Rebuild CV Surface Dialog](image)

Tolerance Rebuilds the surface according to accuracy. The lower the Tolerance value, the more accurate the rebuild. Increasing Tolerance enables the surface to be rebuilt using fewer CVs.

Number (The default.) Lets you alter the number of CVs in the surface. Number in U specifies the number in the U dimension, and Number in V specifies the number in the V dimension. These values default to the numbers that already exist in the surface.

Preview When on (the default), your changes are previewed in viewports.
Rebuild Texture Surface Dialog (NURBS)

Modify panel > Select NURBS surface sub-object. > Surface sub-object level > Material Properties rollout > Texture Channels group box > Turn on Gen. Mapping Coords. > Texture Surface group box > Choose User-Defined. > Edit Texture Surface button > Edit Texture Surface dialog > Rebuild button

This dialog rebuilds the texture surface and lets you change the number of CV rows or columns.

**Interface**

![Rebuild Texture Surface Dialog](image)

**Number in U** Sets the number of CV columns.

**Number in V** Sets the number of CV rows.

Reparameterize Dialog (NURBS)

Modify panel > Select NURBS object. > Stack display > Curve sub-object level > Select an independent CV curve sub-object. > CV Curve rollout > Reparam. button

Modify panel > Select NURBS object. > Stack display > Curve sub-object level > Select an independent CV surface sub-object. > CV Surface rollout > Reparam. button

The Reparam. button for CV curves and surfaces displays this dialog. Reparameterizing a CV sub-object changes its parameter space on page 8674 to provide a better relation between control point locations and the shape of the sub-object.

**TIP** It is a good idea to reparameterize after you have added CVs to a curve or surface by refining or inserting.
Interface

Chord Length Chooses the chord-length algorithm for reparameterization. Chord-length reparameterization spaces knots (in parameter space on page 8674) based on the square root of the length of each curve segment. Chord-length reparameterization is usually the best choice.

Uniform Spaces the knots uniformly. A uniform knot vector has the advantage that the curve or surface changes only locally when you edit it. With chord-length parameterization, moving any CV can potentially change the entire sub-object.

Maintain Parameterization When on, the curve is automatically reparameterized as you edit it, using the currently active method of reparameterization. When off, no reparameterization happens unless you use this dialog. Default=off.

Preview If on (the default), displays the effects of reparameterizing in viewports.

Sub-Object Clone Options Dialog (NURBS)

Modify panel > Select NURBS surface or curve sub-object. > Shift+Clone. > Clone Options dialog

When you Shift+Clone on page 996 a surface or curve sub-object, the Clone Options dialog appears. This dialog asks whether you want the clone to be a relational copy, an independent copy, or a transform.
Interface

**Relational Copy** The cloned object is the same type as the original. If the original object was a dependent object, the clone includes copies of the parents. For example, when you clone a Blend surface, the clone remains a Blend surface and its two parent surfaces are copied along with it. Because all related sub-objects are copied, Relational Copy can be time-consuming.

**Independent Copy** The cloned object is an independent CV curve or CV surface. It has the same shape as the original, but its relational dependencies aren't copied. This method of cloning uses less time and memory, although you lose the relational properties. For example, when you clone a Blend surface, the clone is an independent CV surface.

**Copy as Transform Object(s)** The "clone" is actually a transform curve or transform surface, based on the original object and still dependent on it. This lets you create transform curves and surfaces based on a rotation and scale as well as on translation.

**Include Parent(s)** (Available only for Independent Copy or Copy as Transform Object(s).) Tells the system whether or not to include the parents of the dependent object. For example, if Include Parent(s) is on when you clone a blend surface, the two parent surfaces are also cloned as independent CV surfaces. If Include Parent(s) is off, only the one curve or surface is cloned. Cloning is slower when Include Parent(s) is on, although quicker than Relational Copy.
Select By Material ID Dialog (NURBS)

Modify panel > Select NURBS object. > Stack display > Curve sub-object level > Select By ID button.

This dialog lets you select curve sub-objects by the material ID number assigned to them.

**Interface**

![Select By Material ID Dialog](image)

**ID** Specifies the material ID you want to select.

**Clear Selection** When on, replaces the current selection (if any) by the material ID selection. When off, adds the material ID selection to the current selection set.

**NURBS Curve and Surface Approximation**

Topics in this section describe how you can control the way 3ds Max generates NURBS curves and surfaces.

**NURBS Curve Approximation**

Modify panel > Select top-level NURBS object. > Curve Approximation rollout

Although NURBS curves are analytically generated, in order to generate and display them they must be approximated by line segments.

Curve approximation controls are displayed in the creation parameters for curve objects, and on a Curve Approximation rollout for NURBS models (top-level NURBS objects). At the model level, approximation controls affect all curve sub-objects in the model.
Curve approximation is accomplished by *segments*. One or more line segments, or *steps*, are used to approximate each segment of the curve. For point curves, a segment of a curve is the portion between one point and the next. For CV curves, the segment is determined by the CV’s parametric *knot* on page 8617. The transition from one CV curve segment to another isn't visible in viewports.

Curve approximation parameters aren't animatable.

**Interface**

**Steps** The maximum number of line segments used to approximate each curve segment. If the curve displays or renders with angles, increase this value. This control is unavailable when Adaptive is on. Range=1 to 100.

**Optimize** Turn on this check box to optimize the curve. When on, interpolation uses the specified *Steps* value unless two segments are collinear, in which case they are converted to a single segment. This control is unavailable when Adaptive is on.

**Adaptive** (The default.) Segments the curve adaptively, based on its curvature. In other words, the curve is assigned more segments where its curvature is greatest, and fewer segments where its curvature is less.

**NURBS Surface Approximation**

Modify panel > Select top-level NURBS object. > Surface Approximation rollout

Modify panel > Select NURBS surface sub-object. > Surface Approximation rollout

Although NURBS surfaces are analytically generated, in order to generate and display them they must be approximated by faces. You use the controls described in this section to set the type of approximation used and its parameters.

The Surface Approximation rollout controls how surface sub-objects in the NURBS model are approximated for purposes of rendering and viewport
display. NURBS can be approximated differently in viewports and in the renderer. Typically you want viewport display to be clear and quick, while you want rendered display to be smooth, accurate, and "realistic." However, the approximation you choose for viewports creates a mesh, and the kind of mesh you choose can affect the behavior of modifiers that you later apply to the NURBS model.

The first two controls on this rollout are radio buttons for selecting the kind of display output, viewport or renderer, these parameters control.

Surface approximation parameters are not animatable.

**NOTE** If the size or shape of a surface changes over time, the tessellation used to approximate it can change (automatically) as well. This has the advantage of improving render time in animations. It has the disadvantage that you can't apply image motion blur on page 8606 to NURBS objects whose tessellation changes during animation. The Regular method of tessellation is the exception: it doesn't change when animated, so you can use image motion blur with Regular tessellation.

**Surface Approximation Per Surface**

By default, surface sub-objects use the same approximation settings as the top-level NURBS model. You can override these settings. Each surface sub-object now has a Surface Approximation rollout of its own. The controls on this rollout are disabled unless you turn off the Lock to Top Level toggle. With this toggle turned off, you can choose approximation settings specific to this surface sub-object.
Tessellation group

Viewports When chosen, the rollout affects how surfaces in the NURBS object are displayed interactively in viewports, including shaded viewports, and by the preview renderer.

The Viewports surface settings are also used when you apply a mesh modifier such as Mesh Select to the NURBS object. This is important because the modifier can affect the scene's geometry.

Renderer When chosen, the rollout affects how surfaces in the NURBS object are displayed by the renderer.

The next cluster of buttons lets you choose which portions of the geometry are affected by the surface approximation settings.

Base Surface Settings affect the entire surface. This is the default.

Surface Edge Turn on to set approximation values for tessellating surface edges that are defined by trim curves. With Lock turned off, the surface and edge tessellation values are independent of each other.

For object-level surfaces, this is unavailable unless Lock (described below) is turned off.

Displaced Surface Turn on to set a third, independent approximation setting for surfaces that have a displacement map on page 6059 applied to them. Available only when Renderer is chosen.

Using a preset approximation setting (in the Presets group box) should give you faster results for displaced surfaces.

Lock (for object-level surfaces only) Locks the Base Surface settings to the Surface Edge settings. In other words, surfaces and surface edges have a relational tessellation setting unless Lock is turned off. Default=on.

Tessellation Presets group

Lets you choose a preset low, medium, or high quality surface approximation. While a preset is chosen, the values it uses are displayed on the Tessellation Method rollout.

Preset values are saved in the 3dsmax.ini on page 60 file. You can customize the preset values by using the Surface Approximation utility on page 2748.

Low Selects a (comparatively) low-quality surface approximation. These are the default values:

Viewports, Base Surface:
Method=Spatial and Curvature Edge=50.0 Distance=50.0 Angle=50.0 Merge=0.0
Advanced Parameters > Minimum=0, Maximum=3
Renderer, Base Surface:
Method=Spatial and Curvature Edge=20.0 Distance=20.0 Angle=15.0 Merge=0.01 Advanced Parameters > Minimum=0, Maximum=3
Renderer, Displaced Surface:
Method=Spatial and Curvature Edge=20.0 Distance=20.0 Angle=10.0 Merge=(Unavailable) Advanced Parameters > Minimum=0, Maximum=2
Keyboard shortcut: Alt+1

**Medium**(The default for both viewports and rendering.) Selects a medium-quality surface approximation. These are the default values:
Viewports, Base Surface:
Method=Spatial and Curvature Edge=20.0 Distance=20.0 Angle=15.0 Merge=0.0
Advanced Parameters > Minimum=0, Maximum=3
Renderer, Base Surface:
Method=Spatial and Curvature Edge=10.0 Distance=15.0 Angle=10.0 Merge=0.01 Advanced Parameters > Minimum=0, Maximum=4
Renderer, Displaced Surface:
Method=Spatial and Curvature Edge=10.0 Distance=10.0 Angle=4.0 Merge=(Unavailable) Advanced Parameters > Minimum=0, Maximum=3
Keyboard shortcut: Alt+2

**High** Selects a high-quality surface approximation. These are the default values:
Viewports, Base Surface:
Method=Spatial and Curvature Edge=5.0 Distance=15.0 Angle=10.0 Merge=0.0
Advanced Parameters > Minimum=0, Maximum=3
Renderer, Base Surface:
Method=Spatial and Curvature Edge=5.0 Distance=5.0 Angle=3.0 Merge=0.01 Advanced Parameters > Minimum=0, Maximum=4
Renderer, Displaced Surface:
Method=Spatial and Curvature Edge=5.0 Distance=5.0 Angle=2.0 Merge=(Unavailable) Advanced Parameters > Minimum=0, Maximum=4
Keyboard shortcut: Alt+3
NOTE  The keyboard shortcuts for surface approximation presets don't require that the Keyboard Shortcut Override Toggle be on. You can change the surface approximation of NURBS objects by selecting them in a viewport, and then using Alt+1, Alt+2, or Alt+3. This works for sub-objects as well, but the surface sub-object's Lock to Top Level toggle must be turned off.

Tessellation Method group

The controls in this group affect the display of the NURBS surface in viewports if you have chosen Viewports above, or by the renderer if you have chosen Renderer above. You can choose between five algorithms. Each approximates NURBS surfaces by tessellating them in a different way.

Generally speaking, if the preset values you have chosen give good results, you don't need to adjust the controls on this rollout. Adjust them if you encounter problems with the preset alternative.

Tips

- **Viewport Tessellation:** The tessellation method creates the mesh. If you modify the NURBS object with Mesh Select on page 1500, choose the method that gives the result you need. If you use modifiers heavily, Spatial or Parametric might be better than Curvature, because of their regular tessellation. Curvature-dependent tessellation can cause problems with some modifiers.

- **Renderer Tessellation:** Spatial and Curvature usually obtains the most accurate rendering. Curvature can be the more efficient choice when you render animated surfaces.

**Lock to Top Level** (for sub-object surfaces only) When on, the surface sub-object uses the same surface approximation settings as the top-level NURBS model, and other controls on this rollout are disabled. When turned off, you can set the sub-object approximation to differ from the top-level model. Default=on.

**Regular** Generates a fixed tessellation across the surface based on U Steps by V Steps. Increasing these parameters increases accuracy at a cost of speed, and vice versa, but in general this can be the quickest and least accurate way to approximate a NURBS surface. Very low values for U and V Steps using the Regular method usually doesn't provide good results. Model complexity increases slowly as U and V Steps values increase.
Regular mesh of the NURBS teapot

**Parametric** Generates an adaptive tessellation based on U Steps by V Steps. Low values for U and V Steps using the Parametric method often provide good results. Model complexity increases rapidly as U and V Steps values increase, so take care when you switch from Regular, which generally requires higher U and V values, to Parametric, where lower U and V values generally suffice. For example, if you convert a teapot to NURBS and set the U and V steps to 15, the Regular method generates 4470 faces but the Parametric method generates 204960 faces.

Parametric mesh of the NURBS teapot

**Spatial** Generates a uniform tessellation made of triangular faces. The Edge parameter specifies the maximum length of a triangular face in the tessellation. The value is a percentage of the object’s bounding box. Decreasing this value increases accuracy but increases rendering time.
Spatial mesh of the NURBS teapot

Curvature (The default.) Generates a variable tessellation based on the curvature of the surface. The tessellation has a finer grain where the surface is more curved. Changing surface curvature dynamically changes the curvature tessellation.

The Distance parameter specifies how far the approximation can deviate from the actual NURBS surface. Distance is a percentage of the diagonal of each surface's bounding box. Each surface in an object is tessellated based on its size, independently of other surfaces. Scaling a surface doesn't change its tessellation. Decreasing this value increases accuracy but increases rendering time. When you set Distance to 0.0, 3ds Max ignores this parameter and uses the Angle to control accuracy.

The Angle parameter specifies the maximum angle between faces in the approximation. Decreasing this value increases accuracy but increases rendering time. When you set Angle to 0.0, 3ds Max ignores this parameter and uses Distance to control accuracy.

When both Distance and Angle are 0.0, the surfaces degenerate and can become flat surfaces.
Curvature mesh of the NURBS teapot

**Spatial and Curvature** Combines the spatial (edge-length) method and the curvature (distance and angle) methods, using all three values.

The Edge parameter specifies the maximum length of a triangular face in the tessellation. The value is a percentage of the object's bounding box. Decreasing this value increases accuracy but increases rendering time. When you set Edge to 0.0, the effect is equivalent to the Curvature method.

The Distance parameter specifies how far the approximation can deviate from the actual NURBS surface. Distance is a percentage of the diagonal of each surface's bounding box. Each surface in an object is tessellated based on its size, independently of other surfaces. Scaling a surface doesn't change its tessellation. Decreasing this value increases accuracy but increases rendering time. When you set Distance to 0.0, 3ds Max ignores this parameter and uses the Edge and Angle values to control accuracy.

The Angle parameter specifies the maximum angle between faces in the approximation. Decreasing this value increases accuracy but increases rendering time. When you set Angle to 0.0, 3ds Max ignores this parameter and uses the Edge and Distance values to control accuracy.

When Distance, Angle, and Edge are all 0.0, the surfaces degenerate and can become flat surfaces.
View-Dependent (for the Renderer only) When on, takes the object's distance from the camera into account while calculating tessellation. This can improve rendering time by not generating fine-grained tessellations for objects in the distance of the rendered scene. The view-dependent effect works only when you render camera or perspective views. It doesn't work in orthographic views. This control is disabled while Viewports is active.

For the Spatial, Curvature, and Spatial and Curvature methods, the Distance and Edge values specify pixels instead of 3ds Max units when View-Dependent is on.

NOTE When View-Dependent is on, tessellation quickly reaches the maximum subdivision limit. You might want to increase this value to 7 (the greatest value allowed). See the description of Advanced Parameters, below.

Merge (sub-object surfaces only) Controls the tessellation of surface sub-objects whose edges are joined or very nearly joined. When input to a modifier (such as Mesh Select) requires a mesh, and when NURBS surfaces are tessellated for production rendering, by default 3ds Max adjusts the tessellation of adjoining surfaces to match each other, in terms of the number of faces along the edges. The Merge parameter controls how this is done. If Merge is zero, adjoining faces are unchanged. Increasing the value of Merge increases the distance 3ds Max uses to calculate how edges should match, guaranteeing no gaps between the surfaces when they are rendered. Default=0.0.

In most cases, you don't need to adjust Merge. If rendering shows gaps between nearly adjoining faces, increase Merge to eliminate them.

Technically, the Merge value is 0.1 percent of the diagonal of the object's bounding box. In other words, a Merge value of 1.0 (higher than necessary for most purposes) is 0.1 percent of the length of the diagonal. Because Merge
is based on the object’s dimensions, you can scale the NURBS model without affecting the Merge setting.

**Advanced Parameters** Click to display the Advanced Surface Approximation dialog on page 2747. The parameters in this dialog apply to the Spatial, Curvature, and Spatial and Curvature approximation methods.

**Clear Surface Level** (Appears only for top-level surfaces.) Clears all surface approximation settings assigned to individual surface sub-objects. When you click this button, all surface-specific approximations are lost, and Lock to Top Level is on for surface sub-objects.

### Advanced Surface Approximation Dialog (NURBS)

Modify panel > Select a NURBS surface object or surface sub-object. > Surface Approximation rollout > Tessellation Method group box > Turn off Lock to Top Level > Advanced Parameters button

Select an editable mesh object. > Modify panel > Surface Properties rollout > Advanced Parameters button

This dialog sets parameters that control the tessellation used in the Spatial, Curvature, and Spatial and Curvature approximation methods.

#### Interface

![Advanced Surface Approx. dialog](image)

**Subdivision Style**

Chooses the method used to subdivide the surface:
**Grid** Subdivides the surface using a regular grid.

**Tree** (The default.) Subdivides the surface using a binary tree.

**Delaunay** Subdivides the surface using nearly equilateral triangles.

---

**Delauney surface subdivision style**

**Subdivision Limits**

For Grid or Tree subdivisions, the limits control the number of recursive decompositions that are performed during tessellation.

**Minimum Subdivision Levels** Sets the minimum number of recursions. Default=0.

**Maximum Subdivision Levels** Sets the maximum number of recursions. The maximum can be no greater than 7. Be careful: setting the maximum greater than 5 can result in massive face counts and poor performance. Default=3.

**Maximum Number of Triangles**

For Delaunay subdivision, the Maximum Number of Triangles lets you specify the maximum number of triangles into which the surface will be divided. Default=20000.

---

**Surface Approximation Utility (NURBS)**

Utilities panel > Utilities rollout > More button > Utilities dialog > Surface Approximation
The Surface Approximation utility lets you change approximation and display settings without going into the NURBS model, and is especially useful for changing settings on multiple NURBS objects at once.

It has two rollouts, one for surface approximation and the other for surface display controls:

- **Surface Approximation Rollout** on page 2749
- **Surface Display Rollout** on page 2759

**Procedures**

To use the Surface Approximation utility:

1. On the Utilities panel, click the More button, and choose Surface Approximation from the list.
2. Set the desired options on the Surface Approximation and Surface Display rollouts.
3. Select the NURBS objects to apply the settings to.
4. On the Surface Display rollout, click Set Selected to apply the settings.

**Surface Approximation Rollout**

Utilities panel > Utilities rollout > More button > Utilities dialog > Surface Approximation > Surface Approximation rollout

The controls in the Surface Approximation rollout are the same as the surface approximation on page 2737 controls for NURBS on page 2416 surface objects, with two additional buttons: Set Selected and Reset.
**Iso Parametric Lines group**

The controls in this group box affect the display of the NURBS surfaces in viewports.

**U Lines and V Lines** The number of lines used to approximate the NURBS surfaces in viewports, along the surface's local U and V dimensions, respectively. Reducing these values can speed up the display of the surface, but reduce accuracy of the display. Increasing these values increases accuracy at the expense of time. Setting one of these values to 0 displays only the edge of the object in the corresponding dimension.

**Iso Only** When chosen, all viewports display iso line representations of the surface. Iso (parametric) lines are similar to contour lines. The lines show where the NURBS surface has a constant U value or V value or both. Iso line representations can be less crowded and easier to visualize than wire mesh representations.

**Iso and Mesh** (The default.) When chosen, wireframe viewports display iso line representations of the surface, and shaded viewports display the shaded surface.

**Mesh Only** When chosen, wireframe viewports display the surface as a wire mesh, and shaded viewports display the shaded surface.

In wireframe viewports, this option lets you see the surface approximation used for viewports.

![Iso and mesh displays of a NURBS teapot](image)
Viewports When chosen, the utility affects how surfaces in the NURBS objects are displayed interactively in viewports, including shaded viewports, and by the preview renderer.

The Viewports surface settings are also used when you apply a mesh modifier such as Mesh Select to the NURBS objects. This is important because it can affect the scene’s geometry.

Renderer When chosen, the utility affects how surfaces in the NURBS objects are displayed by the renderer.

Base Surface When on, settings affect entire surfaces in the selection set. Default=on.

Surface Edge When on, settings affect the tessellation of surface edges that are defined by trim curves.

Displaced Surface Enabled only when Renderer is chosen. Turn on to set a third, independent approximation setting for surfaces that have a displacement map on page 6059 or Displace on page 1313 modifier applied to them.

Load Tessellation Preset group

Lets you choose a preset low, medium, or high-quality level of surface approximation. While a preset is chosen, the values it uses are displayed in the Tessellation Method group box.

Preset values are saved in the 3dsmax.ini file. You can customize the preset values by using the buttons in the following group box, Save Tessellation Preset.

Low Selects a (comparatively) low-quality level of surface approximation. These are the default values:

**Viewports, Base Surface:**
Method=Spatial and Curvature
Edge=50.0
Distance=50.0
Angle=50.0
Merge=0.0
Advanced Parameters > Minimum=0, Maximum=3

**Renderer, Base Surface:**
Method=Spatial and Curvature
Edge=20.0
Distance=20.0
Angle=15.0
Merge=0.01
Advanced Parameters > Minimum=0, Maximum=3

**Renderer, Displaced Surface:**
Method=Spatial and Curvature
Edge=20.0 Distance=20.0
Angle=10.0 Merge=(Unavailable)
Advanced Parameters > Minimum=0, Maximum=2

**Medium** (The default for both viewports and rendering.) Selects a medium-quality level of surface approximation. These are the default values:

**Viewports, Base Surface:**
Method=Spatial and Curvature
Edge=20.0
Distance=20.0
Angle=15.0
Merge=0.0
Advanced Parameters > Minimum=0, Maximum=3

**Renderer, Base Surface:**
Method=Spatial and Curvature
Edge=10.0
Distance=15.0
Angle=10.0
Merge=0.01
Advanced Parameters > Minimum=0, Maximum=4

**Renderer, Displaced Surface:**
Method=Spatial and Curvature
Edge=10.0
Distance=10.0
Angle=4.0
Merge=(Unavailable)
Advanced Parameters > Minimum=0, Maximum=3

**High** Selects a high-quality level of surface approximation. These are the default values:

**Viewports, Base Surface:**
Method = Spatial and Curvature  
Edge = 5.0  
Distance = 5.0  
Angle = 3.0  
Merge = 0.01  
Advanced Parameters > Minimum = 0, Maximum = 4

Renderer, Base Surface:
Method = Spatial and Curvature  
Edge = 5.0  
Distance = 5.0  
Angle = 3.0  
Merge = 0.01  
Advanced Parameters > Minimum = 0, Maximum = 4

Renderer, Displaced Surface:
Method = Spatial and Curvature  
Edge = 5.0  
Distance = 5.0  
Angle = 2.0  
Merge = (Unavailable)  
Advanced Parameters > Minimum = 0, Maximum = 4

Save Tessellation Preset group

Click a button to save the current Tessellation Method settings as a new Low, Medium, or High preset. These values are saved in the 3dsmax.ini file.

NOTE  There is a separate Low, Medium, and High preset for Base Surface and Displaced Surface approximation. Check whether Base Surface or Displaced Surface is on before you use the buttons in this group box to save a custom preset.

Customizing preset values overwrites the default presets. To restore the defaults, you can re-enter the default preset values shown above, and then save them with the corresponding button. You can also restore defaults by editing the 3dsmax.ini file to delete the custom preset values.

When you customize the preset values, there is no necessary correlation between the button names and the quality of surface approximation. 3ds Max has no way of knowing how "good" a tessellation is, and you can save a very high-quality surface approximation in the Low preset, for example.

Tessellation Method group

The controls in this group box affect the display of the NURBS surfaces in either viewports, if Viewports is chosen, or by the renderer, if Renderer is
chosen. You can choose between five algorithms. Each approximates NURBS surfaces by tessellating them in a different way.

**NOTE** When Viewports is chosen, you must also choose Mesh Only in order to see the effect of the Mesh Parameter settings in wireframe viewports.

Generally speaking, if the preset values you have chosen give good results, you don’t need to adjust the controls in this rollout further. Use them if you encounter problems with the preset alternative.

**Tips**

- **Viewport Tessellation:** The tessellation method creates the mesh, so if you modify the NURBS object with Mesh Select, choose the method that gives the result you need. If you use modifiers heavily, Spatial or Parametric might be better than Curvature, because of their regular tessellation. Curvature-dependent tessellation can cause problems with some modifiers.

- **Renderer Tessellation:** Spatial and Curvature usually obtains the most accurate rendering. Curvature can be the more efficient choice when you render animated surfaces.

**Regular** Generates a fixed tessellation across the surface based on U Steps by V Steps. Increasing these parameters increases accuracy at a cost of speed, and vice versa, but in general this can be the quickest and least accurate way to approximate a NURBS surface. Very low values for U and V Steps using the Regular method usually doesn’t provide good results. Model complexity increases slowly as U and V Steps values increase.

**Parametric** Generates an adaptive tessellation based on U Steps by V Steps. Low values for U and V Steps using the Parametric method often provide good results. Model complexity increases rapidly as U and V Steps values increase, so take care when you switch from Regular, which generally requires higher U and V values, to Parametric, where lower U and V values generally suffice. For example, if you convert a teapot to NURBS and set the U and V steps to 15, the Regular method generates 4470 faces but the Parametric method generates 204960 faces.
Spatial mesh of the NURBS teapot

Spatial Generates a uniform tessellation made of triangular faces. The Edge parameter specifies the maximum length of a triangular face in the tessellation. The value is a percentage of the object’s bounding box. Decreasing this value increases accuracy but increases rendering time.

Curvature Generates a variable tessellation based on the curvature of the surface. The tessellation has a finer grain where the surface is more curved. Changing surface curvature dynamically changes the curvature tessellation. The Distance parameter specifies how far the approximation can deviate from the actual NURBS surface. Distance is a percentage of the diagonal of each surface’s bounding box. Each surface in an object is tessellated based on its size, independently of other surfaces, and scaling a surface doesn’t change its tessellation. Decreasing this value increases accuracy but increases rendering time. When you set Distance to 0.0, 3ds Max ignores this parameter and uses the Angle to control accuracy.
The Angle parameter specifies the maximum angle between faces in the approximation. Decreasing this value increases accuracy but increases rendering time. When you set Angle to 0.0, 3ds Max ignores this parameter and uses the Distance to control accuracy.

When both Distance and Angle are 0.0, the surfaces degenerate and can become flat surfaces.

Curvature mesh of the NURBS teapot

**Spatial and Curvature** (The default.) Combines the spatial (edge-length) method and the curvature (distance and angle) methods, using all three values. The Edge parameter specifies the maximum length of a triangular face in the tessellation. The value is a percentage of the object's bounding box. Decreasing this value increases accuracy but increases rendering time. When you set Edge to 0.0, the effect is equivalent to the Curvature method.

The Distance parameter specifies how far the approximation can deviate from the actual NURBS surface. Distance is a percentage of the diagonal of each surface's bounding box. Each surface in an object is tessellated based on its size, independently of other surfaces, and scaling a surface doesn't change its tessellation. Decreasing this value increases accuracy but increases rendering time. When you set Distance to 0.0, 3ds Max ignores this parameter and uses the Edge and Angle values to control accuracy.

The Angle parameter specifies the maximum angle between faces in the approximation. Decreasing this value increases accuracy but increases rendering time. When you set Angle to 0.0, 3ds Max ignores this parameter and uses the Edge and Distance values to control accuracy.

When Distance, Angle, and Edge are all 0.0, the surfaces degenerate and can become flat surfaces.

**View-Dependent** (for the Renderer only): When on, takes the object's distance from the camera into account while calculating its tessellation. This can
improve rendering time by not generating fine-grained tessellations for objects that are in the distance of the rendered scene. The view-dependent effect only works when you render camera or perspective views. It doesn't work in orthographic views. This control is disabled while Viewports is active.

For the Spatial, Curvature, and Spatial and Curvature methods, when View-Dependent is on, the Distance and Edge values specify pixels instead of the default 3ds Max units.

**NOTE** When View-Dependent is on, tessellation very quickly reaches the maximum subdivision limit. You might want to increase this value to 7 (the greatest value allowed). See the description of Advanced Parameters, below.

**Merge** Controls the tessellation of surface sub-objects whose edges are joined or very nearly joined. When input to a modifier (such as Mesh Select) that requires a mesh, and when NURBS surfaces are tessellated for production rendering, by default 3ds Max adjusts the tessellation of adjoining surfaces to match each other, in terms of the number of faces along the edges. The Merge parameter controls how this is done. If Merge is zero, adjoining faces are unchanged. Increasing the value of Merge increases the distance 3ds Max uses to calculate how edges should match, guaranteeing no gaps between the surfaces when they are rendered. Default=0.01.

In most cases, you don't need to adjust Merge. If rendering shows gaps between nearly adjoining faces, increase Merge to eliminate them.

Technically, the Merge value is one tenth of one percent of the diagonal of the object's bounding box. In other words, a Merge value of 1.0 (higher than necessary for most purposes) is 0.1 percent of the length of the diagonal. Because Merge is based on the object's dimensions, you can scale the NURBS model without affecting the Merge setting.

**Advanced Parameters** Click to display the Advanced Surface Approximation dialog on page 2747. The parameters in this dialog apply to the Spatial, Curvature, and Spatial and Curvature approximation methods.

**Clear Surfaces** When on, the settings you choose in this utility override all sub-object specific surface approximation settings in the selected NURBS models. When off, the utility affects top-level NURBS models but settings local to individual surface sub-objects remain unaffected. Default=Off.

**Set Selected** Applies the surface approximation values active in the utility to all selected NURBS objects.

**Reset** Resets the values in the utility to the default settings for a NURBS surface.
Surface Display Rollout

Utilities panel > Utilities rollout > More button > Utilities dialog > Surface Approximation > Surface Display rollout

The controls in the Surface Display rollout are the same as the display controls for NURBS surface objects, with two additional buttons: Set Selected and Reset.

Interface

Display group

Lattices When on, displays control lattices, in yellow lines. (You can change the lattice color by using the Colors panel on page 8272 of the Customize User Interface dialog. The Curve CV and Surface CV sub-object levels also have a local Display Lattice toggle, which overrides this global setting at the sub-object level. The Curve CV and Surface CV settings are independent. In other words, at the sub-object level, you can turn on the lattice for an object’s curves but not its surfaces, or vice versa.

Curves When on, displays curves.

Surfaces When on, displays surfaces.

Dependents When on, displays dependent sub-objects.
Surface Trims  When on, displays surface trimming. When turned off, displays all of a surface even if it’s trimmed.

Transform Degrade  When on, transforming a NURBS surface can degrade its display in shaded viewports, to save time. This is similar to using the Adaptive Degradation toggle for playing animations. You can turn off this toggle so surfaces are always shaded while you transform them, but transforms can take longer to create.

Button set

Set Selected  Applies the display settings active in the utility to all selected NURBS objects.

Reset  Resets the values in the utility to the default settings for a NURBS surface.

Tools for Low-Polygon Modeling

A few features help you manage the polygon count for scenes and animations that must not become too complex.

Show Statistics, available from the General viewport label menu on page 8117, lets you monitor the number of polygons, vertices, and so on, in the scene, as well as the frames per second displayed.

The Level of Detail utility, available from the Utilities panel on page 8223, lets you manage the complexity of an object in the scene. For example, Level of Detail enables you to display a complex object as simple geometry when the object is at a distance from the camera.

ProOptimizer is a modifier that helps you reduce the vertex and polygon count of high-resolution models. This feature is also available as a utility, which lets you run it as a batch process on one or more scene files.

Show Statistics

Click or right-click the General viewport label (“[ + ]”). > General viewport label menu on page 8117 > Show Statistics

Keyboard > 7

You can quickly access various statistics related to your current selection and entire scene.
NOTE These statistics are relevant primarily to mesh and poly objects. Some statistics information might be unavailable with certain other types of object.

Procedures

To use the viewport statistics display:

1. Customize the statistics display on the Customize menu > Viewport Configuration dialog > Statistics panel.
2. Activate the viewport in which to display statistics.
3. Toggle the statistics display by pressing 7 or right-clicking the viewport label and choosing Show Statistics.

Interface

You can customize the viewport statistics by turning on and off options on the Statistics on page 8390 panel of the Viewport Configuration dialog. The following statistics reflect all options turned on.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Polys</td>
<td>Displays the number of polygons in the scene and selection.</td>
</tr>
<tr>
<td>Tris</td>
<td>Displays the number of triangle faces in the scene and selection.</td>
</tr>
<tr>
<td>Edges</td>
<td>Displays the number of edges in the scene and selection.</td>
</tr>
<tr>
<td>Verts</td>
<td>Displays the number of vertices in the scene and selection.</td>
</tr>
<tr>
<td>FPS</td>
<td>The frames per second displayed in the viewport.</td>
</tr>
</tbody>
</table>

NOTE This is valid only for poly objects.

NOTE If you select a polygon in a poly object, this option shows two or more triangles.
Level of Detail Utility

Utilities panel > Utilities rollout > More button > Utilities dialog > Level of Detail

The Level Of Detail utility lets you construct an object that alters its geometric complexity or level of detail based on its size in the rendered image. You create several versions of the same object each with different levels of detail, group them as one, and then run the Level Of Detail utility, which automatically creates a special LOD controller as a Visibility track. The LOD controller then hides and unhides the objects in the group, depending on their size in the rendered scene.

The main purpose of this utility is to save time in rendering complex objects and in manipulating objects in the viewports. Since a portion of rendering speed is directly related to the number of faces that must be rendered in a scene, using the Level Of Detail utility lets you reduce the number of rendered faces as an object reduces its apparent size. In addition, you can use this utility to display a simple stand-in for a more complex object in the viewports. Since the stack is not calculated for objects hidden in the viewports, you can speed up viewport manipulation by using this utility to substitute complex stack objects with simple stand-ins.

Procedures

To set up an object for the Level Of Detail utility:

1 Create two or more objects that are identical except for their complexity.

   NOTE It's best to assign materials and mapping coordinates, as well as all modifiers while the objects are still separate.

2 Select all of the objects, and use the Align tool to center all of them about a common center.

3 Group the objects.

4 Choose the Level Of Detail utility.

5 While the grouped object is selected, click the Create New Set button. The name of the objects within the group appear in the Level Of Detail list, in order of complexity; only the least complex object in the group is displayed in the viewports, while all other objects are made invisible.
Use the controls in the Level Of Detail rollout to adjust when the objects will switch their display in the rendered scene.

To access an object's stack:

1. Select the Level Of Detail object, and then choose Group menu > Open.
2. In the Level Of Detail utility, choose the object you want to access from the list window, and then turn on Display In Viewports (or double-click the object's name in the list window).
3. Select the object in the viewport.
4. Open the Modify panel to access that object's parameters.
5. When finished, choose Group menu > Close.

To assign materials within the group:

1. Select the grouped object.
2. Use Display In Viewports in the Level Of Detail utility to display the grouped object you want to assign the material to.
3. Drag the material from the Material Editor (or the Browser) over to the object in the viewport.
4. Choose Assign To Object in the Assign Material alert, and then click OK.

**NOTE** Be sure and choose Assign To Object. If you choose the default Assign To Selection, all objects in the group will be assigned the same material.

To dismantle a Level Of Detail object:

If you look at a Level Of Detail object in Track View, you'll see only the tracks for the sub-object that's currently displayed in the viewports. To see all sub-objects in Track View, you need to turn off Visible Objects.

If you need to dismantle a grouped Level Of Detail object, and restore its sub-objects to their independent states, follow these steps:

1. Open the Filters dialog in Track View, and turn off Visible Objects in the Show Only group box.
2. The tracks for all of the sub-objects in the Level Of Detail object are now visible.
3 Open the hierarchy of each of the sub-objects, and then select each of their Visibility tracks.

4 On the Track View toolbar, click the Delete Controller button.

5 If you also want to remove the grouping, select the grouped objects, and then choose Explode in the Group menu.
Interface

Level of Detail Set group

Lets you create a new set, and add or remove objects from the current set.
Create New Set  Creates a new Level of Detail set based on a currently selected group object.

Add To Set  Adds an object to the Level of Detail set. You must first attach the object you want to add to the group object. To add an object to the set, use Align to center the object with the group object. Select the object you want to add, and then choose Attach from the Group menu, and then click the group object. Finally, click the Add to Set button, and then click the object you want added.

Remove from Set  Removes the object highlighted in the list window from the current set. Note that the object then becomes visible in the viewports, but is still part of the group. To remove the object from the group, choose Group menu > Open, select the object you want removed, and choose Group menu > Detach. Select the group object again, and choose Group menu > Close.

Image Output Size group

Width/Height  The Width and Height spinners in this area are set to the current rendering output size each time you enter the Level of Detail utility. Using the spinners, you can change this to any resolution. If the percent of Target Image option is selected, as you change the Target Image Size, the threshold values change as well.

Reset to Current  Resets both spinners to the current rendering output size.

List window  Lists all of the objects in the group by complexity, with the least complex at the top of the list. The numbers at the left of each object name are the threshold values that indicate at what size the object will be displayed in the rendered scene. The numbers can be one of two types of units, pixels, or percentage of the target image. You set the type of unit in the Threshold Units group.

Display in Viewports  Displays in the viewport the object highlighted in the list window. Only one object in the group is displayed in the viewports at any time. As a default, the least complex object is displayed, but you can look at the other objects by highlighting them in the list and selecting this item. Double-clicking the object name in the list performs the same function.

Threshold Units group

The options in this group box let you choose between two types of threshold units. Switching between these two options does not alter the effect; it alters the method by which you set the thresholds.
**Pixels** The thresholds are determined by specifying the maximum pixel size of the image (measured diagonally). Use when you want to set the transfer thresholds using absolute rather than relative values.

**% of Target Image** Sets the thresholds based on the percentage of the size of the image (measured diagonally) relative to the size of the rendered output.

**Thresholds group**

**Min Size/Max Size** Sets the minimum size of the object before it's replaced by the less complex object, and the maximum size of the object before it's replaced by the more complex object. The values vary depending on the current type of Threshold Unit. The default threshold values are initialized so that the most complex object is 100 percent of the image output size. The remaining thresholds are set using an algorithm based on a ratio of the number of faces between each object. It assumes that all faces are the same size, and then picks thresholds so that the faces would remain a constant size as displayed on the screen. Usually, this will provide the type of smooth transition you need, but you can customize the threshold values. The threshold values are interrelated between the objects, so altering the minimum size of one object, for example, will also alter the maximum size of the next object.

**Reset All** Resets all thresholds for all objects in the list, using the previously described algorithm.

**TIP** You can use the Level of Detail utility to create objects that display very simple geometry in the viewports, while displaying complex geometry in the rendered scene. Create a grouped Level of Detail object consisting of only two objects, the complex object and the simple object. Select the simple object in the list window and, in the Thresholds are, set its Min Size and its Max Size to 0. This will display the simple object in the viewports, but the complex object will always appear in the rendered scene, regardless of its apparent size.

**Close button**

**Close** Closes the utility.

**Optimization Modifiers**

A few 3ds Max modifiers can help you lower the polygon count of your models.

- **MultiRes** on page 1537
The MultiRes modifier reduces the memory overhead needed to render models by decreasing the number of vertices and polygons. This is useful not only within 3ds Max, but for content creators who export models for use outside of 3ds Max, such as in Web-based 3D applications. MultiRes offers several advantages over the Optimize modifier, including faster operation and the ability to specify reduction as an exact percentage or vertex count.

- **Optimize on page 1557**
The Optimize modifier lets you reduce the number of faces and vertices in an object. This simplifies the geometry and speeds up rendering while maintaining an acceptable image. A Before/After readout gives you exact feedback on the reduction as you make each change.

- **ProOptimizer on page 1614**
The ProOptimizer modifier lets you select objects and interactively optimize them.

ProOptimizer is also available as a Batch ProOptimizer utility on page 2768, described in this chapter. This utility lets you optimize multiple scene files at the same time.

### Batch ProOptimizer Utility

Utilities panel > Utilities rollout > More button > Utilities dialog > Batch ProOptimizer

The Batch ProOptimizer utility lets you optimize multiple scene files at the same time. You can optimize 3ds Max (MAX) or Wavefront (OBJ) files.

The ProOptimizer feature is an optimization tool that helps you reduce the number of vertices (and so the number of faces) in an object while preserving the object’s appearance. Options let you maintain material, mapping, and vertex color information in the optimized model.

Optimizing objects can reduce a scene’s memory requirements, simplify modeling because objects have fewer faces, and improve the speed of viewport display and rendering time.

There are two ways to use ProOptimizer:

- **The ProOptimizer modifier on page 1614** lets you select objects and interactively optimize them.
The Batch ProOptimizer utility, described here, lets you optimize multiple scene files (MAX or OBJ files) at the same time.

**TIP** With the Batch ProOptimizer, you can optimize meshes before you import them. This can save time. The Batch ProOptimizer is also a good choice if the original meshes are extremely dense.

Original model
Vertices: 47226
Faces: 93792

Optimized model, Vertex % = 10.0
Batch ProOptimizer Rollout

Utilities panel > Utilities rollout > More button > Utilities dialog > Batch ProOptimizer > Batch ProOptimizer rollout

The Batch ProOptimizer rollout contains a couple of options, and also lets you open the Batch Optimization dialog, which contains the main controls for this utility.
Interface

**Batch Optimization** Click to open the **Batch Optimization dialog** on page 2771.

**Options group**

**Apply Modifier** When on, applies modifiers to objects before optimizing them. After optimization, ProOptimizer collapses the stack. Default=on.

When off, ProOptimizer optimizes base objects only, and does not collapse the stack.

**Validate 3ds Max dialogs automatically during batch processing** Opening and saving files can cause 3ds Max to display dialogs; for example, warnings about missing bitmaps or MAX files that were saved with an earlier version.

When on, ProOptimizer confirms these dialogs. This option prevents the dialog appearing interactively, interrupting the batch process and forcing you to intervene. Default=on.

When off, ProOptimizer does not confirm dialogs. If a 3ds Max dialog appears during batch processing, you must click to confirm it before the batch process continues.

**Batch Optimization Dialog**

Utilities panel > Utilities rollout > More button > Utilities dialog > Batch ProOptimizer > Click Batch Optimization. > Batch Optimization dialog
The Batch Optimization dialog lets you set up and launch a batch optimization task.

The first time you click Batch Optimization, ProOptimizer displays a dialog warning you to close any modeless 3ds Max dialogs and windows that might be open. The batch process runs more quickly if all such dialogs are closed before you begin.

If your current scene has unsaved changes, the ProOptimizer utility also prompts you to save the scene.
Interface

The Batch Optimization dialog has three panels, described in the topics that follow.

**Batch Optimization: Source Files Panel**

Utilities panel > Utilities rollout > More button > Utilities dialog > Batch ProOptimizer > Click Batch Optimization. > Batch Optimization dialog > Source Files panel

On the Source Files panel, you choose which files to optimize.

For options on how to save the optimized files, see Batch Optimization: Optimized Files Panel on page 2777.
Interface

- **Source Directory**
  - File Selection (no file selected)
  - Current Directory (C:\Program Files\Autodesk\3ds Max 2009\)
  - Selected Directory

- **Include Subdirectories**

**File Selection** Lets you choose an one or more files to optimize.

- **Select** Click to open a file selector that lets you choose the file or files to optimize.

**Current Directory** (The default.) Batch optimizes all the eligible files (MAX or OBJ files) in the current directory.

**Selected Directory** Batch optimizes all the eligible files (MAX or OBJ files) in the selected directory.

- **Browse** Click to display a directory browser that lets you choose the directory to process.

**Include Subdirectories** When on, ProOptimizer scans subdirectories and batch processes the eligible files in them. When off, it processes only files in the specified directory (the root). Default=on.

This option is disabled when File Selection is active.

**Batch Optimization: Optimization Panel**

Utilities panel > Utilities rollout > More button > Utilities dialog > Batch ProOptimizer > Click Batch Optimization. > Batch Optimization dialog > Optimization panel

On the Optimization panel, you choose the optimization levels to generate, and the options that will be active.

These settings are comparable to those for the ProOptimizer modifier on page 1614. The main difference is that you can choose to generate multiple files, each of which has a different level of optimization.
This panel is inaccessible if you haven’t used the Source Files panel to choose at least one file or directory to optimize. If you haven’t done so, this alert appears when you click the tab:

![Batch ProOptimizer Alert](image)

**Interface**

![Batch ProOptimizer Interface](image)

**Optimization Level group**

The controls in this group are comparable to the Vertex % control for the modifier (see ProOptimizer Modifier on page 1614), but allow you to generate multiple optimized scenes during batch processing.
**Predefined Vertex %** When Predefined Vertex % is active, you can generate up to five optimized files, using Vertex % values that you enter yourself. Defaults = 25, 50, 65, 75, 90.

If you enter fewer than five values, ProOptimizer generates only as many optimized files as Vertex % values you specify.

**Automatic Vertex %** When Automatic Vertex % is active, ProOptimizer generates multiple optimized files at regular Vertex % intervals. Each interval is greater than zero and less than 100 percent (zero percent would leave no geometry at all, and 100 percent is just the original model).

The number you choose is the number of optimized files that ProOptimizer generates. Default=9.

For example, at the default count of 9, the optimized files use Vertex % values of 10, 20, 30, through 90. If you change the count to 3, the Vertex % values used are 25, 50, and 75. A count of 50 (too large to be practical) would use Vertex % values of 2, 4, 6, through 98.

For options on how to save the optimized files, see Batch Optimization: Optimized Files Panel on page 2777.

**Optimization Options group**

**Crunch Borders / Protect Borders / Exclude Borders** See Optimization Mode Group on page 1621.

**Optimize Hidden Objects** When on, ProOptimizer optimizes hidden objects as well as visible ones. When off, ProOptimizer optimizes visible objects only. Default=on.

**Merge Vertices** When on, applies the Merge Vertices tool before optimizing. Default=off.

**TIP** Use this tool if a model has faces that are disconnected, but should not be.

- **Threshold** The Threshold setting for the Merge Vertices tool. See Merge Tools Group on page 1634.

**Merge Faces** When on, applies the Merge Faces tool before optimizing. Default=off.

**TIP** Use this tool if the model has surfaces that are subdivided into coplanar faces.

- **Threshold Angle** The Threshold Angle setting for the Merge Faces tool. See Merge Tools Group on page 1634.
**Materials and UVs group**

These are equivalent to the modifier options. See Materials and UVs Group on page 1625.

**Vertex Color group**

These are equivalent to the modifier options. See Vertex Colors Group on page 1629.

**Symmetry Options group**

These are equivalent to the modifier options. See Symmetry Options Rollout on page 1638.

**Normals group**

These are equivalent to the modifier options. See Normals Group on page 1632.

**Advanced Options group**

These are equivalent to the modifier options. See Advanced Options Rollout on page 1639.

---

**Batch Optimization: Optimized Files Panel**

Utilities panel > Utilities rollout > More button > Utilities dialog > Batch ProOptimizer > Click Batch Optimization. > Batch Optimization dialog > Optimized Files panel

On the Optimized Files panel, you choose the location of the generated files, their file name format, and file format.

This panel is inaccessible if you haven’t used the Source Files panel to choose at least one file or directory to optimize. If you haven’t done so, this alert appears when you click the tab:
Interface

File Names group

These options tell ProOptimizer how to name the files it generates.

Number by order of creation (The default.) When this option is active, ProOptimizer gives the files it generates the name of the original file, followed by a value that shows the order in which the file was created.
Number by optimization level When this option is active, ProOptimizer gives the files it generates the name of the original file, followed by a value that shows the optimization level (Vertex % value) used to create the file.

Auto rename duplicate files When on, ProOptimizer renames each file it generates if there is a conflict with the name of an existing file. When off, ProOptimizer overwrites existing files that have the same name. Default=on.

Prefix to add to the name Lets you specify a prefix to add to the name of all files generated by ProOptimizer.

Suffix to add to the name Lets you specify a suffix to add to the name of all files generated by ProOptimizer.

Optimized Files Directory group

These options tell ProOptimizer where to save the files it generates.

In the same directory as the source files When active, ProOptimizer saves optimized files in the same directory as the source files.

In a subdirectory of the source files (The default.) When active, ProOptimizer saves optimized files in the directory whose name is shown in the Directory Name field.

In the selected directory When active, you can click the Browse button to choose a particular directory in which to save the optimized files.

Directory Name field When you choose either a subdirectory or specify a particular directory, this field shows the name of the directory used. Default="\Results".

NOTE The combination of defaults means that by default, optimized files are saved in a folder named Result, which is a subdirectory of the directory where the source files are located.

- Browse When “In the selected directory” is active, click Browse to display a directory browser that lets you choose the folder in which to save the optimized files.

Re-create directory tree When on, and “In the selected directory” is active, ProOptimizer creates subdirectories that match the original source tree. When “In a subdirectory of the source files” is active, this option is always on. Default=on.

This option is disabled if you turn off Include Subdirectories on the Source Files panel on page 2773.
**Optimized Files Format group**

With these options, you can choose the format of the generated files.

**Keep source file format if possible, otherwise convert to selected format** (The default.) When active, optimized files are saved in the same format as the source file, unless this is impossible for some reason, in which case they are saved in the format specified by the drop-down list.

**Convert to the selected format** When active, optimized files are saved in the format specified by the drop-down list.

**File Format drop-down list** Lets you choose between MAX (3ds Max) or OBJ (Wavefront) file formats.
Precision and Drawing Aids

3ds Max provides tools that give you control over the positioning and alignment of objects in 3D space. With these tools, you can do the following:

- Choose display units from the most common real-world measuring systems or define your own.
- Use the home grid as a construction plane, or use grid objects to position custom construction planes.
- Select different options to align objects with grids, points, and normals.
- Use 3D object snaps on a modeless dialog as you build and move geometry in your scene. Grid points and lines are among the many snap options.
- Use "helper objects" in your work. This category includes grid objects as well as objects used for positioning and measurement.
Tools for Precision

A set of interrelated tools in 3ds Max gives you precise control of the scale, placement, and movement of objects in your scene. These are especially important tools for those who build precise models in real-world units of measurement.

Basic Tools

The tools for precision are grouped as follows:

Units Define different measurement systems. Besides the generic unit, you have your choice of feet and inches in both decimals and fractions. Metric units range from millimeters to kilometers. You can also define other units.
See Using Units on page 2784.

**Grids** Include the home grid and special grid objects. Both types of grid can act as construction planes. 3ds Max constructs objects using the orientation and position of the active grid. While the home grid is fixed in world space, you can rotate grid objects and place them anywhere in a scene, and align them to other objects and surfaces. You can also give each grid object its own spacing, and display any grid as a dedicated viewport.

See Using Grids on page 2785.

**Object alignment** Matches an object with the position, orientation, or normal of another object, or to a point in space.

See Alignment on page 2799.

**Object snaps** Ensure precise placement when creating and rearranging objects. Keyboard shortcuts let you change object snaps as you work. You can also set snaps to find grid lines and intersections. An angle snap sets the increment for rotation, and a percent snap sets the increment for scaling.

See Using Snaps on page 2804.

**Helpers** These are specialized tools in the same category as grid objects. For example, the Tape object measures distances in current units, and the Protractor object measures angles. The Dummy helper is useful in constructing hierarchies, and the Manipulator helpers let you use custom controls in the program interface.

See Helpers on page 2837.

**Additional Tools** Rounding out the set of precision aids are tools and utilities for checking geometry, measurement, and rescaling units.

See Drawing Assistants on page 2873.

**How the Tools Work Together**

The tools themselves establish a general order of use and interaction, although you can always change settings as needed without following this sequence.

- Choose a measuring unit. The default is generic units, sufficient for many purposes.
- Set grid spacing (the size of the smallest square), based on the measuring unit. The home grid and grid objects can have their own spacing, separate from the grid spacing.
- Move and align grid objects to a useful orientation.
Set or vary snap settings as needed in your work.

Use other helper objects like Point and Tape as part of the precision process.

As you work, you can change your settings (including the measuring unit) without losing any precision.

### Using Units

Units are the key to connecting the three-dimensional world of 3ds Max with the physical world. You define the units you want to use from the Units Setup dialog on page 8366.

#### Changing Display Units

When you change display units, 3ds Max displays measurements in the new unit for your convenience. All dimensions are displayed in the new unit. Essentially, you’re using a new “measuring stick.” No object is changed in this process. As in the physical world, objects in the scene maintain their absolute size, regardless of how you measure them.

#### Type-In Entry

When you enter any dimension, 3ds Max always assumes the number you enter is expressed in the current units. You can also enter a series of numbers: 3ds Max then converts their sum into the current unit. Here are some examples that assume the current units are in centimeters:

- When you enter a dimension of 1’ (one US foot), it converts to 30.48cm.
- If you enter a series of numbers such as 14 286 175 (separated by spaces), the series is totaled to 475.0cm.
- If you enter 1’ 1 (one US foot and 1 centimeter), this is converted and summed into 31.48cm.

When you use US Standard as the display unit scale, you can select either feet or inches as the default for type-in entry. If you select feet and enter 12, the result is 12’ 0”. However, if you enter 1’ 2, 3ds Max identifies the second digit as inches, producing 1’ 2” as the result.
In any unit system, you can enter fractional amounts. For example, assume you’re working in US Standard with feet as the default:

- If you enter 18/3, the result is 6'0".
- If you enter 18/3", the result is 0'6".
- You can specify units in a different system, and they are converted on the fly. For example, if you enter 18/3cm, the result is 0'2.362".

**Understanding the System Unit**

3ds Max keeps track of all measurements in its own internal system unit. No matter what kind of display units you use, measurements are stored in this absolute unit for storage and computation. The default system unit is defined as 1.000 inch. As long as the system unit is left at one inch, you can freely share models and change units on the fly with no effect on the underlying geometry. Except in rare circumstances, you never need to change this default scale. This means you can merge a model created with any standard unit into your scene at true scale.

You can change the system unit setting on the System Unit Setup dialog, available from the Units Setup dialog on page 8366. Changing the system unit is recommended only if your scene has very small (less than one inch) or very large dimensions. See System Unit Setup Dialog on page 8370 for more information.

If you do need to change the system unit, change it before you create or import geometry. Do not change the system unit in an existing scene.

**Using Grids**

Grids are two-dimensional arrays of lines similar to graph paper, except that you can adjust the spacing and other features of the grid to the needs of your work.
One grid establishes the pitch of the boat, another the pitch of the ship

Grids have these primary uses:

- As an aid in visualizing space, scale, and distance.
- As construction planes where you create and align objects in your scene.
- As a reference system for using the Snap feature to align objects.

Home Grid and Grid Objects

3ds Max provides two kinds of grids: the home grid and grid objects. In addition, it includes the AutoGrid feature, an automated way of creating grid objects.

Home grid The home grid is defined by three planes along the world X, Y, and Z axes. Each of these axes passes through the world coordinate system’s origin point (0,0,0). The home grid is fixed; it cannot be moved or rotated.
- The home grid is visible by default when you start 3ds Max, but its display can be turned off.
You can use any view of the home grid as a construction plane by drawing in the viewport in which the grid's view appears.

See Viewing and Navigating 3D Space on page 65 for a complete introduction to the home grid.

Grid objects A grid object is a helper object you can create whenever you need a local reference grid or construction plane somewhere other than the home grid.

- You can have any number of grid objects in your scene, but only one can be active at a time.
- When active, a grid object replaces the home grid in all viewports.
- Each grid object has its own set of XY, YZ, and ZX planes. You can freely move and rotate grid objects, placing them at any angle in space, or attach them to objects and surfaces.
- You can change a viewport to display a plan (top) view of any active grid object.
- Grid objects can be named and saved like other objects, or used once and deleted.

AutoGrid This feature lets you create new objects and grid objects off the surfaces of other objects on the fly. See AutoGrid on page 2792.

Using the Home Grid

The home grid provides ready-to-use construction planes, much like a leveled building site marked with stakes and strings. When you create an object in a viewport, the new object is placed on the home grid plane of that viewport.

To use the home grid effectively for construction, you often need to change the defaults to the job at hand, analogous to moving the stakes and strings to match your own site plan.
Using the home grid to position houses

Changing Home Grid Settings

The home grid is a single system; its three planes use the same settings for grid spacing and major line divisions. You change these settings from a single panel of the Grid and Snap Settings dialog.

To access the Home Grid panel, do one of the following:

1. Choose Tools menu > Grids And Snaps > Grid And Snap Settings, then click the Home Grid tab.
2. Right-click any snap button on page 2807, then click the Home Grid tab.

Setting Grid Spacing

Grid spacing is the size, in current units, of the grid's smallest square. The basic idea is to choose a grid spacing that corresponds to your unit of measurement, then choose a larger spacing for multiple units.

For example, if you have units set to centimeters, you might make one grid space equal to 1.000 (one unit, or one centimeter in this case).
Setting Major Grid Divisions

The home grid displays heavier or “major” lines to mark groups of grid squares. You can use these to represent larger units of measurement.

For example, if you use a grid spacing of one centimeter, you might use a value of 10 so the major grid divisions represent one decimeter.

Setting Color and Intensity

To improve grid visibility, you can change the intensity or color of the home grid. Choose Customize menu > Customize User Interface > Colors panel on page 8272.

Using Grid Objects

Grid objects let you bypass the home grid and work on separately defined grids to create and position objects. You can use as many grid objects as you like, each serving as a custom construction plane with its own grid settings.
Grid objects are 2D parametric objects, with adjustments for overall size and grid spacing. You can adjust their orientation in world space, and match them to a particular surface or object.

**To activate a grid object:**
1. Create or select a grid object.
2. Choose Views > Grids > Activate Grid Object.

**To deactivate a grid object, do one of the following:**
- Select and activate another grid object.
Choose Views > Grids > Activate Home Grid.

Delete the grid object.

Creating and Modifying Grid Objects

You find Grid objects in the Create panel > Helpers category.

When creating an object, you can also create a temporary "AutoGrid" grid object that's tangent to an existing object surface at the point you click. To do this, turn on the AutoGrid on page 2792 check box in the Object Type rollout. You can save this grid by holding the Alt key before you click.

Grid objects are named when you create them and are saved with the scene. You can delete them at any time.

Like other objects created in 3ds Max, standard grid objects are placed on the grid of the current viewport. By default, this is a plane of the home grid, but can also be another activated grid object.

For more information on grid object settings, see Grid on page 2847.

Viewing Grid Objects

An activated grid helper object on page 2847 creates a true plane in 3D space. No matter how small an activated grid object appears on the screen, its plane is effectively infinite, just as if it were a plane of the home grid. However, you can view a given grid object in different ways.

Setting the Display Plane

You can adjust the visible plane of a selected or activated grid object on the Modify panel.

To set the display plane:

1. Open the Modify panel to display the Parameters rollout for the selected grid.

2. In the Display group, choose any of the three planes: XY, YZ, or ZX. The grid rotates in world space to display the corresponding plane, always based on the grid's local axis.

You can move or rotate a grid, either before or after setting its display plane.
Setting Grid Views

You can set the view in any viewport to an orthographic view as well as the display view.

To set grid view:

1. Activate the grid object. on page 2850
2. Click or right-click the Point-Of-View (POV) viewport label and from the
   POV viewport label menu on page 8122 choose Grid to display a submenu
   of possible views.
3. Choose Front, Back, Top, Bottom, Right, Left, or Display Planes. Display
   Planes corresponds to the current setting on the Parameters rollout (XY,
   YZ, or ZX).
   The viewport now shows this view of the grid.

You can set different viewports to different views of the grid. Objects are always
created on a view's orthographic grid, even if you rotate the angle of view. In
other words, you can set up a convenient view and still construct on the
chosen plane.

Deactivating Grid Objects

You can deactivate a grid object in any of the following ways:

- Select and activate another grid object.
- Choose Views > Grids > Activate Home Grid.
- Delete the grid object.

When you deactivate a grid object, any viewports based on that grid switch
to the corresponding orthographic view. For example, a Grid (Front) viewport
becomes a Front viewport. A Grid (Display Planes) viewport always switches
to Top view, regardless of the currently displayed plane.

AutoGrid

Create panel > Any object category > Object Type rollout
Extras toolbar > AutoGrid

AutoGrid lets you automatically create, merge, or import objects on the surface of other objects by generating and activating a temporary construction plane based on normals of the face that you click. This serves as a more efficient way of stacking objects as you create them, rather than building objects and then aligning them as a separate step.
AutoGrid used to position the second block on top of the first

You can use objects within an XRef scene as reference when AutoGrid is on.

**NOTE** If the Smooth check box is turned on in the Parameters rollout of a parametric object, the construction plane is placed tangent to the face of the surface implied by any smoothing present on the surface, not the actual face of the surface.

**Procedures**

Example: To create a box aligned to another object using a temporary construction grid:

1. Create or load a scene containing an object to which you want to align a new box.

2. On the Create panel > Standard Primitives > Object Type rollout, click Box.

3. Turn on AutoGrid.
4 Merge the object you want aligned.

5 Move your cursor over the object to which you want to orient the box you are about to create.
The cursor includes an X,Y,Z tripod to help you orient the position of the new object. As you move over the object, the cursor aligns the Z axis to the surface normal.

6 When the orientation is as you want it, click and use the standard drag-release-move-click method to create the box. The box will be created on the designated surface.

When you click, a temporary, automatic grid is created, and the newly created object is aligned to that grid.

Interface

Object Type rollout

AutoGrid AutoGrid is available only after you select an object button (such as Box). When you turn AutoGrid on, the cursor includes an axis tripod to help you orient the grid. Before clicking and as you position the cursor over a visible mesh object, the cursor jumps to the nearest point on that surface. The tripod's X and Y axes form a plane tangent to the object surface (forming an implied construction grid), and the Z axis is perpendicular to the plane. After creating the object, 3ds Max places it on the temporary construction grid. When creating an object, if the cursor isn't over another object, 3ds Max places the object on the current active grid.

TIP When you create an object that requires multiple clicks, AutoGrid applies only to the first click. So, for instance, if you want to create a Line spline on page 584 that snaps to the faces of a sphere, turn on Snaps on page 2807 (press the S key), and then open the Grid And Snap Settings dialog on page 2819 and turn on Face.
**NOTE** To make the grid permanent, hold down the Alt key before you click. The grid becomes active and 3ds Max turns AutoGrid off.

**Grid Commands**

Tools menu > Grids and Snaps

The Grids commands on the Tools menu > Grids And Snaps submenu provide functions to manipulate the home grid on page 8600 and grid objects on page 8597.

The Snaps system uses grids both as visual references and as physical snap references. In addition, grids serve as construction planes, because the objects you create are built on the active grid in the active viewport.

As a default, 3ds Max uses a construction grid called the home grid. The home grid is the basic reference system, and is defined by three fixed planes on the world coordinate axes. It provides ready-to-use construction planes, intersecting at right angles through the origin. When the home grid is displayed, each orthographic viewport on page 8668 is coplanar (parallel) with one of the grid faces.

A custom grid, or grid object, is a helper object that you can use in place of the home grid. While the home grid is three intersecting planes whose orientation is fixed in world space, a grid object is a free-floating, 2D grid that you can position anywhere and rotate freely, letting you construct objects at any angle in world space. You can also generate grids automatically on existing geometry when creating objects by using AutoGrid on page 2792.

**Show Home Grid**

Views menu > Grid > Show Home Grid

Click or right-click the General viewport label (“+”). > General viewport label menu on page 8117 > Show Grids

Keyboard > G

Show Home Grid toggles the display of the home grid on page 8600 in the active viewport.

Grids are used both as visual references and as physical snap references by the Snap system. In addition, grids are construction planes, since the objects you create are built on the active grid in the active viewport.
As a default, there is a home construction grid called home grid. The home grid is the basic reference system, and is defined by three fixed planes on the world coordinate axes. It provides ready-to-use construction planes, intersecting at right angles through the origin. When the home grid is displayed, each orthographic viewport on page 8668 is coplanar (parallel) with one of the grid faces.

**Procedures**

To toggle the display of the home grid, do one of the following:

1. Choose Views menu > Grids, and click Show Home Grid.
2. Click or right-click the General viewport label (“[ + ]”) and choose Show Grids on the General viewport label menu on page 8117.
3. Press G on the keyboard.

**Activate Home Grid**

Activate a grid other than the Home grid. > Views menu > Grids > Activate Home Grid

This command activates the home grid on page 8600 as the construction grid, and deactivates the active grid object on page 8597.

**Procedures**

To return to the home grid, do one of the following:

- Choose Views menu > Grids > Activate Home Grid.
- Right-click the selected grid object, and choose Activate Home Grid from the quad menu.
  
  This deactivates the grid object and activates the home grid in all views.

**Activate Grid Object**

Select a grid object. > Views menu > Grids > Activate Grid Object
This command activates the selected grid object on page 8597 as the construction grid and deactivates the home grid on page 8600. This menu item is available only when a grid object is selected.

Procedures

To activate a grid object:

1. Select a grid object.
2. Do one of the following:
   - Choose Views menu > Grids > Activate Grid Object.
   - Right-click the selected grid object and choose Activate Grid from the quad menu.
     The grid object changes to show its internal grid structure. Except for its main axes, the home grid disappears in all viewports.
3. Right-click the selected grid object and choose Activate Grid from the quad menu.
   The grid object changes to show its internal grid structure. Except for its main axes, the home grid disappears in all viewports.

Align Grid to View

Activate a grid object. > Views menu > Grids > Align Grid to View

This command aligns a grid object on page 8597 with the current view. The grid object is aligned so that it's coplanar with the view and oriented with the top of the grid at the top of the view.

Procedures

To align a grid object with a viewport:

1. Activate a grid object.
2. Click or right-click in a viewport.
3. Right-click to open the quad menu.
4. In the Tools 1 quadrant, choose Align Grid to View.
   The grid object rotates to align itself with the selected view. The grid object is now planar, or parallel, with the viewport.
Choose Views menu > Grids > Align Grid to View. The grid object rotates to align itself with the selected view. The grid object is now planar, or parallel, with the viewport.

Alignment

3ds Max provides a range of tools for aligning objects. This section includes a couple of brief introductory topics to alignment in 3ds Max; for specific information on the available alignment functions, see Align Flyout on page 966 and Clone and Align Tool on page 961.

Aligning Objects

You can align a selection consisting of one or more objects, called the source, with a target object. There are many uses for this feature. For precision, an important use is grid alignment. You can create a new grid object and align it to an existing object, either manually after creation or automatically during creation using the AutoGrid on page 2792 feature. Conversely, you can move an object onto a grid anywhere in your scene.
Aligning objects by the centers, bottoms, or tops of their bounding boxes

**Source and Target Objects**

Alignment involves two entities: one is the source object or selection set, where the process begins; the other is the target object, where the selection process ends.

**Source object** Object or objects you want to move into alignment with another object. You select one or more source objects to begin the alignment process.

**Target object** Object used to define the alignment. You select the target object during the alignment process. It cannot be selected beforehand.

After selecting the source, choose Tools menu > Align or click the Align button on the Main toolbar, and then select the target object.

Next, the Align dialog appears. For discussion of the Align options, see Align on page 967.
Setting a Coordinate System

The effects of alignment depend on the current reference coordinate system, such as View, World, or Local. You should decide which system you want to use before beginning alignment.

Reference Coordinate System Determines the axes used for positional alignment and the size of the bounding box for maximum and minimum positions.

To align objects using active grid axes:

■ Choose Grid as the reference coordinate system from the list on the toolbar.

To align two objects using their own axes:

■ Choose Local as the reference coordinate system. Alignment is then strictly between the two objects. Object bounding boxes determine maximum and minimum positions.

As a reminder to you during the alignment process, the current reference coordinate system appears in parentheses following the Align Position label in the Align Selection dialog.

Basics of Aligning Objects

Alignment controls are on a single dialog. As you make a setting, the object being aligned moves immediately to the new position. This lets you experiment with alignment until you get what you want. Settings can be made in any order.

You can also work step-by-step, by applying position choices, for example, before deciding on final orientation. You can cancel at any time, returning the scene to its original state. You can also undo any alignment and start over.
Aligning Multiple Objects

Aligning multiple objects to the arrow object (each photo is adjusted in a different correction)

When you select multiple objects for alignment, the same settings apply to all of them. However, the effect on each source object can be different. In practice, you're aligning separate objects at the same time with the same settings.

To align a collection of objects as a single unit, select the objects and group on page 243 them. The alignment now takes place relative to the pivot and bounding box of the entire group.

Sub-Object Alignment

You can use Align with any selection that can be transformed. The tripod axis becomes the source for alignment. You do this by accessing the sub-object level of the object before clicking Align.
Aligning Normals

3ds Max lets you align the normals between any two objects. In the case of mesh objects, the alignment is between individual faces, because each face has its own normal. See Normal Align on page 973.

Normal on the front of the bolt is aligned with the normal of a face on the assembly.

Basics of Aligning Normals

Before you begin, select a view that lets you see both objects you want to align. If necessary, you can navigate the view after selecting the first normal. To see face normals clearly, work in a wireframe viewport.

For details on the procedure and dialog settings, see Normal Align on page 973.

Other Align Options

The Align flyout on the main toolbar has other buttons that provide specialized alignments.
**Align Camera** Orients a camera viewport to a selected face normal, with the normal in the center of the viewport and on the axis of the camera. See Align Camera on page 978.

**Align to View** Orients a local axis of an object or sub-object selection with the current viewport. Options on the dialog are interactive, as they are on the Normal Align dialog. See Align to View on page 979.

**Place Highlight** Orients a face normal to a light. See Place Highlight on page 976 and Lighting in 3ds Max on page 5328.

### Using Snaps

Standard snaps give you control in creating, moving, rotating, and scaling objects. You access the 3ds Max snap features from buttons on the main toolbar.
Snapping to: endpoints, midpoints, edges

You make most snap settings on Grid And Snap Settings, a modeless dialog with four panels. You can move this dialog to any convenient location on your screen and turn options on and off as you work. Panels are reset to defaults for each new session.

You can also make commonly used snap settings on the Snaps toolbar on page 2821. In addition, a Snaps quad menu on page 8062 gives you quick access to some snap options.

Snap settings are stored in the 3dsmax.ini file rather than in the MAX file. This means that the state of the snap settings persists from session to session without your having to modify the maxstart.max file.

**Grid And Snap Settings Dialog and Snaps Toolbar**

The most commonly used grid and object snaps appear on the Grid and Snap Settings dialog on page 2819. This is the general sequence for using these snaps:
1 Turn on snapping by clicking the Snaps Toggle button on the main toolbar, and then right-click this button to display the Grid And Snap Settings dialog.

Two sets of snap types are available: Standard (the default) and NURBS. Both are discussed in Snap Settings on page 2819.

You can also make commonly used snap settings on the Snaps toolbar on page 2821.

2 Turn on OSNAPS on the status bar, then right-click this button to display the Grid and Snap Settings dialog.

3 By default, only the Grid Points snap type is active. Turn on other snap types to activate them. When you create or move objects, these snaps are now in effect anywhere in 3D space, and unaffected by the current transform coordinate system.

As you move the cursor, each snap type is marked by a distinctive icon shown on the Snap panel. The current icon indicates the type and position of the next snap.

Grid points and grid lines are secondary to the other snap types. For example, if both Grid Point and Vertex are active, 3ds Max snaps to a vertex in preference to an equally close grid point.

4 Turn snaps on and off as needed; the easiest way is by pressing the $ key.

For more information on snaps, see 2D Snap, 2.5D Snap, 3D Snap on page 2807 and Snap Settings on page 2819.

Snap Override

Snap Override bypasses currently selected snaps. You use a keyboard-mouse combination or a keyboard shortcut to define a new snap for the next click. You can override on the fly, one snap at a time.

For example, while creating a spline between grid points, you might need to snap to a vertex or midpoint of an object. This is the general procedure:

1 As you use preset snaps to create or move an object, hold down Shift and right-click. This pops up a three-quadrant right-click menu, which you can use to override the current snap setting(s).
NOTE You can begin the creation or transformation process before accessing the override menu. This typically means that you'll be holding down the left button as you Shift+right-click.

2 From the Snap Override quadrant, choose the snap type you want to use. The cursor switches to this type.

3 Make the snap. After the snap, currently set snaps are back in effect.

In addition, the Snap Override quadrant lets you reuse the last override you used (listed by name), and gives you an option for None. None turns off snapping entirely on the next click. The Snap quad menu also contains an Options quadrant, with toggles for snapping within current transform constraints (default=off) and snapping to frozen objects (default=off).

Snap Commands

main toolbar > Snap buttons
Menu bar > Tools menu > Grids and Snaps submenu

Snaps help you precisely control the dimensions and placement of objects when you create them or transform them. There is also a Spinner snap for controlling the entry of values.

You can use objects within an XRef scene as snap references.

The snap commands listed below and described in this section are found on the main toolbar (except for Ortho and Polar; see their topics for details). They’re also available from the Grids And Snaps submenu of the Tools menu.

2D Snap, 2.5D Snap, 3D Snap

Main toolbar > 2D Snap, 2.5D Snap, or 3D Snap on the Snaps Toggle flyout
Tools menu > Grids and Snaps > Snaps Toggle
Keyboard > $ S

The buttons on the Snaps Toggle flyout on page 8582 provide control over the range of 3D space where snaps are active. A wide variety of snap types is available from the Snaps dialog on page 2819, which you can use to activate different snap types as you work.
Object Snapping

Object snapping lets you snap to specific portions of existing geometry during creation and transforms of objects or sub-objects. You can also snap to the grid, and you can snap to tangents, midpoints, pivot points, face centers and other options.

The mode you choose maintains its state when you switch levels.

Transforming Around Snap Points

When snapping is on and Auto Key on page 8090 is off, rotations and scales occur about the snap point. For example, if you're using Vertex snapping and you're rotating a box, you can rotate it about any of its corner vertices. See To use snaps to move an absolute distance: on page 2809 below.

When Auto Key is on and either Select And Rotate or Select And Scale is active, the Snaps Toggle button is disabled, and rotation and scaling take place about the pivot point of the object.

Procedures

To turn snap off during a transform:

Press S to toggle snapping off when it gets in the way. Press S again to turn it back on.

To use snaps to move a relative distance:

1. Turn on Snaps with the S key, or by clicking the Snaps Toggle button.

2. Lock your selection set with the spacebar, or by clicking Lock Selection on the status bar.

3. Wherever you click in the viewport, the snap will stay relative to the distance of your cursor to the object.
To use snaps to move an absolute distance:

1. Turn on Snaps Toggle.
2. Click the selection. Snap uses the point you click for the snap source.
3. Move to whatever target snap you desire. The object will snap to an absolute distance.

To rotate a box around a vertex using snaps:

1. Make sure the Auto Key button is off.
2. Select the box.
3. On the Main toolbar, click Select And Rotate.
4. Turn Snaps on by pressing $S$ on the keyboard.
5. On the Tools menu, choose Grids And Snaps > Grid And Snap Settings. Turn on Vertex and turn off Grid Points.
7. On the toolbar, choose Use Transform Coordinate Center (hold the mouse down on Use Pivot Point Center to expose the flyout).
8. Move your cursor over any vertex in the box. The blue snap cursor will appear, and then you can rotate the box around that vertex.

Interface

There are three snap modes:

- **2D Snap** The cursor snaps only to the active construction grid, including any geometry on the plane of that grid. The $Z$ axis, or vertical dimension, is ignored.

- **2.5D Snap** The cursor snaps only to the vertices or edges of the projection of an object onto the active grid.

Suppose you create a grid object on page 8597 and make it active. You then position the grid object so you can see through the grid to a cube further off...
in 3D space. Now with 2.5D set, you can snap a line from vertex to vertex on
the distant cube, but the line is drawn on the active grid. The effect is like
holding up a sheet of glass and drawing the outline of a distant object on it.

3D Snap  This is the default tool. The cursor snaps directly to any
gometry in 3D space. 3D snapping lets you create and move geometry in all
dimensions, ignoring the construction plane.
Right-click this button to display the Grid and Snap Settings dialog on page
2819, which lets you change snap categories and set other options.

Angle Snap Toggle

Main toolbar > Angle Snap Toggle
Tools menu > Grids and Snaps > Angle Snap Toggle
Keyboard > A
Angle Snap Toggle determines the incremental rotation for a number of
features, including the standard Rotate transform. As you rotate an object (or
group of objects), the object moves around a given axis in the increment you
set.

Angle Snap Toggle also affects Pan/Orbit camera controls, FOV on page 8569
and Roll camera settings, and Hotspot/Falloff on page 8604 spotlight angles.

Procedures

To turn angle snap on:
- Click Angle Snap Toggle on the Main toolbar. When on, angle snap affects
  all rotational transforms.

To rotate an object an even number of degrees:
- Turn on Angle Snap Toggle and rotate the object.
  The rotations take place in 5-degree increments as a default.

To rotate an object a precise degree of rotation, do one of the following:

1  Click Select And Rotate, then right-click it to display the Transform
Type-In dialog on page 899. Enter the exact rotation you want.
2 Choose Select And Rotate from the quad menu, then right-click it to use the Transform Type-In dialog on page 899. Enter the exact rotation you want.

3 Right-click Angle Snap Toggle and click the Options tab on the dialog that is displayed. Set the Angle value in the General group to the precise degree of rotation you need, then rotate the object. Rotation snaps to the angle increment you specified.

**Interface**

The angle increment is set on the Options panel of the Grid and Snap Settings dialog on page 2819. Right-click the Angle Snap Toggle button to display the Options panel of the Grid and Snap Settings dialog. The default is 5 degrees.

### Percent Snap Toggle

Main toolbar > Percent Snap Toggle

Tools menu > Grids and Snaps > Percent Snap Toggle

Keyboard > Shift+Ctrl+P

Percent Snap Toggle increments scaling of objects by the specified percentage.

**Interface**

The snap percent increment is set in the Grid And Snap Settings dialog. The default is 10 percent. Right-click the Percent Snap Toggle button to display the Grid and Snap Settings dialog on page 2819.

This is a general-purpose snap system that applies to any operation involving a percentage, such as scaling or squashing.

### Spinner Snap Toggle

Main toolbar > Spinner Snap Toggle

Spinner Snap Toggle sets the single-click increment or the decrement value for all of the spinners in 3ds Max.
Procedures

To set and toggle spinner snap:

1. Do one of the following:
   - Choose Customize menu > Preferences.
   - Right-click the Spinner Snap Toggle button on the main toolbar.
     Either method opens the Preference Settings dialog > General panel.
     The two controls for spinner snap are in the Spinners group on this panel.

2. Set a value in the Snap field.

3. Turn on Use Snap.
   When you exit the dialog, the Spinner Snap Toggle button is turned on.

4. As you work, use the Spinner Snap Toggle button to toggle the alternate setting.

Interface

The amounts for Spinner Snap are controlled by settings on the General panel on page 8299 of the Preferences dialog. Default=1.0.

Ortho Snapping Mode

When drawing a Line spline on page 584 or Wall object on page 491, Ortho Snapping Mode constrains line creation to the horizontal or vertical directions relative to the active grid. That is, with Ortho on, you can draw only lines that are parallel to lines of the active grid.

Ortho is particularly useful for drawing plans where all lines must be at 90 degrees to each other, such as a house plan. To constrain line-drawing to other angle increments, use Polar Snapping Mode on page 2814 instead.

IMPORTANT By default, Ortho Snapping Mode is not directly accessible in the 3ds Max user interface. To add it as a button on the Snaps toolbar, follow this procedure on page 2813.
The following provisions apply to using Ortho:

- Use of Ortho is mutually exclusive of use of the Polar Snapping Mode toggle on page 2814; only one can be active at a time.

- Ortho Snapping applies primarily to the creation of line splines and wall objects. It can be used while creating other objects, but results are likely to be unsatisfactory.

Ortho mode displays a compass which gives a readout of the current angle of the input relative to the positive direction of the local X axis.

**NOTE** If you hold down the Alt key in Ortho mode, the next point becomes doubly constrained by both the previous point and the first point of the current object. This allows you to close splines precisely. In this mode, two compasses are displayed; one each at the first *and* previous points.

### Procedures

**To add Ortho Snapping Mode to the Snaps toolbar:**

1. Open the Snaps toolbar, if necessary. To do so, right-click an empty part of the main toolbar, such as the area directly below one of the drop-down lists, and choose Snaps.

2. Drag the right end of the toolbar to the right to make room for a new button.

3. Choose Customize menu > Customize User Interface. This opens the Customize User Interface dialog.

4. On the dialog, click the Toolbars tab.

5. Scroll down the Action list on the dialog to the Ortho Snapping Mode item. You can jump to the O section by clicking any item in the list and then pressing O on the keyboard.

6. Drag the Ortho Snapping Mode item from the list to the empty section of the Snaps toolbar. This adds the button to the toolbar.

7. Close the Customize User Interface dialog. 3ds Max automatically saves the toolbar in its revised state and makes the new button a permanent part of the user interface.
To use Ortho:

1  Turn on the Ortho Snapping Mode button.
   The button appears depressed.
2  Begin to draw a Line spline.
   An orange compass appears where you place the first point, along with
   a red number indicating the angle of the current line segment with the
   positive direction of the local X axis.
3  Move the mouse cursor around in the viewport.
   The line jumps to 90-degree angle increments on the local X axis, while
   the compass reading updates to show the current angle.
4  Click to place the next vertex.
5  Repeat steps 3 and 4 until you're ready to complete the shape.
6  Do either of the following:
   ■ To finish the shape at the most recent vertex without closing it,
     right-click anywhere.
   ■ To finish the shape by closing it, position the mouse cursor close to
     the first point and then click. A small dialog opens asking if you want
     to close the spline; click Yes.

Polar Snapping Mode

When drawing a Line spline on page 584 or Wall object on page 491, Polar
Snapping Mode constrains line creation to angle increments determined by
the Angle Snap setting relative to the active grid. To change the Angle Snap
setting, right-click the Angle Snap Toggle button on the main toolbar and in
the Options panel > General group, edit the Angle setting.

IMPORTANT  By default, Polar Snapping mode is not directly accessible in the
3ds Max user interface. To add it as a button on the Snaps toolbar, follow this
procedure on page 2815.

Polar is particularly useful for drawing plans where angles between all lines
must conform to specific angle increments, such as 45 degrees. If all lines must
be at 90-degree angles to each other, use the Ortho Snapping Mode toggle on
page 2812 instead.
The following provisions apply to using Polar:

- Use of Polar is mutually exclusive of use of the Ortho toggle; only one can be active at a time.
- Polar applies primarily to the creation of line splines and wall objects. It can be used while creating other objects, but results are likely to be unsatisfactory.

Polar mode displays a compass that provides a readout of the current angle of the input relative to the positive direction of the local X axis.

**NOTE** If you hold down Alt in Polar mode, the next point becomes doubly constrained by both the previous point and the first point of the current object. This allows you to close splines precisely. In this mode, two compasses are displayed; one each at the first and previous points.

**Procedures**

**To add Polar Snapping Mode to the Snaps toolbar:**

1. Open the Snaps toolbar, if necessary. To do so, right-click an empty part of the main toolbar, such as the area directly below one of the drop-down lists, and choose Snaps.
2. Drag the right end of the toolbar to the right to make room for a new button.
3. Choose Customize menu > Customize User Interface. This opens the Customize User Interface dialog.
4. On the dialog, click the Toolbars tab.
5. Scroll down the Actions list on the dialog to the Polar Snapping Mode item. You can jump to the P section by clicking any item in the list and then pressing P on the keyboard.
6. Drag the Polar Snapping Mode item from the list to the empty section of the Snaps toolbar. This adds the button to the toolbar.
7. Close the Customize User Interface dialog.
   3ds Max automatically saves the toolbar in its revised state and makes the new button a permanent part of the user interface.
To use Polar:

1. Turn on the Polar Snapping Mode button. The button appears depressed.

2. Begin to draw a line spline. An orange compass appears where you place the first point, along with a red number indicating the angle of the current line segment with the positive direction of the local X axis.

3. Move the mouse cursor around in the viewport. The line jumps to specific angle increments from the X-axis, while the compass reading updates to show the current angle. You set the angle increment in the Grid And Snap Settings dialog > Options panel on page 2828 > General group, which you can access by right-clicking the Angle Snap Toggle button on the main toolbar.

4. Click to place the next vertex.

5. Repeat steps 3 and 4 until you're ready to complete the shape.

6. Do any of the following:
   - To finish the shape at the most recent vertex without closing it, right-click anywhere.
   - To finish the shape by closing it, position the mouse cursor close to the first point and then click. A small dialog opens asking if you want to close the spline; click Yes.
   - To finish the shape by closing it while constraining the line to the polar snap, first position the mouse cursor close to the first point, press and hold Alt to constrain the mouse by both the previous point and the first point, and then click. This vertex is automatically placed at the current angle increment from the first point, so that you need only click the first point to close the shape.

Setting Snap Options

You can access a number of snap features from the Options tab of the Grid and Snap Settings dialog. Right-click any of the snap buttons on the main toolbar to display the Grid And Snap Settings dialog or choose Tools menu > Grids And Snaps > Grid And Snap Settings, then click the Options tab.
### Display and General Settings

**Marker settings** Determine the color and size of the snap cursor. To prevent the snap cursor from appearing, turn off Display.

**Snap Radius settings** Determines how close the cursor needs to approach a snap point before the snap preview or actual snap takes place. These are global settings, affecting all snap interactions, and are measured in terms of the pixels in a "search region" around the active point of the cursor.

**Snap to Frozen Objects** Normally, if an object is frozen you can't snap to it; this option lets you snap to frozen objects.

### Settings for Angle and Percent Snap

The following Options settings are for two snap buttons that operate independently of standard snaps.

**Angle (deg)** A global setting, in degrees, that determines the angle of rotation for a number of features in 3ds Max, including the standard Rotate transform.
As you rotate an object (or group of objects), the object moves around a given axis in the increment you set. Angle snap also affects the following:

- Pan/Orbit camera controls
- FOV and Roll camera settings
- Hotspot and Falloff light angles

For more information, see Angle Snap on page 2810.

**Percent** Sets a percentage increment during a scaling operation.
For more information, see Percent Snap on page 2811.

### Rotating and Scaling with Snaps

The effect of rotating and scaling with snaps depends on whether Auto Key on page 8090 is on or off:

- With Auto Key **on**, snap toggles are disabled, while Angle and Percent snaps remain active. Rotation and scaling occur around the pivot point of the object.
- With Auto Key **off**, rotations and scales occur around the snap point. For example, using Vertex snap, you can rotate a box about any of its corners.

### Translation Options

By default, the Use Axis Constraints on page 910 option is off. The current setting on the Axis Constraints toolbar (XY, for example) has no effect. Turning on this option lets you use snaps in conjunction with axis constraints.

The Translation group also lets you toggle display of a rubber band line between the start and end points during a snap operation.

### Settings for Spinner Snap

You set the spinner snap on the General panel on page 8299 of the Preferences dialog. Right-click the Spinner Snap button on the main toolbar to display this panel.

**Spinner snap** Sets a numerical increment for spinner fields. If you're using generic units of 1 inch, a setting of 12 would let you resize objects by one foot with every click, or add 12 segments to a sphere.
The same setting applies to all spinner fields. Since spinner snap is a toggle, you can easily turn it on when needed and use the default at other times. Spinner snap has no effect on dragging a spinner, only on single clicks. For more information, see Spinner Snap on page 2811.

**Grid and Snap Settings**

Tools menu > Grids and Snaps > Grid and Snap Settings

Right-click any snap button

Shift+right-click a viewport. > Snaps shortcut (quad) menu on page 8062 > Snap Options quadrant > Grid and Snap Settings

This command displays the Grid and Snap Settings dialog. This modeless dialog establishes settings and options for snaps, the home grid on page 8600, and user-defined grids.

Controls on the Grid And Snap Settings dialog determine which snap settings are used when you activate snaps by clicking 3D Snap Toggle. Adjusting any of these snap settings does not automatically turn on snaps.

You can use objects within an XRef scene as snap references.

**Procedures**

To change grid and snap settings:

1. Choose Tools menu > Grids And Snaps > Grid And Snap Settings and click the appropriate tab.
2. Choose the type of snap you want (Standard or NURBS).
3. Select the snap settings.

**Snap Settings**

Tools menu > Grids and Snaps > Grid And Snap Settings > Grid And Snap Settings dialog > Grid And Snap Settings tab

Main toolbar > Right-click a snap button

Keyboard > Hold Shift+right-click > Snaps quadrant

Keyboard > S (toggles snaps on and off)
Snapping gives you additional control when creating, moving, rotating, and scaling objects by causing the cursor to “jump” to specific portions of existing geometry and other scene elements during creation and transformation of objects or sub-objects. The controls in this dialog set the snap strength and other characteristics such as the snap target.

NOTE Snapping functionality includes several features that enhance ease of use. For details, see the General Group section of the Snap Options topic on page 2831.

You can specify the portion of the geometry where you will snap. For example, when Vertex is the active snap type, creating and transforming objects snaps to the vertices of existing geometry. You can specify any combination of active snap types to provide multiple snapping points. For example, if Vertex and Midpoint are active, snapping occurs at both vertices and edge midpoints.

The default snap type is Grid Points.

NOTE Snapping is not on by default. You can toggle snapping by pressing the S key at any time, even in the middle of a transform. In this way you can combine snapping with free positioning.

Snapping works at sub-object levels. For example, you can use snaps to position a gizmo to the object on which you’re working, or snap it to other objects in the scene.

You must activate a viewport in order to use snaps. Also, the Z-axis constraints don’t apply to the home grid or grid objects, since grids don’t have a Z axis.

Settings are stored in the 3dsmax.ini on page 60 file. The state of the snap settings persists from session to session.

**Snaps and Axis Constraints**

Snaps take precedence over axis constraints on page 910. If you activate an axis constraint, such as Restrict to X, you can move the object only in X. But if you then turn on snaps, Restrict to X is suspended and not used.

You can override this by turning on Snaps Use Axis Constraint Toggle on the Axis Constraints toolbar on page 8039, or by turning on Use Axis Constraints in Snap Options on page 2828.
The Snaps Toolbar

The most common Snaps settings are available from an optional toolbar. To toggle display of the Snaps toolbar, right-click an empty area of the main toolbar, such as the section under the Reference Coordinate System drop-down, and choose Snaps. The toolbar buttons are shown next to the relevant commands, below and in the Snap Options topic on page 2828.

The same settings are also available from the snap quad menu, available with Shift+right-click.

Procedures

To set grid and snap settings:

1. Turn on the 3D Snap Toggle button to activate snaps.
2. Choose Tools menu > Grids And Snaps > Grid And Snap Settings to display the Grid and Snap Settings dialog.
3. In the Snaps tab, select one or more of the types of snaps you want active.
4. Create an object or transform an object.
   Snap markers appear when the mouse cursor is over existing geometry or on a grid, depending on the active snap types. Each snap type has a different display; clicking when the snap-specific display is visible snaps to that spot.

To display the Snaps shortcut menu:

- Hold Shift and right-click anywhere in any viewport. The quad menu that opens gives you access to various snap settings including Snaps Use Axis Constraints and Snap To Frozen Objects.

To use both constraint and snaps, do one of the following:

1. In the Grid and Snap Settings dialog > Options tab > Translation group, turn on Use Axis Constraints.
2 Hold Shift and right-click in the viewport, and then choose Options > Transform Constraints from the Snap quadrant.

Example: To use 3D snaps and rotation transformations together:
1 Create a box.
2 Select the box and choose Lock Selection.
3 Turn on 3D Snaps and click Rotate on the toolbar.
4 From the Use Center flyout on the main toolbar, choose Use Transform Coordinate Center on page 934.
5 Activate the Perspective viewport and move the cursor over the grid. A blue icon displays when the cursor passes over a grid point.
6 When the blue icon displays, click and drag to rotate the box around the selected grid point.
   You can rotate around anything you can snap to.

To turn snaps on and off during an operation:
■ Use the S keyboard shortcut to turn snap on and off.

TIP You can select something with snap off, and then turn snap on to snap it to a snap target. Alternately you might want to snap to something, then position it freely wherever you want.

Interface

Use these check boxes on the Snaps tab to turn on any combination of snap settings.

After setting snaps, close the dialog using the Close button in the dialog’s upper-right corner. Do not click the Clear All button, or you’ll turn off all the snaps.

Override This label changes to display the temporary snap type used by the Override system. For more information, see Snap Override on page 2826.

Clear All Turns off all of the Snaps check boxes.
NOTE The layout of the Grid And Snap Settings dialog is generated at runtime. Because of this, it might appear slightly different than the illustrations shown here.

Standard snaps

These are the standard snap types used for grids, mesh, and shape objects. Non-grid snap types, when active, take priority over Grid Points and Grid Lines snaps: if the mouse is equally near a grid point and some other snap type, it will choose the other snap type.

NOTE The button images shown below are from the Snaps toolbar on page 2821.

Grid Points Snaps to grid intersections. This snap type is on by default. Keyboard shortcut=Alt+F5.

Grid Lines Snaps to any point on a grid line.
**Pivot** Snaps to pivot points of objects. Keyboard shortcut=Alt+F6.

**Bounding Box** Snaps to one of the eight corners of an object's bounding box.

**Perpendicular** Snaps to the perpendicular point on a spline, relative to the previous point.

**Tangent** Snaps to a tangent point on a spline, relative to the previous point.

**Vertex** Snaps to vertices of mesh objects or objects that can be converted to editable meshes. Snaps to segments on splines. Keyboard shortcut=Alt+F7.

**Endpoint** Snaps to the end points of edges on meshes or spline vertices. Keyboard shortcut=Alt+F8.

**Edge/Segment** Snaps anywhere along edges (visible or invisible) or spline segments. Keyboard shortcut=Alt+F10.

**Midpoint** Snaps to the middle of edges on meshes and spline segments. Keyboard shortcut=Alt+F9.

**Face** Snaps anywhere on the surface of a face. Back faces are culled, so they have no effect. Keyboard shortcut=Alt+F11.

**Center Face** Snaps to the center of triangular faces.
NURBS snaps

These options snap to objects or sub-objects in a NURBS model on page 8656. The NURBS snaps settings are aids for creating and transforming objects, and are not constraints. 3ds Max does not maintain the relationship between the NURBS object and other objects you create or transform.

CV Snaps to a CV sub-object on page 8543 in a NURBS curve on page 8655 or NURBS surface on page 8656.

Point Snaps to a point sub-object on page 8688 in a NURBS model.

Curve Center Snaps to the center of a NURBS curve.
The center of a NURBS curve is calculated parametrically, and might not be the same as the curve's apparent visual center.

Curve Normal Snaps to a point normal to a NURBS curve.
This snap operates only while you are creating a new object that requires two or more clicks to create.

Curve Tangent Snaps to a point tangent to a NURBS curve.
This snap operates only while you are creating a new object that requires two or more clicks to create.

Curve Edge Snaps to the edge of a NURBS curve (the current object moves or is created to lie along the curve).

Curve End Snaps to the end of a NURBS curve.

Surf Center Snaps to the center of a NURBS surface.
The center of a NURBS curve is calculated parametrically, and might not be the same as the curve's apparent visual center.
Surf Normal Snaps to a point on a NURBS surface normal to previous point. This snap operates only while you are creating a new object.

Surf Edge Snaps to the edge of a NURBS surface.

Snap Override

Any viewport > Hold Shift and right-click. > Snaps shortcut (quad) menu on page 8062 > Snap Override > Standard > Choose snaps type.

Any viewport > Hold Shift and right-click. > Snaps shortcut (quad) menu on page 8062 > Snap Override > NURBS > Choose snaps type.

Tools menu > Grids and Snaps > Grid and Snap Settings > Snaps tab

Snap Override lets you supersede all the currently selected snap types and temporarily use only one, or none, of the snap types currently selected on the Grid And Snap Settings dialog. For example, you might be creating a spline while snapping to grid points, but then need to snap one of its vertices to the midpoint of an object.

TIP You can choose the override by cycling through active snap types via a keyboard shortcut instead of using the quad menu. Press Alt+S repeatedly to choose the override snap type. If the Grid and Snap dialog is displayed, the "Override OFF" label changes to display the selected snap type.

Procedures

To use Snap Override (keyboard shortcut method):

1. Activate all the snap types you want to use or override with.
2. Make sure the Grid And Snap Settings dialog is open to the Snaps panel, so you can easily track the override type. Alternatively, if you're using only snap types available on the Snaps toolbar on page 2821, you can keep the toolbar open instead.
3. While creating or moving an object with Snap on, press Alt+S repeatedly. The Grid And Snap Settings dialog > "Override OFF" label changes to display the first available override snap type, chosen from the active snap types. If the Snaps toolbar is open, and the override snap type is available on the toolbar, the override snap type is visible there as well.
4. Press Alt+S repeatedly.
3ds Max cycles through all the active snap types for the override type. The benefit of this method is that it's fast and easy; you don't have to use the quad menu. But if you want to override with a snap type that isn't currently active, it's necessary to use the standard override method, which is described in the next procedure.

To use Snap Override (standard method):

1. While creating or moving an object with Snap on, hold down Shift and right-click in a viewport.
2. Select one of the snap types from the sub-menus in the Snap Override quadrant to make it the only active snap type.
   If the Grid And Snap Settings dialog is open to the Snaps panel, the "Override OFF" label changes to display the active snap override type. When you complete the mouse action, "Override OFF" is again displayed in the dialog, and the previously active snap types are active again.

To use Snap Override during a drag operation:

1. Left-click, press Shift, and then right-click to display the menu.
2. Release the left mouse button, and then left-click to select the snap you want.
3. Release the Shift key, right-click, and continue the drag operation (the geometry remains locked to the mouse).
4. Left-click to complete the operation.

Interface

In addition to the available snap types, the snap quad menu contains these items:

Snap Options quadrant Lets you set the following options:

- Grid and Snap Settings: Toggles display of the Grid And Snap Settings dialog.
- Snaps To Frozen Objects: Turn this on to enable snapping to frozen objects. Default=off.
- Snaps Use Axis Constraints: Turn this on to use the current transform constraints. For example, if you're moving a vertex with Restrict To XY
Plane on and want to snap the vertex to a point removed on the Z axis, turn this off, if necessary. Default=off.

Snap Override quadrant Lets you set the following options:

NURBS/Standard Let you choose a snap type for one-time use. This applies to the next snap only.

None Turns off all snap types for the next mouse action. (This item is unavailable if the Snap Toggle is off.)

[last] Displays the last snap override type you chose from the NURBS or Standard submenu, letting you easily reuse that type.

Snap Toggles quadrant Lets you set six of the most common snap types on an ongoing basis. These remain in effect until you turn them off; it's the same as setting them on the Grid And Snap Settings dialog.

Snap Options

Tools menu > Grids and Snaps > Grid and Snap Settings > Grid and Snap Settings dialog > Options panel
Main toolbar > Right-click 3D Snap Toggle > Grid and Snap Settings dialog > Options panel

The Options panel of the Grid And Snap Settings dialog lets you set options related to snapping.

Procedures

To set snap options:

1. Choose Tools menu > Grids And Snaps > Grid And Snap Settings.
2. Click the Options tab.
3. Set the options as desired.

Example: To use Snap Preview:

The Snap Preview Radius setting lets you preview a snap before it actually happens. The Snap Radius setting determines when actual snapping occurs, providing the same functionality as Snap Strength in previous versions.
This procedure also demonstrates how to cycle through available snap/preview points with the keyboard shortcut.

1. Reset 3ds Max, and then maximize the Perspective viewport.
   
   To maximize the Perspective viewport, make sure it's active (yellow border), and then press Alt+W.

2. Zoom in a bit so the grid squares are relatively large.
   
   Snap and Snap Preview measure in pixels, so if the grid points are relatively far apart, it's easy to see the difference between Snap Preview and Snap.

3. On the main toolbar, click the Snaps Toggle button to turn on snapping, and then right-click the button to open the Grid And Snap Settings dialog to the Snaps panel.
   
   The default Snaps setting is Grid Points only; if this is not the case, make it so. A grid point is the intersection of two grid lines.

4. On the dialog, click the Options tab.
   
   In the General group, Snap Preview Radius is set to 30 pixels and Snap Radius is set to 20 pixels. You can leave this dialog open while you use snaps.

5. On the Create panel, click Shapes, and then click Object Type rollout > Line.
   
   You're now in line-creation mode.

6. Click anywhere in the viewport to start creating a line-type spline object.

7. Move the cursor around the viewport.
   
   As you do so, a rubber-band line connects the mouse cursor to the start point.

8. Position the mouse cursor near a grid point, but not too close, so that the snap cursor (cyan box + crosshairs) appears at the grid point, but the line endpoint remains attached to the mouse cursor.
   
   This shows the snap preview; you'll see its purpose in the next step.

9. Click the left mouse button.
The second line vertex is created not where you clicked but at the grid point indicated by the snap preview. Snap preview lets you see where a snap will occur before it actually happens.

10 Move the cursor toward another grid point.
   At the Snap Preview Radius distance (30 pixels), the snap cursor appears at the grid point.

11 Continue moving the cursor toward the grid point.
   After you move it 10 pixels closer (the difference between Snap Preview Radius and Snap Radius), the line endpoint jumps from the mouse cursor to the grid point. This is the legacy snap functionality.

12 Click to accept the snap.

13 Complete the line, and then zoom out so the grid points are closer together. Start another line, and then position the mouse cursor in the center of a grid square, so the preview snap point appears at one of the grid points.

14 On the keyboard, press and hold Alt+Shift and then press S repeatedly to cycle through the remaining nearby grid points. If nothing happens, try zooming out more or increasing the Snap Preview Radius value.
   By default, 3ds Max uses the closest snap point as the preview location. This keyboard shortcut lets you choose other qualifying snap points.

Interface

NOTE The layout of the Grid And Snap Settings dialog is generated at runtime. Because of this, it might appear slightly different than the illustration shown here.
Marker group

Provides settings that affect the visual display of the snap points.

**Display** Toggles the display of the snap guides. When off, the snaps still function, but there's no display.

**Size** Sets the size, in pixels, of the snap "hit" point. This is the small icon that indicates either the source or target snap point.

**Color** Click the color swatch to display the Color Selector, where you can set the color of the snap display.

General group

Snap functionality includes several features that enhance ease of use. When using Snap, if the cursor comes within distance of a potential snap point that's less than the *Snap Preview Radius* distance but greater than the *Snap Radius* distance, the snap cursor jumps to that point as a preview of where the snap will occur, but no actual snapping occurs.

To use the preview point as the snap point, click or release the mouse button, depending on the context. If, instead, you then continue to move the cursor toward the potential snap point so that it comes within a distance equal to or less than the Snap Radius value, the snap takes place.
**TIP** For best results, keep the Snap Preview Radius value 10 pixels or more higher than the Snap Radius value. This lets you preview any snap before it actually occurs.

**Snap Preview Radius** When the cursor is a distance from a potential snap-to point between the Snap Preview Radius value and the Snap Radius value, the snap marker jumps to the closest potential snap-to point, but no snap occurs. Default=30.

When a snap-to preview point is highlighted, release or click the mouse button (depending on the context) to snap the current selection to that location. Alternatively, before using the displayed snap point, you can cycle through any other available preview and snap points by pressing and holding Alt+Shift and then press S repeatedly.

**NOTE** The Snap Preview Radius value should generally be set higher than the Snap Radius value, so that previewing occurs before snapping. If you attempt to set the Snap Preview Radius value lower than the Snap Radius value, 3ds Max lowers the latter so that the two are equal. This effectively turns off previewing, so that only snapping is in effect.

**Snap Radius** Sets the size of the area around the cursor, in pixels, within which snapping occurs automatically. Default=20.

**NOTE** The Snap Radius value should generally be set lower than the Snap Preview Radius value, so that previewing occurs before snapping. If you attempt to set the Snap Radius value higher than the Snap Preview Radius value, 3ds Max raises the latter so that the two are equal. This effectively turns off previewing, so that only snapping is in effect.

**Angle** Sets the increment at which objects are rotated about a given axis (degrees).

**Percent** Sets the percentage increment for scale transforms.

**Snap to Frozen Objects** When on, snapping to frozen objects is enabled. Default=off. This option is also available from the Snaps shortcut menu, accessed when you hold Shift and right-click in any viewport, as well as from the Snaps toolbar on page 2821. Keyboard shortcut=Alt+F2.
Translation group

**Use Axis Constraints** Constrains the selected object to move only along the axes specified on the [Axis Constraints toolbar](#) on page 8039. When off (the default), the constraints are ignored, and snapped objects can be translated in any dimension (assuming 3D snapping is used). This is also available from the Snaps shortcut menu, accessed when you hold Shift and right-click in any viewport, as well as from the [Snaps toolbar](#) on page 2821 and the Tools menu > Grids And Snaps submenu. Keyboard shortcut=Alt+F3 or Alt+D.

**Display rubber band** When on and you move an selection, a rubber-band line appears between the original location and the mouse position. Use this visual aid for greater accuracy when fine-tuning Default=on.

**Use Axis Center As Start Snap Point** Sets the center of the transform axis of the current selection set to be the initial snap point if there's no other start snap point detected by the snap system. This option works both at the object and sub-object levels.

This lets you, for example, snap the geometric center of a multi-object selection to a grid point.

**Home Grid Settings**

Tools menu > Grids and Snaps > Grid And Snap Settings > Home Grid panel

Main toolbar > Right-click 3D Snaps Toggle. > Grid And Snap Settings > Home Grid panel

The Home Grid panel of the Grid And Snap Settings dialog sets the spacing and other characteristics of the [home grid](#) on page 8600. Choosing useful home grid settings can simplify the construction process. The home grid provides a visual reference for creating objects in a scene.

In 3ds Max, grids have these primary uses:

- An aid in visualizing space, scale, and distance.
- Construction planes where you create and align objects in your scene.
- A reference system for using grid snaps.
Procedures

To set grid spacing for unit measure:

1. From the menu bar, choose Tools menu > Grids And Snaps > Grid And Snap Settings.
2. Click the Home Grid tab.
3. Adjust the value for Grid Spacing, which is in current units.
   For example, if you have units set to centimeters, you might make one grid space equal to 1.000 (one unit, or one centimeter in this case).

To set major grid divisions for multiple units:

1. From the menu bar, choose Tools menu > Grids And Snaps > Grid And Snap Settings.
2. Click the Home Grid tab.
3. Adjust the Major Lines Every Nth Grid Line value, which is the number of grid squares between major lines. The minimum is 2.
   For example, if you use a grid spacing of one centimeter, you might use a value of 10 so the major grid divisions represent one decimeter.
   In perspective viewports, you can set a fixed size for the displayed home grid. If Inhibit Perspective View Grid Resize is turned off however, the grid size adjusts as you zoom in or out.

To set view update options:

1. From the menu bar, choose Tools menu > Grids And Snaps > Grid And Snap Settings.
2. Click the Home Grid tab.
3. Under Dynamic Update, choose either Active Viewport (the default) or All Viewports.

To allow subdivision below grid spacing:

1. From the menu bar, choose Tools menu > Grids And Snaps > Grid And Snap Settings.
2. Click the Home Grid tab.
3. Turn off Inhibit Grid Subdivision Below Grid Spacing.
When you turn off this box, you can zoom indefinitely "deep" into any plane of the home grid. Each grid square subdivides into the same number of smaller grid spaces.

**Interface**

**NOTE** The layout of the Grid And Snap Settings dialog is generated at runtime. Because of this, it might appear slightly different than the illustration shown here.

**Grid Dimensions group**

**Grid spacing** Grid spacing is the size of the grid's smallest square. Use this spinner to adjust the spacing (which is in current units), or enter the value directly.

For example, if you have units set to centimeters, you might make one grid space equal to 1.000 (one unit, or one centimeter in this case).

**Major Lines every Nth Grid Line** The home grid displays heavier or "major" lines to mark groups of grid squares. Use spinners to adjust the value, which is the number of grid squares between major lines, or you can enter the value directly, the minimum is 2.
For example, if you use a grid spacing of one centimeter, you might use a value of 10 so the major grid divisions represent one decimeter.

**Perspective View Grid Extent** Sets the size of the home grid in the Perspective viewport.

This value is specified in terms of the Grid Spacing value, and represents the length of half the grid along an axis. This means that if Grid Spacing=10.0 and Perspective View Grid Extent=7, you will have a grid that is 140 x 140 units in size.

---

**Inhibit Grid Subdivision Below Grid Spacing** Causes 3ds Max to treat the grid as a fixed set of lines when you zoom in on the home grid. In effect, the grid stops at the grid space setting. If you keep zooming, the fixed grid is lost from view. Zooming out is not affected. When you zoom out, the home grid expands indefinitely to maintain the major grid divisions. Default=on.

When this is turned off, you can zoom indefinitely into any plane of the home grid. Each grid square subdivides into the same number of smaller grid spaces.

For a grid spacing of one centimeter and a major division of 10, the next level down subdivides into millimeter spaces, and so on.

**Inhibit Perspective View Grid Resize** Causes 3ds Max to treat the grid in the Perspective viewport as a fixed set of lines when you zoom in or out. In effect, the grid maintains one size, no matter how much you zoom. Default=on.

When this is turned off, the grid in the Perspective viewport will subdivide to adjust its size when you zoom in or out.

**Dynamic Update group**

**Dynamic Update** By default, only the active viewport updates as you change values for Grid Spacing and Major Lines every Nth. The other viewports update after you have completed changing the values. Choose All Viewports to have all viewports update as you change the values.

**User Grid Settings**

Tools menu > Grids and Snaps > Grid And Snap Settings > Grid And Snap Settings dialog > User Grids tab

The User Grids panel controls automatic activation of grid objects on page 2847 and settings for AutoGrid on page 2792.
Interface

NOTE The layout of the Grid And Snap Settings dialog is generated at runtime. Because of this, it might appear slightly different than the illustration shown here.

Grid object automation group

Determines if 3ds Max automatically makes grids active upon creation.

Activate grids when creating  
Turn on to automatically activate the grid you created.

TIP If not turned on, you can activate the grid by selecting the grid, then right-clicking and choosing Activate Grid.

AutoGrid group

AutoGrid allows you to automatically create grids on the surface of objects. The task of creating objects that are aligned to other object surfaces has been simplified. Turn on AutoGrid in the Object Type rollout of a command panel. When you turn on AutoGrid, 3ds Max uses the setting in the User Grids dialog for world or object space.

World space Aligns grids to world space.

Object space Aligns grids to object space.

Helpers

Create panel & Helpers
Create menu > Helpers

Helper objects play a supporting role, like stagehands or construction assistants.

Several categories of helpers are available from the drop-down list on the Create panel:

- **Standard helpers** on page 2839
- **Atmospheric Apparatuses** on page 7236
- **Camera match** on page 5615
- **Assembly Head Helper Object** on page 271
  - **Character Assembly** on page 254
  - **Luminaire Helper Object** on page 271
- **Manipulator Helper Objects** on page 2861
- **Particle Flow helpers** on page 3044
- **VRML97 Helper Objects** on page 7809
- **reactor** on page 4219

Other helper objects might be available, depending on your configuration.

---

**Select And Manipulate**

Main Toolbar > Select And Manipulate button

The Select And Manipulate tool lets you edit the parameters of certain objects, modifiers, and controllers by dragging "manipulators" in viewports.

**NOTE** Unlike Select And Move and the other transforms, this button's state is non-exclusive. As long as Select mode or one of the transform modes is active, and Select And Manipulate is turned on, you can manipulate objects. However, you must turn off Select And Manipulate before you can select a manipulator helper.

You can add these custom manipulators to your scene:

- **Cone Angle Manipulator** on page 2861
- **Plane Angle Manipulator** on page 2865
These features have manipulators built in, which you can use to change parameters on these objects:

- **Slider Manipulator** on page 2868
- **IK Solver Properties Rollout (HI Solver)** on page 3700
- **Reaction Controllers** on page 3527
- **Target Spotlight** on page 5399
- **Target Directional Light** on page 5405
- **mr Area Spotlight** on page 5421
- **Free Spotlight** on page 5402
- **Spotlight Parameters** on page 5439
- **UVW Map Modifier** on page 1932

**Primitives** on page 385 with a Radius parameter have a built-in manipulator for the radius.

### Standard Helper Objects

Create panel > Helpers > Standard > Object Type rollout

Create menu > Helpers

Helper objects play a supporting role, like stage hands or construction assistants.

The helpers in this section serve mainly as precision and drawing aids, while you can find links to other kinds of helpers in the See Also list, following.

<table>
<thead>
<tr>
<th>Object Type</th>

- reactor Helpers on page 4246

**Dummy Helper**

Create panel > Helpers > Standard > Object Type rollout > Dummy
Create menu > Helpers > Dummy

A Dummy helper object is a wireframe cube with a pivot point at its geometric center. It has a name but no parameters, you can't modify it, and it doesn't render. Its only real feature is its pivot, used as a center for transforms. The wireframe acts as a reference for transform effects.

The dummy object is used primarily in hierarchical linkages. For example, you can use a dummy object as a center of rotation by linking a number of different objects to it. When you rotate the dummy, all of its linked children rotate with it. A dummy is often used this way to animate linked motion.

Another common usage of a dummy object is in the animation of target cameras. You can create a dummy and position a target camera within the dummy object. Then you can link both the camera and its target to the dummy, and animate the dummy with a path constraint. The target camera will follow the dummy along the path.

Dummy objects are always created as cubes. You can change the proportions of dummies by using non-uniform scaling, but avoid this on dummies that are within a hierarchical linkage; this can introduce unexpected results.
Procedures

To create a dummy object:

■ Click Dummy and drag a cube to any convenient size.

Interface

Dummy objects don't have any parameter rollouts or settings.

Expose Transform Helper

Create panel > Helpers > Standard > Object Type rollout > ExposeTm
Create menu > Helpers > Standard > ExposeTm

The Expose Transform helper exposes values of non-keyed objects for use in expressions and scripts. This lets riggers and animators access a select set of transforms for an object, and between an object and its parent, such as a bone in an IK chain. For example, using the Expose Transform helper, you could write a script or use parameter wiring that tests the angle of an character's arm bone that's controlled by IK (thus, has no keys), and once it exceeds a specific value, rotate the corresponding clavicle bone to deform the shoulder area.

In the viewports, the Expose Transform helper object looks just like a Point helper on page 2853.

Procedures

To use the Transform helper:

1  Click ExposeTm and choose the appearance characteristics from the Display rollout.

2  Adjust the size of the helper object by using the Size spinner on the Display rollout. Default=20.0

3  Click anywhere in your scene to add the helper object.
   The helper object's position has no bearing on its functionality.

4  On the Modify panel > Parameters rollout, click the Expose Node button (default label: None) and select the object whose transform values you want to expose.
The object's name appears on the button, and its transform values appear in the fields on the Expose Values rollout.

5 Optionally, turn off Parent and choose a Local Reference Node object. This option is used by the Local Euler Angles, Distance To Reference, and Angle parameters. If the object has no parent and you don't specify a Local Reference Node object, these fields use the world center (0,0,0) as the reference node.

6 To use a transform value in a script or expression, first click the M button next to the parameter value. This copies the transform name, using MAXScript notation, to the copy buffer.

7 Paste the contents of the buffer to your script or expression. A sample result of this is "$ExposureTransform01.localPositionX". 3ds Max interprets this as the local position, on the X axis, of the Expose Node object.
### Interface

#### Parameters rollout

These settings let you specify the exposed node, a reference object other than the parent, and rotation and timing parameters.

**Expose Node** The object from which the values are generated. Click the button, and then select the object. Thereafter, the object name appears on the button.

**Local Reference Node** The object whose relationship with the Expose Node object is used to generate local data for rotation, distance, and angle. Click the button, and then select the object. Available only when Parent is off. By default, this is the parent object, but you can turn off Parent and then specify a different object.

**Parent** When on, the Local Reference Node is set automatically to the parent of the Expose Node. When off, you can pick an object to refer to for local data. Default=on.
This is used by the Local Euler Angles, Distance To Reference, and Angle parameters. If the object has no parent and you don't specify a Local Reference Node object, these fields use the world center (0,0,0) as the reference node.

**Rotation Order** These three settings determine the order in which the Expose Transform helper will look for an Euler rotation.

This parameter corrects for anomalies that can be introduced when a local rotation value is generated in relation to other rotation values. For example, when Z Order is set to XYZ, the Z value is generated in reference to X and then Y. Or when X Order is set to ZXY, the Z value is generated directly in reference to the parent, regardless of X and Y rotations.

**Strip NU Scale** When on, removes any non-uniform scaling that could influence the rotation data. It does not strip non-uniform scaling from the object; only from the values generated.

**Use Time Offset** When on, lets you specify a frame other than the current one from which to gather data. The Offset value is added to the current frame to derive the frame from which data is gathered.

For example, if the current frame is 20 and you wish to gather data from frame 15, turn on Use Time Offset and set Offset to -5.

**Display rollout**

- **Center Marker** Displays a small X marker at the center of the helper object.

*2844* | Chapter 11 Precision and Drawing Aids
**Axis Tripod** Displays a tripod axis indicating the position and orientation of the helper object.

**Cross** Displays an axis-aligned cross.

**Box** Displays a small axis-aligned box at the center of the helper object.

**Size** Sets the size for the helper object. Use this setting to minimize the helper object, or increase its size to aid in locating it. Default=20.0.

**Constant Screen Size** Keeps the size of the helper object constant, regardless of how much you zoom in or out.

**Draw On Top** Displays the helper object on top (or in front) of all other objects in the scene.
This rollout provides readouts of values for all transform values of the Expose Node object. Each value has a button labeled “M” next to it; click this button to copy the MAXScript associated with the value to the clipboard, which you can then paste into a script.

**Display Exposed Values** When on, transform values for the Expose Node object appear on this rollout, and update as the values change. When off, values don’t appear, but the M buttons still function normally.

**Local Euler Angles** Rotation values with respect to the parent or Local Reference Node object.

**World Euler Angles** Rotation values in the world coordinate system.

**Local Position** Position values with respect to the Expose Node object’s local coordinate system.

**World Position** Position values in the world coordinate system.

**Bounding Box** The maximum dimensions of the object.

**Distance to Reference** The distance between the Expose Node object and its parent or the designated Local Reference Node object. If neither exists, this shows the distance to the world center (0,0,0).

**Angle** The angle between the Expose Node object and its parent or the designated Local Reference Node object.

**Grid Helper**

Create panel > Helpers > Standard > Object Type rollout > Grid
Create menu > Helpers > Grid

The grid, also called User Grid or Custom Grid, is a 2D parametric object with adjustments for overall size and grid spacing. You can move and orient user grids anywhere in world space.

You can create any number of grid objects in your scene. You name them when you create them and save them with the scene. You can delete them at any time.

Like other objects you create in 3ds Max, grid objects are placed on the grid of the current viewport. By default, this is a plane of the home grid, but it can also be another activated grid object.
NOTE You can use AutoGrid on page 2792 to create a temporary or permanent user grid off the surface of any object.

Using the Grid Object

You can use the grid object as a construction plane on all three orthographic planes in both directions. Here's how it works:

In the Parameters rollout of each grid object is a Display group with three options: XY Plane, YZ Plane, and ZX Plane. These determine which of the three planes of the grid object is displayed in the viewport.

When you activate a grid object, the displayed plane is the construction plane for all viewports. When you create a grid viewport, you can choose from one of six orthographic views (Front, Top, Left, and so on), or you can choose a special Display Planes grid viewport. (When you press the G key to create a grid viewport, the Display Planes type becomes the default.) The Display Planes type of grid viewport always displays the plane chosen by the three option buttons under Display. Thus, as you switch between XY Plane, YZ Plane, and ZX Plane, the view through the grid viewport switches accordingly, and objects created in that viewport are created on the displayed plane.

When you use the Point-Of-View (POV) viewport label menu on page 8122 (or go to the Layout tab of the Viewport Configuration dialog), you can choose six additional types of grid viewports, based on the six orthographic views. These are available by a cascading Grid menu that provides Left, Right, Front, Back, Top, Bottom, and Display Planes. Each of the orthographic directions is local to the grid object, regardless of its orientation in the scene.

When you choose a specific orthographic grid viewport (as opposed to the Display Planes viewport), the construction of objects in that viewport is on the plane specified in the viewport title regardless of the displayed plane of the grid object.

You can create more than one viewport based on the same grid object, with each using a different plane. For example, you can have a Grid (Front) viewport and a Grid (Top) viewport, as well as a Grid (Display Planes) viewport.

When you deactivate a grid object, its remaining viewports show the assigned orthographic view. Thus, a Grid (Front) viewport becomes a Front viewport, for example. A Grid (Display Planes) viewport always reverts to a Top view, regardless of the currently displayed plane.
Scaling Not Advised

As a rule, don’t use scaling to resize a grid object. Scaling enlarges or reduces the apparent size of the grid object but has no effect on grid spacing. A sphere 20 units in radius created on a grid object appears smaller than another 20-unit sphere created on a scaled-up version of the same grid.

If you want to change the actual size of the grid object, select it and go to the Modify panel > Parameters rollout > Grid Size group, and change the Length and Width settings.

Locating Grid Tools

Grid tools are spread throughout the 3ds Max interface.

- In the Views menu, under Grids, are the commands to activate home and user grids. The same tools are available with a right-click anywhere in the viewport when a grid helper is selected.
- Right-click anywhere in the viewport while a grid object is selected and the Tools1 quadrant of the quad menu provides commands to activate the home and user grids.
- Choose Tools menu > Grids And Snaps > Grid And Snap Settings to display the Grid and Snap Settings dialog on page 2819. Two tabs are devoted to Grid tools, one for home, another for user grids. You can change parameters of any active grid using the Modify panel.

See also:

- Viewing Grid Objects on page 2791

Procedures

To create a grid object:

1. Do one of the following:
   - Click Create panel > Helpers > Standard > Object Type rollout > Grid.
   - Choose Create menu > Helpers > Grid.

The Parameters rollout appears on the Create panel.
In a viewport, drag out a rectangle and release the mouse button. This creates and selects a grid object, which appears in white wireframe, divided into four quadrants with coordinate axes at the center.

While the newly created grid object is still selected, you can change its settings on the Parameters rollout.

You can also create a grid object during object creation. Turn on AutoGrid, then press Alt during object creation. A grid is created at the same time as the object and remains displayed and active. See AutoGrid on page 2792 for more information.

To activate a grid object:

A grid object requires activation before use. Standard selection doesn't activate it unless you turn on the option to do so (see User Grids on page 2836).

Only one grid can be active for construction at a time, whether it's the home grid or a grid object. Activating a user grid “deactivates” the home grid.

Activating a grid object enables options to reactivate the home grid on the Views menu > Grids submenu and the Quad menu.

If you have more than one grid object in your scene, you have to activate each one separately. Select the grid object you want to make active and follow the same procedure. Activating another grid object deactivates the current one.

1. Select a grid object.
2. Do one of the following:
   - From the Views menu, choose Grids > Activate Grid Object.
   - Right-click the selected grid object and choose Activate Grid from the quad menu.

   The grid object changes to show its internal grid structure. Except for its main axes, the home grid disappears in all viewports.

To reactivate the home grid, do one of the following:

1. From the Views menu, choose Grids > Activate Home Grid.
2. Right-click the selected grid object and choose Activate Home Grid from the quad menu.

   This deactivates the grid object and returns the home grid in all views.
   If you delete an activated grid object, the home grid also reactivates.
You can assign a keyboard shortcut to Activate Home Grid in the Keyboard panel on page 8250 of the Customize User Interface dialog. This is useful if you need to move back and forth between different grids.

**To use a grid object as construction plane:**

When activated, a grid object replaces the home grid as the frame of reference for creating objects.

An activated grid object creates a true plane in 3D space. No matter how small an activated grid object appears on screen, its XY plane is effectively infinite, just as if it were the XY plane of the home grid.

1. Activate the grid object.
2. Create any category of object.
   3ds Max creates the object directly on the plane of the grid object, with the object’s Z axis perpendicular to the plane.
3. Use Application menu on page 7989 > Import > Merge to import an object.
   3ds Max creates the object directly on the plane of the grid object, with the object’s Z axis perpendicular to the plane.

See Align on page 967 for details on aligning objects and grids.

Like other objects in 3ds Max, you can move and rotate grid objects freely using standard transformation methods. These transforms, along with alignment, are essential in positioning a construction plane in 3D space.

**To nudge a grid object up or down:**

1. Activate the grid object.
2. Use Customize User Interface on page 8249 to specify controls for the Nudge Grid Down and Nudge Grid Up actions. For example, you could set the + and – keys on the numeric keypad to move the grid object up and down.
   Adjust the nudge strength with the Grid Nudge Distance on page 8312 setting on the Viewports panel of the Preferences dialog.
Interface

Grid Size group

Sets the overall size of the grid object. This size determines the extents of a viewport set to the grid object. It doesn't affect the useful limits of the grid, which extend infinitely.

Length/Width  Specifies the length and width of the grid.

Grid Spacing group

Grid  Specifies the size of the smallest square in the visible grid. This setting appears on the status line when the grid is activated.
**NOTE** You can set Grid Spacing when a grid is selected, but you won’t see the grid spacing until the grid is activated.

**Active Color group**

Determines the color used to draw the grid in viewports when it's not selected.

- **Gray** The active grid object is two shades of gray.

- **Object Color** The main grid lines use the assigned object color, while the secondary lines use a lighter intensity.

- **Home Color** The grid object uses the home grid color assigned via the Customize User Interface dialog on page 8249.

- **Home Intensity** The grid object uses the grid intensity settings assigned to the home grid in the Customize User Interface dialog on page 8249.

**Display group**

**XY Plane, YZ Plane, ZX Plane** Determines which of the three planes of the grid object are displayed in the viewport.

**Point Helper**

Create panel > Helpers > Standard > Object Type rollout > Point

Create menu > Helpers > Point

Point provides a specific location in 3D space that can be used as a reference or by other program functions.

**Procedures**

**To create a point in space:**

1. Click `Point` and check the type of display from the Parameters rollout.

2. Adjust the size of the point object by using the Size spinner in the Parameters rollout. Default=20.0

3. Left-click and drag anywhere in your scene.

   The point follows the cursor until you release the mouse button, indicating the current location of the point object.
4 Move the cursor to where you want the point object and release the mouse button.

The point object appears using the display setting you chose.
You can move and rotate the point as needed using standard transformation methods.

**Interface**

![Parameters window](image)

**Center Marker** Displays a small X marker at the center of the point object.

**Axis Tripod** Displays a tripod axis indicating the position and orientation of the point object. The axis remains visible when the point object is no longer selected.

**Cross** Displays an axis-aligned cross.

**Box** Displays a small axis-aligned box at the center of the point object.

**Size** Sets the size for the point object. Use this to minimize the point object, or increase its size to aid in locating it. Default=20.

**Constant Screen Size** Keeps the size of the point object constant, regardless of how much you zoom in or out.

**Draw On Top** Displays the point object on top of all other objects in the scene.
NOTE You can also choose to activate multiple display settings.

Tape Helper

Create panel > Helpers > Standard > Object Type rollout > Tape
Create menu > Helpers > Tape Measure

Tape provides an on-screen "tape measure" for determining and setting distances. The tape is composed of two named objects, in the same way targeted lights and cameras are. By default, these are named Tape## and Tape##.Target. The tape and target icons are connected by a line representing the current distance between them.

Using a tape helper to measure the distance from floor to window frame.

You can drag a length (the default), or enter a specific length by turning on Specify Length. You can snap or align either end of the tape or link to objects in your scene. Deleting either end deletes the tape.
When you add a Tape helper object, 3ds Max automatically assigns a Look At controller to it, with the tape's target object assigned as the Look At target. You can use the controller settings on the Motion panel to assign any other object in the scene as the Look At target.

**Selection**

You can select a tape-measure object from either end, or from the middle. When you click the connecting line, both ends of the tape object become selected so you can move them as one. Note that the same is true of target cameras and lights.

**NOTE** Line selection is available only when clicking with the mouse. Region selection doesn't work for this.

**TIP** The Length readout of the tape object is displayed in the Modify panel only when you select the tape end of the object (as opposed to the target or link line). You can lock the Length display by activating the Pin Stack button while the tape end is selected, and then proceed to adjust any part of the tape object or any other object in your scene.

See also:

- Measure Distance Tool on page 2881

**Procedures**

To measure a distance:

1. Click Tape and drag from one point to create the tape, and then drag to a second point and release the mouse button to create the target. The distance between tape and target appears in the Length field. The number in the Length field is gray to indicate that this is a read-only measurement.

   **NOTE** To snap the tape ends to object vertices, edges and so on, turn on Snap on page 2807 with the appropriate snap settings activated.

2. Move either end to a new location. The line between stretches to the new distance, shown in the Length field.
NOTE For accurate results when moving a tape endpoint with Snap, you must turn on Pivot in the Snap Settings panel as well as the types of sub-object you want to snap to; see Snaps on page 2819. This is because the endpoints are actually pivots.

To set a distance:

- Turn on Specify Length in the Parameters rollout, enter a length, and then create the tape. The connector line is the length you specified, although you can still set the target to any offset by dragging. You can reorient this line as required.

NOTE Clearing Specify Length will adjust the connector line length to meet the target and the new length appears in the Length field.

Interface

![Parameters rollout]

**Parameters rollout**

**Length** Specifies the length of the tape object. You must select the Specify Length check box to enable this option.
Specify Length  Activates the Length parameter setting. Otherwise the tape object’s length will be specified by clicking and dragging in the viewport.

World Space Angles group

To X/Y/Z Axis  Displays the angle of the tape object relative to each axis in world space.

To XY/YZ/ZX Plane  Displays the angle of the tape object relative to each of these home planes.

Protractor Helper

Create panel > Helpers > Standard > Object Type rollout > Protractor
Create menu > Helpers > Protractor

Protractor measures the angle between a point and any two objects in your scene.

The names of the two objects appear above their respective buttons, and the angle formed at the protractor object between the pivot points of the two objects is displayed in the Angle field. Lines are drawn between the protractor and the two selected objects.

NOTE  The line to the first selected object uses the Target Line color, and the line for the second selected object uses the color of the protractor. The Target Line color is set with Customize User Interface dialog > Colors panel on page 8272 > Elements drop-down list > Gizmos group. The Protractor color is set by choosing the Tape Object in Customize User Interface dialog > Colors panel on page 8272 > Elements drop-down list > Objects group.

You can reselect the protractor at any time, enter the Modify panel on page 8184, and pick new objects to measure. You can move either of the two objects or the protractor itself to change the angle.

NOTE  If you need to watch the Angle readout while moving either of the objects, first select the protractor, then click the Pin Stack button on the Modify panel. You can now select and move the other objects while the stack remains pinned to display the protractor angle.
**Procedures**

**To use the protractor:**

1. After selecting Protractor in the Create panel > Helpers section, click in the viewport to place and create the protractor icon. You can also drag to move it before releasing the mouse button.

2. Click the Pick Object 1 button, and then select one of the objects in the scene.
   The name of the selected object appears above the button.

3. Click Pick Object 2, and then select a second object in the scene.
   The Angle parameter shows the angle formed by lines from the protractor object to the two picked objects.

**Interface**

**Parameters rollout**

**Pick Object 1** Click this and select the first of the two objects whose angle you want to measure.

**Pick Object 2** Click this and select the second of the two objects whose angle you want to measure.

**Angle** Displays the angle formed by the lines from the protractor to the two objects.
**Compass Helper**

Create panel > Helpers > Standard > Object Type rollout > Compass

Create menu > Helpers > Compass

Compass displays as a non-rendering compass rose, with indicators for North, South, East, and West. A compass is part of a Daylight or Sunlight system on page 5491; you create a compass automatically when you create sunlight. In a Sunlight system, the orientation of the compass indicates the orientation of the scene, relative to the path of the sun (the ecliptic).

Use the Compass helper object if you want to create an orientation symbol in your scene, but don’t need to create a sunlight system.

**Procedures**

**To create a compass object:**

1. Choose Compass in the Create panel > Helpers section.
2. Click and drag to define the radius of the compass.
3. Select and rotate the compass object to orient it.

**Interface**

**Parameters rollout**

Show Compass Rose Displays the non-rendering compass rose in the viewport.

Radius Specifies the radius of the compass object.
Manipulator Helper Objects

Create panel > Helpers > Manipulators > Object Type rollout
Create menu > Helpers > Manipulators

Manipulator helpers are objects you can create to manipulate other objects. They let you add customized controls to your scene that provide visual feedback in viewports. To control other objects, manipulators use the parameter wiring feature on page 3610.

Manipulators can be especially useful when you create a scene that will be used by more than one animator.

There are three kinds of manipulator helpers: Cone Angle, Plane Angle, and Slider.

See also:
- Wire Parameters on page 3610
- Parameter Wiring Dialog on page 3612
- Select And Manipulate on page 2838

Cone Angle Manipulator

Create panel > Helpers > Manipulators > Object Type rollout > Cone Angle button
Create menu > Helpers > Manipulators > Cone Angle

The Cone Angle manipulator is a cone whose base you can adjust. By wiring its Angle value to a parameter of another object, you can create a custom control, with visual feedback, within a scene.
Cone angle manipulators are used by a spotlight's Hotspot and Falloff controls.

**Procedures**

**To create a cone angle manipulator:**

1. In the Create panel, go to Helpers and choose Manipulators from the drop-down list.
2. Click to turn on Cone Angle.
3. Drag in a viewport, and then release the mouse.
   The cone angle manipulator is created along the negative Z axis of the viewport in which you drag. In other words, its initial position points away from you.

**To change the angle of a cone angle manipulator:**

1. Turn on Select And Manipulate.

   **TIP** If you are still in the Create panel, turn on Select Object before using the manipulator. Otherwise, it is too easy to create a new one.

2. In a viewport, move the mouse over the manipulator.
The manipulator turns red when the mouse is over it and it is available to be manipulated. Also, a tooltip appears, showing the name of the manipulator and its current value.

3 Drag the base of the cone angle manipulator's cone. The Angle value changes as you drag the manipulator. This value can range between 0.0 and 180.0.

To select a cone angle manipulator:

1 Turn on Select Object. You can also use Select And Move, Select And Rotate, and the scale options on a cone angle manipulator.

2 Turn off Select And Manipulate. If you don't turn off Select And Manipulate, you adjust the manipulator's Angle value without affecting its properties.

3 Adjust the properties of the selected manipulator.

To connect a cone angle manipulator so it controls another object:

1 Select the cone angle manipulator.

NOTE Select And Manipulate must be off before you can select the manipulator.

2 Choose Animation > Wire Parameters > Wire Parameters. You can also right-click the manipulator and choose Wire Parameters from the Transform (lower-right) quadrant of the quad menu. A pop-up menu appears over the manipulator.

3 In the pop-up menu, choose Object (Cone Angle Manipulator) > Angle.

4 Click the object you want to manipulate.
A pop-up menu appears over the object.

5 In the pop-up menu, choose Object, then the name of the parameter you want to manipulate.

The Parameter Wiring dialog on page 3612 appears.

6 On the Parameter Wiring dialog, click the “control direction” arrow between the two upper lists that goes from the manipulator to the object (or both directions), and then click Connect.

7 Close the Parameter Wiring dialog.

Now when you turn on Select And Manipulate and use the manipulator, the object updates under the manipulator’s control.

**Interface**

![Parameter Wiring Interface](image)

- **Angle** The initial angle of the manipulator.
- **Distance** The length of the manipulator, in 3ds Max units. Default=the distance of mouse drag when the manipulator was created.
- **Use Square** When on, the base of the cone is square or rectangular, rather than circular. Default=off.
- **Aspect** When Use Square is on, adjusts the aspect ratio of the rectangular cone base. Default=1.0.
Plane Angle Manipulator

Create panel > Helpers > Manipulators > Object Type rollout > Plane Angle button

Create menu > Helpers > Manipulators > Plane Angle

The Plane Angle manipulator looks like a lever or joystick. By wiring its Angle value to a parameter of another object, you can create a custom control, with visual feedback, within a scene.

Plane angle manipulator at different angles
Procedures

To create a plane angle manipulator:

1. In the Create panel, go to Helpers and choose Manipulators from the drop-down list.
2. Click to turn on Plane Angle.
3. Drag in a viewport, and then release the mouse.
   The plane angle manipulator is always created vertically, along the Y axis of the viewport in which you drag.

To change the angle of a plane angle manipulator:

1. Turn on Select And Manipulate.

   TIP: If you are still in the Create panel, turn on Select Object before using the manipulator. Otherwise, it is too easy to create a new one.

2. In a viewport, move the mouse over the manipulator.
   The manipulator turns red when the mouse is over it and it is available to be manipulated. Also, a tooltip appears, showing the name of the manipulator and its current value.
3. Drag the handle of the plane angle manipulator.
   The Angle value changes as you drag the manipulator. This value can range between –100000.0 and 100000.0.

To select a plane angle manipulator:

1. Turn on Select Object.

   You can also use Select And Move, Select And Rotate, and the scale options on a plane angle manipulator.
2 Turn off Select And Manipulate.
   If you don't turn off Select And Manipulate, you adjust the manipulator's
   Angle value without affecting its properties.

3 Adjust the properties of the selected manipulator.

To connect a plane angle manipulator so it controls another object:

1 Select the plane angle manipulator.

   **NOTE** Select And Manipulate must be off before you can select the
   manipulator.

2 Choose Animation > Wire Parameters > Wire Parameters.
   You can also right-click the manipulator and choose Wire Parameters
   from the Transform (lower-right) quadrant of the quad menu.
   A pop-up menu appears over the manipulator.

3 In the pop-up menu, choose Object (Plane Angle Manipulator) > Angle.

4 Click the object you want to manipulate.
   A pop-up menu appears over the object.

5 In the pop-up menu, choose Object, then the name of the parameter you
   want to manipulate.
   The **Parameter Wiring dialog** on page 3612 appears.

6 On the Parameter Wiring dialog, click the “control direction” arrow
   between the two upper lists that goes from the manipulator to the object
   (or both directions), and then click Connect.

7 Close the Parameter Wiring dialog.
   Now when you turn on Select And Manipulate and use the manipulator,
   the object updates under the manipulator's control.
Interface

![Parameters Interface]

**Angle** The angle of the manipulator, from 0.0 to 360.0 (both values are perpendicular in the Y axis of the viewport where you created the manipulator, unless you have rotated the manipulator object). Default=0.0.

**Distance** The length of the manipulator, in 3ds Max units. Default=the distance of mouse drag when the manipulator was created.

**Size** The size of the manipulator's handle, in 3ds Max units. Default=1.0.

**Slider Manipulator**

Create panel > Helpers > Manipulators > Object Type rollout > Slider button

Create menu > Helpers > Manipulators > Slider

The Slider manipulator is a graphic control that appears in the active viewport. By wiring its Value to a parameter of another object, you can create a custom control, with visual feedback, within a scene.

![Slider manipulator]

**NOTE** Because the slider manipulator is a custom control, its Value has no inherent unit. It takes on the unit of the parameter to which it is wired. When the minimum is 0.0 and the maximum is 100.0, the slider Value can represent a percentage.
Using a Slider Manipulator

Slider manipulator components:
1. Label
2. Value
3. Move
4. Show/hide
5. Slider bar
6. Adjust value
7. Change width

The slider appears in the same location in whichever viewport is active.

You can adjust the slider’s value by dragging the triangle below the slider bar. The triangle turns red when you move the mouse over it. It represents the slider’s value, and the value changes as the triangle is dragged. You can also make the following changes without going into the Modify panel:

- Dragging the small square at the left moves the slider.
- Dragging the diamond at the right changes the width of the slider.
- Clicking the plus sign (next to the move icon at the left) hides all of the slider except for the label and the move icon.

Like the Value triangle, these components also turn red when you move the mouse over them.
Procedures

To create a slider manipulator:

1. In the Create panel, go to Helpers and choose Manipulators from the drop-down list.
2. Click to turn on Slider.
3. Click a viewport.
   The slider manipulator is created with its default width of 100 units. It will appear at the same viewport location in whichever viewport is active.

To change the value of a slider manipulator:

1. Turn on Select And Manipulate.
   The slider turns green.

   TIP
   If you are still in the Create panel, turn on Select Object before using the manipulator. Otherwise, it is too easy to create a new one.

2. In a viewport, move the mouse over the triangle below the slider bar.
   The triangle turns red when the mouse is over it and it is available to be dragged.
3. Drag the value triangle of the slider manipulator.
   The slider's value display changes as you drag the triangle.

To move a slider manipulator:

1. Turn on Select And Manipulate.

2. In the active viewport, move the mouse over the move icon, which is the small square at the left of the slider, below the sliders label (if there is one) and value display.
   The square turns red when the mouse is over it and it is able to be dragged.
3. Drag the box to move the slider.
Unlike angle manipulators, transforms have no effect on sliders.

To connect a slider manipulator so it controls another object:

1. Select the slider.

   **NOTE** Select And Manipulate must be off before you can select the slider.

2. Choose Animation > Wire Parameters > Wire Parameters.
   You can also right-click the manipulator and choose Wire Parameters from the Transform (lower-right) quadrant of the quad menu.
   A pop-up menu appears over the manipulator.

3. In the pop-up menu, choose Object > Value.

4. Drag to the object you want to manipulate, and click it.
   A pop-up menu appears over the object.

5. In the pop-up menu, choose Object, then the name of the parameter you want to manipulate.
   The **Parameter Wiring dialog** on page 3612 appears.

6. In the Parameter Wiring dialog, make sure the direction goes from the slider to the object (or both directions), and then click Connect.

7. Close the Parameter Wiring dialog.
   Now when you turn on Select And Manipulate and use the slider, the object updates under the slider's control.

**Label** The slider name that appears in viewports. Default=none.

**Value** The value of the slider, based on the position of the slidable triangle. Default=0.0.

**Minimum** The minimum possible value of the slider. Default=0.0.

**Maximum** The maximum possible value of the slider. Default=100.0.

When the minimum is 0.0 and the maximum is 100.0, the slider Value can represent a percentage.

**X Position** The slider's X location in the active viewport. Default=Viewport X location you clicked when you created the slider.

**Y Position** The slider's Y location in the active viewport. Default=Viewport Y location you clicked when you created the slider.

**Width** The slider's width, in 3ds Max units. Default=100.0.

**Snap** When on, the slider "snaps" to incremental values determined by the Snap Value setting. Default=on.

**Snap Value** The increment used by the slider when Snap is on. Default=0.01.

**Hide** When on, hides all of the slider except for the label and the move and show/hide components. Default=off.
Drawing Assistants

The tools and utilities described in this section can help with drawing and precision. The xView toolset gives you visual feedback for a variety of mesh-object metrics. The Measure Distance tool lets you quickly calculate the distance between two points. The Measure utility returns the measurements of a selected shape or 3D object. And the Rescale World Units utility rescales either a selection or an entire scene.

Access xView from the Views menu and the Shading viewport label menu. Measure Distance is available from the Tools menu. Access the Measure utility and Rescale World Units from the Utilities panel on page 823.

xView

Views menu > xView
Shading Viewport Label menu on page 8130 > xView > Choose a command.
Activate xView. > Active viewport > Click xView message (test name/result).
xView analyzes mesh models, flags various potential problems and errors, and displays the results in the viewports both graphically and as text. Tests include isolated and overlapping vertices, open edges, various UVW statistics, and more.

In addition, xView can convert its graphical display, such as highlighted vertices or edges, to a sub-object selection. And you can change the tolerance setting (distance) for relevant checks such as overlapping edges.

While a test is active, its name appears at the top or bottom of the active viewport; you determine the position by toggling the Display On Top command on the xView menu. You can open the xView menu by clicking this text.

The xView viewport display

Next to the test name is a status message. If the test has been successful, the message indicates the results, such as “14 Vertices.” Otherwise, the message
indicates a possible reason for the failure of the test, such as “No selection” (xView works only on selected objects) or “Unsupported object type” (xView works only on editable mesh and poly objects).

If the active test is configurable, the message “Click Here To Configure” appears on a second line after the test name. Typically the configurable parameter is a Tolerance setting that determines the maximum distance for the test, such as between vertices. To change the value, click the message or use the xView menu > Configure command.

Customizing xView

Every command on the xView submenu is available from the Customize User Interface (CUI) on page 8249, so you can define keyboard shortcuts or a custom toolbar for frequently used functions. Also available in the CUI xView category are additional actions to cycle through the command list, toggle the viewport display, and more.

Procedure

To use xView:

1. Select the geometry to check; typically an Edit/Editable Mesh/Poly object. There is no need to access a sub-object level.

2. Choose the type of test to perform from the xView menu. By default, you can find this menu on the Shading Viewport Label menu on page 8130 (the rightmost viewport label menu) and the Views menu.

   The test is performed immediately and the results, if any, display in the viewports as green-highlighted sub-objects: vertices, edges, or faces. At the same time, the name of the test and its numerical results display at the bottom or top of the viewport.

   **NOTE** If any of the flagged sub-objects are already selected, they remain selected and display normally at the relevant sub-object level. Thus they are not highlighted in green when the relevant sub-object level is active. However, they’re still flagged and, if you deselect the sub-objects, retain the green highlighting.
3 To convert the highlighted sub-objects to a sub-object selection, reopen the xView menu and choose Select Results. To use the selection, access the relevant sub-object level.

**Interface**

The xView functions work on editable/edit poly and mesh objects; most other object types (including primitives) are unsupported.

All of the modes relate to sub-objects: vertices, edges, and faces (whether geometry or UVW). However, you need not be at a sub-object level for a checker to display its results. The checker results appear at the object level and at all sub-object levels.
Face Orientation  Highlights the back side (see 2-Sided (Double Sided) on page 8493) of each face in the selection. This is useful for checking for inadvertently flipped faces.

Overlapping Faces  Highlights interpenetrating, coplanar faces. This should be avoided when possible to prevent rendering anomalies. Technically, this test checks for at least one vertex of one face lying in the plane of another, so if only edges of two faces overlap, the test won't find them. The Tolerance value specifies the distance from the vertex to the plane of the overlapping face.

Open Edges  Edges that are not shared with any other polygons; that is, at the outer edge of a surface.

Multiple Edges  Checks for edges that are common to more than two faces. This doesn't happen in Edit/Editable Poly objects, but is possible in Edit/Editable Mesh objects. However, if you have any flipped polys in an Edit/Editable Poly, xView flags edges where they adjoin non-flipped polys as multiple edges.
NOTE Because of the underlying nature of Edit/Editable Mesh objects, an internal edge can show two different IDs on the Selection panel when selected twice in succession. However, this does not necessarily indicate a multiple edge, and the Multiple Edges test does not indicate such edges.

**Isolated Vertices** Flags vertices that are not associated with any edges or faces.

**Overlapping Vertices** Flags vertices that lie within a certain distance of each other. The configurable Tolerance parameter indicates the maximum distance in world units within which the test is performed.

**T-Vertices** Flags vertices that lie at the intersection of three edges or faces. Applies to poly objects only.

The T-Vertex is highlighted in green

**Missing UVW Coordinates** Highlights faces that lack texture-mapping coordinates. 3ds Max has internal safeguards against this, but it might happen with certain imported geometry.

**Flipped UVW Faces** Highlights texture-mapping faces whose normals point opposite the usual direction.

**Overlapped UVW Faces** Highlights any texture-mapping faces that coincide with other texture-mapping faces.

**Select Results** Selects sub-objects flagged and highlighted by the active test. To see the selection, go to the relevant sub-object level.

**See-Through** Shows all highlighted sub-objects regardless of any intervening geometry.
Auto Update When on, xView automatically redraws the screen to show the result of parameter changes.

Display On Top When on, the text display appears at the top of the active viewport. When off (the default), the text displays at the bottom of the viewport.

Configure Opens a small dialog for setting the current test’s parameters, if there are any. If there are not, this option is unavailable.

Measuring Distances

3ds Max provides several options for measuring various aspects of your scene. The tape, protractor and compass helpers measure distance, angles and direction respectively. The Measure utility has a floater to display various measurements of any selected object.

You can quickly measure the distance between two points with the Measure Distance tool on page 2881.

Helper Objects for Measurement

Tape Helper

You can create a Tape helper on page 2855 by dragging between any two points in 3D space, much like using a physical tape measure. You then read the length on the Parameters rollout.

If you turn on Specify Length, the length field lets you enter a value in current units. This is like locking a tape measure to a set length. You can position the tape object and snap to its ends.
To display length and angle settings, select only the tape helper object (the pyramid icon).

To move the entire tape including its target (the cube icon), select the connecting line.

Two sets of World Space Angles give you current readouts to the three world axes (X, Y, Z) and the three world planes (XY, YZ, ZX).

**TIP** When measuring with precision, it is helpful to use snaps to force the ends of the tape object to exact locations. If there are no specific points to snap to, you can use dummy or point helpers to set points.

### To measure with a tape helper using snaps:

1. Locate points in the scene to which you can snap to accurately make a measurement. If no points like this exist, create point objects on page 2853 at measurement extremes.

2. Choose 3D from the Snap Toggle flyout.

3. Right-click the Snap Toggle button to display the Grid And Snap Settings dialog. On the Snaps tab, set the snap type to the type you will use for measurement. For example, if you are going to use point objects for measurement, check the Pivot option so you can snap to the point objects' pivot points. Close the dialog.

4. On the Create panel, click the Helpers button, then click Tape. Move the cursor over the first measurement point until the snap cursor appears, then click and drag to the other measurement point.
5  Read the length of the tape on the Parameters rollout.

**Protractor**

The **Protractor helper** on page 2858 measures the angle between pivot points of two objects and the protractor object. As with the tape helper, point objects and snap tools can be used to aid in precise measurement of angles.

**To measure an angle with a protractor:**

1. **On the Create panel, click the Helpers button, then click Protractor. Click in a viewport to place the protractor object.**
2. **On the Parameters rollout, click Pick Object 1 and select an object in your scene. The name of the selected object appears above the pick button. A line connects the protractor to the center of the object.**
3. **Click Pick Object 2 and pick a second object. The angle between the protractor and the two objects appears on the rollout.**
4. **To move either object while watching the Angle readout, turn on Pin Stack below the modifier stack. This locks the stack to the Protractor’s Parameters rollout.**

**Compass**

The **Compass helper** on page 2860 establishes an orientation for your scene. You create this object with a single click and drag to define the radius, usually in a Perspective or Top view. On its parameters rollout, you can adjust the apparent radius of the compass rose. Like all helper objects, this object is for reference only and does not render.

**Measure Utility**

The **Measure Utility** on page 2882 provides measurements of a selected object or shape.
To use the Measure utility:

1. On the Utilities panel, click Measure to display the Measure rollout.
2. Select any shape or object and read out the measurements. If you select multiple objects, the sum of the measurements is displayed.
3. Click New Floater to display a modeless Measure dialog with all the same information.
4. Use the Measure dialog to display the length of a spline, like a line or circle, as you create it.

Measure Distance Tool

The Measure Distance tool quickly calculates the distance between two points.

To measure the distance between two points:

1. Choose Tools menu > Measure Distance.
2. Click in the viewport where you want to start measuring from.
3. Click again in the viewport where you want to measure to.

A distance is returned in the Mini Listener. Additional information, detailing the distance along the X, Y, and Z coordinates is displayed in the status bar.
A distance is returned in the status bar. Additional information, detailing the distance along the X, Y, and Z coordinates is displayed as well.

**Measure Utility**

Utilities panel > Utilities rollout > Measure button

The Measure utility provides measurements of a selected object or shape.

**See also:**

- Measure Distance Tool on page 2881

**Procedures**

To measure an object:

1. On the Utilities panel, click the Measure button.
2. Select the object you want to measure.

   If both an object and a shape are in the selection, information is displayed for both types. If several objects are in a selection, the sum of their measurements is displayed.
**Interface**

- **Text display** Displays the name of the object in the current selection. If more than one object is in the selection, Multiple Objects Selected is displayed.

- **Lock Selected** Prevents the displayed data from changing when you change selection. For example, you might need to select and manipulate another object that affects the currently selected object.

**Objects group**

Displays information about renderable mesh objects.

- **Surface Area** Displays the total surface area of all objects in the selection, in units squared.
Volume Displays the total volume of all objects in the selection, in units cubed. Note that objects with "holes" caused by missing faces can result in inaccurate volume values. When an object has one or more holes, an asterisk appears beside the Volume number.

Center Of Mass Displays the world coordinates of the location of the center of mass for the object or the center of mass of the selected objects.

Create Center Point Creates a point helper object on page 2853 at the center of mass.

Shapes group
Displays information about shape objects.

Length Displays the sum of the length of all splines in all selected shapes.

Dimensions group
Displays the dimensions of the object, as they appear in world space. For example, if it were a box with the created dimensions of 15 x 10 x 25, and that box were scaled 200 percent, then this group would report dimensions of 30 x 20 x 50.

Button set

New Floater Launches a modeless Measure dialog that displays the same information found under the Objects, Shapes, and Dimensions groups on the Utilities panel. In addition, you can expand the dialog horizontally, in case the values are too long to be viewed in the default dialog size.

TIP While the Measure floater is displayed, you can view the length of a spline while you're creating it.

Close Closes the utility.

Rescale World Units Utility

Utilities panel > Utilities rollout > More button > Utilities dialog > Rescale World Units

This utility rescales the world units of either the entire scene or selected objects in the scene. The Rescale World Units dialog controls scale factor and whether it is applied to the entire scene or the current selection.
Procedures

To rescale an object:

1. Select an object in the viewport.
2. On the Utilities panel, click the More button, and on the Utilities dialog, choose Rescale World Units from the list.
3. On the Utilities panel, click the Rescale World Units button.
4. On the Rescale World Units rollout, click the Rescale button.
5. Set the Scale Factor to the desired scale. For example, setting the scale to a value of 2.0 doubles the size of the object that it’s applied to.
6. In the Affect group, choose the Selection option.
7. Click OK to apply the scale.

Interface

Rescale World Units rollout

Rescale After selecting the objects you want to rescale, click this to display the Rescale World Units dialog.
Rescale World Units dialog

Scale Factor Specifies the scaling factor.

Affect
- **Scene** Applies the scale to the entire scene.
- **Selection** Applies the scale only to the current selection.

OK Applies the scale.

Cancel Cancels the operation.
Space Warps and Particle Systems

Space warps and particle systems are additional modeling tools. Space warps are “force fields” that deform other objects, creating the effect of ripples, waves, blowing wind, and so on. Particle systems generate particle sub-objects for the purpose of simulating snow, rain, dust, and so on. (You use particle systems primarily in animations.)

Left: Fountain spray created as a particle system
Insets on right: Wind space warp changes the direction of fountain spray

Space Warp Objects

Create panel > Space Warps
Space warps are nonrenderable objects that affect the appearance of other objects. Space warps create force fields that deform other objects, creating the effect of ripples, waves, blowing wind, and so on.

Space warps behave somewhat like modifiers, except that space warps influence world space, rather than object space, as geometric modifiers do.

When you create a space warp object, viewports show a wireframe representation of it. You can transform the space warp as you do other 3ds Max objects. The position, rotation, and scale of the space warp affect its operation.

Surfaces deformed by space warps
Left: Bomb
Right: Ripple
Rear: Wave

A space warp affects objects only when the objects are bound to it on page 2893. The warp binding appears at the top of the object's modifier stack. A space warp is always applied after any transforms or modifiers.

When you bind multiple objects to a space warp, the space warp's parameters affect all the objects equally. However, each object's distance from the space
warp or spatial orientation to the warp can change the warp's effect. Because of this spatial effect, simply moving an object through warped space can change the warp's effect.

You can also use multiple space warps on one or more objects. Multiple space warps appear in an object's stack in the order you apply them.

**NOTE** You can take advantage of the AutoGrid feature to orient and position new space warps with respect to existing objects. See AutoGrid on page 2792 for details.

**Space Warps and Supported Objects**

Some types of space warps are designed to work on deformable objects, such as geometric primitives, meshes, patches, and splines. Other types of warps work on particle systems such as Spray and Snow.

Five space warps (Gravity, PBomb, Wind, Motor, and Push) can work on particle systems and also serve special purposes in a dynamics simulation. In the latter case, you do not bind the warps to objects, but rather assign them as effects in the simulation.

On the Create panel, each space warp has a rollout labeled Supports Objects Of Type. This rollout lists the kind of objects you can bind to the warp.

**Basics of Using Space Warps**

Follow these general steps to use space warps:

1. Create the space warp.
2. Bind objects to the space warp.

   ![Click Bind To Space Warp](click_bind_to_space_warp.png)

   Click Bind To Space Warp on the main toolbar (available from the Select And Link flyout), and then drag between the space warp and the object.

   The space warp has no visible effect on your scene until you bind an object, system, or selection set to it.
3. Adjust the space warp's parameters.
4. Transform the space warp with Move, Rotate, or Scale. The transforms often directly affect the bound object.

You can animate space warp parameters and transforms. You can also animate space warp effects by animating transforms of an object bound to the warp.
Particle Leakage and Deflector Space Warps

A deflector is a space warp that acts as a barrier to particles in particle systems. Occasionally stray particles can leak through a deflector under the following circumstances:

- When a particle happens to hit the deflector too near the end or beginning of a time interval, and numerical error in the solution doesn't report a hit
- When a particle hits too near the edge of a face referenced by a UDeflector, and neither face finds it
- When a particle is moving quickly and first appears too close to the deflector, so the very first update cycle within the particle system takes it past the deflector without the deflector ever seeing it

Often this isn't a problem because the particles bounce off solid objects, so you don't see the errant particles. When it does cause problems, you can use a planar deflector instead of a UDeflector, a collection of planars to approximate the mesh, or a simple mesh to replace the planar. The solutions vary, so where one has a glitch the other might work just fine.

If particles are moving fast and the deflector is in a particular position (for example, it might be too close to the emitter) many particles can leak through deflectors. Sometimes you can fix this leakage by changing the particle system's Subframe Sampling setting or the particle speed. Other times you must reposition the deflector farther away from the emitter.

In addition, particles imbued with bubble motion on page 3356 can leak through deflectors, particularly when set to high amplitudes. To avoid this, use alternative methods of implementing bubble-like motion, such as varying speed (see Particle Generation Rollout (PArray) on page 3338), setting a higher angle for the stream spread with spray systems (see Spray Particle System on page 3306, Super Spray Particle System on page 3315), or using larger particles with an animated texture map.

Space Warp Categories

There are four categories of space warps, available via the list on the Create panel's Space Warps category.

Forces

These space warps are used to affect particle systems and dynamics systems. All of them can be used with particles, and some can be used with dynamics.
The Supports Objects of Type rollout indications which systems each space warp supports.

**Motor Space Warp** on page 2898

**Push Space Warp** on page 2894

**Vortex Space Warp** on page 2903

**Drag Space Warp** on page 2908

**Path Follow Space Warp** on page 2919

**PBomb Space Warp** on page 2914

**Displace Space Warp** on page 2930

**Gravity Space Warp** on page 2923

**Wind Space Warp** on page 2926

**Deflectors**

These space warps are used to deflect particles or to affect dynamics systems. All of them can be used with particles and with dynamics. The Supports Objects of Type rollout indicates which systems each space warp supports.

**PDynaFlect Space Warp** on page 2941

**POmniFlect Space Warp** on page 2935

**SDynaFlect Space Warp** on page 2948

**SOmniFlect Space Warp** on page 2946

**UDynaFlect Space Warp** on page 2951
**Geometric/Deformable**

These space warps are used to deform geometry.

- **FFD(Box) Space Warp** on page 2962
- **FFD(Cyl) Space Warp** on page 2969
- **Wave Space Warp** on page 2979
- **Ripple Space Warp** on page 2983
- **Displace Space Warp** on page 2930
- **Conform Space Warp** on page 2987
- **Bomb Space Warp** on page 2991

**Modifier-Based**

These are space-warp versions of object modifiers (see **Modify Panel** on page 8184). Read more about these in **Modifier-Based Space Warps** on page 2995.

- **Bend Modifier** on page 1165
- **Noise Modifier** on page 1544
- **Skew Modifier** on page 1664
- **Taper Modifier** on page 1807
- **Twist Modifier** on page 1833
- **Stretch Modifier** on page 1749

**Procedures**

**To create a space warp:**

1. On the Create panel, click Space Warps.
   The Space Warps panel is displayed.
2 Choose a category of space warp from the list.
3 On the Object Type rollout, click a space warp button.

**TIP** You can take advantage of the AutoGrid feature to orient and position new space warps with respect to existing objects. For details, see AutoGrid on page 2792.

4 Drag in a viewport to create the space warp.
See the topics for the various space warps for further details.

---

**Bind to Space Warp**

Main toolbar > Bind to Space Warp

Use the Bind to Space Warp button to attach the current selection to a space warp on page 8727 or vice versa.

**Procedures**

To bind the current selection to a space warp:

1 Select an object

2 Click Bind to Space Warp.

3 Drag a line from the selected object to the space warp object. You can also press H to select the space warp by name.
The space warp object flashes for a moment to show that the bind was successful.

**Forces**

Forces affect particle systems and dynamics systems.
Push Space Warp

Create panel > Space Warps > Forces > Object Type rollout > Push
Create menu > Space Warps > Forces > Push

For particle systems, Push applies a uniform, unidirectional force. For dynamics systems, it provides a point force: like pushing something with your finger.

Push disperses a cloud of particles

The Push space warp applies a force to either particle systems on page 2997 or dynamics systems on page 4190. The effect is different, depending on the system:

- **Particles**: Applies a uniform, unidirectional force in a positive or negative direction. A positive force moves in the direction of the pad on the
hydraulic jack. The breadth of the force is infinite, perpendicular to the direction; you can limit it using the Range option.

- **Dynamics**: Provides a point force (also called a point load) away from the pad of the hydraulic jack icon. A negative force pulls in the opposite direction. In dynamics, applying a force is the same as pushing something with your finger.

Procedures

To create a Push space warp:

1. On the Create panel, click Space Warps. Choose Forces from the list, and then on the Object Type rollout, click Push.
2. Drag in a viewport to define the size.
   The Push warp appears as a hydraulic jack icon.
Interface

  - Particle Effect Range
    - Enable
    - Range: 1000.0
  - Display Icon
    - Icon Size: 10x388
Timing group

On Time/Off Time The numbers of the frames in which the space warp begins and ends its effect. Because Push moves the particles to which it’s applied over time, no keyframes are created.

Strength Control group

Basic Force The amount of force exerted by the space warp.

Newtons/Pounds This option specifies the units of force used by the Basic Force spinner.

A pound is about 4.5 Newtons, and one newton is one kilogram-per-second-squared. When Push is applied to particle systems, these values have only subjective meaning because they depend on the built-in weighting factors and time scaling used by the particle system. However, when used in a dynamics system, the value listed is precisely the value used.

Feedback On When on, the force varies depending on the speed of the affected particles relative to the specified Target Speed. When off, the force remains constant, regardless of the speed of the affected particles.

Reversible When on, if the particle's speed exceeds the Target Speed setting, the force is reversed. Available only if you turn on Feedback On.

Target Speed Specifies the maximum speed in units per frame before the Feedback takes effect. Available only if you turn on Feedback On.

Gain Specifies how quickly the force adjusts to approaching the target speed. If set to 100 percent, the correction is immediate. If set lower, a slower and "looser" response occurs. Available only if you turn on Feedback On.

NOTE Setting Gain above 100 percent can result in over-correction, but is sometimes necessary to overcome damping from other system settings, such as IK damping.

Periodic Variation group

These settings introduce variations into the force by affecting the Basic Force value randomly. You can set two waveforms to produce a noise effect.

Enable Turns on the variations.

Period 1 The time over which the noise variation makes a full cycle. For example, a setting of 20 means one cycle per 20 frames.
Amplitude 1 The strength of the variation (in percent). This option uses the same types of units as the Basic Force spinner.

Phase 1 Offsets the variation pattern.

Period 2 Provides an additional variation pattern (a second wave) to increase the noise.

Amplitude 2 The strength of the variation of the second wave (in percent). This option uses the same types of units as the Basic Force spinner.

Phase 2 Offsets the variation pattern of the second wave.

Particle Effect Range group

Lets you restrict the Push effect's range to a specific volume. This affects particle systems only; it has no effect on dynamics.

Enable When on, limits the range of the effect to a sphere, displayed as a tri-hooped sphere. The effect falls off increasingly as the particles near the boundary of the sphere.

Range Specifies the radius of the range of the effect, in units.

Display Icon group

Icon Size Sets the size of the Push icon. This is for display purposes only, and does not alter the Push effect.

Motor Space Warp

Create panel > Space Warps > Forces > Object Type rollout > Motor
Create menu > Space Warps > Forces > Motor

The Motor space warp works like Push on page 2894, but applies rotational torque to the affected particles or objects rather than a directional force. Both the position and orientation of the Motor icon affect particles, which swirl around the Motor icon.
Motor disperses a cloud of particles

When used in dynamics, the position of the icon relative to the affected object has no effect, but the orientation of the icon does.

Motor viewport icon (with particle system on the left)
Procedures

To create a motor space warp:

1 On the Create panel, click Space Warps > Forces > Motor. Choose Forces from the list, then on the Object Type rollout, click Motor.

2 Click and drag in a viewport to define the size.

The Motor warp appears as a box-shaped icon with an arrow indicating the direction of the torque.

Interface

Timing group

On Time/Off Time The numbers of the frames in which the space warp begins and ends its effect. Because Motor moves the objects to which it’s applied over time, no keyframes are created.

Strength Control group

Basic Torque The amount of force exerted by the space warp.
N·m/Lb-ft/Lb-in Specify the unit of measure for the Basic Torque setting, using common world measurements of torque. N-m stands for Newton meters, Lb-ft stands for pound-force feet, and Lb-in stands for pound-force inches.

Feedback On When on, the force varies depending on the speed of the affected objects relative to the specified Target Speed. When off, the force remains constant, regardless of the speed of the affected objects.

Reversible When on, if the object’s speed exceeds the Target Speed setting, the force is reversed. Available only if you turn on Feedback On.

Target Revs Specifies the maximum revolutions before the feedback takes effect. Speed is specified in units traveled per frame. Available only if you turn on Feedback On.

RPH/RPM/RPS Specifies the units of measure for Target Revs in revolutions per hour, minute, or second. Available only if you turn on Feedback On.

Gain Specifies how quickly the force adjusts to approaching the target speed. If set to 100%, the correction is immediate. If set lower, a slower and "looser" response occurs. Available only if you turn on Feedback On.

NOTE Setting Gain above 100% can result in over-correction, but is sometimes necessary to overcome damping from other system settings, such as IK damping.
**Periodic Variation group**

These settings introduce variations into the force by affecting the Basic Torque value randomly. You can set two waveforms to produce a noise effect.

**Enable** Turn on to enable the variations.

**Period 1** The time over which the noise variation makes a full cycle. For example, a setting of 20 means one cycle per 20 frames.

**Amplitude 1** The strength of the variation (in percent). This option uses the same types of units as the Basic Torque spinner.

**Phase 1** Offsets the variation pattern.

**Period 2** The next two spinners provide an additional variation pattern to increase the noise.
Amplitude 2 The strength of the variation of the second wave in (percent). This option uses the same types of units as the Basic Torque spinner.

Phase 2 Offsets the variation pattern of the second wave.

Particle Effect Range group

Lets you restrict the Motor effect’s range to a specific spherical volume. This affects particles systems only; it has no effect on dynamics.

Enable When on, limits the range of the effect to a sphere, displayed as a tri-hooped sphere. The effect falls off increasingly as the particles near the boundary of the sphere.

Range Specifies the radius of the range of the effect, in units.

Display Icon group

Icon Size Sets the size of the Motor icon. This is for display purposes only, and does not alter the Motor effect.

Vortex Space Warp

Create panel > Space Warps > Forces > Object Type rollout > Vortex

Create menu > Space Warps > Forces > Vortex

The Vortex space warp applies a force to particle systems on page 2997, spinning them through a whirling vortex, and then moving them down a long, thin spout or vortex well. Vortex is useful for creating black holes, whirlpools, tornadoes, and other funnel-like objects.

The space warp settings let you control the vortex shape, the well characteristics, and rate and range of particle capture. The shape of the vortex is also affected by particle system settings, such as speed.
Particle stream caught in a vortex

**Procedures**

To create a Vortex space warp:

1. On the Create panel, click Space Warps. Choose Forces from the list, and then click Vortex.

2. Determine which world axis you want the vortex to spiral around, and then drag in the appropriate viewport to create the space warp. For example, if you want the vortex to spin around the vertical world axis, create the space warp in the Top viewport. You can rotate the warp later to change the vortex direction, and animate the warp orientation.
The Vortex warp appears as a curved-arrow icon in the plane you drag in, with a second, perpendicular arrow indicating the axis of rotation as well as the direction of the well. This second axis is called the drop axis.

**NOTE** The position of the space warp plays an important role in the results. The vertical position affects the shape of the vortex, and the horizontal position determines its location. If you want the particles to spiral around the particle emitter, place both at the same location.
**Interface**

**Timing group**

*Time On/Time Off* The frame numbers at which the space warp becomes active and becomes inactive.
**Vortex Shape group**

**Taper Length** Controls the length of the vortex, as well as its shape. Lower settings give you a "tighter" vortex, while higher settings give you a "looser" vortex. Default=100.0.

**Taper Curve** Controls the shape of the vortex. Low values create a vortex with a wide, flared mouth, while high values create a vortex with nearly vertical sides. Default=1.0. Range=1.0 to 4.0.

**Capture and Motion group**

This group contains basic settings for Axial Drop, Orbital Speed, and Radial Pull, with Range, Falloff, and Damping modifiers for each.

**Unlimited Range** When on, Vortex exerts full damping strength over an unlimited range. When off, the Range and Falloff settings take effect.

**Axial Drop** Specifies how quickly particles move in the direction of the drop axis.

**Range** The distance from the center of the Vortex icon, in system units, at which Axial Damping has its full effect. Takes effect only when Unlimited Range is turned off.

**Falloff** Specifies the distance beyond the Axial Range within which Axial Damping is applied. Axial Damping is strongest at the Range distance, decreases linearly out to the limit of the Axial Falloff, and has no effect beyond that. Takes effect only when Unlimited Range is turned off.

**Damping** Controls the degree to which particle motion parallel to the drop axis is restrained per frame. Default=5.0. Range=0 to 100.

For subtle effects, use values of less than 10%. For more overt effects, try using higher values that increase to 100% over the course of a few frames.

**Orbital Speed** Specifies how quickly the particles rotate.

**Range** The distance from the center of the Vortex icon, in system units, at which Orbital Damping has its full effect. Takes effect only when Unlimited Range is turned off.

**Falloff** Specifies the distance beyond the Orbital Range within which Orbital Damping is applied. Orbital Damping is strongest at the Range distance, decreases linearly out to the limit of the Orbital Falloff, and has no effect beyond that. Takes effect only when Unlimited Range is turned off.
**Damping** Controls the degree to which orbital particle motion is restrained per frame. Smaller values produce a wide spiral, while larger values produce a thin spiral. Default=5.0. Range=0 to 100.

**Radial Pull** Specifies the distance from the drop axis at which the particles rotate.

**Range** The distance from the center of the Vortex icon, in system units, at which Radial Damping has its full effect. Takes effect only when Unlimited Range is turned off.

**Falloff** Specifies the distance beyond the Radial Range within which Radial Damping is applied. Radial Damping is strongest at the Range distance, decreases linearly out to the limit of the Radial Falloff, and has no effect beyond that. Takes effect only when Unlimited Range is turned off.

**Damping** Controls the degree to which Radial Pull is restrained per frame. Default=5.0. Range=0 to 100.

**CW/CCW** Determines whether particles rotate clockwise or counterclockwise.

**Display group**

**Icon Size** Specifies the size of the icon.

---

**Drag Space Warp**

Create panel > Space Warps > Forces > Object Type rollout > Drag

Create menu > Space Warps > Forces > Drag

The Drag space warp is a particle motion damper that reduces particle velocity by a specified amount within a specified range. The damping can be applied linearly, spherically, or cylindrically. Drag is useful for simulating wind resistance, transfers into dense media (like water), impacts with force fields, and other, similar situations.

With each damping type, you can control the damping effect along several vectors. The damping is also affected by particle system settings, such as speed.

---

**NOTE** To create a uniform drag effect, the default value for all directional parameters is 5.0%.
Drag slows down a stream of particles.

Procedures

To create a Drag space warp:

1. On the Create panel, click Space Warps. Choose Forces from the list, and then click Drag.

2. Drag in a viewport to create the space warp.
   The space warp appears initially as a box within a box, indicating that it’s using the default Linear Damping mode.

3. To apply the damping spherically or cylindrically, choose Spherical Damping or Cylindrical Damping in the command panel.
NOTE The position and orientation of the space warp plays an important role for all three damping types.

4 Change the settings for the current damping type as necessary.

Forces | 2911
Timing group

Time On/Time Off  The frame numbers at which the space warp becomes active and becomes inactive.

Damping Characteristics group

This group lets you choose Linear Damping, Spherical Damping, or Cylindrical Damping, plus a set of parameters for each.

Unlimited Range  When on, Drag exerts full damping strength over an unlimited range. When off, the Range and Falloff settings for the current damping type take effect.

- **Linear Damping**  Motion for each particle is separated into vectors for the space warp's local X, Y, and Z axes. The area over which damping is exerted for each vector is an infinite plane whose thickness is determined by the corresponding Range setting.

  X Axis/Y Axis/Z Axis  Specifies the percentage of particle motion along the local Drag space warp axis that's affected by the damping.

  Range  Sets the thickness of the "range plane," or the infinite plane perpendicular to the specified axis. Takes effect only when Unlimited Range is turned off.

  Falloff  Specifies the distance beyond the X, Y, or Z Range within which Linear Damping is applied. Damping is strongest at the Range distance, decreases linearly out to the limit of the Falloff, and has no effect beyond that. While Falloff takes effect only beyond the Range, it is measured from the center of the icon, and always has a minimum value equal to the Range value. Takes effect only when Unlimited Range is turned off.

- **Spherical Damping**  When Drag operates in Spherical Damping mode, its icon is a sphere within a sphere. Particle motion is broken up into radial and tangential vectors. Damping is applied for each vector within a spherical volume whose radius is set by the Range setting, when Unlimited Range is off.

  Radial/Tangential  Radial specifies the percentage of particle motion toward or away from the center of the Drag icon that's affected by the damping. Tangential specifies the percentage of particle motion across the body of the Drag icon that's affected by the damping.
Range
Specifies the distance from the center of the Drag icon, in system units, within which damping is in full effect. Takes effect only when Unlimited Range is turned off.

Falloff
Specifies the distance beyond the Radial/Tangential Range within which Linear Damping is applied. Damping is strongest at the Range distance, decreases linearly out to the limit of the Falloff, and has no effect beyond that. While Falloff takes effect only beyond the Range, it is measured from the center of the icon, and always has a minimum value equal to the Range value. Takes effect only when Unlimited Range is turned off.

Cylindrical Damping
When Drag operates in Spherical Cylindrical mode, its icon is a cylinder within a cylinder. Particle motion is broken up into radial, tangential, and axial vectors. Damping is applied within a spherical volume for the radial and tangential vectors and on a planar basis for the axial vector.

Radial/Tangential/Axial
Damping controls the percentage of particle motion toward or away from the center of the circular portion of the icon (Radial), across the radial vector (Tangential), or along the length of the icon's long axis (Axial) that's affected by the damping, on a per-frame basis.

Range
Specifies the distance from the center of the Drag icon, in system units, within which Radial and Axial damping are in full effect. Range also specifies the thickness of the infinite plane that governs the range of Axial damping. Takes effect only when Unlimited Range is turned off.

Falloff
Specifies the distance beyond the Radial/Tangential/Axial Range within which Linear Damping is applied. Damping is strongest at the Range distance, decreases linearly out to the limit of the Falloff, and has no effect beyond that. While Falloff takes effect only beyond the Range, it is measured from the center of the icon, and always has a minimum value equal to the Range value. Takes effect only when Unlimited Range is turned off.

Display group
Icon Size  Specifies the size of the icon.

Forces | 2913
PBomb Space Warp

Create panel > Space Warps > Forces > Object Type rollout > PBomb
Create menu > Space Warps > Forces > PBomb

The PBomb space warp creates an impulse wave to blow up a particle system, as distinguished from the Bomb space warp on page 2991, which blows up geometry. The PBomb is particularly well suited to the Particle Array (PArray) system with Particle Types set to Object Fragments. This space warp also applies an impulse as a dynamics effect.

The general usage is as follows:

- Create a particle system (recommended: a PArray system on page 3331 set to Object Fragments).

- Create a PBomb and use Bind to Space Warp on page 2893 to bind it to a non-event-driven particle system. Be sure to bind the PBomb to the particle system and not to the distribution object. Or, if using Particle Flow, use a Force operator on page 3189 to apply the space warp to the particle system.

- Adjust the parameters of both the PBomb and the particle system.

Right: PBomb viewport icon
Above: PArray particle system

Below: Torus knot used as the PArray's distribution object

Effect of blowing up the torus knot

**Procedures**

**Example: To use PBomb with PArray:**

You can use the Particle Bomb bound to a Particle Array to blow an object into fragments. The following steps demonstrate the basic setup.

Begin by binding a particle array to an object, and setting parameters.

1. Create the object you want to blow up.
2. Create a PArray and use Pick Object to assign the object to blow up as the PArray object-based emitter.
3. In the Basic Parameters rollout > Viewport Display group, choose Mesh to display the fragments as mesh objects in the viewports.
4 On the Particle Generation rollout of PArray, set Speed and Divergence to 0.0. This prevents PArray from moving the particles, letting PBomb do the work.

5 On the Particle Generation rollout, set Life to the length of the active time segment, so that the fragments appear during the entire animation.

6 In the Particle Type rollout > Particle Types group, choose Object Fragments. In the Object Fragment Controls group, choose Number of Chunks, and set the Minimum to about 50, depending on your distribution object and the effect you want.

Now create a particle bomb, and bind it to the particle array.

1 In the Space Warps panel > Particles & Dynamics category, click the PBomb button and drag in a viewport to create the PBomb icon.

2 Use Bind to Space Warp to bind the PArray icon to the PBomb icon. (Don’t bind the distribution object by mistake.)

3 Select the PBomb icon and move to the Modify panel.

4 In the Explosion Parameters group, set Blast Symmetry to Spherical, Start Time to 10, Duration to 1, and Strength to 1.0. Choose Linear, if it’s not already chosen.

5 Drag the time slider between frames 9 and 20 to see the effect.

6 Go to frame 12 and try out various settings. Notice that increasing Strength expands the explosion effect at the current frame. If you decrease Range enough, the bomb no longer affects all or part of the object (depending on the placement of the PBomb icon). Test the three Blast Symmetry settings by placing the bomb in the center of the object and then seeing the different blast patterns.

Once you get an explosive effect you like, you can return to the PArray settings, add spin or thickness to the fragments, and so on.
Interface

Blast Symmetry group

These options specify the shape, or pattern of the blast effect.

**Spherical** The blast force radiates outward from the PBomb icon in all directions. The icon looks like a spherical anarchist's bomb.

**Cylindrical** The blast force radiates outward from and normal to the central axis, or core of the cylindrical icon. The icon looks like a stick of dynamite with a fuse.

**Planar** The blast force radiates both up and down, perpendicular to the plane of the planar icon. The icon looks like a plane with arrows pointing up and down along the direction of the blast force.

**Chaos** The blast forces vary for each particle or each frame, an effect similar to Brownian motion, with a rate of change in the direction of force equal to
the rendering interval rate. Note: This setting is effective only when the
Duration spinner is set to 0.

**Explosion Parameters group**

**Start Time** The frame number at which the impulse forces are first applied to
the particles.

**Duration** The number of frames, beyond the first, over which the forces are
applied. This value should typically be a small number, such as between 0 and
3.

**Strength** The change in velocity along the blast vector, in units per frame.
Increasing Strength increases the speed with which the particles are blown
away from the bomb icon.

**Unlimited Range** The effects of the bomb icon reach all bound particles
throughout the scene. This option ignores the Range setting (which specifies
the distance of the PBomb effect).

**Linear** The impulse forces decay linearly between the full Strength setting to
a value of 0 at the specified Range setting.

**Exponential** The impulse forces decay exponentially between the full Strength
setting to a value of 0 at the specified Range setting.

**Range** The maximum distance, in units, over which the PBomb icon affects
the bound particle system. If the Range is large enough to reach only a portion
of the particle system, only that part of the system is affected.

If you turn on Range Indicator (see following), the extent of the range is
indicated by a tri-ahooped sphere. If you choose Unlimited Range, this
parameter has no effect.

**Display Icon group**

These options affect the visual display of the PBomb icon.

**Icon Size** Alters the overall size of the PBomb icon.

**Range Indicator** Displays a wireframe sphere that indicates the volume of
the particle bomb's influence. If you choose Unlimited Range, turning this
on has no effect.
Path Follow Space Warp

Create panel > Space Warps > Forces > Object Type rollout > Path Follow
Create menu > Space Warps > Forces > Path Follow
The Path Follow space warp forces particles to follow a spline path.

Particles following a spiral path

Procedures

To create a Path Follow space warp:

1. On the Create panel, click Space Warps. Choose Forces from the list, then on the Object Type rollout, click Path Follow.

2. Click and drag in a viewport to define the size.
   The Path Follow warp appears as a box-shaped icon containing curved lines that indicate hypothetical paths.

To set up and use Path Follow:

1. Create a shape consisting of a single spline. (You can use shapes with multiple splines, but 3ds Max uses only one spline for the path.)

2. Create a particle system and set its parameters to emit particles over a range of frames.
3 On the Create panel, click Path Follow, and drag in a viewport to create the Path Follow icon (a cube with wavy lines). The display and position of this icon don’t affect the particles.

4 On the Basic Parameters rollout, click Pick Shape Object and select the spline you created earlier.

5 Bind the Path Follow icon to the particle system.

6 Adjust the Path Follow parameters to create the particle movement you want.

**NOTE** You can further animate the particle effect by animating the spline vertices.

**TIP** To adjust the position of the path or particle system while maintaining access to the Path Follow parameters, select the Path Follow space warp and then turn on Pin Stack, below the modifier stack.

If the particles don't follow the emitter after it's moved, then change any PathFollow parameter, and the motion will be corrected.
Interface

- Basic Parameters
  - PARTICLE PATH FOLLOW
    - Current Path: <None>
    - Pick Shape Object
      - Unlimited Range
        - Range: 100.0

      - Diverge
      - Both
      - Stream Swift: 1.0
      - Variation: 0.0
      - Clockwise
      - Counterclockwise
      - Bidirectional
  - Uniqueness:
    - Seed: 12345
  - Display Icon
    - Icon Size: 36.218
Current Path group

Lets you choose the path for the particles, and specify the range of influence of the Space Warp.

Object Displays the name of the currently assigned path.

Pick Shape Object Click this, and then click a shape in the scene to select it as a path. You can use any shape object as a path; if you select a multiple-spline shape, only one the lowest-number spline is used. You can also use NURBS curves as paths.

Unlimited Range When off, the range of influence of the space warp is limited to the value set in the Distance spinner. When on, the space warp influences all bound particles in the scene, regardless of their distance from the path object.

Range Specifies the range of influence when Unlimited Range is off. This is the distance between the path object and the particle system. The position of the Path Follow space warp's icon is ignored.

Motion Timing group

These controls affect how long particles are influenced by Path Follow.

Start Frame The frame at which Path Follow begins to influence the particles.

Travel Time The time each particle takes to traverse the path.

Variation The amount by which each particle's travel time can vary.

Last Frame The frame at which Path Follow releases the particles and no longer influences them.

Particle Motion group

The controls in this area determine the motion of particles.

Along Offset Splines The distance between the particle system and the path alter the effect of the particle motion. If the first vertex of the spline is at the birthplace of the particle, the particle follows the spline path. If you move the path away from the particle system, the particles are affected by the offset.

Along Parallel Splines Particles follow a copy of the selected path, parallel to the particle system. In this mode, the position of the path relative to the particle system does not matter. The orientation of the path, however, affects the particle stream.
**Constant Speed** When on, all particles travel at the same speed.

**Stream Taper** Causes particles to converge or diverge toward the path over time, or to simultaneously converge and diverge. You specify the effect by choosing Converge, Diverge, or Both (see following). This provides a tapering effect over the length of the path.

**Variation** The amount by which Stream Taper can vary for each particle.

**Converge** When Stream Taper is greater than 0, the particles move in toward the path as they follow the path. The effect is that the stream tapers from larger to smaller over time.

**Diverge** Provides the opposite effect of Converge. The particles diverge from the path over time.

**Both** Splits the particle stream, causing some particles to converge and others to diverge.

**Stream Swirl** Specifies the number of turns by which particles spiral about the path. In conjunction with Stream Taper, alters the diameter of the spiral. Stream Swirl is generally more effective when you choose Along Offset Splines.

**Variation** The amount by which each particle can vary from the Spiral value.

**Clockwise** Particles spiral in a clockwise direction.

**Counterclockwise** Particles spiral in a counterclockwise direction.

**Bidirectional** The stream is split so that particles spiral in both directions.

**Uniqueness group**

Provides a seed number for unique generation of the particle pattern.

**Seed** Specifies the seed number for the current Path Follow.

**Display Icon group**

Affects the display of the Path Follow icon.

**Icon Size** Specifies the size of the Path Follow icon. Does not alter the Path Follow effect.

**Gravity Space Warp**

Create panel > Space Warps > Forces > Object Type rollout > Gravity
Create menu > Space Warps > Forces > Gravity

The Gravity space warp simulates the effect of natural gravity on particles generated by a particle system. Gravity is directional. Particles moving in the direction of the gravity arrow accelerate. Particles moving against the arrow decelerate.

Particles falling because of gravity

In the case of spherical gravity, motion is toward the icon. Gravity can also be used as an effect in dynamics simulations. See Dynamics Utility on page 4190.

Gravity effect on snow

Procedures

To create gravity:

1. On the Create panel, click Space Warps. Choose Forces from the list, then on the Object Type rollout, click Gravity.
2 Drag in a viewport.

The Gravity icon appears. For planar gravity (the default), the icon is a wireframe square with a direction arrow on one side. For spherical gravity, the icon is a wireframe sphere.

The initial direction of planar gravity is along the negative Z axis of the construction grid that is active in the viewport where you drag. You can rotate the gravity object to change the direction.

**Interface**

![Parameters interface](image)

**Force group**

**Strength** Increasing Strength increases the effect of gravity; that is, how objects move in relation to the Gravity icon's direction arrow. Strength less than 0.0 creates negative gravity, which repels particles moving in the same direction and attracts particles moving in the opposite direction. When Strength is set to 0.0, the Gravity space warp has no effect.

**Decay** When Decay is set to 0.0, the Gravity space warp has the same strength throughout world space. Increasing the Decay value causes gravity strength to diminish as distance increases from the position of the gravity warp object. Default=0.0.
**Planar** Gravity effect is perpendicular to the plane of the Gravity warp object throughout the scene.

**Spherical** Gravity effect is spherical, centered on the Gravity warp object. This choice is effective for creating water fountain or planetary effects.

**Display group**

**Range Indicators** When on, and when the Decay value is greater than 0.0, icons in the viewports indicate the range at which the force of gravity is half the maximum value. For the Planar option, the indicators are two planes; for use the Spherical option, the indicator is a double-hooped sphere.

**Icon Size** Size of the Gravity warp object icon, in active units. You set the initial size when you drag to create the Gravity object. This value does not change the gravity effect.

**Wind Space Warp**

Create panel > Space Warps > Forces > Object Type rollout > Wind
Create menu > Space Warps > Forces > Wind

The Wind space warp simulates the effect of wind blowing particles generated by a particle system. Wind is directional. Particles moving in the direction of the wind arrow accelerate. Particles moving against the arrow decelerate. In the case of spherical wind, motion is toward or away from the icon.
Wind changing the direction of the spray of a fountain

Wind is similar in effect to the Gravity space warp, but has added parameters for turbulence and other features characteristic of wind in the natural world. Wind can also be used as an effect in dynamics simulations. See Dynamics Utility on page 4190.
Procedures

To create wind:

1. On the Create panel, click Space Warps. Choose Forces from the list, then on the Object Type rollout, click Wind.

2. Drag in a viewport.
   The wind icon appears. For planar wind (the default), the icon is a wireframe square with a direction arrow coming out of one side. For spherical wind, the icon is a wireframe sphere.
   The initial direction of planar wind is along the negative Z axis of the construction grid that is active in the viewport where you drag. You can rotate the wind object to change the direction.
Interface

Force group

These settings are comparable to the Gravity parameters.

**Strength** Increasing Strength increases the wind effect. Strength less than 0.0 creates a suction. It repels particles moving in the same direction and attracts particles moving in the opposite direction. When Strength is 0.0, the Wind warp has no effect.

**Decay** When Decay is set to 0.0, the Wind warp has the same strength throughout world space. Increasing the Decay value causes wind strength to diminish as distance increases from the position of the Wind warp object. Default=0.0.

**Planar** Wind effect is perpendicular to the plane of the Wind warp object, throughout the scene.
Spherical Wind effect is spherical, centered on the Wind warp object.

Wind group

These settings are specific to the Wind space warp.

Turbulence Causes particles to change course randomly as the wind blows them. The greater the value, the greater the turbulence effect.

Frequency When set greater than 0.0, causes turbulence to vary periodically over time. This subtle effect is probably not visible unless your bound particle system generates a large number of particles.

Scale Scales the turbulence effect. When Scale is small, turbulence is smoother and more regular. As Scale increases, turbulence grows more irregular and wild.

Display group

Range Indicators When the Decay value is greater than zero, icons appear in the viewports that represent the range at which the force of wind is half the maximum value. When you use the Planar option, the indicators are two planes; when you use the Spherical option, the indicator is a double-hooped sphere.

Icon Size Size of the Wind warp object icon, in active units. You set the initial Icon Size value when you drag to create the wind object. This value does not change the wind effect.

Displace Space Warp

Create panel > Space Warps > Geometric/Deformable > Object Type rollout > Displace
Create menu > Space Warps > Geometric/Deformable > Displace

The Displace space warp acts as a force field to push and reshape an object’s geometry. Displace affects both geometry (deformable objects) and particle systems.
There are two basic ways to use the Displace space warp:

- Apply the gray scale of a bitmap to generate the displacement amount. Black areas of the 2D image are not displaced. Whiter areas push outward, causing a 3D displacement of geometry.

- Apply displacement directly by setting displacement Strength and Decay values.

The Displace space warp works similarly to the Displace modifier, except that, like all space warps, it affects world space rather than object space. Use the Displace modifier when you need to create detailed displacement of a small number of objects. Use the Displace space warp to displace particle systems, a large number of geometric objects at once, or an object relative to its position in world space.

For geometry, the detail of the displacement depends on the number of vertices. Use the Tessellate modifier to tessellate faces you want to show in greater detail.
Procedures

To create a Displace space warp:

1. On the Create panel, click Space Warps. Choose Geometric/Deformable from the list, and then on the Object Type rollout, click Displace.

2. Drag in a viewport to create the Displace warp object, which appears as a wireframe. Its shape depends on the active mapping parameter settings. Regardless of the mapping, a single drag creates the space warp.

3. Bind the space warp to an appropriate object.

To assign a bitmap to a displace space warp:

1. Select the Displace warp object.

2. In the Parameters rollout > Displacement group, click the Bitmap button (labeled "None" by default). Use the selection dialog to choose a bitmap.

3. Set the Strength value. Vary the strength of the field to see how the bitmap displaces the object's geometry.
Interface

Displacement group

These are the basic controls for Displace space warps.
**Strength** When set to 0.0, the Displace warp has no effect. Values greater than 0.0 displace object geometry or particles away from the position of the Displace space warp object. Values less than 0.0 displace geometry toward the warp. Default=0.0

**Decay** By default, the Displace warp has the same strength throughout world space. Increasing Decay causes displacement strength to diminish as distance increases from the position of the Displace warp object. Default=0.0

**Luminance Center** By default, the Displace space warp centers the luminance by using medium (50%) gray as the zero displacement value. Gray values greater than 128 displace in the outward direction (away from the Displace warp object) and gray values less than 128 displace in the inward direction (toward the Displace warp object). You can adjust the default using the Center spinner. With a Planar projection, the displaced geometry is repositioned above or below the Planar gizmo. Default=0.5. Range=0 to 1.0.

**Image group**

These options let you choose a bitmap and map to use for displacement.

**Bitmap** (Labeled "None" by default.) Click to assign a bitmap or map from a selection dialog. After you choose a bitmap or map, this button displays the bitmap's name.

**Remove Bitmap** Click to remove the bitmap or map assignment.

**Blur** Increase this value to blur or soften the effect of the bitmapped displacement.

**Map group**

This area contains mapping parameters for a bitmapped Displace warp. The mapping options are comparable to those options used with mapped materials. The four mapping modes control how the Displace warp object projects its displacement. The warp object's orientation controls where in the scene the displacement effect will appear on bound objects.

**Planar** Projects the map from a single plane.

**Cylindrical** Projects the map as if it were wrapped around the cylinder.

**Spherical** Projects the map from a sphere, with singularities at the top and bottom of the sphere, where the bitmap edges meet at the sphere's poles.

**Shrink Wrap** Truncates the corners of the map and joins them all at a single pole, creating one singularity.
**Length, Width, Height** Specify the dimensions of the bounding box of the space warp gizmo. Height has no effect on planar mapping.

**U/V/W Tile** The number of times the bitmap repeats along the specified dimension. The default value of 1.0 maps the bitmap once; a value of 2.0 maps the bitmap twice, and so on. Fractional values map a fractional portion of the bitmap in addition to copies of the whole map. For example, a value of 2.5 maps the bitmap two and one-half times.

**Flip** Reverses the orientation of the map along the corresponding U, V, or W axis.

---

**Deflectors**

Deflectors are used to deflect particles or to affect dynamics systems.

**POmniFlect Space Warp**

Create panel > Space Warps > Deflectors > Object Type rollout > POmniFlect

POmniFlect is a planar version of the omniflector on page 8663 type of space warp. It provides enhanced functionality over that found in the original Deflector space warp, including refraction and spawning capabilities.
**Procedures**

To create a POmniFlect space warp:

1. On the Create panel, click Space Warps. Choose Deflectors from the list, then on the Object Type rollout, click POmniFlect.

2. Drag in a viewport to create the planar icon.

   **NOTE** Because particles bounce off the icon, the size of the icon affects particle deflection.

3. Apply the deflector to the particle system using the appropriate method:
   - If using Particle Flow on page 2997, specify the deflector in the Collision test on page 3236 or Collision Spawn test on page 3241 parameters.
   - If using a non-event-driven particle system on page 3292, bind on page 2893 the particle system to the deflector icon.
4 Position the POmniFlect icon to interrupt the particle stream.
5 Adjust the POmniFlect parameters as necessary.

</table>
**Timing group**

The two spinners specify the start frame and end frame of the deflection effect.

**Time On/Off** Time On specifies the frame at which the deflection begins, and Time Off specifies the frame at which the deflection ends.

**Reflection group**

These options affect the reflection of particles from the space warp. The POmniFlect can reflect or refract particles, or perform a combination of the two.

**Reflects** Specifies the percentage of particles to be reflected by the POmniFlect. See also Refracts, later in this topic, for methods of combining the two effects.

**Bounce** This is a multiplier that specifies how much of the initial speed of the particle is maintained after collision with the POmniFlect. Using the default setting of 1.0 causes the particle to rebound with the same speed as it collides. A real-world effect would usually be less than 1.0. For a “flubber” effect, set greater than 1.0.

**Variation** Specifies the variation of Bounce applied to the range of particles. For example, a Variation of 50% applied to a Bounce setting of 1.0 would result in randomly applied Bounce values ranging from 0.5 to 1.5.

**Chaos** Applies a random variation to the bounce angle. When set to 0.0 (no chaos), all particles bounce off the POmniFlect surface perfectly (like banking pool balls). A nonzero setting causes the deflected particles to scatter.

**Refraction group**

These settings are similar to those in the Reflection group, but these affect the refraction of particles as they pass through the POmniFlect, causing the direction of the particles to change.

**Refracts** Specifies the percentage of particles not already reflected that will be refracted by the POmniFlect.

**NOTE** The Refracts value affects only those particles not already reflected because the reflected particles are processed before the refracted particles. Thus, if you set Reflects to 50% and Refracts to 50%, you would not get a 50/50 split of particles. Rather, half the particles would be reflected, and then half the remainder (25% of the total) would be refracted. The remaining particles either pass through without being refracted or are passed on to Spawn Effects.
To get a 50/50 split of reflection and refraction, set Reflects to 50% and Refracts to 100%.

**Pass Vel** Specifies how much of a particle’s initial speed is maintained after passing through the POmniFlect. The default setting of 1 retains the initial speed is retained, so there's no change. A setting of 0.5 reduces the speed by half.

**Variation** Specifies the variation of Pass Velocity applied to the range of particles.

**Distortion** Controls the angle of refraction. A value of 0 means there's no refraction. A value of 100% sets the angle of the particles to be parallel with the POmniFlect surface. A value of −100% sets the angle perpendicular to the surface. The Distortion effect is reversed when particles strike the POmniFlect from the back side.

**NOTE** Distortion and Refraction do not work properly when particles strike the POmniFlect surface at exactly 90 degrees. In this case, any positive Distortion settings cause a scattering of particles, while negative values have no effect.

**Variation** Specifies a range of variation of the Distortion effect.

**Diffusion** Applies a diffusion effect to the refraction by randomly modifying each particle's Distortion angle by the Diffusion angle. This effectively scatters the particles into a hollow cone.

**Variation** Specifies a range of variation of the Diffusion value.

**Common group**

**Friction** The amount by which particles are slowed as they move along the deflector surface. A value of 0% means they’re not slowed at all. A value of 50% means they’re slowed to half their original speed. A value of 100% means they stop moving when they strike the surface. Default=0%. Range=0% to 100%.

**TIP** To have particles slide along a deflector surface, set Bounce to 0. Also, unless influenced by a force such as Wind or Gravity, particles meant to slide should strike the surface at an angle other than 90 degrees.

**Inherit Vel** (Velocity Inheritance) Determines how much of a moving POmniFlect’s speed is applied to reflected or refracted particles.
For example, if Inherit Vel is 1.0, particles with no motion that are hit by a moving PomniFlect inherit the speed of the POmniFlect at the point of collision.

**Spawn Effects Only group**

These settings affect only particles set to Spawn On Collision that do not either reflect or refract from the omniflector. See Particle Spawn Rollout (PArray) on page 3358. The Spawns percentage spinner works like the Reflects and Refracts percentage spinners, but is the third in line to be processed. Thus, if either Reflects or Refracts are set to 100%, no particles are affected by these settings. Note also that reflective or refractive particles spawn upon collision, regardless of the settings in this group.

**Spawns** Specifies the percentage of particles that can use spawn effects.

**Pass Vel** Specifies how much of the particle’s initial speed is maintained after passing through the POmniFlect.

**Variation** Specifies the variation of the Pass Velocity setting applied to the range of particles.

**Display Icon group**

**Width/Height** Specify the width and height of the POmniFlect icon. This is for display purposes only and does not influence the deflector effect.

**PDynaFlect Space Warp**

Create panel > Space Warps > Deflectors > Object Type rollout > PDynaFlect

PDynaFlect (planar dynamics deflector) is a planar version of the dynaflector on page 8557, a special class of space warp that lets particles affect objects in a dynamics situation. For example, if you want a stream of particles to strike an object and knock it over, like the stream from a firehose striking a stack of boxes, use a dynaflector.

**NOTE** You use dynaflectors in the same way as omniflectors; that is, you can use them as deflectors alone, with no dynamics simulation. Because they take physics into account, dynaflectors are slower than omniflectors. Therefore, it is recommended that you use dynaflectors only when a dynamics simulation is involved.
Procedures

Many dynaflector parameters are the same as those for omniflectors. However, the procedure of associating the dynaflector with both the particle system and the object to be affected is more complex than the simple binding used by omniflector.

To create a particle/dynamics system:

1. Create or load a scene containing a non-event-driven particle system on page 3292 and an object to be affected by the particles (hereafter called "the object"). Position and orient the two as desired so that the particles strike the object.
   - The icon for the particle system must be visible in at least one non-disabled viewport.
   - On the Basic Parameters rollout of the particle system, set Percentage of Particles to 100%. Otherwise, only those particles displayed in the viewport will be calculated.
2 On the Create panel, click Space Warps. Choose Deflectors from the drop-down list, and then click one of the dynaflector buttons (PDynaFlect, SDynaFlect, or UDynaFlect). Drag in a viewport to create the deflector.

3 Do either of the following:
   ■ If using a PDynaFlect or SDynaFlect, position the space warp icon where the particles strike (or will strike) the object. Resize and orient it as needed.
   Also, link the PDynaFlect or SDynaFlect as a child of the object. This step isn't absolutely necessary, but allows the deflector to follow the object as it moves.
   ■ If using a UDynaFlect, go to the Modify panel > Parameters rollout, click the Pick Object button, and then select the object. The position of the space warp icon doesn't matter, and it's not necessary to link the two.

4 Bind the particle system to the dynaflector using the toolbar Bind to Space Warp button on page 2893.

5 Go to the Utilities panel and open the Dynamics utility.

6 On the Dynamics rollout, click New to create a new simulation.

7 Click Edit Object List, and add the object to the dynamics simulation.

8 Click Edit Object. On the Edit Object dialog, click Assign Object Effects and assign the dynaflector to the object.

9 On the Dynamics rollout, turn on the Update Display w/Solve check box above the Solve button.

10 Solve the simulation.
Interface

Timing group

The two spinners specify the start frame and end frame of the deflection effect.
Time On/Off Time On specifies the frame at which the deflection begins, and Time Off specifies the frame at which the deflection ends.

**Particle Bounce group**

These settings affect the reflection of particles from the space warp.

**Reflects** Specifies the percentage of particles to be reflected by the PDynaFlect. This affects both the particles and the dynamics reaction of the object struck by the particles. The more particles that strike the affected object, the more force applied to that object. If set to 0.0, the particles have no effect on the object.

**Bounce** This is a multiplier that specifies how much of the initial speed of the particle is maintained after collision with the PDynaFlect. Using the default setting of 1.0 causes the particle to rebound with the same speed as it collides. A real-world effect would usually be less than 1.0. For a "flubber" effect, set greater than 1.0.

**Variation** Specifies the variation of Bounce applied to the range of particles. For example, a Variation setting of 50% applied to a Bounce setting of 1.0 would result in randomly applied Bounce values ranging from 0.5 to 1.5.

**Chaos** Applies a random variation to the bounce angle. When you set Chaos to 0.0 (no chaos), all particles bounce off the PDynaFlect surface perfectly (like banking pool balls). A nonzero setting causes the deflected particles to scatter.

**Friction** The amount by which particles are slowed as they move along the deflector surface. A value of 0% means they're not slowed at all. A value of 50% means they're slowed to half their original speed. A value of 100% means they stop moving when they strike the surface. Default=0%. Range=0% to 100%.

**TIP** To have particles slide along a deflector surface, set Bounce to 0. Also, unless influenced by a force such as Wind or Gravity, particles meant to slide should strike the surface at an angle other than 90 degrees.

**Inherit Vel** (Velocity Inheritance) Determines how much of a moving PDynaFlect's speed is applied to reflected or refracted particles. For example, if Inherit Vel is 1.0, particles with no motion that are hit by a moving PDynaFlect inherit the speed of the PDynaFlect at the point of collision.
Physical Properties group

These options let you set the mass of each particle.

**Mass** Specifies the mass based on the chosen unit.

- **gram** One gram equals 1/1000 kg or 22/1000 Lbm at a gravity of 1.0.
- **Kg** One kg (kilogram) equals 1000 grams or 2.2 Lbm at a gravity of 1.0.
- **Lbm** One Lbm (pounds-mass) equals 5/11 kg or 454 5/11 grams at a gravity of 1.0. (Pounds-mass, the amount of mass in one pound of weight, is dependent on gravity. For pounds-mass values at a gravity other than 1.0, multiply the pounds-mass value by the gravity factor.)

Display Icon group

**Width/Height** Specify the width and height of the PDynaFlect icon. This is for display purposes only and does not influence the deflector effect.

SOmniFlect Space Warp

Create panel > Space Warps > Deflectors > Object Type rollout > SOmniFlect

SOmniFlect is the spherical version of the omniflector on page 8663 type of space warp. It provides more options than the original SDeflector. Most settings are the same as those in POmniFlect on page 2935. The difference is that this space warp provides a spherical deflection surface rather than the planar surface. The only settings that are different are in the Display Icon area, in which you set the Radius, instead of the Width and Height.

**NOTE** Opposite sides of the deflectors reverse the distortion effect. Thus, a refracted particle passing through the SOmniFlect hits its outside surface first, and then its inside surface. A positive Distortion value warps the particles toward the perpendicular; then, as the particles pass through the inside surface, the same positive Distortion value warps them toward the parallel.
Procedures

To create an SOmiFlect space warp:

1. On the Create panel, click Space Warps. Choose Deflectors from the list, then on the Object Type rollout, click SOmiFlect.

2. Drag in a viewport to create the spherical icon.

   **NOTE** Because particles bounce off the icon, the size of the icon affects particle deflection.

3. Apply the deflector to the particle system using the appropriate method:
   - If using *Particle Flow* on page 2997, specify the deflector in the *Collision test* on page 3236 or *Collision Spawn test* on page 3241 parameters.
   - If using a *non-event-driven particle system* on page 3292, bind on page 2893 the particle system to the deflector icon.
Position the SOmniFlect icon to interrupt the particle stream.
Adjust the SOmniFlect parameters as necessary.

**SDynaFlect Space Warp**

Create panel > Space Warps > Deflectors > Object Type rollout > SDynaFlect

The SDynaFlect space warp is a spherical dynaflector on page 8557. It’s like the PDynaFlect on page 2941 warp, except that it’s spherical, and its Display Icon spinner specifies the icon’s Radius value.

---

**UOmniFlect Space Warp**

Create panel > Space Warps > Deflectors > Object Type rollout > UOmniFlect

UOmniFlect, the universal omniflector on page 8663, provides more options than the original UDeflector. This space warp lets you use any other geometric
object as a particle deflector. The deflections are face accurate, so the geometry can be static, animated, or even morphing or otherwise deforming over time.

**NOTE** Some particle “leakage” can occur with this deflector, particularly when you use many particles and a complex deflector object. To avoid this, perform a test render to check for leaking particles, and then add POmniFlects to catch the strays.

![UOmniFlect viewport icon](image)

**Procedures**

To use the UOmniFlect space warp:

To use a universal omniflector, you need a minimum of three objects in the scene:

1. The particle system
2. The UOmniFlect space warp
3. The object used as the deflector
4. Add or select an object used as the deflector.
5 Create a particle system whose particles intersect the deflector object.

6 On the Create panel, click Space Warps. Choose Deflectors from the list, and then click UOmniFlect.

7 Click and drag in a viewport to place the space warp icon.

**NOTE** The size and position of the UOmniFlect icon do not alter the effect.

8 Apply the deflector to the particle system using the appropriate method:
   - If using Particle Flow on page 2997, specify the deflector in the Collision test on page 3236 or Collision Spawn test on page 3241 parameters.
   - If using a non-event-driven particle system on page 3292, bind on page 2893 the particle system to the deflector icon.

9 On the Modify panel > Parameters rollout > Object-Based OmniFlector group, click Pick Object, and then select the object to use as a deflector.

10 Adjust the particle system and UOmniFlect parameters as necessary.

**Interface**

**Parameters rollout**

The settings for the UOmniFlect are the same as those for POmniFlect on page 2935, with the following additions:

**Object-Based OmniFlector group**

Lets you choose the object to use as a deflector.

**Item** Displays the name of the selected object.

**Pick Object** Click this, and then select any renderable object to use as a deflector.

**Display Icon group**

**Icon Size** Specifies the size of one side of the square UOmniFlect icon.
UDynaFlect Space Warp

Create panel > Space Warps > Deflectors > Object Type rollout > UDynaFlect

The UDynaFlect space warp is a universal dynaflector on page 8557 that lets you use the surface of any object as both the particles deflector and the surface that reacts dynamically to the particle impact.

The procedures and options for using UDynaFlect are the same as for PDynaFlect on page 2941, with the following changes and additions.

NOTE When you use UDynaFlect, you must indicate the object to be affected with the Pick Object button. Linking is not necessary.

Display Icon group

**Icon Size** Specifies the size of the UDynaFlect icon.

SDeflector Space Warp

Create panel > Space Warps > Deflectors > Object Type rollout > SDeflector

Create menu > Space Warps > Deflectors > SDeflector

The SDeflector space warp serves as a spherical deflector of particles.
Procedures

To create an SDeflector:

1. On the Create panel, click Space Warps. Choose Deflectors from the list, then on the Object Type rollout, click SDeflector.

2. Drag in a viewport to create the spherical icon.

   **NOTE** Because particles bounce off the perimeter of the spherical icon, the size of the icon affects particle deflection.

3. Apply the deflector to the particle system using the appropriate method:
   - If using Particle Flow on page 2997, specify the deflector in the Collision test on page 3236 or Collision Spawn test on page 3241 parameters.
   - If using a non-event-driven particle system on page 3292, bind on page 2893 the particle system to the deflector icon.

4. Position the SDeflector icon to interrupt the particle stream.
5 Adjust the SDeflector parameters as necessary.

### Interface

![Particle Bounce group]

#### Particle Bounce group

These settings determine how the deflector affects the bound particles.

**Bounce** Determines the speed with which particles bounce off the deflector. At 1.0, the particles bounce at the same speed as they approach. At 0, they don't deflect at all.

**Variation** The amount by which each particle can vary from the Bounce setting.

**Chaos** The amount of variation from the perfect angle of reflection (found when Chaos is set to 0.0). 100% induces a variation in reflection angle of up to 90 degrees.

**Friction** The amount by which particles are slowed as they move along the deflector surface. A value of 0% means they're not slowed at all. A value of 50% means they're slowed to half their original speed. A value of 100% means they stop moving when they strike the surface. Default=0%. Range=0% to 100%.
TIP To have particles slide along a deflector surface, set Bounce to 0. Also, unless influenced by a force such as Wind or Gravity, particles meant to slide should strike the surface at an angle other than 90 degrees.

Inherit Vel (Velocity Inheritance) When the value is greater than 0, the motion of the deflector affects particles as well as the other settings. For example, to animate the SDeflector passing through a passive array of particles, turn up this value to affect the particles.

Display Icon group
This option affects the display of the icon.
Diameter Specifies the diameter of the SDeflector icon. This setting also alters the effect of the deflection, because particles bounce off the perimeter of the icon. The scale of the icon also affects the particles.

UDeflector Space Warp
Create panel > Space Warps > Deflectors > Object Type rollout > UDeflector
Create menu > Space Warps > Deflectors > UDeflector
The UDeflector is a universal deflector that lets you use any object as a particle deflector.
Particles scatter when they strike a UDeflector object

Procedures

To create a UDeflector:

1. On the Create panel, click Space Warps. Choose Deflectors from the list, then on the Object Type rollout, click UDeflector.

2. In a viewport, drag out a rectangle to add a UDeflector warp to the scene.

3. On the command panel, click the Pick Object button and select an object to be a particle deflector.

4. Apply the deflector to the particle system using the appropriate method:
   - If using Particle Flow on page 2997, specify the deflector in the Collision test on page 3236 or Collision Spawn test on page 3241 parameters.
   - If using a non-event-driven particle system on page 3292, bind on page 2893 the particle system to the deflector icon.
5 Position the UDeflector icon to interrupt the particle stream.
6 Adjust the UDeflector parameters as necessary.

**Interface**

**Object-Based Deflector group**

Specifies the object to use as a deflector.

**Item** Displays the name of the selected object.

**Pick Object** Click this, and then click any renderable mesh object to be used as a deflector.
Particle Bounce group

**Bounce** Determines the speed with which particles bounce off the deflector. At 1.0, the particles bounce at the same speed as they approach. At 0, they don't deflect at all.

**Variation** The amount by which each particle can vary from the Bounce setting.

**Chaos** The amount of variation from the perfect angle of reflection (found when Chaos is set to 0.0). 100% induces a variation in reflection angle of up to 90 degrees.

**Friction** The amount by which particles are slowed as they move along the deflector surface. A value of 0% means they're not slowed at all. A value of 50% means they're slowed to half their original speed. A value of 100% means they stop moving when they strike the surface. Default=0%. Range=0% to 100%.

**TIP** To have particles slide along a deflector surface, set Bounce to 0. Also, unless influenced by a force such as Wind or Gravity, particles meant to slide should strike the surface at an angle other than 90 degrees.

Inherit Vel (Velocity Inheritance) When greater than 0, the motion of the deflector affects particles as well as the other settings. For example, to animate the SDeflector passing through a passive array of particles, turn up this value to affect the particles.

Display Icon group

**Icon Size** This spinner displays and lets you change the size of the icon.

Deflector Space Warp

Create panel > Space Warps > Deflectors > Object Type rollout > Deflector
Create menu > Space Warps > Deflectors > Deflector

The Deflector space warp acts as a planar shield to repel the particles generated by a particle system. For example, you can use Deflector to simulate pavement being struck by rain. You can combine a Deflector space warp with a Gravity space warp to produce waterfall and fountain effects.
Two streams of particles striking two deflectors

See also:
- SDeflector Space Warp on page 2953
- UDeflector Space Warp on page 2956

Procedures

To create a deflector:

1. On the Create panel, click Space Warps. Choose Deflectors from the list, then on the Object Type rollout, click Deflector.

2. Drag in a viewport to define the deflection area. The deflector appears as a wireframe rectangle.
3 Apply the deflector to the particle system using the appropriate method:

- If using Particle Flow on page 2997, specify the deflector in the Collision test on page 3236 or Collision Spawn test on page 3241 parameters.

- If using a non-event-driven particle system on page 3292, bind on page 2893 the particle system to the deflector icon.

Interface

The deflector's effect is controlled mainly by its size and orientation in the scene, relative to the particle system that is bound to it. You can also adjust how strongly the deflector deflects particles.

**Bounce** Controls the speed at which particles bounce off the deflector. At a setting of 1.0, particles bounce off the deflector at the same speed they struck it. At 0.0, particles do not bounce at all. At values between 0.0 and 1.0, particles bounce off the deflector at a speed reduced from their initial speed. At values greater than 1.0, particles bounce off the deflector at a speed greater than their initial speed. Default=1.0.

**Variation** The amount by which each particle can vary from the Bounce setting.
**Chaos** The amount of variation from the perfect angle of reflection (found when Chaos is set to 0.0). 100% induces a variation in reflection angle of up to 90 degrees.

**Friction** The amount by which particles are slowed as they move along the deflector surface. A value of 0% means they're not slowed at all. A value of 50% means they're slowed to half their original speed. A value of 100% means they stop moving when they strike the surface. Default=0%. Range=0% to 100%.

**TIP** To have particles slide along a deflector surface, set Bounce to 0. Also, unless influenced by a force such as Wind or Gravity, particles meant to slide should strike the surface at an angle other than 90 degrees.

**Inherit Vel** (Velocity Inheritance) When the value is greater than 0, the motion of the deflector affects particles as well as the other settings. For example, if you want an animated SDeflector passing through an array of particles to affect the particles, turn up this value.

**Width** Sets the deflector's width.

**Length** Sets the deflector's length.

**Geometric/Deformable**

These space warps are used to deform geometry.

**FFD(Box) Space Warp**

Create panel > Space Warps > Geometric/Deformable > Object Type rollout > FFD(Box)

Create menu > Space Warps > Geometric/Deformable > FFD(Box)

Free-form deformations (FFDs) provide a method of deforming an object by adjusting the control points of a lattice. The offset position of the control points to the original lattice source volume causes the distortion of the affected object. The FFD(Box) space warp is a box-shaped lattice FFD object similar to the original FFD modifiers. This FFD is available as both an object modifier and a space warp. For information on the object-modifier version, see FFD (Box/Cylinder) Modifiers on page 1436.
You create FFD space warps as separate objects similarly to the way you create standard primitives: by dragging the mouse in the viewport. The result is a lattice of control points. The source lattice of an FFD modifier is fitted to the geometry it's assigned to in the stack. This might be a whole object or a sub-object selection of faces or vertices.

Because FFD space warps are separate objects, they carry their own adjustable dimension parameters among the creation parameters.

You can apply object modifiers to space warp objects. For example, you can use the Linked XForm modifier with a space-warp FFD.
Object and object surrounded by an FFD lattice
Moving control points in the lattice deforms the object.

Procedures

To use the FFD(box) space warp:

1. On the Create panel, click Space Warps. Choose Geometric/Deformable from the list, then on the Object Type rollout, click FFD(Box).

2. Drag in a viewport to create the base. Release the mouse button, and then move the mouse to define the height of the FFD lattice. Click to finish the lattice.

3. Bind the lattice to the object you want to deform.

4. Determine the relative placement of the lattice to the object. If the lattice is to be outside of the object, turn on All Vertices. To affect only those vertices inside the lattice, choose Only In Volume, and position the lattice accordingly.
5 In the modifier stack display, choose Control Points as the sub-object level for FFD(box).

6 Adjust the control points.

**NOTE** The distortion effect of an FFD modifier is based on the positional offset of the control points from their original positions in the source volume. If you don't move control points, there is no effect on the target object. Keep this in mind when using space-warp version of the FFD.

If you're using the Deform group > All Vertices option, once you've distorted the object you can set the Falloff value to adjust how much the lattice affects the object, based on distance. This is particularly useful if the lattice is animated to approach or move away from the target object. When Falloff is set to 0, all the vertices are affected, regardless of distance.

**NOTE** When you're at the base-parameters level of an FFD modifier in the Stack, the Show End Result button is turned off and spring-loaded, as it is in an Edit Mesh modifier.
This rollout lets you set the size and resolution of the lattice, and how it displays and deforms.

**Dimensions group**

These options let you adjust the unit dimensions of the source volume, and specify the number of control points in the lattice. Note that the point dimensions are displayed beside the modifier name in the Stack list.

**Length, Width, Height** These three spinners display and let you adjust the length, width, and height of the lattice. To create the space warp, you drag the mouse in the same way that you would to create a standard Box primitive. Note that these spinners don't exist in the object-modifier version of the FFD.

**Label** Displays the current number of controls points in the lattice (for example: 4x4x4).

**Set Number of Points** Displays a dialog containing three spinners labeled Length, Width, and Height, plus OK/Cancel buttons. Specify the number of control points you want in the lattice, and then click OK to make the change.

**NOTE** Make changes to the dimensions before you adjust the positions of the lattice control points. When you change the number of control points with this dialog, any adjustments you've already made to the control points are lost; however, you can undo this use of the dialog.

**Display group**

These options affect the display of the FFD in the viewports.

**Lattice** When turned on, lines are drawn connecting the control points to make a grid. Although viewports can become cluttered when these extra lines are drawn, they help to visualize the lattice.

**Source Volume** When on, the control points and lattice are displayed in their unmodified state. This display is helpful when you're adjusting the source volume to affect specific vertices that lie within or without it. See the All Vertices and Only in Volume options, later in this topic.

**Deform group**

These options provide controls that specify which vertices are affected by the FFD.

**Only In Volume** Only vertices that lie inside the source volume are deformed. Vertices outside the source volume are not affected.
All Vertices All vertices are deformed regardless of whether they lie inside or outside the source volume, depending on the value in the Falloff spinner. The deformation outside the volume is a continuous extrapolation of the deformation inside the volume. The deformation can be extreme for points far away from the source lattice.

Falloff This spinner, enabled only when you choose All Vertices, determines the distance from the lattice that the FFD effect will decrease to zero. When this spinner is set to 0, it’s effectively turned off, and there is no falloff; that is, all vertices are affected regardless of their distance from the lattice. The units of the Falloff parameter are specified relative to the size of the lattice: A falloff of 1 means that the effect will go to 0 for points that are a lattice width/length/height away from the lattice (depending on which side they are on).

Tension/Continuity Lets you adjust the tension and continuity of the deformation splines. Although you can’t see the splines in an FFD, the lattice and control points represent the structure that controls the splines. As you adjust the control points, you alter the splines (which move through each point). The splines, in turn, deform the geometry of the object. By altering the tension and continuity of the splines, you alter their effect on the object.

Selection group

These options provide additional methods of selecting the control points. You can toggle the state of any combination of the three buttons to select in one, two, or three dimensions at once.

All X, All Y, All Z When one of these buttons is on and you select a control point, all control points along the local dimension specified by the button are selected as well. By turning on two buttons, you can select all control points in two dimensions.

About Displays a dialog with copyright and licensing information.

FFD(Cyl) Space Warp

Create panel > Space Warps > Geometric/Deformable > Object Type rollout > FFD(Cyl)

Create menu > Space Warps > Geometric/Deformable > FFD(Cyl)

Free-form deformations (FFDs) provide a method of deforming an object by adjusting the control points of a lattice. The offset position of the control
points to the original lattice source volume causes the distortion of the affected object. The FFD(Cyl) space warp uses a cylindrical array of control points in its lattice. This FFD is available as both an object modifier and a space warp. For information on the object modifier version, see FFD (Box/Cylinder) Modifiers on page 1436.

You create FFD space warps as separate objects similarly to the way you create standard primitives: by dragging the mouse in the viewport. The result is a lattice of control points. The source lattice of an FFD modifier is fitted to the geometry it's assigned to in the stack. This might be a whole object or a sub-object selection of faces or vertices.

Because FFD space warps are separate objects, they carry their own adjustable dimension parameters among the creation parameters.

You can apply object modifiers to space warp objects. For example, you can use the Linked XForm modifier with a space-warp FFD.

**Procedures**

**Example: Create an animated tablecloth:**

![Finished tablecloth using FFD (Cyl) space warp](image)

This example shows how to use the FFD(Cyl) space warp to create a tablecloth that flies in and drapes itself over a table.
Begin by creating the table and tablecloth.

1. Create a table from two cylinders. Make the table top with a radius of 30 units, and a height of 2 units. Make the “table stand” cylinder with a radius of 3 and a height of 60.

2. Make a tablecloth from a box 100 units square and 0.5 units in height. Increase Length and Width Segments to 30, and keep Height Segments at 1.

3. Position the tablecloth so it’s level with or slightly above the table top, and a little less than 100 units to the left of the table edge, as seen from the Top view.

4. Apply a nice wood grain to the table, and a checker to the tablecloth. (Set the checker tiling to about 15x15, and choose any color for the checkers.)

Now, set up a cylindrical FFD space warp that will form the drape of the tablecloth over the table.

1. From the Create panel > Space Warps > Geometric/Deformable, choose FFD(Cyl).

2. In the Top viewport, create a cylindrical FFD space warp, centered on the table top, with a radius of 45 and a height of 5.

3. Click the Set Number of Points button and, in the Set FFD Dimensions dialog, set Side points to 12, Radial points to 5, and Height points to 2.

4. Move the entire FFD lattice up until it’s just over the surface of the table, as seen from the Front viewport.
Next, adjust the control points of the lattice to drape over the table.

1. **Zoom Extents All Selected.**

2. On the Modify panel, in the stack display (below "Modifier List"), click the FFD(cyl) item so it turns yellow. This means you've enabled direct access to the FFD space warps control point sub-objects.

3. In the FFD Parameters rollout > Selection group, turn on All X. This lets you select control points around the perimeter of the FFD cylinder.

4. In the Top viewport, use the **Select and Move tool** on page 914 and region-select the two visible control points of the two outer rings of control points at the nine-o’clock position. (This is easier shown than described. You can actually region-select any number of vertices in the two outer concentric rings of vertices. Because All X is on, all control points for the two rings will be selected.)

5. **On the status bar, click the Selection Lock Toggle button to lock the selection. In the Front viewport, drag the selected points halfway down the height of the table.**

6. Unlock the selection, and then region-select any control point in the outer ring to select all points in the outer ring.
7 Lock the selection and, in the Front viewport, drag the outer ring of points down to the floor.

![Diagram]

You now have a truncated cone shape over the table.

8 Unlock the selection. In the Top viewport, again select all the control points in the two outer rings.

9 Scale the selected control points in, until the radius of the inner ring of points is slightly larger than the table top.

10 Select only the outer ring of points, and scale them so their radius is slightly larger than the inner ring.
   If necessary, move the points, as seen from the Front viewport, down to touch the floor again.
   You now have a lattice of control points draped over the table.

In this next series of steps, you'll bind the tablecloth to the FFD lattice, and then animate it to move over the table.

1 In the stack display, click the FFD(cyl) entry again to exit the sub-object level. It turns gray.

2 In the main toolbar, click the Bind to Space Warp button, and drag between the FFD and the tablecloth.
3 Select the FFD lattice.

4 Choose Deform group > All Vertices.
   The tablecloth is immediately deformed because all vertices are now
   affected, including those outside the lattice volume, and Falloff is set to
   0. A falloff value of 0 means that the distance of the vertices from the
   lattice doesn't matter. Any number greater than 0, however, limits the
   effect.

5 Set the Falloff spinner to 0.4.
   No longer influenced by the FFD space warp, the tablecloth returns to
   its square shape.

6 Turn on Auto Key, and go to frame 100.

7 In the Top viewport, select the tablecloth, and move it until it's centered
   over the table.

8 As the tablecloth nears the table, it droops down to the floor, sweeps up
   and over the table, and finally drapes itself over the table.

9 As you move the time slider back and forth and examine the animation,
   you might find that the bottom of the tablecloth is deformed to the point
   where it's hanging below the floor. To fix this, turn off Auto Key, go to
   frame 100, select the lower ring of control points, and move them up
until the tablecloth is at the height you want it. You can also adjust the position of the other control points to create drapes, and so on.

10 On the Display command panel > Hide by Category rollout, turn on Space Warps to hide the FFD space warp.

11 Set up appropriate lights and a camera, and play your animation.
Chapter 12  Space Warps and Particle Systems
This rollout lets you set the size and resolution of the lattice, and how it displays and deforms.

**Dimensions group**

These options let you adjust the unit dimensions of the source volume, and specify the number of control points in the lattice. Note that the point dimensions are displayed beside the modifier name in the Stack list.

**Radius, Height** These two spinners display and let you adjust the length, width, and height of the lattice. To create the space warp, drag the mouse in the same way that you would to create a standard Cylinder primitive. Note that these spinners don’t exist in the object-modifier version of the FFD.

**Label** Displays the current number of controls points in the lattice (for example: 4x8x4).

**Set Number of Points** Displays a dialog containing three spinners labeled Side, Radial, and Height, plus OK/Cancel buttons. Specify the number of control points you want in the lattice, and then click OK to make the change.

**Side** The number of control points around the perimeter of the lattice.

**Radial** The number of control points, radially, from the center to the outer perimeter of the lattice.

**Height** The number of control points along the height of the lattice.

**NOTE** Make changes to the dimensions before you adjust the positions of the lattice control points. When you change the number of control points with this dialog, any adjustments you’ve already made to the control points are lost; however, you can undo this use of the dialog.

**Display group**

These options affect the display of the FFD in viewports.

**Lattice** When on, lines are drawn connecting the control points to make a grid. Although viewports can become cluttered when these extra lines are drawn, they help to visualize the lattice.

**Source Volume** When on, the control points and lattice are displayed in their unmodified state. This display is helpful when you’re adjusting the source volume to affect specific vertices that lie within or without it. See the All Vertices and Only in Volume options, later in this topic.
Deform group

These options provide controls that specify which vertices are affected by the FFD.

Only In Volume When on, only vertices that lie inside the source volume are deformed. Vertices outside the source volume are not affected. This is the default choice.

All Vertices When on, all vertices are deformed regardless of whether they lie inside or outside the source volume, depending on the value in the Falloff spinner. The deformation outside the volume is a continuous extrapolation of the deformation inside the volume. Note that the deformation can be extreme for points far away from the source lattice.

Falloff This spinner, enabled only when you choose All Vertices, determines the distance from the lattice that the FFD effect will decrease to zero. When this spinner is set to 0, it’s effectively turned off, and there is no falloff; that is, all vertices are affected regardless of their distance from the lattice. The units of the Falloff parameter are specified relative to the size of the lattice: A falloff of 1 means that the effect will go to 0 for points that are a lattice width/length/height away from the lattice (depending on which side they are on).

Tension/Continuity Lets you adjust the tension and continuity of the deformation splines. Although you can’t see the splines in an FFD, the lattice and control points represent the structure that controls the splines. As you adjust the control points, you alter the splines (which move through each point). The splines, in turn, deform the geometry of the object. By altering the tension and continuity of the splines, you alter their effect on the object.

Selection group

These options provide additional methods of selecting control points. You can toggle any combination of the three buttons to select in one, two, or three dimensions at once.

All X, All Y, All Z When one of these buttons is on and you select a control point, all control points along the local dimension specified by the button are selected as well. By turning on two buttons, you can select all control points in two dimensions.

About Displays a dialog with copyright and licensing information.
**Wave Space Warp**

Create panel > Space Warps > Geometric/Deformable > Object Type rollout > Wave

Create menu > Space Warps > Geometric/Deformable > Wave

The Wave space warp creates a linear wave through world space. It affects geometry and behaves the same as the Wave modifier on page 2000. Use the Wave space warp when you want the wave to affect a large number of objects, or to affect an object relative to its position in world space.
Using a wave to deform a box

See also:
- Ripple Space Warp on page 2983

Procedures

To create a Wave space warp:

1. On the Create panel, click Space Warps. Choose Geometric/Deformable from the list, then on the Object Type rollout, click Wave.

2. Drag in a viewport to define the initial size of the wave object icon. The icon is displayed as a flat mesh wireframe.

3. Release the mouse button to set the icon size; then move the mouse to define the initial amplitude of the wave.

4. Click to set the wave amplitude.
The initial amplitude sets both Amplitude 1 and Amplitude 2. Set these parameters to unequal values to create a cross wave.

**Wave group**

These options control the wave effect.

**Amplitude 1** Sets wave amplitude along the wave warp object's local X axis. Amplitude is expressed in units. The wave is a sine wave along its Y axis and parabolic along its X axis. Another way to think of the difference between the amplitudes is that Amplitude 1 is at the center of the wave gizmo and Amplitude 2 is at the edge of the gizmo.

**Wave Length** Sets the length of each wave along the wave's local Y axis, in active units.
Phase  Offsets the phase of the wave from its origin at the wave object's center. Whole values have no effect; only fractional values do. Animating this parameter makes the wave appear to travel through space.

Decay  When set to 0.0, the wave has the same amplitude or amplitudes throughout world space. Increasing the Decay value causes amplitude to diminish as distance increases from the position of the wave warp object. Default=0.0.

Display group

These options control the geometry of the Wave warp gizmo. In some cases, such as when the two Amplitude values differ, they change the effect of the wave.

Sides  Sets the number of side segments along the wave object's local X dimension.

Segments  Sets the number of segments along the wave object's local Y dimension.

Divisions  Adjusts the size of the wave icon without altering the wave effect as scaling would.

Flexibility parameter (Modify panel)

The Wave space warp also has a Flexibility parameter that you can adjust individually in each bound object's stack, at the Wave Binding level. The parameter belongs to each binding; it doesn't appear with the Wave warp parameters.
Flexibility Makes the bound object more or less responsive to the wave by multiplying the amplitude by this value.

**Ripple Space Warp**

Create panel > Space Warps > Geometric/Deformable > Object Type rollout > Ripple

Create menu > Space Warps > Geometric/Deformable > Ripple

The Ripple space warp creates a concentric ripple through world space. It affects geometry and behaves the same as the Ripple modifier on page 1650. Use the Ripple space warp when you want the ripple to affect a large number of objects, or to affect an object relative to its position in world space.
Using a ripple to deform a surface

See also:

- Wave Space Warp on page 2979

Procedures

To create a Ripple space warp:

1. On the Create panel, click Space Warps. Choose Geometric/Deformable from the list, then on the Object Type rollout, click Ripple.

2. Drag in a viewport to define the initial size of the ripple object icon. The icon is displayed as a wireframe spider web.

3. Release the mouse button to set the icon size, and then move the mouse to define the initial amplitude of the ripple wave.

4. Click to set the wave amplitude.
The amplitude value set by dragging applies equally in all directions. The ripple’s Amplitude 1 and Amplitude 2 parameters are initially equal. Set these parameters to unequal values to create a ripple whose amplitude varies relative to the local X and Y axes of the space warp.

**Ripple group**

**Amplitude 1** Sets ripple amplitude along the ripple warp object’s local X axis. Amplitude is expressed in active units.

**Amplitude 2** Sets ripple amplitude along the ripple warp object’s local Y axis. Amplitude is expressed in active units.

**Wave Length** Sets the length of each wave, in active units.

**Phase** Offsets the phase of the wave from its origin at the ripple object’s center. Whole values have no effect; only fractional values do. Animating this parameter makes the ripple appear to travel through space.
Decay When set to 0.0, the ripple has the same amplitude or amplitudes throughout world space. Increasing the Decay value causes amplitude to diminish as distance increases from the position of the ripple warp object. Default=0.0.

Display group

The options control display of the Ripple warp object's icon. They don't change the effect of the ripple.

Circles Sets the number of circles in the ripple icon.

Segments Sets the number of segments (pie slices) in the ripple icon.

Divisions Adjusts the size of the ripple icon without altering the ripple effect as scaling would.

Flexibility parameter (Modify panel)

The Ripple space warp also has a Flexibility parameter that you can adjust individually in each bound object's stack, at the Ripple Binding level. The parameter belongs to each binding; it doesn't appear with the Ripple warp parameters.
Flexibility Makes the bound object more or less responsive to the wave by multiplying the amplitude by this value.

**Conform Space Warp**

Create panel > Space Warps > Geometric/Deformable > Object Type rollout > Conform

Create menu > Space Warps > Geometric/Deformable > Conform

The Conform space warp modifies its bound object by pushing its vertices in the direction indicated by the space warp icon, until they hit a specified target object, or until the vertices move a specified distance from their original position.

After creating a Conform space warp, you specify a target object in the Conform parameters, and then bind the Conform to the object you want to deform. You rotate the Conform icon to specify the travel direction (toward the target object). The vertices of the deformed object move until they hit the target object.
There is also a Conform compound object on page 688 that provides additional methods of conforming one object to another.

Conform viewport icon (a surface is below it)

**Procedures**

**Example: Using the Conform space warp:**

Begin by making two objects.

1. Create a terrain by making a wide, flat box with plenty of Length and Width segments (or a quad patch). Apply a Noise modifier and adjust its parameters to result in a bumpy terrain (not mountainous, but low and irregular).

2. Create a short, wide cylinder whose radius is about one-eighth the area of the box (like a coin). You'll animate the cylinder to float diagonally over the surface of the terrain.

3. Set Cap Segments in the cylinder to 4, and position the cylinder to float over the terrain.

4. Set the object color of the cylinder to contrast with the color of the terrain.

5. Move the cylinder inside one corner of the terrain as seen from the Top viewport. Turn on Animate, move to frame 100, and move the cylinder to the opposite corner of the terrain.
The coin/disk moves from one corner of the terrain to the other.

The terrain will become the target object, and the cylinder the deformed object. The next step is to create the Conform space warp and bind it to the cylinder.

1. On the Create panel, choose Space Warps, and then, from the drop-down list, choose Geometric/Deformable. Click the Conform button.
2. In the Top viewport, in the center of the terrain, drag outward to create the Conform space warp.
3. Click the Pick Object button, and then click the terrain box.
4. In the Front viewport, drag the space warp up until it’s above the cylinder. As seen in the Front viewport, the terrain is at the bottom, the cylinder is between the terrain and the space warp, and the space warp is at the top.
5. Bind the space warp to the cylinder. The cylinder becomes a disk that seems to be painted on the surface of the terrain.
6. Drag the time slider to see the cylinder/disk move across the box, following the terrain.

Because the vertices are pushed almost to the level of the terrain, the faces of the two object might intersect. In the following steps, you'll fix this by adjusting the standoff distance between the target surface and the pushed vertices. Then you'll go on to affect only selected vertices in the cylinder.

1. Select the Conform space warp, and open the Modify panel.
2. Set Standoff Distance to 3. You can now clearly see the surface of the disk above the terrain.
3. Set the Standoff Distance to 20. The disk floats 20 units above the terrain. Next, change the affected vertices.
4. Select the disk/cylinder.
5. In the modifier stack display, click the Cylinder item so it’s highlighted in gray.
6. Apply a Mesh Select modifier.
7  At the Vertex sub-object level, in the Front viewport, region-select the bottom cap vertices of the cylinder.

8  Remain at the sub-object level, and in the stack display click the Conform Binding item.

9  In the viewport, select the Conform icon.

10  In the Modify panel, turn on Use Selected Vertices.
    Now that only the bottom cap vertices are selected, the rest of the cylinder is restored. If you adjust the viewing angle and play the animation, you’ll see that the bottom face of the cylinder follows the terrain, while the rest of the cylinder retains its shape.

Interface
Wrap To Object group

These options provide controls to select the target object.

Pick Object  Click this, and then select an object in the scene. The object you select becomes the barrier against which the bound object's vertices will be pushed.

Object  Displays the name of the picked object.

Move Vertices group

These options affect how the vertices are moved.

Default Projection Distance  The distance a vertex in the bound object moves from its original location if it does not intersect the target object.

Standoff Distance  The distance maintained between the vertex and the surface of the target object. For example, if set to 5, the vertices can be pushed no closer than 5 units from the surface of the target object.

Use Selected Vertices  When on, only the sub-object selection of vertices on the Stack are pushed. When off, all vertices in the object are pushed regardless of the Stack selection.

Display group

Icon Size  Specifies the size of the icon.

Bomb Space Warp

Create panel > Space Warps > Geometric/Deformable > Object Type rollout > Bomb

Create menu > Space Warps > Geometric/Deformable > Bomb

The Bomb space warp explodes objects into their individual faces.
Procedures

To create a Bomb space warp:

1. On the Create panel, click Space Warps. Choose Geometric/Deformable from the list, and then on the Object Type rollout, click Bomb.

2. Create mesh objects to be exploded.
3 On the toolbar, click the Bind to Space Warp button.

4 Drag the mouse between each object and the Bomb space warp.

5 Adjust Bomb parameters to achieve different effects.

**Interface**

**Explosion group**

**Strength** Sets the power of the bomb. Larger values make the particles fly farther. The closer an object is to the bomb, the greater the effect of the bomb.
Spin The rate at which fragments rotate, in revolutions per second. This is also affected by the Chaos parameter (which causes different fragments to rotate at different speeds), and by the Falloff parameter (which causes the force of the explosion to be weaker the farther the fragment is from the bomb).

Falloff The distance from the bomb, in world units, of the effect of the bomb. Fragments past this distance are not affected by the Strength and Spin settings, but are affected by the Gravity setting.

For example, this is useful for blowing up the base of a building, and having the top of the building topple. To see the effect, place a bomb at the base of a tall cylinder with many height segments, and adjust Falloff to be less than the height of the cylinder.

Falloff On Turn on to use the Falloff setting. The falloff range appears as a yellow, tri-hooped sphere.

Fragment Size group

These two parameters define the number of faces per fragment. Any given fragment will have a number of faces, randomly determined, between the Min and Max values.

Min Specifies the minimum number of faces per fragment to be randomly generated by the "explosion."

Max Specifies the maximum number of faces per fragment to be randomly generated by the "explosion."

General group

Gravity Specifies the acceleration due to gravity. Note that gravity is always in the direction of the world Z axis. You can have negative gravity.

Chaos Adds random variation to the explosion to make it less uniform. A setting of 0.0 is totally uniform; 1.0 is a realistic setting. A value greater than 1.0 makes the explosion extra chaotic. Range=0.0 to 10.0.

Detonation Specifies the frame at which the bomb goes off. Bound objects are unaffected before this time.

Seed Change to alter randomly generated numbers in the bomb. You can achieve a different bomb effect by changing Seed while maintaining the other settings.

Although you can animate strength and gravity, the equations used for projectile motion assume they are constant. Therefore, the motion will not
be physically correct, but it might look interesting. Also, if the bomb object is in motion during the blast, the result is not physically correct.

**Modifier-Based Space Warps**

Create panel > Space Warps > Modifier-Based

Create menu > Space Warps > Modifier-Based

Modifier-based space warps duplicate the effects of standard object modifiers. Like other space warps, they must be bound to objects, and they work in world space. They are useful when you want to apply effects such as Twist or Bend to a widely scattered group of objects.

Creating Modifier-Based Space Warps

You create modifier-based space warps the same way that you create other space warps. Modifier-based space warps are listed on the Create panel as a separate category under Space Warps.

All the modifier-based space warps use a box-shaped (nonrenderable) object. When you create one, you use the mouse in the viewport as you do when creating a Box primitive.

Unlike their modifier versions, these space warps do not have sub-object levels.
Interface

Gizmo Parameters rollout

![Gizmo Parameters rollout]

Gizmo Size group

Length/Width/Height Let you adjust the warp object's dimensions.

Deformation group

Decay When is set to 0, there is no decay, and the space warp affects its bound object regardless of its distance from the object. When you increase the decay, the effect on the bound object falls off exponentially. See the topics on the individual modifiers for more information.

Parameter rollout

The parameters for a modifier-based space warp are identical to those of the modifier on which the space warp is based:

- Bend Modifier on page 1165
- Taper Modifier on page 1807
- Noise Modifier on page 1544
- Twist Modifier on page 1833
- Skew Modifier on page 1664
- Stretch Modifier on page 1749
Particle Systems

Particle systems are useful for a variety of animation tasks. Primarily, they're employed when animating a large number of small objects using procedural methods; for instance, creating a snowstorm, a stream of water, or an explosion. 3ds Max provides two different types of particle systems: event-driven and non-event-driven. The event-driven particle system, Particle Flow on page 2997, tests particle properties, and, based on the test results, sends them to different events. Each event assigns various attributes and behaviors to the particles while they're in the event. In the non-event-driven systems on page 3292, particles typically exhibit consistent properties throughout the animation.

**IMPORTANT** Particle systems can involve a great many entities, each of which is potentially subject to any number of complex calculations. For this reason, when using them for advanced simulations, you should have a very fast computer and as much memory as possible. Also, a powerful graphics card helps speed the display of particle geometry in the viewports. Even so, it's still easy to overburden the system; if you encounter loss of responsiveness, wait for the particle system to finish its calculations, and then reduce the number of particles in the system, implement a cache, or use other methods to optimize performance.

Which Particle System to Use?

Having access to a wealth of particle systems in 3ds Max leads to the need to decide which system to use for a particular application. In general, for a simple animation, such as falling snow or a water fountain, setup is faster and easier with a non-event-driven particle system. With more complex animations, such as an explosion that generates different types of particles over time (for example: fragments, fire, and smoke), use Particle Flow for greatest flexibility and control.

Particle Flow

Particle Flow is a versatile, powerful particle system for 3ds Max. It employs an event-driven model, using a special dialog called Particle View on page 3015. In Particle View, you combine individual operators on page 8665 that describe particle properties such as shape, speed, direction, and rotation over a period of time into groups called events on page 8564. Each operator provides a set of parameters, many of which you can animate to change particle behavior during the event. As the event transpires, Particle Flow continually evaluates each operator in the list and updates the particle system accordingly.
To achieve more substantial changes in particle properties and behavior, you can create a flow on page 8581. The flow sends particles from event to event using tests on page 8741, which let you wire on page 8763 events together in series. A test can check, for example, whether a particle has passed a certain age, how fast it's moving, or whether it has collided with a deflector. Particles that pass the test move on to the next event, while those that don't meet the test criteria remain in the current event, possibly to undergo other tests.

**NOTE** Operators and tests are known collectively as actions on page 8495.

See also:
- Non-Event-Driven Particle Systems on page 3292

---

**What's New in Particle Flow**

New in Autodesk 3ds Max 2010 is a set of operators and other tools that extend the capabilities of Particle Flow.

Before using PflowAdvanced, you should be familiar with Particle Flow in 3ds Max. If you have never used Particle Flow, do some of the Particle Flow tutorials that come with 3ds Max before working with PflowAdvanced.

**Operators and Tests**

The new operators appear in the Particle View depot alongside the original Particle Flow operators, sorted by category and then by name. They are highlighted in the following illustration.
If you have used other particle-related plug-ins, you will recognize some of the new operators and tests as improved versions of those found in other particle system extensions. However, many operators and tests are completely new with Autodesk 3ds Max 2010.

**Birth Paint operator on page 3222** Generates particles by using the data from a Particle Paint helper on page 3197.

**Birth Texture operator on page 3057** Generates particles by using animated color data from emitter objects. The operator can translate mapping from emitters to particles, and control particle scale by texture color.

**Group operator on page 3076** Uses operators from an external event to modify a subset of particles defined by a Group Selection operator.

**Group Selection operator on page 3078** Defines a subset of particles based on particle properties and other means.

**Initial State operator on page 3069** Makes a snapshot of a particle system or Particle Flow events at Start Time, and uses it to generate clone particles at Emit Time.

**Lock/Bond test on page 3264** A test for attaching particles to animated objects.

**Mapping Object operator on page 3158** Assigns mapping from reference objects to particles.

**Placement Paint operator on page 3224** Initializes position, rotation, and script data from a Particle Paint helper.
Preset Flow on page 3230 Lets you create initial custom particle systems, or add predefined sets of events, operators, and objects to the scene.

Shape operator on page 3137 Replaces the original Shape operator with an extended set of 2D and 3D particle shapes.

Split Group test on page 3084 Checks whether a particle belongs to a selection group as defined by a Group Selection operator.

Additional Tools

Painting Particles on page 3197 The Particle Paint system starts with the Particle Paint Helper on page 3197, which lets you spray particle seeds onto the surface of one or more objects. The seeds can then be used with the Birth Paint and Placement Paint operators to generate particles.

Tools menu on page 3025 The Tools menu in Particle View provides several useful functions to Particle Flow.

How Particle Flow Works

Particle View on page 3015 is the primary interface for building and modifying Particle Flow systems. The first event in the system is always a global event, whose contents affect all particles in the system. It has the same name as the Particle Flow source icon.

By default, the global event contains a single Render operator that specifies rendering properties for all particles in the system. You can add other operators here to have them act globally, such as Material, Display, and Speed. When you use an operator globally, be sure not to use the same operator locally (that is, in any other events in the system) to avoid potential conflicts.

The global event also serves as the Particle View representation of the particle system. You can create a new system by duplicating this event, or by adding an Empty Flow or Standard Flow. Conversely, if you clone the Particle Flow icon in a viewport, or add a new PF Source, the new system appears in Particle View as well.

The second event is called the birth event, because it must contain a Birth operator. The Birth operator should exist at the top of the birth event, and in no other place. The default birth event also contains a number of operators that act locally to specify properties of particles while in that event. The default particle system provides a basic global event and birth event that serve as a
useful starting point for creating your own system. If you like, you can instead start with an empty system that lets you build a particle system from scratch.

1. Event display
2. Particle diagram
3. Global event
4. Birth event
5. Depot
To add an action to the particle diagram, you drag it to the event display from the depot (the area at the bottom of the Particle View dialog). If you drag an action to an event, you can add it to the event or replace an existing action, depending on where you drop it. If you drop it in an empty area, it creates a new event. Then, to customize the action, you click its event entry, and then edit its settings in the parameters panel at the side of Particle View.

To add complexity to the particle system, you can add a test to an event, and then wire the test to another event. You can adjust the test parameters to affect particle behavior, as well as determine whether specific conditions exist. When particles meet these conditions, they become eligible for redirection to the next event.

Particle Flow provides a number of tools for determining where in the system particles currently reside, including the ability to change particle color and shape on an event-by-event basis. You can also easily enable and disable actions and events, and determine the number of particles in each event. To speed up checking particle activity at different times during the animation, you can cache particle motion in memory. Using these tools, plus the ability to create custom actions with scripting, you can create particle systems of a level of sophistication previously unachievable.

The Life of a Particle

Another way of looking at Particle Flow is from the perspective of an individual particle. Each particle first comes into existence, or is born, via the Birth operator on page 3052, which lets you specify when to start and stop creating particles, and how many to create.

The particles first appear at an object called an emitter. By default, the emitter is the Particle Flow source icon using the Position Icon operator on page 3086, but you can alternatively use the Position Object operator on page 3089 to specify that particles should be born on the surface of or within any mesh object in the scene.

After being born, particles can remain stationary at the emission point, or start moving in two different ways. First, they can move, physically, within the scene at a speed and in a direction specified by various actions. These are typically Speed operators, but other actions can also affect particle motion, including Spin on page 3099 and Find Target on page 3247. In addition, you can use the Force operator on page 3189 to affect their motion with outside forces.
1. Particle immediately after creation, with no speed.
2. The Speed operator sets the particle in motion.
3. The particle continues moving until acted upon by another action.

The second way that particles move is logically, from event to event through the particle diagram, as constructed in Particle View on page 3015. Each event can contain any number of operators that can affect, in addition to motion, a particle's surface appearance, its shape and size, and others.

The particles start out in the birth event, which typically is the first event after the global event. During a particle's residence in an event, Particle Flow evaluates each of the event's actions from top to bottom, once per integration step, and makes any applicable changes to the particle. If the event contains a test, Particle Flow determines whether the particle tests True for the test's parameters, such as whether it has collided with an object in the scene. If it does, and if the test is wired to another event, Particle Flow sends the particle to the next event. If it doesn't, the particle remains in the current event, and may be further acted upon by its operators and tests. Thus, each particle exists in only one event at a time.

An action in an event can change the particle shape (1), or the particle spin (2), or spawn new particles (3).
Actions can also apply forces to particles (1), specify collision effects (2), and alter surface properties (3).

In this way, the particle continues to travel through the system. Due to the flexible nature of schematic construction in Particle Flow, a particle may be redirected to the same event several times. But at some point, you might want the particle's life to end. For this purpose, you'd use the Delete operator on page 3067 or the Collision Spawn test on page 3241 or Spawn test on page 3281. Otherwise, the particle lives throughout the entire animation.

Particle age can be used to kill a particle.

As a particle moves through the system, it's accompanied by a number of channels. For example, each particle has a speed channel that defines how fast it moves, and a material ID channel that lets Particle Flow know which sub-material to apply to it. However, the material itself is not defined by a channel, but by a Material operator that acts locally or globally. Properties that are defined by channels persist, unless altered by an action. For example, the Material Dynamic operator on page 3168 can change a particle's material ID. In effect, by setting up a particle diagram and modifying how particles look and act during the animation, you're deciding how channel values change based on events and animation keyframes.
Particle Flow FAQ

This topic offers answers to a number of questions users commonly ask when first learning to use Particle Flow. The first section contains links to all the questions, and the subsequent sections contain the questions and answers organized by category.

Question List

How does Particle Flow handle time? on page 3006
When I go to a different frame, 3ds Max sometimes seems to freeze for a while. What's going on? on page 3007
Is there a way to pre-calculate portions of a particle simulation, as in "baking" the animation? on page 3007
What else can I do to optimize performance? on page 3008
How do I use Particle Flow to make an object explode? on page 3008
How can I control the accuracy of the Particle Flow simulation? on page 3008
Can I use MAXScript to affect particles? on page 3008
Can I use more than one object as instanced geometry? on page 3009
How can I exclude particles from certain light sources? on page 3009
How do I open Particle View without clicking Particle View button on the command panel? on page 3009
Do I need multiple Particle Views to manage more than one particle system? on page 3009
Can I selectively disable or "turn off" portions of a particle system? on page 3009
I sometimes see events named “Action Recovery” in Particle View. Where did they come from? on page 3010
How do I animate action parameters? on page 3010
How can I synchronize an animated bitmap texture to particle age? on page 3010
Do I still need to bind my Particle Flow particles to space warps? on page 3010
How do I make particles follow a path? on page 3010
Can I use Snapshot or dynamics with Particle Flow? on page 3011
How do I use motion blur with Particle Flow? on page 3011

How do I use the Particle Age and Particle MBlur maps with Particle Flow? on page 3011

I’m trying to apply Particle Flow to an animation created with a dynamics system. Why am I getting strange results such as unexpected spawning of particles? on page 3012

How can I make all particles appear in the first frame while giving them different ages? on page 3012

How can I specify the time frame in which animated parameters are applied to particles? on page 3012

How can I apply bubble motion to particles? on page 3012

How can I branch an event to several other events? on page 3013

Does it matter which order I put actions in an event? on page 3013

How can I tell which particles are in a certain event? on page 3014

Why do my particles lose their material when they move to another event? on page 3014

Can I have an event receive input from multiple events? on page 3014

I changed an operator setting, but it doesn’t seem to have any effect on the particle system. on page 3014

Can an event be isolated in Particle View and not connected to anything? on page 3015

General

How does Particle Flow handle time?

Parameters that measure time in Particle Flow, such as Birth on page 3052 > Emit Start/Stop and Age Test on page 3235 > Test Value, are specified in frames. However, Particle Flow is always aware of the current system frame rate (fps), and if you change this rate, it adjusts all time-related parameters to keep the same timing. For instance, if you set Test Value to 60 when you’re using the NTSC frame rate (30 fps), and then switch to PAL (25 fps), Particle Flow automatically changes the value to 50, so the age that’s tested for is still two seconds.

On the other hand, rate parameters, such as Speed, are measured in units per second, so they don’t change when you go to a different frame rate.
When I go to a different frame, 3ds Max sometimes seems to freeze for a while. What's going on?

Most of the animation in Particle Flow is history dependent; that is, to be able to draw the particles in a particular frame, Particle Flow needs to know what happened in all previous frames. Normally, when you change a parameter value, Particle Flow needs to recalculate all frames between the start and the current frames. Or, if you go to a different frame, Particle Flow must recalculate one or more animation frames. If you go forward, it must calculate the frames between the current frame and the one you go to. So, for example, if you just go to the next frame, relatively little calculation is needed. But if you go backward, even only by one frame, it must calculate all frames from the start of the animation to the frame you go to.

If a lot of calculation is needed, there is a delay. Meanwhile, 3ds Max displays a message like “PF Source 01 Update xx% (Press Esc to cancel)” in the status bar, so you can get an idea of how the recalculation is progressing. If, when you see this message, you press the Esc key, Particle Flow displays an alert with the message “Click OK to turn off PF Source 01.” If you click OK, the recalculation stops, giving you the opportunity to optimize the animation. For example, you could reduce the number of particles for testing purposes. You must turn the source back on to continue. If you click Cancel, the calculation continues.

**TIP** An easy way to speed up recalculation and rendering of particles is by adjusting the total number of particles. To do this, select the Particle Flow source icon, and then go to the Modify panel > Emission rollout > Quantity Multiplier group. Here you can increase or decrease by percentage the total number of particles, separately for viewport display and rendering.

**TIP** To speed up animation playback when you’re not adjusting parameters, use the Cache operator (see the following item).

Is there a way to pre-calculate portions of a particle simulation, as in "baking" the animation?

Yes. Particle Flow's [Cache operator](#) on page 3178 lets you store all or part of a particle animation in memory, and then play back the animation from memory rather than having to recalculate particle motion. This makes it much faster to jump between different parts of the animation. You can even save the cached animation to disk as part of the scene file.
**What else can I do to optimize performance?**

Particle Flow can place heavy processing and resource demands on your computer. For optimal performance, the most important thing you can do is to use the fastest available CPU. Also, when using particle systems with many particles, install as much memory as possible in your computer, especially if you're using caching.

Other ways to improve performance include reducing the percentage of viewport particles with the Quantity Multiplier setting, and temporarily disabling flows and actions that you're not currently working with. When making parameter changes, return to the first frame and play forward, or set Particle View > Options menu > Update Type to “Forward”. That way, if you change a setting, the particle system is not forced to recalculate its state from the very beginning. The change will affect only animation from the current frame forward. On the other hand, the result could be misleading, because you won't be able to see the difference right away.

Also, be cautious when using spawning; it can quickly create very large numbers of particles, especially when you use the By Travel Distance option in the Spawn test on page 3281.

**How do I use Particle Flow to make an object explode?**

Particle Flow doesn't have a fragmentation operator, but by utilizing the **PArray particle system** on page 3331 in a Birth Script operator, you can implement fragmentation in Particle Flow. You can find example scenes, with commented Birth Script operators, in the files on the second disc in the directory **Samples\Scenes\Particle Flow\Fragments\**.

**How can I control the accuracy of the Particle Flow simulation?**

On the command panel > System Management rollout on page 3041 of the PF Source icon, you can adjust the integration step independently for viewport playback and rendering. The smaller the integration step, the more times Particle Flow calculates particle motion per frame, resulting in greater accuracy at the cost of calculation time.

**Can I use MAXScript to affect particles?**

Yes. Particle Flow includes a **Script operator** on page 3196 and a **test** on page 3280, as well as a **Birth Script operator** on page 3056, that let you fully customize the particle system. Each scriptable action includes a sample script, which also lists all relevant scriptable functions. You can also control parameters of the
Force operator on page 3189 and Keep Apart operator on page 3131 with script wiring, described in the respective topics.

In addition, you can execute a script at each integration step, and another just before each frame is viewed or rendered; see Script rollout on page 3042.

Can I use more than one object as instanced geometry?

Yes. With the Shape Instance operator on page 3142, you can use groups, hierarchies, and objects consisting of multiple elements, with each member of the combined object constituting a separate particle. These objects can be emitted in a specific order, or in a random order. For example, you can use a text object, with the letters emitted in the order in which they appear in the text.

How can I exclude particles from certain light sources?

To prevent particles from being affected by a light source, use the light’s Exclude function, found on the General Parameters rollout (Modify panel), to specify any events containing particles to be excluded. Specifying the PF Source XX object (default name) has no effect; you must specify all objects listed as PF Source XX->Event XX.

Particle View

How do I open Particle View without clicking Particle View button on the command panel?

Press the 6 key. It might be necessary to first turn on the Keyboard Shortcut Override Toggle.

Do I need multiple Particle Views to manage more than one particle system?

No: All particle systems appear in Particle View. You can scroll and zoom the event display to see the different systems.

Can I selectively disable or “turn off” portions of a particle system?

Yes. Particle View gives you a number of different ways of doing this. You can click an action's icon or an event's light-bulb icon to turn it off, or use the right-click menu, or use Edit menu's Turn On and Turn Off commands. Also, if you press Esc while Particle Flow is calculating, 3ds Max gives you the
opportunity of turning off the entire particle system, thus immediately returning control of 3ds Max to you. You can then analyze the system to determine the area of slowdown, optimize or simplify the particle flow, and then recalculate the animation.

I sometimes see events named “Action Recovery” in Particle View. Where did they come from?

When you merge a scene containing Particle Flow data, you can import entire events and isolated actions. If you merge an action without its events, Particle Flow places it in an event named “Action Recovery.”

Animation

How do I animate action parameters?

Use the same Auto Key on page 3373 method as with animating any other parameter in 3ds Max.

NOTE Avoid animating Particle Flow parameters with Set Key mode or with Shift+right-click. Also, to see animation keys for actions in the track bar, make sure the Particle Flow source icon is selected.

How can I synchronize an animated bitmap texture to particle age?

Use the Material Dynamic operator on page 3168 in conjunction with the Bitmap 2D map on page 6213. You'll find a procedure that describes the method in detail here on page 3169.

Do I still need to bind my Particle Flow particles to space warps?

No; you use the Collision test on page 3236, Collision Spawn test on page 3241, or Force operator on page 3189 to affect particle motion with 3ds Max space warps. The ability to do this on a global and local (per-event) basis gives you much greater control over how space warps affect the particles than with previous systems.

How do I make particles follow a path?

You can use the Speed By Icon operator on page 3112 or the Find Target test on page 3247, assigning the icon or target to a spline path. You'll find illustrative procedures in both topics.
Can I use Snapshot or dynamics with Particle Flow?

No. The Snapshot tool is not currently compatible with Particle Flow, nor is reactor or the legacy dynamics system.

How do I use motion blur with Particle Flow?

You can apply motion blur on a per-event basis by editing the event’s object properties on page 283 with the right-click menu in Particle View, or on a global basis by editing the global event’s object properties. In the Particle View dialog, highlight the event to edit and then right-click and choose Properties. On the Object Properties dialog, edit the Motion Blur group settings.

Alternatively, you can apply motion blur to an entire Particle Flow system without the need to set properties by using the multi-pass motion blur effect on page 5594 with a camera.

NOTE You can also use Object Properties to set other properties for events and the particle system, as with any object in 3ds Max. Do this only within Particle View, not using the source icon in the viewports (right-click menu > Properties or Edit menu > Object Properties).

NOTE When using Object Motion Blur, if an event contains a Material Dynamic operator that uses a material with a Particle Age, Particle MBlur, or Bitmap map, the event should not also contain a Delete operator, or a Spawn or Collision Spawn test. Also, the event should not contain any tests that are wired to another event. The only exception to this is the Age Test operator when set to Absolute Time without any variation; that is, all particles leave the event at the same time. This applies to the use of Object Motion Blur only; there are no restrictions with Image Motion Blur.

How do I use the Particle Age and Particle MBlur maps with Particle Flow?

To use the Particle Age map with Particle Flow, you must use the Delete operator to give the particles a finite life span. For further information, see Delete Operator on page 3067.

Also note the following:

- Particle Age, Particle MBlur and a Bitmap map containing an animated bitmap can be used only with Material Dynamic operator on page 3168, with Same As Particle ID turned on. You’ll find procedures for using Bitmap and Particle Age at this topic.
- The particle material cannot be a submaterial; it must be the main material.
In the non-event-driven particle systems in 3ds Max, Particle MBlur is used with a control named Direction Of Travel\MBlur and an accompanying Stretch parameter. In Particle Flow, you can replicate the stretching effect by using a Scale operator, turning off Scale Factor > Constrain Properties, and scaling the particle along one axis.

I'm trying to apply Particle Flow to an animation created with a dynamics system. Why am I getting strange results such as unexpected spawning of particles?

The dynamics system probably generates rotation keys using the Euler XYZ controller. To avoid interpolation discontinuities, change the rotation controller for such objects to TCB Rotation.

How can I make all particles appear in the first frame while giving them different ages?

Use a negative frame range in the Birth operator on page 3052. For example, to get a particle-age spread of 30 frames, set Emit Start to -29 and Emit Stop to 0.

How can I specify the time frame in which animated parameters are applied to particles?

You can animate many of the Particle Flow parameter values with keyframing. In most actions, you can choose the time frame by which to apply this animation to the particles from a drop-down list labeled Sync By. You can apply this animation to particles in the time frame of the entire animation, or at a specific time of each particle's life (particle age), or based on the length of time the particle has been in the current event. See the individual operator and test topics for details.

How can I apply bubble motion to particles?

Although Particle Flow doesn't have the bubble motion option on page 3356 found in PArray, you can simulate the effect by following this procedure:

1. Add an object to serve as particle geometry and a dummy helper object on page 2840.
2. Position the dummy away from the center of the particle geometry object and link on page 3630 your particle geometry to the dummy so that the dummy is the parent object (that is, drag from the geometry object to

3012 | Chapter 12  Space Warps and Particle Systems
the dummy). The distance between the pivots on page 3762 of the two objects determines the radius of the bubble motion.

3  In Particle View, add a Shape Instance operator on page 3142 and a Spin operator on page 3099 to the event in which the bubble motion is to occur.

4  Click the Shape Instance operator and specify the dummy object as the particle geometry object.

5  Click the Spin operator and set appropriate values for Spin Rate and Variation. For Spin Axis, keep the default setting of Random 3D.

The result is particle motion in which the particles bob about while moving along their paths, similar to bubble motion.

Events

How can I branch an event to several other events?

Particle Flow includes several Split tests, which let you send some particles to another event based on quantity, selection, or source. You can use any number of these in a single event to send parts of the particle stream to different events, and then use a Send Out test on page 3280 to redirect the remaining particles to another event. Keep in mind that any tests subsequent to the first can work only with particles remaining in the event, not necessarily all particles that begin in the event.

Does it matter which order I put actions in an event?

It depends. If an event contains two or more operators of the same type, such as Shape, the last one overrides the rest. If an event contains two or more tests, they are evaluated and particles redirected in the order in which the tests appear.

However, if two actions in an event control the same properties, the interaction is more complex. An action that works on a continuous basis will typically prevail over one that affects particles only when they first enter the event. For example, both the Find Target test on page 3247 and Speed operator on page 3108 can control particle speed and direction, but the test works continuously, while the operator takes effect only once. If an event contains both, particle speed and direction will be primarily controlled by the test, in general, even if the operator comes after the test. However, the operator's settings will still have some influence over particle behavior, particularly if its Speed value is significantly higher than that of the test. For a list of actions' effective time frames, see Action Time Frames on page 3046.
Also, if you're testing for a specific condition that can be affected by other actions in an event, be sure to place the test after the actions. For example, in an event with a Force operator on page 3189 and a Collision test on page 3236, place the Collision test after the Force operator. This avoids the possibility of the force pushing particles past the deflector before Particle Flow can test for the collision, which would allow the particles to penetrate the deflector. In general, place tests at the end of the event.

**How can I tell which particles are in a certain event?**

One way is to set the Type option for the Display operator on page 3186 in each event to a different choice. For example, the first event could use Ticks, the second Circles, and the third Lines. This way the particles change appearance in the viewports as they move from event to event. You can also use the Display operator to change particle colors, to further distinguish them.

Another way is to select all particles in a certain event. Select the Particle Flow source icon, and then go to the Modify panel > Selection rollout and click the Event icon. You can then click an event in the Select By Event list to highlight all of its particles in the viewports.

**Why do my particles lose their material when they move to another event?**

A material is a static property of an event. It does not travel along with the particles from event to event. A particle's material ID does, but its material does not. If you want particles always to use the same material, define the material in the global event on page 8594 with a Material operator on page 3156 or a Shape Instance operator on page 3142. Otherwise, you need to define it in each local event.

**Can I have an event receive input from multiple events?**

Particle Flow lets you wire any number of tests to a single event.

**I changed an operator setting, but it doesn't seem to have any effect on the particle system.**

A similar operator in the global event might be overriding your local operator. By default, Particle Flow evaluates local operators first, and then global operators. If a global operator affects the same property, such as speed, as a local one, the particle system will use the value set by the global operator. You can set local operators to override global ones by choosing Particle View > Options menu > Action Order > Globals First.
Can an event be isolated in Particle View and not connected to anything?  

Yes, but it won’t affect the particle system at all.

Particle Flow User Interface

This section describes the interface to Particle Flow.

Particle View

Select a Particle Flow source icon > Modify panel > Setup rollout > Click Particle View (or press 6).

Create panel > Geometry > Particle Systems > Object Type rollout > Click PF Source. > Setup rollout > Click Particle View (or press 6).

Particle View provides the main user interface for creating and modifying particle systems in Particle Flow. The main window, known as the event display, contains the particle diagram, which describes the particle system. A particle system consists of one or more events wired together, each of which contains a list of one or more operators on page 3050 and tests on page 3233. Operators and tests are known collectively as actions.

The first event is called the global event, because any operators it contains can affect the entire particle system. The global event always has the same name as the Particle Flow icon; by default, this is PF Source ## (starting with 01 and counting upward). Following this is the birth event, which must contain a Birth operator on page 3052 if the system is to generate particles. By default, the birth event contains this operator as well as several others that define the system’s initial properties. You can add any number of subsequent events to a particle system; collectively, the birth event and additional events are called local events. They’re called this because a local event’s actions typically affect only particles currently in the event.

You use tests to determine when particles are eligible to leave the current event and enter a different one. To indicate where they should go next, you wire the test to another event. This wiring defines the schematic, or flow, of the particle system.

By default, the name of each operator and test in an event is followed by its most important setting or settings in parentheses. Above the event display is a menu bar, and below is the depot, containing all actions available for use in the particle system, as well as a selection of default particle systems.
The easiest way to open Particle View is by pressing the 6 key. It’s not necessary to first select a Particle Flow icon.

1. Menu bar
2. Event display
3. Parameters panel
4. Depot
5. Description panel
6. Display tools

Particle View comprises the following elements:

- The menu bar on page 3017 provides functions for editing, selection, adjusting the view, and analyzing the particle system.
The event display on page 3027 contains the particle diagram, and provides functions for modifying the particle system.

The parameters panel contains rollouts for viewing and editing parameters of any selected actions. Basic functionality is identical to that of rollouts on the 3ds Max command panels, including usage of the right-click menu. To toggle display of the parameters panel, choose Display menu > Parameters.

The depot contains all Particle Flow actions, as well as several default particle systems. To see an item's description, click its entry in the depot. To use an item, drag it into the event display on page 3027. The contents of the depot fall into three categories: operators on page 3050, tests on page 3233, and flows on page 3229.

To toggle display of the depot, choose Display menu > Depot.

The Description panel displays a brief description of the highlighted depot item.

To toggle display of the description panel, choose Display menu > Description.

The icon-based display tools in the bottom-right corner of the Particle View dialog let you pan and zoom the event display window. For descriptions, see Display menu on page 3022.

Particle View Menu Bar

Select a Particle Flow source icon. > Modify panel > Setup rollout > Click Particle View (or press 6).

Create panel > Geometry > Particle Systems > Object Type rollout > Click PF Source. > Setup rollout > Click Particle View (or press 6).

The menu bar provides access to a number of important Particle View functions.

Procedures

To render only particles in specific events:

1. In Particle View, highlight the events containing the particles you want to render.

2. Choose Select menu > Assign Selection To Viewport.
3 Render using one of the Render Type on page 6542 > Selected options.

To bring a Particle Flow setup into a different scene:

1 In Particle View, highlight the events containing the particles you want to merge with a different scene. For example, to designate only a particular flow, you might highlight its global event, and then choose Select menu > Select Downstreams.

2 Choose Select menu > Save Selected, and use the file dialog to specify a file to save.

**NOTE** Any scene objects on which Particle Flow depends are also saved. For instance, if a Shape Instance operator on page 3142 in one of the highlighted events refers to a certain object, that object is saved along with the designated events.

3 Open or create the scene with which the saved Particle Flow setup will be combined, and then use Merge on page 7572 to merge the file from step 2.

**Interface**

**Edit menu**

<table>
<thead>
<tr>
<th>New</th>
<th>Insert Before</th>
<th>Append To</th>
</tr>
</thead>
<tbody>
<tr>
<td>Turn On All</td>
<td>Turn Off All</td>
<td>Turn On Selected</td>
</tr>
<tr>
<td>Turn Off Selected</td>
<td>Make Unique</td>
<td>Wire Selected</td>
</tr>
<tr>
<td>Copy</td>
<td>Paste</td>
<td>Paste Instanced</td>
</tr>
<tr>
<td>Delete</td>
<td>Rename</td>
<td></td>
</tr>
</tbody>
</table>
Each of the first three commands on this menu presents a submenu containing all actions. Choose the command, and then choose an action from the submenu.

**NOTE** The Undo and Redo commands are available from the main 3ds Max Edit menu, and their default keyboard shortcuts are the same: Ctrl+Z and Ctrl+Y, respectively.

**New** Adds a new event containing the chosen action to the event display.

**Insert Before** Inserts the chosen item above each highlighted action. Available only when one or more actions are highlighted.

**Append To** Inserts the chosen item at the end of each highlighted event. Available only when one or more events are highlighted.

**Turn On All** Turns on all actions and events.

**Turn Off All** Turns off all actions and events.

**Turn On Selected** Turns on any highlighted, turned-off actions or events. Available only when one or more highlighted items are turned off.

**Turn Off Selected** Turns off any highlighted, turned-on actions or events. Available only when one or more highlighted items are turned on.

**Make Unique** Converts an instanced action to a copy that's unique to its event. Available only when one or more instanced actions are highlighted.

**Wire Selected** Wires one or more highlighted tests to a highlighted event, or one or more highlighted global events to a highlighted birth event. Available only when one or more tests and a single event are highlighted, or when one or more global events and a single birth event are highlighted.

**Copy** Copies any highlighted events, actions, and wires to the paste buffer. Keyboard equivalent: Ctrl+C.

**Paste** Pastes the contents of the paste buffer to the event display. Keyboard equivalent: Ctrl+V.

The result of copying and then pasting multiple items depends on what you copied:

- If you copied multiple actions, pasting adds them all to a single new event, even if they originally came from different events.
- Copying multiple events or wires pastes them exactly as copied.
If you copied a combination of actions and events, pasting creates a new event for each group of actions from a single event. For example, if you highlight event A, some actions from event B, and some actions from event C, copying and then pasting would add three events: a copy of event A, a second event with the actions from event B, and a third event with the actions from event C.

**Paste Instanced** Pastes the contents of the paste buffer to the event display, making instances of any pasted actions and their originals.

For the results of pasting multiple copied items, see Paste, above.

**Delete** Deletes any highlighted items. Keyboard equivalent: Delete.

Deleting an event also deletes all of its actions.

**Rename** Lets you enter a new name for any single highlighted item in the event display. Available only when one action or test is highlighted

---

**Select menu**

- Select Tool
  - Select All
  - Select None
- Select Actions
  - Select Operators
  - Select Tests
  - Select Sources
  - Select Events
  - Select Wires
  - Select Downstreams
- Save Selected
- Get Selection From Viewport
  - Assign Selection To Viewport
  - Sync Source/Events Selection In Viewport
By default, the Select tool is active when Particle View is open, as indicated by the arrow-shaped mouse cursor. You can use this tool to highlight, move, and copy events, actions, tools, and wires. You can also use the commands on this menu to highlight all elements, no elements, or elements by category.

**NOTE** When you render using any of the Selected options, 3ds Max renders only events that are selected in the viewports. You can use the last three commands on this menu to manage and coordinate selection of events and flows between Particle View and the viewports. This also applies to use of the Views menu > Shade Selected command.

**Select Tool** Activates the Select tool. Choose this to return to the Select tool after using interactive tools for panning and zooming the event display. Alternatively, simply right-click anywhere in the event display to activate the Select tool.

**Select All** Highlights all items in the event display.

**Select None** Deselects all items in the event display. Alternatively, click an empty area in the event display.

**Select Actions** Highlights all operators and tests in the event display.

**Select Operators** Highlights all operators in the event display.

**Select Tests** Highlights all tests in the event display.

**Select Events** Highlights all events in the event display.

**Select Wires** Highlights all wires in the event display.

**Select Downstreams** Highlights all events after currently highlighted events. Available only when one or more events are highlighted.

**Save Selected** Saves only highlighted elements in the event display to a MAX file. You can then open this file, or combine it with an existing scene with Application menu on page 7989 > Import > Merge.

**NOTE** The Particle View > Save Selected command saves all items selected in Particle View and in the scene. So if a PF Source icon is selected in the scene, then this command will save its global event as well as any birth events associated with it, if you want to save only parts of a Particle Flow setup, first unselect everything in the scene.

Also, if an action references an object (for example, a Shape Instance operator on page 3142 uses a geometry object), and the action or its parent event is
highlighted when you use Save Selected, then the reference object is saved as well.

**Get Selection From Viewport** Highlights global events whose source icons are selected in the viewports.

**Assign Selection To Viewport** Transfers an event selection to the viewports. Use this to render only particles in specific events. First, in Particle View, highlight the events to render. Next, choose this command, and finally, render using one of the **Render Type** on page 6542 > Selected options.

**Sync Source/Events Selection In Viewport** Selects all events of any source icons selected in the viewports. You can then propagate this selection to Particle View with the Get Selection From Viewport command.

Use this function to render a specific particle flow using one of the **Render > Selected options**.

**Display menu**

<table>
<thead>
<tr>
<th>Pan Tool</th>
<th>Zoom Tool</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zoom Region Tool</td>
<td>Zoom Extents</td>
</tr>
<tr>
<td>No Zoom</td>
<td></td>
</tr>
</tbody>
</table>

The first five commands on this menu are also available as icons, in the Display tools section on the right side of the bottom border of the Particle View dialog. Each command’s Display tools icon is shown below.

**Pan Tool** Drag in the event display to move the view. The mouse cursor changes to a hand icon. You can also pan the view by dragging with the middle mouse button or wheel button held down.

To exit this mode, right-click in the event view or choose the command again.
Zoom Tool Drag in the event display to zoom the view. The mouse cursor changes to a magnifying-glass icon. Drag upward to zoom in, or downward to zoom out. To exit this mode, right-click in the event view or choose the command again.

Zoom Region Tool Drag in the event display to define a zoom rectangle. The mouse cursor changes to the image of a magnifying glass inside a zoom region. When you release the mouse button, the display zooms to show only the area defined by the region. To exit this mode, right-click in the event view or choose the command again.

Zoom Extents Sets the zoom to show the entire particle diagram in the event display.

No Zoom Sets the zoom to the default level. This is the level displayed when you first open Particle View in a given session.

Parameters Toggles display of the parameters panel, on the right side of the Particle View dialog. Default=on.

Depot Toggles display of the depot, below the Particle View dialog. Default=on.

Description Toggles the Description panel, to the right of the depot. Default=on. The Description panel displays a brief description of any action highlighted in the depot.

Options menu

This menu contains a number of options useful in analyzing and debugging particle systems.
Default Display Determines whether the Display operator is applied locally or globally to new particle systems and events. Default=Local.

- **Global**  When you create a new particle system, Particle Flow adds a single Display operator to the global event. It does not add a Display operator to each new event.

- **Local**  Particle Flow adds a Display operator to each new event. This lets you easily distinguish particles in different events in the viewports.

Action Order For predictable results, don’t use similar actions in the global and local events. However, if comparable actions do exist in both the global event and other events, Particle Flow applies them to the system in the order specified here. Typically, the effect that’s applied last is the one that’s visible in the particle system. Default=Locals First.

For example, consider a situation in which the global event contains a Shape operator set to Cube, and the other events in the same system contain Shape operators set to Tetra or Sphere. By default, Particle Flow applies the global Shape operator last at each integration step, overwriting any local shapes, so all particles would be cubes. But if you set Action Order to Globals First, the local shapes are applied last, and particles appear as tetrahedrons or spheres, depending on which event they’re in.

- **Globals First**  At each integration step, Particle Flow first applies actions in the global event, and then actions in the other (local) events. Typically, the result is that actions in the local events override comparable actions in the global event.

- **Locals First**  At each integration step, Particle Flow first applies actions in the local events, and then actions in the global event. Typically, the result is that actions in the global event override comparable actions in the local events.

Update Type This setting determines how Particle Flow updates the system when you change a parameter during playback. Because the state of the particle system at any given frame can depend on events in previous frames, using the Complete option can provide a more accurate depiction of the result of the change, at a cost in speed; it takes more time to recalculate the entire system starting at the first frame. Default=Complete.

- **Complete**  When you change a setting during playback, Particle Flow updates the entire system, starting at the first frame.

- **Forward**  When you change a setting during playback, Particle Flow updates the system starting at the current frame.
**Track Update** Provides options for visualizing the particle system status in Particle View.

- **Particle Count**  Adds a tab above each event that shows the number of particles in the event. The global event's count shows the total number of particles in the particle system. Use this, in addition to the ability to display particles differently in each event, to trace particle progress through the system.

- **Update Progress**  Highlights each action in color whenever Particle Flow evaluates it. The highlighting is very fast, but this option can add significant computational overhead to the particle system, with the result that real-time playback might skip a greater number of frames. To see all frames, turn off Time Configuration > Real Time.

**Use Dynamic Names** When on, action names in events are followed by their most important setting or settings, in parentheses. When off, only the names appear. Default=on.

---

**Tools menu**

The Tools menu in Particle View provides several utilities for managing Particle Flow.

- **Synchronize Layers** Synchronizes Particle Flow geometry with source objects. Use this option after you move PF Source objects to different layers. The Synchronize Layers option does not change objects' layers, but rather synchronizes Particle Flow geometry with source objects so they will function correctly.
  - **MAXScript** particleFlowUtility.synchronizeLayers()

- **Repair Cache System** Repairs the cache system if it stops working. If a Cache operator ends up in a different event from the one it was originally placed in, whether through direct manipulation or from being merged into another Particle Flow system, the operator might stop functioning because of ID conflicts. In such cases, use this function to restore the cache to working condition.
  - **MAXScript** particleFlow.repairCacheSystem(bool doReport)
**Preset Manager** Opens the Particle Flow Preset Manager dialog (see following).

- **MAXScript** `particleFlow.presetManager()`

**Particle Flow Preset Manager dialog**

You can use the Preset Manager to save a scene as a preset for later retrieval via **Preset Flow** on page 3230 in Particle View. Keep in mind that all objects in the scene are saved as a part of the preset, regardless of whether they are part of the Particle Flow. This ensures that any Particle Flow reference objects are included in the preset.

To save a new preset, enter a Preset Name and Preset Description, and then click **Save Scene As Preset Flow**.
**Preset Name** Enter an identifying name for the new preset.

**Preset Description** Enter a description for the new preset.

**Presets** A list of the current presets in the system. Click a preset to see its description.

**Save Scene as Preset Flow** Saves the current scene as a preset. The preset is saved as a pair of files: *preset_name.txt* with the description of the preset; and *preset_name.max* file with the scene itself. Both files are saved in \plugcfg\ParticleFlow\Presets\ within the install folder. Since presets are saved as files, it is possible to exchange or modify the presets by manipulating the files.

**Particle View Event Display**

Select a Particle Flow source icon. > Modify panel > Setup rollout > Click Particle View (or press 6).

Create panel > Geometry > Particle Systems > Object Type rollout > Click PF Source. > Setup rollout > Click Particle View (or press 6).

The event display on page 8566 in Particle View contains the particle diagram, and provides a complete range of intuitive functions for editing the particle system.

**NOTE** A number of these functions are also available from the event display right-click menu on page 3031, as well as the menu bar on page 3017.

**Editing the Particle Diagram and Particle System**

Interactive functionality in event display includes the following:

**General**

- To add an action to the particle system, drag it from the depot to the event display. If you drop it in an empty area of the event display, it creates a new event. If you drag it to an existing event, the result depends on whether a red line or a blue line appears when you drop it. If a red line, the new action replaces the underlying action. If a blue line, the action is inserted in the list.

- To edit an action's parameters, click its name in an event. The parameters appear on the right side of Particle View. If not, it means the parameters panel is hidden; to display it, choose Display menu > Parameters.
To wire a test to an event, drag from its test output, the blue dot that by default sticks out to the left of the test, to the event’s event input, which sticks out from the top, or vice-versa. Similarly, you can wire a global event to a birth event by dragging between the source output on the bottom of the global event and the event input. The mouse cursor changes to the first depicted image when you can begin this operation, and to the second image when you can complete it.

To pan or zoom the event display, use the controls available from the Display menu on page 3022, the right-click menu on page 3031, or as icons at the bottom-right of the dialog.

**Modifying Actions and Events in the Event Display**

- To change the color used by a Display operator, click its color swatch to the right of its name.

- To toggle an operator (that is, turn it off and on), click its icon in the event. The mouse cursor changes to the depicted image when this action is possible.

  A turned-off operator does not affect the particle system, and appears as gray in the event list; however, its parameters are still available for editing.

  Toggling an instanced operator doesn’t affect its other instances.

- To toggle an event (that is, turn it off and on), click the light-bulb icon next to its name in the title bar. Turning off an event is equivalent to turning off all of its operators and tests, although you cannot turn the operators and tests back on individually. The event’s items do not affect the particle system, and appear as gray in the event list. All particles entering a turned-off event are immediately passed on to the next event, if any.
To make a test result always True or False, click its icon’s left or right side, respectively. The mouse cursor changes to the first image at the left (with the left-pointing arrow) when you can click for always True, and to the second image at the left (without the left-pointing arrow) when you can click for always False.

The test icon changes to a green or red light bulb to indicate current functionality: green for always True, and red for always False.

To return to the original functionality, click the icon again. The mouse cursor changes to the depicted image when this action is possible.

## Selecting, Moving, and Copying

To copy an action or event, first press and hold the Shift key and position the mouse cursor over the item to copy. When the plus sign (+) appears next to the mouse cursor arrow, drag the item to a new location. When you release the mouse button, the Clone Options dialog appears; choose Copy or Instance and click OK. In the Clone Options dialog, the Event And Particle System group is unavailable, as a reminder that you cannot instance these elements. Reference is not an option when cloning Particle System elements. Cloning an event or particle system simply creates a new event or particle system containing clones of the original’s actions. Any instanced actions have identical properties. Changing one instance’s values changes them all. On the other hand, copied actions can have different values.

To clone multiple items, highlight them all before Shift+dragging. If you attempt to clone a combination of actions and events, or actions from different events, the result depends on where you start dragging from. If you drag a highlighted action, you’ll clone only actions from that event. If you drag an event, only highlighted events are cloned.

**NOTE** When you highlight an instanced action, Particle View indicates all of its other instances by changing their background color to a lighter shade of gray.
To move an event, drag its title bar, or the icon of any of its actions. If you drag the event to an edge of the display, and scrolling is possible, the display window will automatically scroll in that direction.

To resize an event, drag its right edge.

To highlight multiple items, drag a rectangle around them, or Ctrl+click them individually.

To delete an event, action, or wire, highlight it and then press Delete. Be sure the Particle Dialog is active, or you might inadvertently delete a selection in the scene instead.

To move an action, drag its name (not its icon) to the new location. If you drag the event to an edge of the display, and scrolling is possible, the display window will automatically scroll in that direction.

If you drag an action to an event, you can insert the action or replace an existing action, depending on where you position the mouse cursor before releasing the button. A blue line (before releasing) indicates that it will be inserted at that location, and a red line indicates that it will replace the underlying action. If you drag the action to an empty space in the event display, it will form a new event, and, by default, the system will add a new Display operator.

NOTE Particle Flow doesn't let you perform illegal operations. For instance, a Birth operator must always be the first item in a birth event on page 8521; the system doesn't let you position it elsewhere. You can place a Birth operator in an isolated event, but you can't then wire that event into a particle system, except in parallel with another birth event. For more information, see the Birth operator topic on page 3052.

To move a test output or switch it to the opposite side of the event, drag from just inside the test output to the desired new location. The mouse cursor changes to the depicted image when this operation is possible.

Getting Information

To see a renamed action's original type, position the mouse cursor over its event list entry until the tooltip appears.

To see a brief description of an action, click it in the depot. The description appears on the Description panel, to the right of the depot.
Event Display Right-Click Menu

Select a Particle Flow source icon. > Modify panel > Setup rollout > Click Particle View (or press 6). > Right-click in event display.

Create panel > Geometry > Particle Systems > Object Type rollout > Click PF Source. > Setup rollout > Click Particle View (or press 6). > Right-click in event display.

The event display right-click menu provides handy access to a number of contextual commands. The contents of the menu, as well as the results of its commands, depend in some cases on where you click, in other cases on what’s highlighted, and in still other cases, on both.

In the following descriptions, “item” means an action or event, or, in some cases, a wire.

Interface

**Insert** Displays a submenu of all actions, and when you choose a new action, inserts it where you originally right-clicked. Available only when you right-click over an event or action.

If you right-click over an action, and then insert an action, the inserted action replaces the old one. If you right-click above or below an action (no tooltip appears), the new action is added to the event at that location. If you right-click over an event, the action is inserted at the first available position.

**Append** Displays a submenu of all actions, and when you choose a new action, inserts it at the end of the event. Available only when you right-click over an event or action.

**Turn On** Turns on the event or action under the mouse cursor. Available only when the item under the mouse cursor is turned on.

To affect an event, the mouse cursor must be over its title bar. Turning on a highlighted item affects all highlighted items.

**Turn Off** Turns off the event or action under the mouse cursor. Available only when the item under the mouse cursor is turned off.

To affect an event, the mouse cursor must be over its title bar. Turning off a highlighted item affects all highlighted items.

**Make Unique** Converts an instanced action to a copy that’s unique to its event. Available only when the mouse cursor is over an instanced action.
If you right-click over a highlighted, instanced action, Make Unique affects all such actions.

**Wire** Wires one or more highlighted tests to a highlighted event, or one or more highlighted global events to a highlighted birth event. Available only when one or more tests and a single event are highlighted, or when one or more global events and a single birth event are highlighted, and when you right-click over an eligible, highlighted item.

**Copy** Copies any highlighted events, actions, and wires to the paste buffer. Available only when the mouse cursor is over an highlighted action, but affects all highlighted items.

**Paste** Pastes the contents of the paste buffer to the event display at the mouse cursor.

If the cursor is over a list, and you copied actions, the actions are added to the event. If the cursor is over an empty area of the event display, Particle Flow creates a new event containing the pasted actions. A copied event can be pasted only in an empty area of the event display.

The result of copying and then pasting multiple items depend on what you copied and the position of the mouse cursor:

- If you copied multiple actions, pasting adds them all to the event under the mouse cursor, or, if the cursor is over an empty area, to a new event, even if they originally came from different events.

- Copying multiple events and/or wires pastes them exactly as copied, but in this case Paste is available only when the mouse cursor is over an empty area.

- If you copied a combination of actions and events, you can paste them only when the mouse cursor is over an empty area. Pasting creates a new event for each group of actions from a single event. For example, if you highlight event A, some actions from event B, and some actions from event C, copying and then pasting would add three events: a copy of event A, a second event with the actions from event B, and a third event with the actions from event C.

**Paste Instanced** Pastes the contents of the paste buffer to the event display, making instances of any pasted actions and their originals.

For the results of pasting multiple copied items, and the limitations based on mouse position, see Paste, above.
New  Add a new item to the event display from the submenu. The submenu contents are identical to that of the depot. Available only when the mouse cursor is over an empty area.

Delete  Deletes the item under the mouse cursor. Available only when the mouse cursor is over an item.
If the mouse cursor is over a highlighted item, choosing Delete deletes all highlighted items.

Rename  Lets you rename the item under the mouse cursor. Enter a new name from the keyboard.

Properties  Opens the Object Properties dialog for the event under the mouse cursor. Available only when the mouse cursor is over the title bar of a highlighted event.
Particle Flow lets you set object properties on a per-event basis. This lets you set attributes such as Hide, Renderable, and Motion Blur separately for each event. Alternatively, you can set properties for the entire particle system from the global event.
For more information, see Object Properties on page 283.

NOTE Set properties for events and the particle system only within Particle View, not via the source icon in the viewports (using the right-click menu > Properties or Edit menu > Object Properties).

Use Script Wiring  Lets you use a script to specify certain parameters in the Force operator on page 3189 and Keep Apart operator on page 3131. This command appears only when you right-click either of the specified, highlighted operators in an event.

Comments  Lets you add comments to each action and event, and view existing comments. Available only when the mouse cursor is over an action or the title bar of an event.
Choosing Comments opens a window for entering text from the keyboard. Begin typing, and click OK to finish. A commented event or action has a red triangle near its name to indicate the presence of the comment. You can click this triangle to open the comment.
Commented actions; click the triangle to view a comment.

**NOTE** A comment is specific to the action or event to which it's applied. If you copy a commented event or action, the comment is not included in the copy, because it's probably not applicable to the copy.

**Pan** Switches to the Pan tool. Drag in the event display to change the view; right-click to exit. Available only when you click over an empty area of the event display.

**Zoom** Switches to the Zoom tool. Drag upward in the event display to zoom in, and downward to zoom out; right-click to exit. Available only when you click over an empty area of the event display.

**Zoom Region** Switches to the Zoom Region tool. Drag a rectangle in the event display to specify the area to zoom into; right-click to exit. Available only when you click over an empty area of the event display.

**Particle Flow Source**

Add a Particle Flow system to the scene. > Create panel
Select a PF Source icon. > Modify panel

**Particle View** on page 3015 > Click a global event (title bar). > Parameters panel

The Particle Flow source is the viewport icon for each flow on page 8581, and also serves as the default emitter. By default, it appears as a rectangle with a central logo (see illustration), but you can change its shape and appearance using the controls described in this topic.
When you select a source icon in the viewport, the Particle Flow emitter-level rollouts appear on the Modify panel. Alternatively, click the title bar of a global event in Particle View to highlight it, and to access the emitter-level rollouts from the parameters panel on the right side of the Particle View dialog. Use these controls for setting global attributes, such as icon properties and the maximum amount of particles in the flow.

The particle source icon is roughly equivalent to the corresponding global event on page 8594 in Particle View. They have the same name, but selecting one does not select the other. If you delete a particle source icon from the scene, Particle Flow converts the global event to an isolated local event in Particle View, retaining its operators with their settings intact. Any other events in the system remain in Particle View, along with their wiring. However, if you delete a global event, Particle Flow also removes any local events used exclusively by that system, as well as the corresponding particle source icon. To retain the local events, first delete the wire from the global event, and then delete the global event.

If you clone a particle source in a viewport with Shift+transform or Edit menu > Clone, an equal number of copies of the global event appear in Particle View, each wired to the original birth event on page 8521. The Clone Options dialog offers only the Copy option. However, if you clone a global event in Particle View, the Clone Options dialog also lets you create instances of the cloned operators and tests. It's not possible to create instances of global and local events, so these options are unavailable in the Clone Options dialog, as a reminder. Also, global events cloned in Particle View are not automatically wired to the original birth event.
Interface

Modifier stack

In the modifier stack, expanding the hierarchy of a Particle Flow source object provides access to two sub-object levels: Particle and Event. For further information, see Selection rollout on page 3039.

Setup rollout

Use these controls to turn the particle system on and off, and to open Particle View.

NOTE This rollout appears only on the Create and Modify panels, not on the Particle View dialog > parameters panel.

Enable Particle Emission Turns the particle system on and off. Default=on. You can also turn off all particle flows in Particle View with Edit menu > Turn Off All, or a specific particle flow by right-clicking its global event's title bar and choosing Turn Off.

Particle View Click to open the Particle View dialog on page 3015.
Emission rollout

Sets the physical characteristics of the emitter (particle source) icon, and the percentage of particles produced in the viewports and when rendering.

Emitter Icon group

Logo Size  Sets the size of the Particle Flow logo, which appears at the center of the source icon, as well as the arrow that indicates the default direction of particle motion.
By default, the logo size is proportional to that of the source icon; with this control, you can make it larger or smaller.
This setting affects only the viewport display of the logo; changing it has no effect on the particle system.

Icon Type  Choose the basic geometry of the source icon: Rectangle, Box, Circle, or Sphere. Default=Rectangle.
This choice matters only if you use the source icon as the particle emitter. The available size settings depend on which icon type you choose, and, again, are important only if you use the source icon as an emitter.
The default icon type is Rectangle. If you add a particle system, and then change the icon type to Box, the icon continues to resemble a rectangle. To make it look like a box, increase the Height setting.

Length/Diameter  Sets the length of the Rectangle and Box icon types, and the diameter of the Circle and Sphere icon types.
Width  Sets the width of the Rectangle and Box icon types. Unavailable with
the Circle and Sphere icon types.

Height   Sets the height of the Box icon type. Available only with the Box icon
type.

Show Logo/Icon   Turns display of the logo (with arrow) and icon on and off,
respectively.

These settings affect only the viewport display of these items; they have no
effect on the particle system.

Quantity Multiplier group

These settings determine the percentage of the total number of particles in
each flow on page 8581 that are actually produced in the viewports and at render
time. They don’t affect the percentage of particles that are visible; those are
determined by the Display operator on page 3186 and Render operator on page
3194. You can use them to quickly decrease or increase the number of particles
consistently throughout all events in the particle system. The maximum
setting, 10,000%, lets you multiply the number of particles generated by the
flow by 100.

The total number of particles is determined by the combined effects of the
following operators and tests: Birth on page 3052, Birth Script on page 3056, Delete
on page 3067, Collision Spawn on page 3241, and Spawn on page 3281. Scripted
operators and tests can also affect this number.

Viewport   Sets the percentage of the total number of particles in the system
produced in the viewports. Default=50.0. Range=0.0 to 10000.0.

Render   Sets the percentage of the total number of particles in the system
produced at render time. Default=100.0. Range=0.0 to 10000.0.
Selection rollout

Use these controls for selecting particles on a per-particle or event basis. Selection of particles at the Event level is for debugging and tracking purposes. Particles selected at the Particle level can be acted upon by the Delete operator on page 3067, the Group Selection operator on page 3078, and the Split Selected test on page 3290. You cannot directly manipulate selected particles with standard 3ds Max tools such as Move and Rotate.

**NOTE** This rollout appears only on the Modify panel, not on the Create panel or Particle View dialog > parameters panel.

**Particle** Lets you select particles by clicking them or dragging a region.

**Event** Lets you select particles by event. At this level, you can select all particles in one or more events by highlighting the event(s) in the Select By Event list on page 3040, or in the viewports with standard selection methods. To convert a selection from the Event level to the Particle level for use with the Delete operator or Split Selected test, use Get From Event Level on page 3040.
Selected particles appear in the viewports in red (if not geometry), in the form designated by the Display operator > Selected setting on page 3189.

**Select by Particle ID group**

Each particle has a unique ID number, starting with 1 for the first particle and counting up. Use these controls to select and deselect particles by their ID numbers. Available only at the Particle selection level.

**TIP** You can display particle IDs in the viewports by turning on Display operator > Show Particle IDs.

**ID** Use this to set the ID number of the particle you want to select. You can set only one number at a time.

**Add** After setting the ID number of a particle to select, click Add to add it to the selection. By default, selecting a particle doesn't deselect any others.

**Remove** After setting the ID number of a particle to deselect, click Remove to remove it from the selection.

**Clear Selection** When on, clicking Add to select a particle deselects all other particles.

---

**Get From Event Level** Click to convert an Event-level selection to the Particle level. Available only at the Particle level.

---

**Select By Event** This list shows all events in Particle Flow, and highlights selected events. To select all of an event's particles, click its list entry, or use standard viewport-selection methods.

**# Particles Selected** Shows the number of selected particles.
System Management rollout

Use these settings to limit the number of particles in the system, and to specify the frequency of updating the system.

Particle Amount group

Upper Limit The maximum number of particles the system may have. Default=100000. Range=1 to 10000000.

TIP You can have more than 10,000,000 particles in a single system by using multiple particle sources and wiring them to the same birth event. Note, however, that Particle Flow is limited to sending a maximum of 5,000,000 particles per event to the renderer.

Integration Step group

At each integration step, Particle Flow updates the particle system, applying each active action to particles in its event. A smaller integration step can improve accuracy, at the cost of calculation time. These settings let you apply different integration steps to the particle animation in the viewports and at render time.

In most cases, the default Integration Step settings work fine. One instance in which increasing the integration-step frequency might help is when fast-moving particles that should collide with a deflector penetrate it instead.

Viewport Set the integration step for animation playback in the viewports. Default=Frame (once per animation frame). Range=1/8 Frame to Frame.

Render Set the integration step at render time. Default=Half Frame (twice per animation frame). Range=1 Tick to Frame.

There are 4,800 ticks in a second; thus, at the NTSC video rate of 30 frames per second, there are 160 ticks per frame.
Script rollout

This rollout lets you apply a script to the particle system at each integration step, as well as after the last integration step of each frame you view. Use an Every Step Update script to set up history-dependent properties, and a Final Step Update script to set up history-independent properties.

Every Step Update group

The Every Step Update script is evaluated at the end of each integration step, after all actions in the particle system are evaluated, and all particles are finally in their respective events. When, for example, you are setting up Material ID according to a particle index, it is important to be sure that particles are not about to jump to another event.

When you set up history-dependent properties, such as speed, it is important to do that at every integration step, because otherwise the final position would be quite different.

Enable Script Turn on to cause a script in memory to be executed at each integration step. You can modify this script by clicking the Edit button, or load and use a script file with the remaining controls in this group.

The default script modifies particle speed and direction, causing particles to follow a wavy path.

Edit Click this button to open a text-editor window with the current script. When Use Script File is on, this is the default Every Step Update script (3dsmax\scripts\particleflow\example-everystepupdate.ms). When Use Script File is on, this is the loaded script, if you've loaded one. If you haven't, clicking Edit displays the Open dialog.
Use Script File When on, you can load a script file by clicking the button below.

[button] Click this button to display an Open dialog that lets you specify a script file to load from disk. After you load a script, the name of script file appears on the button.

**Final Step Update group**

The Final Step Update script is executed after the last integration step has been completed for each frame that you view (or render). For example, if you play the animation in the viewport with Real Time turned off, Particle Flow runs this script at each frame, immediately before the particle system is rendered to the viewport. However, if you simply jump to a different frame, the script is run once only, so if the script assumes a certain history, you might get unexpected results.

For this reason, it's best to use the Final Step Update script to modify history-independent properties. For example, if no operators in the system depend on the material indices, you could use it to modify the material index. In this case there's no need to set those indices in every intermediate integration step. Also, you can set up a position channel in the Final Step Update script if you know the analytical expression for the position.

Enable Script Turn on to cause a script in memory to be executed after the final integration step. You can modify this script by clicking the Edit button, or load and use a script file with the remaining controls in this group.

The default script modifies particle speed and direction, causing particles to follow a bulb-shaped path.

Edit Click this button to open a text-editor window with the current script.

When Use Script File is off, this is the default Final Step Update script (3dsmax\scripts\particleflow\example-finalstepupdate.ms). When Use Script File is on, this is the loaded script, if you've loaded one. If you haven't, clicking Edit displays the Open dialog.

Use Script File When on, you can load a script file by clicking the button below.

[button] Click this button to display an Open dialog that lets you specify a script file to load from disk. After you load a script, the name of script file appears on the button.
Particle Flow Helpers

Create panel > Helpers > Particle Flow > Object Type rollout
Create menu > Helpers > Particle Flow

In general, Particle Flow helpers take the form of icons that are automatically created in the scene when you add the associated test or operator. A special case is the Particle Paint helper, which must be added explicitly.

With the exception of Particle Paint, when you add a Particle Flow helper to the scene, Particle Flow creates the associated action in Particle View.

Interface

Initial State on page 3069
Group Select on page 3078

Particle Flow Keyboard Shortcuts

To use Particle Flow keyboard shortcuts, the Keyboard Shortcut Override Toggle on the main toolbar must be turned on.

To view and customize these shortcuts, open the Customize User Interface dialog from the Customize menu, and then, from the Group drop-down menu, choose Particle Flow.

<table>

</table>

* These functions are specific to Particle View. It is recommended that you use Customize User Interface to change their keyboard shortcuts only, and not assign them to toolbars, quads, or menus.

**MAXScript/CUI-Only Tools**

New in Particle flow are two commands for resetting Particle View and for cleaning up Particle Flow that are available from Customize User Interface and MAXScript.
Interface

Reset Particle View Moves the Particle View dialog to its default position. If a scene is opened and saved on different computer systems with different resolutions, you might find that the Particle View dialog has been placed off-screen with regard to your system. Reset Particle View option restores the default position and makes the dialog visible on any computer system.

- Customize User Interface (CUI) action  Reset Particle View
- Shortcut  Alt+Ctrl+R
- MAXScript  particleFlowUtility.resetParticleView()

Clean Up Particle Flow Removes items that can slow down rendering and editing. When a you create or modify a Particle Flow system, invisible items are sometimes created in the flow network. If you change the PF system during playback, these items allow the PF system to display changes immediately in viewports. However, the items might slow down rendering or editing. Clean Up Particle Flow deletes the invisible items safely, improving render speed and interactivity during Particle View editing.

It is recommended that you use this option after editing Particle View wiring and before rendering or saving the scene.

- Shortcut  Alt+Ctrl+P
- MAXScript  particleFlow.cleanUpParticleFlow(bool doReport)
  Returns number of items removed (cleaned up) from Particle Flow. The bool doReport parameter specifies whether or not to show a message box with the report.

Actions

The Particle Flow components for creating particle systems are known collectively as actions. These are subdivided into three main categories: Operators, Flows, and Tests.

Action Time Frames

Most actions in Particle Flow operate on particles in either of two time frames: once, when the particle first enters the event, or on a continuous basis, potentially changing particle behavior at each integration step (that is, the
whole time the particle is in the action’s event). Some actions can work only in one time frame, while others can work on an instantaneous or continuous basis, depending on their settings. The tables in this topic list each action with its time frame.

**Operators**

Once, except continuous with Speed Space Follow | Spin |
Continuous | Split Group |
n/a=not applicable

Tests

Most tests in Particle Flow function only as tests. At each integration step, they check each particle for the specified conditions, and then return the test result: True or False. So, as tests, they work on a continuous basis. For example, Age Test checks each particle's age at every integration step, because particles might not reach the specified age until remaining in the event for a while, and also because another action in the event might change or reset particle age.

The principal exceptions to this are the Split tests, which test each particle only when it first enters the event. That is, a Split test splits the particle stream only once for each particle that enters the event. Any particles that remain in the event are not subject again to being split off from the stream by the same test. Also, the Send Out test performs no test, but simply moves particles along to the next event.

Some tests also function as operators, in that they directly affect particle behavior. These are the ones listed here, and the specified time frame is related to the operator functionality, not the test.

Test | Time Frame
---|---
Continuous | Collision Spawn
Continuous | Find Target
Continuous | Go To Rotation
Depends on script | Script Test
<table>

</tr>
</tbody>
</table>

**Operators**

The operator is the basic element of the particle system: you combine operators into events to specify the particles' characteristics over a given period of time. Operators let you describe particle speed and direction, shape, appearance, and more.

The operators reside in two groups in the Particle View depot, and within each group appear in alphabetical order. Each operator's icon has a blue background, except for the Birth operators, which have a green background. The first group contains operators that directly affect particle behavior, such as transformation.

The second group, found at the end of the depot listing, contains four operators that serve more of a utility function: Cache, for optimizing particle-system playback; Display, for determining how particles appear in the viewports; Notes, for adding comments; and Render, for specifying render-time characteristics.

The primary operators in Particle Flow are:

- **Birth Operator** on page 3052
- **Birth Paint Operator** on page 3222
- **Birth Script Operator** on page 3056
Birth Texture Operator on page 3057
Delete Operator on page 3067
Force Operator on page 3189
Group operator on page 3076
Group Selection Operator on page 3078
Initial State operator on page 3069
Keep Apart Operator on page 3131
Mapping Object operator on page 3158
Mapping Operator on page 3175
Material Dynamic Operator on page 3168
Material Frequency Operator on page 3166
Material Static Operator on page 3163
Placement Paint operator on page 3224
Position Icon Operator on page 3086
Position Object Operator on page 3089
Preset Flow on page 3230
Rotation Operator on page 3097
Scale Operator on page 3102
Script Operator on page 3196
Shape Operator on page 3137
Shape Facing Operator on page 3139
Shape Instance Operator on page 3142
Shape Mark Operator on page 3149
Speed Operator on page 3108
Speed By Icon Operator on page 3112
Speed By Surface Operator on page 3122
Spin Operator on page 3099

The utility operators are:
Birth and Death

These operators control the creation of new particles and the elimination of particles that are no longer needed.

See also:
- Birth Paint Operator on page 3222

Birth Operator

Particle View on page 3015 > Click Birth in an event or add a Birth operator to the particle system and then select it.

The Birth operator enables creation of particles within the Particle Flow system using a set of simple parameters. In general, use Birth as the first operator in any event connected directly to a global event on page 8594; this is called the birth event on page 8521.

You can specify a total number of particles, or a rate of particles born per second. You can also tell the system when to begin emitting particles, and when to stop.
NOTE  The Birth operator must always come at the beginning of a particle stream; the system doesn't let you position it elsewhere. You can place a Birth operator in an isolated event, but you can't then wire that event in series with a stream that already uses a Birth operator. However, you can wire multiple Birth operators, each in its own event, into a particle stream with an existing Birth operator, in parallel. The following procedure illustrates this. If you need to create particles midstream, use the Spawn Test on page 3281 or Collision Spawn Test on page 3241 test.

See also:
■ Birth Script Operator on page 3056

Procedures

To use the Birth operator:

This procedure demonstrates the impossibility of using multiple Birth operators in series, and shows how to use multiple Birth operators in parallel.

1  Start or reset 3ds Max, and add a new PF Source object to the scene.
2  Press 6 to open Particle View.
   The default particle system contains a Birth operator as the first action in the birth event.
3  Try to drag the Birth operator elsewhere in Event 01.
   You can't. As you drag over the different actions in Event 01, a red line appears at the top of the event, showing that the Birth operator will be placed here, no matter where you release the mouse button.
4  Try to drag a new Birth operator from the depot to Event 01.
   As in the previous step, the only place you can drop the Birth operator is at the top of the event, replacing the existing Birth operator.
5  From the depot, drag the Birth operator to an empty area in the event display.
   Particle Flow creates a new birth event, Event 02, containing the Birth operator and a Display operator.
6  Wire the output of the global event, PF Source 01, to the event input of Event 02.
   Each birth event must be associated with a global event to be able to generate particles.
From the depot, add a Send Out test at the end of both Event 01 and Event 02.

Try to wire the test output of Event 02 to the event input of Event 01. Particle Flow doesn’t let you, because this would result in two Birth operators in series.

Try to wire the test output of Event 01 to the event input of Event 02. Again, Particle Flow doesn’t let you, because this would result in two Birth operators in series.

Drag a Speed operator to an empty area of the event display. Particle Flow creates a new event, Event 03.

Wire the test output of Event 01 to the event input of Event 03.

Wire the test output of Event 02 to the event input of Event 03. There’s no problem wiring the two birth events to a single, third event. The birth events exist in the particle stream in parallel, each generating particles independently and then feeding its particle stream into a common event, where the two streams are combined.

If the second birth event had its own global event, you could, at any point further downstream, separate the streams back out according to their origin using the Split Source test on page 3291. To do this, delete the wire from PF Source 01 to Event 02, add an Empty Flow on page 3232 to the system, and then wire it to Event 02.

### Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.
**Emit Start** The frame number at which the operator begins emitting particles.

**Emit Stop** The frame number at which the operator stops emitting particles.

**NOTE** The Emit Start and Emit Stop values are tied to the system frame rate. If you change the frame rate, Particle Flow automatically adjusts the Emit values accordingly. For example, if you set Emit Start to 120 and Emit Stop to 300 using the default NTSC frame rate (30 fps), and then switch to PAL (25 fps) using the Time Configuration dialog, you've reduced the frame rate to 5/6 of the original value. Thus, Particle Flow automatically uses the same ratio to adjust the Emit settings, resulting in an Emit Start value of 100 and an Emit Stop value of 250. This allows the particle system to retain the timing you specify, no matter which frame rate you use.

**NOTE** With Subframe Sampling off, such adjustments are rounded off to the nearest integer frame number. With Subframe Sampling on, fractional frame values that result from such adjustments will be used, but not displayed.

**Amount** To specify the total number of particles emitted by the operator, choose Amount, and then set the quantity of particles. Using the Amount option, the first particle is always emitted at the Emit Start frame, and the last particle is always emitted at the Emit Stop frame. Particles emitted between these endpoints appear at equal intervals within the emission period. For example, if you set Amount to 3, the second particle is emitted halfway through the emission period.

To determine the number of particles emitted per frame when using Amount, divide the Amount value by the number of emission frames (Emit Stop-Emit Start+1).

**Rate** To specify the number of particles emitted per second, choose Rate, and then set the value. The operator emits this number of particles per second starting at the Emit Start frame and ending at the Emit Stop frame.

If you specify a birth rate value that isn’t an integer multiple of the system frames-per-second value (set in the Time Configuration dialog), Particle Flow uses interpolation to determine when to emit particles. For example, if you use the system default rate of 30 frames per second, and set the birth rate to 4, the system would emit each particle at intervals of seven or eight frames if Subframe Sampling is off, or at intervals of 7.5 frames if Subframe Sampling is on.

**Total** The calculated total number of particles emitted by the operator.
Subframe Sampling  Turning this on helps avoid particle "puffing" by emitting particles at a much higher subframe resolution (that is, throughout each frame), rather than using the relatively coarse frame resolution. Default=on. "Puffing" is the effect of emitting separate "puffs" or clusters of particles, rather than a continuous stream. This effect is especially noticeable when the emitter is animated.

Turn off Subframe Sampling to cause particles to be emitted exactly at frame times. This makes it easier to sort particles by their age later.

TIP  If, when using the Collision on page 3236 or Collision Spawn test on page 3241, you experience an irregular particle stream, try turning off Subframe Sampling.

Birth Script Operator

Particle View on page 3015  >  Click Birth Script in an event or add a Birth Script operator to the particle system and then select it.

The Birth Script operator enables creation of particles within the Particle Flow system using a MAXScript script. The script can use any program functionality available to MAXScript.

The default script (3dsmax\scripts\particleflow\example-scriptbirth.ms) emits particles for 100 frames in a wavy, circular path. To see this, turn off or delete any Speed and Position operators in the event.

See also:

- Birth Operator on page 3052

Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.
**Edit Script** Click this button to open the current script in a MAXScript Editor window.

For detailed information about the MAXScript utility, open the MAXScript Help, available from Help menu > MAXScript Help.

**Emit Start** The frame number at which the operator begins emitting particles.

**Uniqueness group**

The Uniqueness setting provides a randomization seed that the script can use or ignore.

**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.

---

**Birth Texture Operator**

[Particle View](#) on page 3015 > Click Birth Texture in an event or add a Birth Texture operator to the particle system and then click it.

The Birth Texture operator uses an animated texture to calculate the timing, location, and scale of particles. In general, Birth Texture causes particles to emit from the object where the texture is white or a bright color.

The Birth Texture operator controls are available in two areas of 3ds Max. First, the **Birth Texture rollout** on page 3059, which appears in Particle View, regulates the overall timing of particles.

Second, adding a Birth Texture operator to a Particle Flow system creates a 3D icon, or helper, that you can select in viewports. The icon is placed at the world origin (0,0,0). When you select this icon, the **Parameters rollout** on page 3060 opens on the Modify panel. These controls let you specify the timing, placement, and scaling of particles. You can also access the Birth Texture operator’s parameters via the operator in Particle View, by clicking Initialization Parameters.
Birth Texture icon

Procedure

To use the Birth Texture operator:

1. Create an object, and apply a material to it that includes an animated map with variations of light and dark colors. For example, you could apply a Checker map as the Diffuse map with an animated Offset parameter.

2. Create a PF Source.

3. In Particle View, replace the Birth operator with a Birth Texture operator. This creates the Birth Texture icon at the world center: 0,0,0.

4. On the Birth Texture rollout in Particle View, set Emit Stop to 100 (or any other value you prefer) and turn off Lock To Emitters.

5. Click Initialization Parameters. This selects the Birth Texture icon and opens the Modify panel.

6. On the Modify panel, in the Timing group of controls, set Stop to the value you used in step 4.

7. In the Emitter Objects group, select the object with the material as the emitter.

8. At the top of the Parameters rollout, click Initialize Particle Emission. This process runs through the animation, and places particle seeds (white) on the object’s surface where white or light areas appear.
TIP If no particles appear, try turning down the Whiteness setting in the Emission By group. This lowers the threshold of texture brightness required to emit particles.

9 In Particle View, remove or disable the Position Icon operator and then play the animation.

The seeds turn into particles whenever the area under the seeds turns white; the particles then move away from the object.

Interface

Birth Texture rollout

This rollout appears in Particle View when the Birth Texture operator is selected.

 Emit Start The frame at which the operator begins emitting particles.

 Emit Stop The frame at which the operator stops emitting particles. The exact timing of start and stop may vary due to the timing of individual particles, which depends on the emitter’s animated texture.

 Reset To Original Timing Sets the Emit Start and Emit Stop values to the current values of Timing > Start and Stop on page 3063 as initialized (that is, when you last clicked Initialize Particle Emission on page 3061). If Emit Start and Emit Stop differ from the original timing, the particle timing is scaled to fit into the emission interval. This lets you change the overall timing of the emission without the long process of pre-calculation.

 Lock On Emitters Causes all particle pivot points to be “glued” to the emitter objects. This control is similar to the Lock On Emitter option of the Position
Icon operator. It tells the Birth Texture operator to continue controlling particle position even after the particles are born.

**Total Particles** This read-only value shows the total number of pre-calculated particles. The amount of particles actually generated depends on the Quantity Multiplier of the master PF Source object. If the multiplier value is less than 100%, the operator samples the pre-calculated particles. If the multiplier is greater than 100%, some particle seeds are able to generate multiple particles.

**Initialization Parameters** Selects the Birth Texture icon and switches to the Modify panel to show controls related to the particle timing and placement pre-calculation (see following).

**Parameters rollout**

This rollout is available on the Modify panel when you select the Birth Texture icon or click Initialization Parameters (see preceding).
The color of this icon indicates the calculation status of particle seeds. When blue-green, the operator has generated particle seeds according to the current set of parameters, and is up to date. When red, parameters have been changed since the last initialization, and you must update the particle seeds by clicking Initialize Particle Emission.

Initialize Particle Emission

Click to calculate particle seed timing, placement and scaling according to the current set of parameters. If the emitters geometry or textures are complex, the initialization process can be lengthy. The overall progress of calculation is indicated as a percentage in the status bar. When calculation is complete, the Green/Red concentric color box turns green.

This option is available only after you have picked at least one emitter in the Emitter Objects group.

Quantity group

The Birth Texture operator offers several methods for determining the quantity and placement of particle seeds. In general, each of these methods covers the emitter with the maximum number of particle seeds allowed for the chosen method, then the texture's coloring or brightness defines if and when a seed is converted to a particle.

NOTE These parameters control particle seeds, not the particles themselves. A particle seed is converted to a particle based on the parameters in other rollouts, and on the color and brightness of the texture itself.

Choose one option in this group:

- **Amount**  Randomly covers the emitter surface with the specified number of particle seeds. Then the animated texture is used to define if and when a seed generates a particle. This option can be used when you don’t want particles to be generated in the same place multiple times when the texture is animated.

- **Max. Rate**  Sets the maximum number of particles that can be generated per frame over the entire surface, when the texture color exceeds the Whiteness value. The rate is expressed in particles per frame. First, the emitter surface is randomly covered with seeds at the Max. Rate, starting with the Start frame. Then the texture for the current frame defines at that frame whether each seed generates a particle. The unused seeds are not used. At the next frame, a new set of particle seeds is generated. This option generates particle seeds in this manner from the Start frame to the Stop frame. This option can be used when it doesn’t matter whether particles are generated in the same place multiple times.
Separate  Sets the distance by which particle seeds are separated, in units. The emitters surface is evenly covered with particle seeds, and the seeds are placed in such a way that they are separated by the Separate value. Then the animated texture is used to define if and when a seed generates a particle. The Separate option guarantees the absence of dense clusters and overlapping particles. This option guarantees that particles will not be generated in the same place multiple times.

When you choose Separate, two additional options become available:

- **Adjust By Scale Factor**  When the Separate option is chosen and you've specified a Scale Factor option on page 3066 other than None, this option adjusts the separation distance according to particle scale. In other words, when Adjust By Scale Factor is on, Particle Flow can place smaller particles closer together, while increasing the distance between larger particles.

- **Fast Approx. Separation**

**Vertices/Edges**  Places particle seeds on surface vertices. The total amount of particle seeds is defined by the number of vertices.

**Subdivide**  Places particle seeds on visible edges as well as vertices. The seeds are distributed evenly along edges, spaced by a distance approximately equal to the Subdivide value. Then the animated texture is used to define if and when a seed generates a particle. The total amount of particle seeds is defined by the number of vertices, and the lengths of visible edges.

**Faces**  Places particle seeds at face centers. If the Subdivide option is on then each face is subdivided to a point when every faces edge is less than the Subdivide value, and a particle seed is placed at the center of the sub-faces. Then the animated texture is used to define if a seed generates a particle, and when. The total amount of particle seeds is defined by the number of faces and their size (if Subdivide is on). The Faces option with Subdivide on generates the most evenly distributed particles over the emitter surface, with some regular properties. If the Subdivide value is less than a particle size then the particles are able to cover the entire emitter surface without any holes.

**Subdivide**  The option is available for the Vertices/Edges and Faces amount types only. When On, edges and faces are subdivided to generate the greater amount of particles.
**Amount Limit** This control is available if you choose Vertices/Edges or Faces and also turn on Subdivide. Small values of Subdivide can generate so many particle seeds that they exceed available memory: this value limits the number of seeds, so 3ds Max doesn’t hang. Range = 10 to 50000000 (fifty million). Default=1000000 (one million).

**Total Amount** This read-only value shows the total number of particles pre-calculated for the emission. Because the animated texture might not reach required whiteness level over the emitter surface, this value is usually smaller then Amount or Max. Rate*(Stop-Start) values.

**Timing group**

These parameters determine the time interval over which particles are generated. The operator analyzes the emitter texture over the time interval, using the data to define the precise birth moment for each particle. The timing for each particle is stored as a floating-point value ranging from 0.0 to 1.0. This indicates its timing relative to the start (0.0) or end (1.0) of the interval and makes it possible to adjust the overall timing of the particle emission without recalculation.

You can also adjust particle timing in Particle View by changing the Emit Start and Emit Stop values.

**Start** The first frame of the interval over which particles are generated.

**Stop** The last frame of the interval over which particles are generated.

**Delay Var** Variation in particle emission, in frames.

**Latency** Causes particle seeds to accumulate brightness over time, and to be converted to particles only if they accumulate a certain brightness value. The Latency value is multiplied by the Whiteness % on page 3065 value to determine the whiteness that needs to be achieved. Then particle seeds accumulate Luminance values for the texture at each frame, and are converted to particles when they achieve the multiplied whiteness value. Latency can be used to cause a sweep of particles to be generated over a gradient map without having to animate the map.

For example, if Latency is off, Whiteness is 100%, and the texture where a particle seed resides is white [256,256,256], a particle will be generated. But if Latency is on and set to 3, the multiplied whiteness required to convert to a particle is 300%, which the particle seed accumulates after 3 frames.
Following are more examples of how adjusting Latency affects how particles are generated:

- Texture color=[128,128,128] (50% brightness); Whiteness=100%; Latency=7:
  The particle seed requires 700% brightness to emit a particle, which would be achieved after 14 frames.

- Texture color=[32,32,32] (12.5% brightness); Whiteness=50%; Latency=2:
  The particle seed requires 100% brightness to emit a particle, which would be achieved after eight frames.

**Precision**
The level of accuracy for particle timing calculation. If the texture has more than a single image per frame, to include the sub-frame images choose a sub-frame sampling method. The available choices are Frame, Half Frame, 1/4 Frame, 1/8 Frame.

**Emission By group**

Particle seeds are converted to particles when the particle seeds are located on an area of the texture that exceeds the Whiteness value. The parameters in this group define how Particle Flow interprets the texture information to see if it exceeds the Whiteness value.

The Emission By choices are as follows:

- **Material**
  Gathers colors from the emitter’s material.

- **Sub-Material**
  Gathers colors from a single sub-material, and generates particles only on faces with the specified sub-material ID (Material ID). The sub-material ID is set by the Sub-Mtl ID parameter (see following).

- **Sub-Mtl Global**
  Gathers colors from a single sub-material, and generates particles over the entire emitter surface regardless of the faces’ Material IDs. The sub-material ID is set by the Sub-Mtl ID parameter (see following).

- **Vertex Color**
  Gathers colors from the Vertex Color channel.

- **Vertex Alpha**
  Gathers colors from the Vertex Alpha channel.

- **Vertex Illum**
  Gathers colors from the Vertex Illum channel.

- **Mapping**
  Gathers colors from a mapping channel. A mapping channel can be used by the Vertex Paint modifier to color vertices. The mapping channel index is defined by the Channel parameter.
TIP  For information about these channels, see the VertexPaint Modifier topic in the 3ds Max Help.

R/G/B  These buttons let you define the set of color channels to be considered for particle generation. For example, if only the R (red) button is active, then only the red color data is used to determine whether particles are generated. If more than one button is active, the average of the chosen channels is used.

Sub-Mtl ID  Specifies the sub-material ID when Emission By (see preceding) is set to Sub-Material or Sub-Material Global. Typically the sub-material is a component of a Multi/Sub-Object material, and you can find the IDs on the material’s Basic Parameters rollout.

Whiteness %  Sets the color trigger level. If a color at a particle seed location exceeds this threshold, then a particle is generated. A 0% Whiteness corresponds to RGB value (0,0,0), while a 100% Whiteness corresponds to the RGB value (255,255,255).

Emitter Objects group

Use these controls to assign objects to be used as particle emitters.

Add  Adds an object to the list.

By List  Opens the Select Emitter Geometry dialog where you can add multiple objects to the list.

Remove  Removes a highlighted object from the list.

Animated Emitters  Indicates that the emitter objects are animated, either with transforms or surface animation. This option affects the display of particle seeds, but doesn’t affect particle generation, because all particles are generated on the surface regardless of whether it is animated. Toggling this option does not affect calculation status.

Surface Normal Offset  When on, lets you specify an offset range from the emitter surface for particle placement. Negative values place particle seeds below the surface.

Offset Min/Max  When Surface Normal Offset is on, you can specify the range of offset distance from the object surface. The Min value cannot exceed the Max value, and the Max value cannot go below the Min value.

Scale Factor group

The operator can initialize particle scaling according to the characteristics of the texture the particles are generated from. So, for example, you can vary the
sizes of particles emitted from different parts of the surface with a gradient map. The scale value calculation uses the texture's state at the current frame, disregarding any animation the texture has. Since a color has three floating-point values, each value defines a different component of the scale vector. To have a uniform scale factor, use textures with no hue (black/gray/white gradients).

**Scale By** Defines the source of color to calculate particle scaling. The available choices are:

- **None** No particle scaling is set.
- **Sub-Material** Uses a single sub-material to set the scale, and uses this scale over the entire emitter surface regardless of the faces' Material IDs. The sub-material ID is set by the Sub-Mtl ID parameter.
- **Vertex Color** Uses the Vertex Color channel to define particle scale.
- **Vertex Alpha** Uses the Vertex Alpha channel to define particle scale.
- **Vertex Illum** Uses the Vertex Illum channel to define particle scale.
- **Mapping** Defines particle scale with a mapping channel that is used for vertex coloring by the Vertex Paint modifier. The mapping channel index is defined by the Channel parameter.

**TIP** For information about these channels, see the VertexPaint Modifier topic in the 3ds Max Help.

**Sub-Mtl ID** When Scale By (see preceding) is set to Sub-Material, specifies the sub-material ID. Typically the sub-material is a component of a Multi/Sub-Object material, and you can find the IDs on the material’s Basic Parameters rollout.

**Black Scale %** Defines the scale value for particles that fall on pure black areas of the texture. This value should be used to set the scale percentage for the smallest particles in the range. The Black Scale % must be lower than or equal to the White Scale %.

**White Scale %** Defines the scale value for particles that fall on pure white areas of the texture. For intermediate gray colors, the scale value is linearly interpolated between the Black Scale % and White Scale %.

The Black Scale % and White Scale % can influence the particle distribution if the Separate option in the Quantity group is chosen, and Adjust By Scale Factor is on.
Display group

The operator is able to show the particles in interactive, non-history-dependent mode. Usually, if you want to see particle animation, you have to place the operator into an event that is wired to an active PF Source event. However, this might require heavy calculation for history-dependent particle animation. The parameters in the Display group give you the ability to see how particles will be created without the overhead of generating a particle system.

Show Particles Displays calculated particle seeds as ticks.

All / By Timing Defines the mode for showing particles:
- All All pre-calculated particles are shown.
- By Timing Each particle is displayed at the frame at which it will be born. The timing shown with the By Timing method might differ from the actual particle emission because the Emit Start and Emit Stop values in the Birth Texture operator can adjust the overall particle timing.

Only When Selected When on, particle seeds appear in the viewports only when the Birth Texture icon is selected. When off, particle seeds always appear.

Icon Size Sets the size of the 3D icon of the operator. The size of the icon has no effect on particle size or emission.

Color Coordinated When on, the color of the 3D icon is synchronized with the color set by the Display operator in the same event as the corresponding Birth Texture operator. When off, the icon uses the standard Particle Flow operator color: blue.

Uniqueness group

The Uniqueness settings enable you to change the randomization of the particle generation where appropriate.

Seed Specifies a randomization value.

New Calculates a new seed using a randomization formula.

Delete Operator

Particle View on page 3015 > Click Delete in an event or add a Delete operator to the particle system and then select it.
Use the Delete operator to remove particles from the particle system. By default, particles live “forever,” that is, for the duration of the animation. The Delete operator lets you give them a finite life span. This is useful for eliminating particles once they’ve served their purpose in the animation.

The Delete operator is also necessary when using the Particle Age map, which, when incorporated into the Material Dynamic operator, applies different materials to particles depending on their age. Because the map works on the basis of a percentage of the particle’s life span, you need to use a Delete operator to define the particles' maximum age. For an example of usage, see Material Dynamic operator on page 3168.

**Interface**

![Delete Operator Interface](image)

The user interface appears in the Parameters panel, on the right side of the Particle View dialog.

**Remove group**

Choose whether to delete all particles, selected particles, or particles past a specific age.

The Uniqueness setting enables randomization of maximum particle age using the By Particle Age > Variation setting.

**All Particles** Deletes all particles in the event immediately.

**Selected Particles Only** Deletes particles selected at the Particle sub-object level in the event immediately. See Selection rollout on page 3039.
By Particle Age Deletes particles in the event after they've existed for a specific length of time, with an optional random variation. Choosing this makes the Life Span and Variation settings available.

**Life Span** The number of frames of life allowed to the particles. After this period, they're deleted. Default=60.

**Variation** The maximum amount by which Life Span may vary. To get each particle's actual life span, this value is multiplied by a random number between -1.0 and 1.0, and then added to Life Span. Default=10.

**Uniqueness group**

The Uniqueness setting enables randomization of maximum particle age using the By Particle Age > Variation setting.

**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.

---

**Initial State Operator**

Particle View on page 3015 > Click Initial State in an event or add an Initial State operator to the particle system and then click it.

The Initial State operator is a birth operator that uses a snapshot of another particle system or other events as a starting point for a new event. The particle system or events from which the Initial State operator gets its snapshot must be different from those of the Initial State operator itself.

The Initial State operator can make use of an icon in the scene, whose default size is 0.0. The icon is visible only if the Icon Size parameter is greater than 0.

You can also use the Initial State helper object (in the Particle Flow category) to create an Initial State icon and a corresponding Initial State event at the same time.

---

**NOTE** To avoid looping dependencies, create the Initial State operator *after* you create the particle system or events from which it obtains its initial state.

**Initial State Usage**

The Initial State operator is particularly useful when a large number of particles are generated before frame 0, and you want to use the state of particles at frame 0.

In the following example, the left side of the image shows the original wiring without the Initial State operator. Because 1,000,000 particles are born starting at frame -750, a great deal of calculation is required to calculate the particles at frame 0.

In a particle system like this, you can save time by using the Initial State operator. In this case, you could set the Viewport Quantity Multiplier in the original system to 100%, and then let the system calculate the particles at frame 0, which could take 15 minutes or more. Then you would use the Calculate Initial State function in the Initial State operator to acquire the starting state of particles at frame 0. The first time you perform this operation, it will take as long as particle calculation without the Initial State operator. The advantage is that the initial particle state at frame 0 does not have to be calculated again unless you change parameters that affect the initial state.

The original system generates particles from frame -750 to 144, but the Initial State operator captures the state at frame 0. Therefore, you would need an additional Birth operator to generate particles from frames 0 to 144. To determine how many particles to generate from frames 0 to 144, look at the Initial State operator to get the number of particles generated, and subtract
this number from the original total; the result is the number of particles should be generated with the new Birth operator. In the example shown above, the amount is $1,000,000 - 834,000 = 166,000$.

If the original particle system has Position and Speed operators, be sure to instance them in the new event with the Birth operator. There is no need to instance these operators in the event that contains the Initial State operator, as this information is already included in the referenced event. All other operators can go into a common event where the Birth and Initial State events merge.

**Procedure**

**To use Initial State:**

1. Create a particle system.
2. Go to the frame where the particle system is in the desired initial state.
3. Drag the Initial State operator to a blank area of Particle View to create a new, separate event. Alternatively, you can use the Initial State helper to create an Initial State icon and a new event at the same time.
4. Decide if you want the whole particle system, or distinctive events for the initial state, and choose the appropriate option in the Initial State From group.
5. Select the particle system or events.
6. Click Calculate Initial State. The Initial State UI makes a snapshot at the current frame, and also reports the number of the particles in the initial state and the amount of memory used.
7. At this point, you can disable the original particle system if you like.
8. Drag an Empty Flow to a blank area of Particle View to create a new global event.
9. Wire the new global event to the event that includes the Initial State operator.
Interface
**Calculate Initial State** Creates a snapshot of a particle system or selected events at the current frame. The snapshot uses only particles visible in the viewport, and is reflected by the Amount and the Memory Used statistics. This button becomes available after you specify a particle system or events.

Initial State uses the Viewport % and Render % in the PF Source's Quantity Multiplier group. If Viewport % is set to 100, all particles in the snapshot are used. If Viewport % is less than 100, then only some particles of the original initial state are used. If Viewport % is greater than 100, the operator spawns particles from the original state to meet the percentage. The Initial State operator moves the particles apart in order to separate the spawns visually, and can modify the speed of the spawns.

**Emit Time** All particles in the initial state are generated at the Emit Time.

**Auto Sync Emit Time** Sets the Emit Time value to the current frame automatically when you click Calculate Initial State button. This action synchronizes the referenced particle system's timing with the operator.

**Amount** Read-only field shows the number of particles in the initial state, which is the number of visible particles in the original particle system during the snapshot. Keep in mind that the operator grabs the viewport state of a particle system. What you have in the viewport at the snapshot frame is what you get for the initial state.

**Memory Used** Read-only field shows the amount of system memory used to keep the initial-state data when the scene is saved into a file, in kilobytes.

**Initial State From** Choose a source option for the initial state and then make settings as appropriate.

- **Particle System** Lets you derive the initial state from an entire particle system. Click the button to choose the particle system. You cannot use the particle system that contains the Initial State operator.

- **Selected Events** Lets you choose any number of events to use for the initial state. To add events to the list, click Add. You cannot add the event the Initial State operator is in. To remove an event from the list, highlight the event and click Remove.

**Initial State Data group**

The options in this group serve two purposes:

- Before you click Calculate Initial State, the settings define the types of data to get from the particle system or events for the initial state.
After you click Calculate Initial State, the settings define the data to be used during particle generation.

When you click Calculate Initial State, the operator reads the status of the check boxes in this group and acquires the indicated data from the particle system or events. If a check box is on and the data corresponding to that checkbox is available from the particle system or events, the checkbox text is black. Otherwise, it is gray. You can toggle a check box whether its text is black or gray.

If the data is available (the checkbox text is black) and you turn off the check box, the data is not used when particles are generated.

**Age** When off, all particles are born with age 0. When on, each particle retains its age as of the moment of the snapshot.

**Speed/Scale/Rotation/Spin/Shape** When on, these options derive the corresponding type of data from the snapshot.

**Mapping** Takes data from a Mapping operator. To make this option work properly, turn on Show Map in Viewport for the original Mapping operator.

**Material ID** Takes the sub-material index assignment, To make this option work properly, turn on Assign Material ID and Show in Viewport for all Material operators.

**Script Data** Takes the Script Float, Integer, Vector and Matrix data created by Script operators. This data can be used later by Script operators as well as by the Script Vector option of the Find Target test > Point setting.

**Selection** Takes particle selection data. Any selections in the Initial State operator's particle system is overwritten by the snapshot selection.

**For Quantity Multiplier > 100% group**

The options in this group have an effect on particles only if the Viewport % (or Render %) in the PF Source's Quantity Multiplier group is greater than 100%. To meet the requirement of the Quantity Multiplier, the operator has to spawn the acquired particles.

**Position Variation Max. Spread** The maximum offset of spawned particles’ placement from the original location.

**Speed Variation Magnitude** % Variation in the speed magnitude for spawned particles. The variation is defined as the maximum percentage change from the original speed. For example, if the original speed is 100 units per second
and Magnitude is 20%, then the spawned particle may have any speed from 80 to 120.

**Speed Variation Divergence** Directional variation of the speed for the spawned particles, in degrees, with a range from 0 to 180.

**Lock To Icon TM group**

The options in this group are used to link initial particle placement and speed to the operators 3D icon.

- **Position** When on, you can modify the particles’ initial placement by moving, rotating, and scaling the operator icon.
- **Speed** Causes the particles’ initial speed after the snapshot to be affected by transform animation of the operators icon.
- **Icon Size** Sets the icon size. If you create the operator in Particle View, the default size is 0, and the icon is not visible in viewport. If you create the operator as a Particle Flow helper object, then the size is set when you drag in a viewport during the icon-creation process.
- **Color Coordinated** When this option is turned on, the color of the 3D icon is synchronized with the color of the Display operator in the same event. When this option is off, the icon has a standard Particle Flow operators color (blue).

**Uniqueness Group of Controls**

The Uniqueness setting enables changing the randomization of the position and speed variation when Quantity Multiplier is greater than 100% (see the For Quantity Multiplier > 100% group).

- **Seed** Specifies a randomization value.
- **New** Calculates a new seed using a randomization formula.

**Groups**

The group actions in Particle Flow let you identify and act on subsets of particles, specified either explicitly or procedurally according to any of a number of different conditions. You can create as many groups as you like, and apply any event’s actions to any group.
**Group Operator**

**Particle View** on page 3015 > Click Group Operator in an event or add a Group Operator operator to the particle system and then click it.

The Group Operator applies an entire event to the particles specified by one or more Group Selection operators on page 3078. The Group Operator is useful when you want to apply an event to a subset of particles, but you don't want to split the particles from the current event. It affects the selected particles only while they remain in the current event.

This operator is useful when you want to apply a complex event to a subset of particles. It is also useful when you want to apply the same series of operators to different subsets of particles in different events.

The Group Operator does not wire the external event to the current event, but rather, it refers the current event to the external event.

---

Group operator is not wired to the event that it calls.
In the Particle Flow network shown above, all particles in Event 01 that pass the Age test are directed to Event 02, but only those that were selected by the Group Selection operator in Event 02 will use the operators in the Rotation event. Then all particles that flowed to Event 02 (including both the particles selected with the Group Selection operator, and those not selected) are directed to Event 03 via the Spawn test.

**Interface**

**Group Selection Operators** Lists one or more Group Selection operators that specify the particle selection(s) to which the event should be applied.

To add one or more groups, click the Add button and use the Select Group Selection Operator dialog to specify the groups to add. To remove a group from the list, highlight its name and then click Remove.

**Selection Condition** When the Group Selection Operators list (see preceding) contains multiple entries, use this option to specify how to qualify particles in overlapping groups:

- **Selected In All Groups** A particle qualifies only if it belongs to all listed groups.
- **Selected In Any Group** A particle qualifies if it belongs to any listed group.
- **Selected In Single Group** A particle qualifies only if it belongs to only one of the listed groups.
**Modify Particles By Event**  Specifies the event with operators/tests to be used on the selected particles. Click the button and then choose the event from the selection dialog.

If the referred-to event has tests, the particles are not redirected to another event. All other operators in the event are performed on the specified particles.

---

**Group Selection Operator**

[Particle View on page 3015 > Click Group Selection in an event or add a Group Selection operator to the particle system and then click it.]

The Group Selection operator extends Particle Flow's ability to select particles. Originally in Particle Flow, you select a single group of particles explicitly that remains selected throughout the entire flow. With Group Selection, however, you can specify any number of groups according to various criteria: location, particle properties, at random, and more.

You can divert selected particle groups to another event with the Split Group test on page 3084, or indicate an outside event to affect particles with the Group Operator on page 3076. The Group Selection icon can be scaled and transformed to change the particle selection dynamically over the course of the particle flow.

You can instance the Group Selection operator in different events to define the same selection subset. If the particles converge into another event, the selection subsets are united, and a Group Operator works with the combined selection subset.

The Group Selection operator doesn't change particle properties. It adds a data channel that indicates the selection status of a particle corresponding to the selection operator. To modify particles based on their selection status, use a Group Operator or Split Group test.

**Group Selection icon**

Adding a Group Selection operator to a Particle Flow system creates a 3D icon, or helper, that you can select in viewports. The icon is placed at the world origin (0,0,0). When you select this icon, the Parameters rollout opens on the Modify panel that provides the controls described in the following section. The position of the icon is used by Particle Flow when you choose the Inside Icon Volume on page 3081 option.
Group Selection icon
Interface
Selection Update Choose how to calculate the selection status:

- **Once** The operator determines the selection status only once, at the time a particle enters the event.

- **Continuous** Calculates the selection status anew at every frame.

Depending on other options, the Group Selection operator may detect the selection status change in between frames, on sub-frame sampling basis.

Reverse Selection Inverts the particle selection.

Selection Condition Determines the method the operator uses to select particles. The choices are as follows:

- **Entire Particle Stream** Selects all particles in the event. Use this option if particle selections are merging in the current event, and in a later event you plan to separate particles with an instanced Group Selection operator.

- **By Snapshot** Selects particles based on those currently selected in the PF Source sub-object level, or all particles present in the event at the current frame. The number of selected particles appears next to By Snapshot. To select the particles, choose one of the following sources from the dropdown menu and then click Generate Snapshot:

  - **Selected in PF Source** Selects the particles currently selected at the Particle sub-object level of the PF Source. Before using this option, make sure both of the PF Source object’s Quantity Multiplier settings (Viewport % and Render %) are the same.

  - **All in Current Event** Selects all particles in the event at the current frame.

- **Generate Snapshot** Click to select the particles as specified by the choice in the drop-down list. The number of selected particles appears next to By Snapshot.

  Once you have generated a snapshot, you can change the frame or sub-object particle selection without affecting the selection in this Group Selection operator. Keep in mind that the selection is based on the particle IDs. Therefore, if the number of particles in the viewport and the rendering are different, the overall effect can differ drastically. To use this type of selection effectively, synchronize the percentage of particles in the viewport and renderer.

- **Inside Icon Volume** Displays the Group Selection icon in the viewports, and selects all particles within the icon. If Selection Update (see preceding) is set to Once, only particles that are inside the icon at the start of the
event are selected. If Selection Update is set to Continuous, particles are members of the group only when present inside the icon volume; thus, the selection can change throughout the animation.

- **Icon Type**  Sets the overall shape of the icon: Box, Cylinder, or Sphere. The initial size of the icon is set by the Icon Size parameter, near the bottom of the rollout. To change the icon size and shape, change this parameter or use either uniform and non-uniform scaling. You can also move, rotate, and animate the icon to change the selection area.

- **Subframe Sampling**  When off, the motion of the icon or the reference object is considered to be linear between frames. If the icon or the object has fast, complex motion, turn on this option for greater precision in the calculation of the icon/object location.

  **NOTE**  This setting also applies to the Inside Object option (see following).

- **Inside Object**  Lets you designate an arbitrary object as the volume for selecting particles for the group. After choosing this option, click the “None” button and then select a reference object to use as a selection bounding area. All particles inside the reference object are selected. If the object doesn’t define a closed space, the resulting selection might not be consistent.

  **NOTE**  The Subframe Sampling option (see preceding) applies to Inside Object as well as Inside Icon Volume.

- **Animated Shape**  If the reference object is animated in a way that changes its shape or volume, turn on this option.

- **Select By Particle Property**  Uses particle properties to define the selection set. This choice appears in parentheses in the event, after the operator name. From the Property list, choose one of the following:
  - **Age**  Uses particle age to define the subset. All particles with ages in the From/To range become selected. Use the Variation parameter to vary the selection status.
  - **Birth ID**  Uses a unique particle ID is used to define the subset. All particles with IDs in the From/To range become selected. Use the Variation parameter to vary the selection status.
NOTE. The Birth ID property is not scalable in reference to the Quantity Multiplier parameters of the PF Source object.

- **Direction** Uses the particle speed vector and the icon direction vector to determine the selection subset. Particles are selected if their speed vectors are close in direction to the icon vector. When this option is selected, the icon shows an arrow with a surrounding cone to show the effects of the Divergence parameter. All particles with a speed vector within the cone become selected. The Divergence and Variation parameters are expressed in degrees.

- **Scale** Uses particle scale value to define the selection subset. Since the scale value is a vector, and From and To values are scalar, the maximum value of the scale components is used to define the range inclusion.

- **Script Float** Uses a particle float data channel to define the selection subset. The Float data channel is usually controlled by a Script operator.

- **Size** Uses particle size to define the selection subset. Particle size is controlled by Shape and Scale operator parameters. As with the Scale option, the operator uses the maximum value of the size vectors components to define the range inclusion.

- **Speed** Uses particle speed to define the selection subset. The From, To, and Variation parameters are defined in units per second.

- **Uniform Index** A scalable particle ID parameter. If the Quantity Multiplier is set to 100%, then the Uniform Index is the same as the Birth ID index. If the Uniform Index parameter is used, then the area with selected particles is consistent regardless of the Quantity Multiplier parameters.

- **Randomly Selected** Selects particles at random. The Chance % parameter defines how many particles will be selected. 100% means that all particles are selected; 50% means that roughly half of the particles are selected.

- **Combine Groups** Selects particles using a combination of the selection subsets defined by other Group Selection operators. Buttons A and B define the other Group Selection operators. The available combinations are:
  - **A and B** A particle is selected if it is selected by both operators A and B.
- **A or B** A particle is selected if it is selected by operator A or operator B.

- **A or B not both** A particle is selected if it is selected by operator A but not by operator B, or vice-versa.

- **A and not B** A particle is selected if it is selected by operator A but not by operator B.

**Icon Size** Sets the size of the 3D icon. Available only for the selection conditions Inside Icon Volume and Select By Particle Property: Direction.

**Logo Size** Sets the logo size, which has no effect on particles.

**Color Coordinated** When on, the color of the 3D icon is synchronized with the Display operator in the current event. When off, the icon has a standard Particle Flow operator color (blue).

**Uniqueness Group**

These controls set randomization for the Randomly Selected and Select By Particle Property selection conditions.

- **Seed** Specifies a randomization value.

- **New** Calculates a new seed using a randomization formula.

### Split Group Test

**Particle View** on page 3015 > Click Split Group in an event or add a Split Group test to the particle system and then click it.

The Split Group test splits the particle stream based on the particles’ selection status, as defined by a **Group Selection operator** on page 3078.
Interface

**Group Selection Operators**  Lists the Group Selection operators holding the particle selection to split. If a single Group Selection operator exists in the event, that operator will be added to the list automatically.

**Use Proxy Particles**  When on, you can split the particles based on their selection status in a particle system other than the one that contains the Split Group test.

**Proxy Particle System**  To specify a proxy particle system, click this button and then select the proxy’s icon. If the current event contains particles that meet the “Test True if Particle” condition (see following) as specified by a Group Selection operator on page 3078 in the proxy system, Particle Flow will send those particles to the next event.

**Proxy Index --> Particle Index**

- **Multiplier**  Applies a multiplier for index values of particles in the proxy system. So, for example, if Multiplier is set to 2.0 and the particles that test
true in the proxy system have index values 4, 5, and 8, then the particles that actually get split off will be those with index values 8, 10, and 16.

- **Index Offset**  Adds the specified value to index values of particles in the proxy system. So, for example, if Index Offset is set to 5 and the particles that test true in the proxy system have index values 4, 5, and 8, then the particles that actually get split off will be those with index values 9, 10, and 13.

**Test True if Particle** Lets you specify how to determine whether particles should pass the test and move on to the next event. The choices are:

- **Selected In All Groups**  Only particles that belong to all listed groups can pass the test.
- **Selected In Any Group**  Particles that belong to any listed group can pass the test.
- **Selected In Single Group**  Only particles that belong to only one listed group can pass the test.
- **Not Selected In Any Group**  Only particles that belong to none of the listed groups can pass the test.

### Transforms

Transform operators control particle position, rotation, scale, and angular velocity.

**See also:**

- **Lock/Bond Test** on page 3264
- **Placement Paint Operator** on page 3224

### Position Icon Operator

**Particle View** on page 3015 > Click Position in an event or add a Position operator to the particle system and then select it.

By default, particles are born, or *emitted*, from the Particle Flow icon. This topic uses the term *emitter* to refer to this icon. Use the Position Icon operator to control the initial placement of particles on the emitter. You can set the
emitter to emit particles from its surface, volume, edges, vertices, or center. And, if you animate the emitter, you can cause its motion to be imparted to the particles it emits.

Alternatively, you can use Position Object on page 3089 to emit particles from any other object.

**Interface**

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Lock On Emitter** When on, causes all particles to remain at their initial positions on the emitter. In effect, they’re “glued” to the emitter. When off, each particle's birth position is determined by the emitter's current location. Default=off.

**Inherit Emitter Movement** When on, Particle Flow sets each particle's rate and direction of motion to that of the emitter at the time of birth. When off, the emitter movement doesn’t affect that of the particles. Available only when Lock On Emitter is off. Default=off.

**NOTE** If a Speed operator exists later in the event, it overrides any motion imparted by Inherit Emitter Movement.
Multiplier Determines, as a percentage, the extent to which particles inherit the emitter's motion. Available only when Inherit Emitter Movement is on. Default=100.

To have the particles move half as fast as the emitter, set Multiplier to 50. To have them move the same speed, use the default setting of 100. To make the particles move twice as fast as the emitter, set Multiplier to 200.

Location group

The Location drop-down list lets you specify where on the emitter the particles appear. You can create a variety of emission behaviors by varying the icon type on page 3037, Location setting, and direction of emission. Default=Volume.

- **Pivot** Emits particles from the center of the icon.
- **Vertices** For the Box and Rectangle icon types, emits particles from the corners of the icon. For the Sphere icon type, emits particles from the six intersections of the three circles that define the sphere. For the Circle icon type, emits particles from the center.
- **Edges** Emits particles from random points along the edges of the icon.
- **Surface** Emits particles from random points on the surface of the icon.
- **Volume** Emits particles from random points within the volume of the icon.

Distinct Points Only Limits emission to a specific number of points (see Total, below) on the specified Location type.

Emission points are still randomized; change the Uniqueness setting to alter these.

**Total** Sets the number of emission points. Available only when Distinct Points Only is on. Default=10.

Subframe Sampling When on, the operator acquires animation of the emitter icon on a tick basis (every 1/4800th of a second) rather than a frame basis. This provides greater precision in allowing the particle positions to follow animation of the emitter icon. Default=off.

Uniqueness group

The Uniqueness setting lets you alter the randomization of emission points.
Seed Specifies a randomization value.

New Calculates a new seed using a randomization formula.

**Position Object Operator**

*Particle View* on page 3015 > Click Position Object in an event or add a Position Object operator to the particle system and then select it.

By default, particles are born, or *emitted*, from the Particle Flow icon. The Position Object operator lets you emit particles from any other object or objects in the scene instead. This topic uses the term *emitter* to refer to an object or objects used to emit particles with this operator. For example, use it to create a meteor’s fiery trail.

Use the Position Object settings to control the initial placement of particles on the emitter. You can set the emitter to emit particles from its surface, volume, edges, vertices, or pivot, or from a sub-object selection. You can also control particle emission with a material applied to the object.

Alternatively, you can use the Position Icon operator on page 3086 to emit particles from the Particle Flow icon.

**NOTE** Typically, you would use Position Object in a birth event, so the particles appear initially at the emitter object(s). If you use it in a non-birth event, the particles jump to the designated emitter(s) upon entering the event. This could be useful for a teleportation effect.

**TIP** The default speed operator, Speed on page 3108, typically uses the Particle Flow icon to control the direction of the particle flow, so if the emitter object(s) and the icon aren’t coincident and aligned, you might get unexpected results. For better control over the direction of particle movement when using Position Object, use the Speed By Surface operator on page 3122 instead and designate as Surface Geometry the same object(s) as with Position Object.

**Procedures**

To use Position Object:

1. Create a Particle Flow system and one or more mesh objects to use as emitters. Animate the emitter objects and set particle system parameters as necessary.
2 In Particle View, add a Position Object operator to the birth event, replacing the Position Icon operator if one exists. Click the operator to display its parameters.

3 In the Emitter Objects group, click Add, and then select an object to serve as the emitter. Alternatively, click By List and then use the Select Emitter Objects dialog to designate one or more objects as emitters.

4 Use the Location drop-down list to choose where the particles should appear on the emitter: surface, vertices, and so forth.

5 Set other options as necessary. For example, if you want the particles to use the same motion as the emitter at the time of emission, turn on Inherit Emitter Movement. Or if you’re using an emitter object whose shape is animated, turn on Animated Shape.
The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Lock On Emitter** When on, causes all particles to remain at their initial positions on the emitter. In effect, they’re “glued” to the emitter. When off, each particle’s birth position is determined by the emitter’s current location. Default=off.

**Inherit Emitter Movement** When on, Particle Flow sets each particle's speed and direction of motion to those of the emitter at the time of birth. When off, the emitter movement doesn't affect that of the particles. Available only when Lock On Emitter is off. Default=off.

**NOTE** If a Speed operator exists later in the event, it overrides any motion imparted by Inherit Emitter Movement.

**Multiplier** Determines, as a percentage, the extent to which particles inherit the emitter's motion. Available only when Inherit Emitter Movement is on. Default=100.

To have the particles move half as fast as the emitter, set Multiplier to 50. To have them move the same speed, use the default setting of 100. To make the particles move twice as fast as the emitter, set Multiplier to 200.

**Variation** Determines, as a percentage, the extent to which inherited emitter motion can vary per particle. To determine the final multiplier for each particle, the Variation value is multiplied by a random number between -1.0 and 1.0, and then added to the Multiplier value. Default=0.

**Emitter Objects group**

Use these controls to assign objects to be used as particle emitters. The list in this group shows the objects, or reference geometry, that the operator uses as emitters.

If you don’t assign any objects, Particle Flow uses the world origin (0,0,0) as the emitter source.

With more than one emitter object, the division of particles among the objects depends on which option you choose for Location. If you set Location to Pivot, then each object has one emission point and each object emits the same number of particles (total number of particles/number of objects). But if you set Location to any other option, each object emits a number of particles proportionate to the number of available emission points per object. For instance, if you set Location to Volume, then a larger object will emit more particles than a smaller one. Similarly, with Location set to Vertices, an object with 100 vertices will emit twice as many particles as an object with 50.
If you delete from the scene an object designated as an emitter, its entry in the list is replaced with “<deleted>”.

Use the Add and Remove buttons to edit this list.

**Add** Adds an object to the list. Click Add, and then click an object in the viewport.

**By List** Adds multiple objects to the list. Click By List to open the Select Emitter Objects dialog. This works just like Select From Scene on page 206: Highlight the objects to use as emitters, and then click the Select button.

**Remove** Removes an object from the list. Highlight the object in the list, and then click Remove.

**Animated Shape** Turn on to allow particles to emit from the surface of an object whose form is animated by morphing or with modifiers.

**Subframe Sampling** When on, the operator acquires animation of the emitter shape on a tick basis (every 1/4800th of a second) rather than a frame basis. This provides greater precision in allowing the particle positions to follow animation of the emitter object’s form.

### Location group

The Location drop-down list lets you specify where on each emitter the particles appear. This choice applies to all emitter objects. Default=Surface.

The Selected Vertices/Edges/Faces options in this list let you emit particles from a specific part of the emitter object by using an existing sub-object selection. To create this selection, first convert the object to an editable mesh or poly, or apply a Mesh Select or Poly Select modifier (or equivalent), select the sub-objects that are to emit particles, and then choose the corresponding Location option. If Particle Flow doesn't find a sub-object selection, it uses all sub-objects of the indicated type.

**Pivot** Emits particles from the original position of the emitter object's pivot. Moving the pivot does not affect this option.

**Vertices** Emits particles from randomly selected vertices of the emitter objects.

**Edges** Emits particles from random points along the edge sub-objects of the emitter objects.

**Surface** Emits particles from random points on the surface of the icon.

**Volume** Emits particles from random points within the volume of the icon.

**Selected Vertices** Emits particles from the current vertex sub-object selection.
**Selected Edges** Emits particles from the current edge sub-object selection.

**Selected Faces** Emits particles from the current face or polygon sub-object selection.

---

You can modify the Location choice with any combination of the following:

**Surface Offset** Lets you specify a range of distances from the object surface for particle placement.

Surface Offset is unavailable when Location is set to Pivot or Volume. Use the Min and Max parameters to set the range.

**NOTE** Negative values offset the particles below the surface.

**Min/Max** When Surface Offset is on, these let you specify the range of offset distances from the object surface. The Min value cannot exceed the Max value, and vice-versa. If you try to raise Min above Max, or lower Max below Min, both values change equally.

**Density by Material** Varies emission over the emitter surface based on properties of the material applied to the emitter. For example, if the object is assigned a black-and-white checkered diffuse map and you choose the Grayscale option, particles are emitted only from the white checks.

**IMPORTANT** For material-influenced emission to appear properly in the viewports, two conditions are required:

- At least one viewport must be set to a shaded display mode.
- The material or map must have Show Map In Viewport turned on in the Material Editor.

The options are as follows:

- **Grayscale** Particle Flow internally converts the material-based coloring (diffuse) to grayscale, and then emits more particles in lighter areas and fewer in darker areas.
The box emitter is mapped with a gradient. With Position Object set to Density By Material > Grayscale, the particles appear with greater frequency in the lighter areas of the box.

- **Opacity**  
  Particles are more likely to appear on opaque areas than on transparent areas.

- **Grayscale & Opacity**  
  Combines the two: More particles appear on light, opaque areas than on dark, transparent areas.

- **Red/Green/Blue**  
  Considers only the specified color channel. The higher its value at any given pixel, the more likely particles are to appear there.

**Use Sub-Material**  
When on, uses a sub-material from the Multi/Sub-Object material assigned to the emitter to define density values. This option allows usage of “invisible” materials for particle placement. If the emitter uses a Multi/Sub-Object material but its geometry doesn't use the ID
that corresponds to one of the sub-materials, the sub-material doesn’t appear. However, the operator can use it to calculate the density of particle placement. Particle Flow assumes the material to be applied to the entire object surface.

**Mtl ID** Specifies the material ID of the sub-material to be used for particle emission.

**Separation** When on, Particle Flow attempts to keep the particles apart by the amount specified in Distance. The likelihood of successfully separating particles depends on the number of particles, the specified distance, and the Attempts Max value.

**Distance** Specifies the distance, in system units, by which Particle Flow should try to keep the particles separate. Default=1.0.

**Distinct Points Only** Limits emission to a specific number of points (see Total, below) on the specified Location type. Emission points are still randomized; change the Uniqueness setting to alter these.

**Total** Sets the number of emission points. Available only when Distinct Points Only is on. Default=10.

**If Location Is Invalid group**

**Delete Particles** When on, if Particle Flow cannot place a particle according to the current option, it deletes the particle. When off, particle placement is undefined; that is, it depends on other variables. Default=off.

If the number of particles is more important than the position on the object, leave this off. However, if exact placement is of higher priority than the number of particles, turn Delete Particles on.

**Uniqueness group**

The Uniqueness setting enables randomization of placement on the emitters.

**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.

**Attempts Max** When using the Separation option, this specifies the maximum number of times Particle Flow will try to set particle positions that maintain the requested distance. If unsuccessful within this number of attempts, particles might be closer together than the requested distance. Also affects placement with Density By Material using either of the Grayscale options.
Rotation Operator

Particle View on page 3015 > Click a Rotation operator in an event or add a Rotation operator to the particle system and then select it.

The Rotation operator lets you set and animate particle orientation during an event, with optional random variation. You can apply orientation in any of five different matrices: two random and three explicit. For some options you can set a degree of random variation or divergence from the specified orientation.

To cause particles to spin, use the Spin operator on page 3099.

Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.
**Orientation Matrix group**

**Orientation drop-down list** The Orientation Matrix drop-down list includes options that give particles random orientations, or let you specify orientation in any of three different ways. Default=Random 3D.

- **Random 3D**  
  Gives each particle an arbitrary, random 3D orientation.

- **Random Horizontal**  
  Gives each particle an arbitrary, random 3D orientation about the Z axis only. Rotation about the X and Y axes doesn't change (unless Divergence is used), so the particles remain vertical.

- **World Space**  
  Orientation is specified in the world coordinate space. Use the X/Y/Z settings to specify the orientation for all particles.

- **Speed Space**  
  The coordinate space for particle orientation is determined by the particles' direction upon entering the event. By default, using the Speed operator on page 3108 > Along Icon Arrow option, particles are aimed straight down when born. Use the X/Y/Z settings to specify the orientation for all particles.

- **Speed Space Follow**  
  The coordinate space for particle orientation is determined continually while the particles are in the event. Thus, by default, particles constantly reorient themselves to "aim" in the direction they're traveling. For example, if you add a Find Target test on page 3247 to the end of the default Event 01, move the target sideways, and set Rotation to Speed Space Follow, the particles start out pointing straight down, as oriented by the Speed operator, and then gradually reorient themselves to point in the direction they're traveling: toward the target. Use the X/Y/Z settings to specify the orientation for all particles. The Divergence setting is unavailable when using Speed Space Follow.

- **X/Y/Z**  
  Set the basic orientation about the particles' local axes. Unavailable with the Random 3D and Random Horizontal options.

- **Divergence**  
  Defines the range of variation (in degrees) for particle orientation. The actual deviation is calculated at random within this range. Unavailable with the Random 3D or Speed Space Follow option. Default=0.0.

- **Restrict Divergence To Axis**  
  When on, lets you use the Divergence Axis controls to set the axis to which divergence will be applied. When off, Particle Flow uses a random axis for each particle. Unavailable with the Random 3D or Speed Space Follow option. Default=off.
Divergence Axis Use the X/Y/Z settings to set the axis to which divergence will be applied. Default=1,0,0. Range=-1.0 to 1.0.

To specify one of the world axes, set the corresponding parameter to any nonzero value, and the others to 0. A negative value flips the axis. The numeric values come into play when you want to use an axis that’s not aligned with the X, Y, or Z axis. In that case, you specify multiple nonzero values whose effect is relative to one another. For example, if you want the axis to be oriented halfway between the positive X and Y axes, you would set X and Y to the same positive amount. The actual value doesn’t matter. Similarly, to set the axis to 30 degrees (1/3 of the angle) from the X axis to the Y axis, you’d set the Y value to twice that of the X value. For example, X=0.2 and Y=0.4, or X=0.5 and Y=1.0.

Uniqueness group

The Uniqueness setting affects the randomization of orientation with the Random 3D and Random Horizontal options, and also Divergence.

Seed Specifies a randomization value.

New Calculates a new seed using a randomization formula.

Spin Operator

Particle View on page 3015 > Click a Spin operator in an event or add a Spin operator to the particle system and then select it.

The Spin operator gives an angular velocity to particles in an event, with optional random variation. Spin is applied once per event per particle, except when using the Speed Space Follow option; however, the settings can be animated.

To simply specify particle orientation, use the Rotation operator on page 3097.
Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Spin Rate** The rate of revolution in degrees per second.

**Variation** The maximum amount, in degrees per second, by which the spin rate can vary. The actual variation is calculated once, at random, for each particle.

**Spin Axis group**

**Spin Axis drop-down list** The Spin Axis setting includes options that let you apply the spin on a random or specific axis, with optional random variation of the spin axis. Default=Random 3D.

- **Random 3D** Spins each particle about an arbitrary, random 3D axis.
- **World Space** The spin axis is specified in the world coordinate space. Use the X/Y/Z settings to specify the spin axis.
- **Particle Space** The spin axis is specified in the local coordinate space of each particle. Use the X/Y/Z settings to specify the spin axis.
- **Speed Space** The coordinate space for particle orientation is determined by the particles' direction upon entering the event.
The X axis is aligned with the particle direction, while the Z axis is perpendicular to the X axis and is pointed upward with respect to world space as much as possible.

Use the X/Y/Z settings to specify the orientation for all particles.

- **Speed Space Follow**  The coordinate space for particle orientation is determined by the particles' direction throughout the event. Use this option to allow particles that change direction during the event to keep the spin axis aligned with their direction.
  The X axis is aligned with the particle direction, while the Z axis is perpendicular to the X axis and is pointed upward with respect to world space as much as possible.
  Use the X/Y/Z settings to specify the orientation for all particles.

**X/Y/Z** Use these to set the spin axis. Unavailable for the Random 3D option. Default=0,0,1. Range=–1.0 to 1.0.

To specify a single axis, set the corresponding parameter to any nonzero value, and the others to 0. A negative value flips the axis, and reverses the direction of rotation. The numeric values come into play when you give more than one axis a nonzero value, in which case their effect is relative to one another. For example, if you want the spin axis to be oriented halfway between the positive X and Y axes, you would set X and Y to the same positive amount. The actual value doesn't matter. Similarly, to set the spin axis to 30 degrees (1/3 of the angle) from the X axis to the Y axis, you'd set the Y value to twice that of the X value. For example, X=0.2 and Y=0.4, or X=0.5 and Y=1.0.

- **Divergence** Defines the range of variation (in degrees) for spin-axis orientation. The actual deviation is calculated at random within this range. Unavailable for the Random 3D option. Default=0. Range=0 to 180.

**Uniqueness group**

The Uniqueness setting affects the randomization of spin rate variation, spin axis with the Random 3D option, and Divergence with the other options.

- **Seed** Specifies a randomization value.
- **New** Calculates a new seed using a randomization formula.
Scale Operator

Particle View on page 3015 > Click a Scale operator in an event or add a Scale operator to the particle system and then select it.

The Scale operator lets you set and animate particle size during an event, with optional random variation. Options for how scaling and animation are applied give this operator a great deal of flexibility.

Procedures

Example: To animate particle scale:

This procedure gives an overview of animating particles to grow for 30 frames, remain at full size for the next 30 frames, and then shrink for 30 frames. It also gives an option for having the particles pulsate in size during the middle period. To follow this procedure, you should be familiar with the basic usage of Particle Flow and Track View.

1. Set up a default Particle Flow system. Set the Shape operator to Sphere, and set the Display operator to Geometry.

2. Add a Send Out test to Event 01.

3. Add a new Scale operator to the event display, creating a new event. Set the new event's Display operator to Geometry, and make sure it's a different color than the one in Event 01.

4. Wire the Send Out test in Event 01 to Event 02.

5. In the Event 02 > Scale operator, set Type to Absolute, and animate the Scale Factor values from 10 to 100 over frames 0 to 30. In the Animation Offset Keying group, set Sync By to Event Duration.

6. Add an Age Test to Event 02. Set it to Event Age, set Test Value to 30, and Variation to 0.

   In this event, particles grow from 10 percent of their original size to full size over the first 30 frames of their existence, which is the same as their duration in the event. At that point, they'll be eligible to move to the next event.

7. Use a new Scale operator to create a new event, Event 03. Set the new event's Display operator to Geometry, and make sure it's a different color than the others.

8. Wire the Age Test in Event 02 to Event 03.
9 In the Event 03 > Scale operator, Set Type to Absolute, and in the Animation Offset Keying group, set Sync By to Event Duration.

10 Copy and paste the Age Test as an instance from Event 02 to Event 03. Particles in Event 03 remain at full scale for 30 frames, and then move on to the next event.

11 Use a new Scale operator to create a new event: Event 04. Set the new event's Display operator to Geometry, and make sure it's a different color than the others.

12 Wire the Age Test in Event 03 to Event 04.

13 In the Event 04 > Scale operator, set Type to Absolute, and animate the Scale Factor values from 100 to 10 over frames 0 to 30. In the Animation Offset Keying group, set Sync By to Event Duration.

14 Copy and paste the Age Test as an instance from Event 03 to Event 04. In this event, particles shrink from full size to 10 percent of their original size over 30 frames.

15 Play the animation.
   Next, you'll use a Noise controller to cause the particles in Event 03 to pulsate in size.

16 Add a second Scale operator to Event 03, below the existing Scale operator. Set it to Relative Successive, and set Sync By to Event Duration. The name of this operator should be Scale 04.

17 In Particle view, right-click the Scale Factor X % parameter field on the Scale 04 rollout, and choose Show In Track View. The Curve Editor opens with the X Scale Factor parameter highlighted.

18 Right-click the X Scale Factor item and choose Assign Controller from the menu.

19 In the Assign Float Controller dialog, double-click Noise Float. The Noise Controller dialog opens.

20 Set Strength to 200, and to the right of Strength, turn on the >0 check box.

21 Copy this controller, and then paste it as instances to Y Scale Factor and Z Scale Factor.
Although the Scale operator defaults to constraining all scale factors to the same value, thus scaling particles uniformly, changing controllers in Track View works on a per-parameter basis.

22 Play the animation.
This time, the particles grow in size for 30 frames, then pulsate in size for the next 30 frames, and then shrink from the size at the end of Event 03 to 10 percent of that over the next 30 frames.

Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.
Type

The scaling Type setting includes options that let you scale particles once in an event or repeatedly, and apply scaling as an absolute or relative factor. Default=Overwrite Once.

**Overwrite Once** Sets the scale *one time only* as an absolute percentage value, disregarding any previous scaling.

To produce a range of different birth sizes, and specify the scaling explicitly, use Overwrite Once with animated scale factors.

**Inherit Once** Sets the scale *one time only* as a percentage of existing scaling. The existing scaling should be specified with a previous Scale operator, the Scale setting in the Shape operator on page 3137, or a Shape Instance operator on page 3142.

For instance, if you previously used Scale with Overwrite Once to scale particles' birth size within a range, and then want to scale them to half their previous size, use Inherit Once and set Scale Factor to 50%.

**Absolute** Sets the scale *continuously*, while the particle is in the event, as an absolute percentage value, disregarding any previous scaling.

Use Absolute if you want to animate the particles' scale explicitly.

**Relative First** Sets the scale *continuously*, while the particle is in the event, as a percentage of existing scaling. The existing scaling should be specified with a previous Scale operator, or a Shape Instance.

Use Relative First when you want to scale the particles relative to the scaling at which they enter the event, and optionally animate the scaling, or before a Relative Successive operator.

**Relative Successive** Scales the particles *continuously*, relative to scaling set earlier in the same event.

**NOTE** Always precede Relative Successive *in the same event* with an operator that modifies the scale channel all the time, such as a Scale operator set to Absolute or Relative First, or a Shape Instance operator with the Scale check box turned on (it's on by default).

Scale Factor group

The operator performs scaling on each particle's local axes. It can scale particles on a single axis or on any combination of axes.
X/Y/Z Sets the scaling as a percentage of the particle's current size. To scale uniformly, turn on Constrain Proportions, and then change any axis setting. Range=0 to 10000000. Default=100.

Constrain Proportions When on, retains the current ratio of scale factor settings, so that changing any axis setting changes all of them. Default=on.

Scale Variation group

X/Y/Z Sets the scaling variation as a percentage of the particle's previous size. To scale uniformly, turn on Constrain Proportions, and then change any axis setting. Range=0 to 100. Default=0.

Constrain Proportions When on, retains the current ratio of scale variation settings, so that changing any axis setting changes all of them. Default=on.

Bias Lets you choose how to distribute the scaling variation within the specified range or ranges. Default=None.

- **None**  No bias; scaling variation is distributed equally through the range.

- **Centered**  Scaling variation is concentrated near the middle of the range; that is, at 0.0%.
  With this choice, scaling will occur more frequently with low percentage values than with ones near the values you set. In other words, most scaling variants will be close to the specified scaling value.

- **Towards Minimum**  Scaling variation is concentrated near the lower end of the range (base-variation); that is, most scaling variants will be smaller than the scaling value.

- **Towards Maximum**  Scaling variation is concentrated near the upper end of the range (base+variation); that is, most scaling variants will be larger than the scaling value.

Animation Offset Keying group

If you animate the Scale Factor or the Scale Variation settings or both, Particle Flow can begin applying this animation to all particles as of the start frame of the animation or the first frame of the current event, or to each particle based on its age. For instance, if you set Sync By to Particle Age, and set Scale Factor keys at frames 0 and 30, then Particle Flow will animate the scaling factor for each particle between its birth and its 30th frame of existence, if the particle is in the scaling event or a prior event. Following this example, any particle that has already reached its 30th frame of existence before reaching the event will enter the event fully scaled. That is, Particle Flow will apply the
Scale Factor value that you set at frame 30 to each particle aged 30 or above at the moment it enters the scaling event. However, any particle that leaves the scaling event before reaching age 30 will stop scaling as of its exit frame. In other words, with respect to particles in other events, animation of action parameters is retroactive, but not post-active.

Alternatively, if you set Sync By to Absolute Time, the scaling is animated from frame 0 to frame 30 of the animation, regardless of particle age, and even if no particles are in the event at that time. Or, if you set Sync By to Event Duration, the scaling animation is applied to each particle as of the time that it enters the event.

NOTE With the Overwrite Once and Inherit Once scaling types, scaling always occurs with respect to the entire animation; that is, in Absolute Time mode. Thus, when either of those scaling types is in effect, the Sync By setting is unavailable. Also, if you animate Scale Factor or Scale Variation when using Overwrite Once or Inherit Once, it doesn't cause scaling animation in the particles, but rather applies one-time scaling to particles born during that period. For instance, if you animate Scale Factor on all three axes from 100% to 200% over frames 0 to 30, particles born at frame 0 are normal size, particles born at frame 15 are one-and-one-half times normal size, and particles born at frame 30 (and thereafter) are twice normal size.

Sync By Choose the time frame for applying animated parameters:

- **Absolute Time** Any keys set for parameters are applied at the actual frames for which they're set.

- **Particle Age** Any keys set for parameters are applied at the corresponding frames of each particle's existence.

- **Event Duration** Any keys set for parameters are applied to each particle starting when it first enters the event.

Uniqueness group

The Uniqueness setting affects the randomization of scale variation.

Seed Specifies a randomization value.

New Calculates a new seed using a randomization formula.
**Speed**

Speed operators control particle speed, direction, and some other aspects of particle movement.

**Speed Operator**

[Particle View on page 3015 > Click Speed in an event or add a Speed operator to the particle system and then select it.]

This is the default Speed operator, which appears in the first event when you create a new Particle Flow icon. It provides basic controls over particle speed and direction.

Directional controls provided by the Speed operator are based on the position and orientation of the Particle Flow icon. For best results when using other objects as emitters, use the Speed By Surface Operator on page 3122 operator instead.

**See also:**
- Speed By Icon Operator on page 3112
- Keep Apart Operator on page 3131

**Procedures**

**Example: To change particles' speed:**

The Speed operator works on an instantaneous basis: It sets each particle's speed once only, when it enters the event. Even if you animate the Speed value, each particle moves at a constant rate of speed, defined by the value at the time it enters the event. This procedure demonstrates a trick you can use to change particle speed with an animated Speed value, thanks to Particle Flow's looping ability.

1. Create a default particle system, and position it at the top of the Perspective viewport.

2. Play the animation.
   - The particles fall downward at the default rate: 300 units per second.

3. Add a Send Out test at the bottom of Event 01.
4 Add a Speed operator to an empty area of the event display. This creates a new event.

5 Turn on Auto Key, and move the time slider to frame 30.

6 In Particle View, click the new Speed 02 operator, and then in the Particle View parameters panel, set Speed to 0. This animates the Speed value from 300 at frame 0 to 0 at frame 30.

7 Turn off Auto Key.

8 Wire the Send Out test in Event 01 to Event 02.

9 Play the animation. The particles born later move slower, but all still move at a constant rate of speed.

10 Add a Send Out test at the end of Event 02.

11 Create a new event using an Age Test. Click the Age Test to display its parameters, and then set the following:
   ■ Event Age
   ■ Test Value=1
   ■ Variation=0

12 Wire the Send Out test in Event 02 to Event 03.

13 Wire the Age Test in Event 03 to Event 02.

14 Play the animation. All the particles slow down simultaneously and eventually come to a stop.

   Here's how it works: As each particle enters Event 02, its speed is set to the current Speed value in the Speed operator. Particle Flow then sends the particle immediately to Event 03, where it sits for one frame. Event 03 then returns the particle to Event 02, whose Speed value is now lower. Particle Flow perceives the returned particle as newly entering the event, so it changes its speed to the current Speed value. Thus, the particles continually return to Event 02 one frame later than before, and are assigned a progressively lower speed.
If you wanted the particles to do something else after they stop, you could add a Speed Test to Event 02, above the Send Out test, set Test True If Particle Value to Is Less Than Test Value, and set Test Value to a very low value, such as 0.01. Then wire the Speed Test to a different event.

Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Speed** The particle speed in system units per second. Default=300.
A positive Speed value moves the particles in the direction determined by the Direction setting; a negative Speed value moves the particles in the opposite direction.

**NOTE** Speed sets each particle’s speed once only: when the particle enters the event (or is born, in the case of a birth event). If you animate the Speed value, particle speed does not vary: rather, each particle is given a constant speed equal to the current Speed value when it enters the event.

**Variation** The amount by which particle speed can vary, in system units per second. Default=0.0.
To obtain each particle’s speed, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then adds the result to the Speed value. For example, if Speed=300 and Variation=100, then each particle’s speed would be between 200 and 400.
Direction group

The Direction drop-down list lets you specify which way the particles go after they're born. Default=Along Icon Arrow. In most cases, the actual direction also depends on the icon orientation. The primary exception is when Position > Location is set to Pivot.

Particle movement is always in a straight line unless influenced by other factors.

Along Icon Arrow Particles move parallel to the icon arrow. Rotate the icon to change the direction.

Icon Center Out Each particle moves along an imaginary line drawn between the particle's location and the icon center.

With the flat icon types (Rectangle and Circle), this results in all the particles moving in one plane, unless you increase Divergence above 0.0. With icons that have height (Box and Sphere), the particles move outward in three dimensions.

Particles at the center, as is the case when the Position operator's Location parameter is set to Pivot, arbitrarily move along the world X axis.

Icon Arrow Out Each particle moves along an imaginary line drawn between the particle's location and the icon arrow. The line is perpendicular to the icon arrow, which is considered an infinite line for this purpose.

With the flat icon types (Rectangle and Circle), this results in all the particles moving in one plane, unless you increase Divergence above 0.0. With icons that have height (Box and Sphere), the particles move outward in a cylindrical formation.

Random 3D Particles move in all directions. This option is affected by the Uniqueness setting.

Random Horizontal Each particle moves in a random horizontal direction; that is, parallel to the world XY plane. This option is affected by the Uniqueness setting.

Inherit Previous Uses the current direction of motion.

If you choose Inherit Previous but no direction was previously specified, the speed and direction are undefined; the particles don't move.

Reverse When on, the direction is reversed. Default=off.

Using Reverse is the equivalent of multiplying the Speed value by -1. This option is unavailable if Random 3D or Random Horizontal is chosen.
**Divergence** When on, spreads out the particle stream. Use the numeric setting to define the extent of the divergence, in degrees. Range=0 to 180. Default=0. The value can be animated.

This option is unavailable if Random 3D is chosen.

**TIP** For a fountain-like spray, set Position > Location to Pivot, set Direction to Along Icon Arrow, set Divergence to the desired angle, and rotate the icon so its arrow points upward.

**Uniqueness group**

The Uniqueness setting enables randomization of speed variation, and randomization of direction with the Random 3D and Random Horizontal options.

**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.

**Speed By Icon Operator**

**Particle View** on page 3015 > Click Speed By Icon in an event or add a Speed By Icon operator to the particle system and then select it.

Click a Speed By Icon operator icon in the viewport > Modify panel > Create panel > Helpers > Particle Flow > SpeedByIcon

The Speed By Icon operator lets you use a special, non-rendering icon to control particle speed and direction.
When you add a Speed By Icon operator to the particle system in Particle View on page 3015, the Speed By Icon operator icon, or helper, appears in the scene at the world origin (0,0,0). When animated, the operator icon's motion is imparted to the particles. If you delete the icon, Particle Flow also deletes the operator.

**NOTE** If you add Speed By Icon from the Create panel, Particle Flow creates a separate event for the operator in the particle diagram.

**WARNING** If you delete a Speed By Icon operator icon in the viewport, you also delete the corresponding operator in the Particle Flow system.

See also:
- Speed Operator on page 3108
- Speed By Surface Operator on page 3122
- Keep Apart Operator on page 3131

**Procedures**

**To use the Speed By Icon operator:**

1. Add a Speed By Icon operator to an event. Be sure to add it after any existing Speed operators in the event. Alternatively, delete or turn off any existing Speed operators.

   The Speed By Icon operator icon appears at the world origin (0,0,0).
2 Animate the icon as you would any object. You can do this manually, or with a controller such as Path Constraint. See the following procedure for an example of this.

The particles' motion is now under the influence of the animated icon.

3 Set the Speed By Icon parameters. With the icon selected, you can do this in the Modify panel.

In general, the default Icon Animation > Sync By setting, Event Duration, works best. It causes the icon animation to be applied to the particles within the time frame of the event containing the Speed By Icon operator.

Example: To send particles along a path:

1 Reset 3ds Max, and then add a Particle Flow system in the Perspective viewport.

2 On the Create panel, choose Shapes > Splines > Helix, and then, in the Perspective viewport, at the center of the grid, create a helix shape. Then, on the Parameters rollout, set the following:

   ■ Radius 1=100
   ■ Radius 2=20
   ■ Height=20
   ■ Turns=3
   ■ Bias=0

   This will serve as the particle path.

3 Move and rotate the Particle Flow source icon so that it's at the start of the helical path, and aimed along the path, as shown. Get the base of the arrow as close as possible to the start of the path.
4 Open Particle View (press 6).

5 In Event 01, click the Position Icon operator and set Location to Pivot. This causes the particles to be emitted in a thin stream.

6 Insert a Speed By Icon operator at the end of Event 01. The operator icon appears at the world origin.

7 Select the operator icon, and then, from the Animation menu, choose Position Controllers > Path Constraint on page 3596. When you move the mouse cursor into the viewport, a rubber-band line joins the cursor to the icon.

8 Select the Helix object. The command panel switches to the Motion tab, and the controls indicate that 3ds Max has applied a Position List controller to the icon, with the listed controllers being a Position XYZ and a Path Constraint. You can
delete the former if you like, but it doesn’t make any difference for the purposes of this procedure.

9 Close Particle View, and then drag the time slider back and forth between its extents a few times.

**TIP** The best way to view the results is from the Top viewport.

The particles follow the path fairly closely, but diverge noticeably at the end of the path, where the turns are tightest. Correcting divergence in tight turns typically requires an increase in the acceleration limit.

10 Stop at frame 100.

This will let you see the results of changing the Speed By Icon parameters as you make the changes.

11 Open the Modify panel, and, if necessary, select the Speed By Icon operator icon.

The operator parameters appear on the Modify panel. This is the case with any action that uses a unique icon, and lets you adjust the parameters without using Particle View.
12 On the Parameters rollout, use the Accel Limit spinner to slowly increase the value as you observe the changes to the particle path.

As you approach a value of 150, the end of the particle path comes closer and closer to the Helix. You shouldn’t see much change above 150.

The endpoints now coincide.

13 Drag the time slider again.

The particle path remains similar to that of the Helix for the entire duration of the animation. With other setups, you might need to use different values for Influence %, and for paths with tight twists and turns, you might need to increase Accel Limit as well.

You might be wondering why you didn’t simply replace the default Speed operator with the Speed By Icon operator. To see why not, try this:

14 Go to frame 100, open Particle View, and click the Speed 01 operator’s icon to turn it off. Play the animation.

The entire particle path is offset from the Helix, so it’s difficult to tell how closely it follows the latter’s curves.

15 Try adjusting the Speed By Icon’s Accel Limit and Influence % setting to get the particles to follow the helical path more closely.
It's not easy. You get more reliable results using the Speed operator to set the initial speed, and then Speed By Icon to set the particle path.

To use the Use Icon Orientation option:
The Use Icon Orientation option applies arc-like motion to the particles based on rotation animation of the icon. To best understand how it works, it's necessary to isolate its influence by eliminating any potentially conflicting factors.

1. Reset 3ds Max, and then add a Particle Flow system in the Perspective viewport. Set its position to the world origin: (0,0,0).

2. Open Particle View and click the Birth operator. Set Emit Stop=0. This causes all particles to appear at frame 0.

3. Click the Speed operator and press the Delete key to delete it.

4. Drag a Speed By Icon operator from the Depot to the end of Event 01. The Speed By Icon operator icon appears at the world origin.

5. Select the Speed By Icon operator icon, and then right-click the icon and choose Rotate from the menu. Go to frame 20, turn on Auto Key, and rotate the icon 180 degrees about the X axis.

6. Turn off Auto Key.

7. Drag the time slider.
The particles aren't affected by the icon animation.
Because the Speed By Icon operator icon is selected, the operator's parameters appear on the Modify panel.

8. On the Modify panel, turn on Use Icon Orientation. Drag the time slider again.
This time, the particles move in unison with the icon rotation, as if they were glued to an infinite plane coincident with the icon.

9. Go to frame 10, select the Particle Flow source icon (not the Speed By Icon operator icon), and then right-click the icon and choose Move from the menu. Move the icon straight up, on the Z axis, about 100 units.
As you drag upward, the particles move away from the icon.
10 Drag the time slider again. This time the particles move in an arc around the icon.

11 Try moving and rotating the two icons, playing the animation each time you make a change. Also set Emit Stop back to 30.

As you can see, the possibilities with just this simple setup are myriad. In combination with the many other variables and options in Particle Flow, they're endless.

Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog. When the icon is selected, the parameters also appear on the Modify panel.

**Accel(eration) Limit** The maximum amount, in system units per second per second, by which the particles' speed can change in order to match the speed of the operator icon. Default=100.0.
If the operator icon changes speed or direction rapidly, increase this value to let the particles follow it more closely.

**TIP** Use a lower Accel Limit value for smooth motion, and a higher value when greater accuracy is needed, such as when the particles should hit a small target. You can animate this setting (use Sync By > Event Duration) to specify different appropriate values, depending on the required results.

**Influence %** Determines the mix of the previous speed with the speed of the operator icon. Default=100.0. Range=0.0 to 100.0.

At the default value of 100, the speed is controlled only by that of the icon. At 0, the icon speed doesn't affect particle speed at all. At in-between values, the mix proportion is determined by the Influence % value.

**Speed Variation** Enables random variation of the particles' speed, so they don't all move at exactly the same rate as the icon. Turn this on, and then set the minimum and maximum percentages of variation. Default=off.

Using Speed Variation can help keep the particles from bunching up as they travel along the animation path. Note, however, that each individual particle's speed doesn't vary; it travels at a constant speed.

**Min %/Max %** Set the minimum and maximum percentages, respectively, of particle speed variation. Default=50.0 (Min %), 100.0 (Max %).

For example, if you set Min % to 50 and Max % to 200, the particles will vary in speed between half and two times the speed of the icon.

**Use Icon Orientation** Applies animation of the icon's orientation to the particles.

By default, Speed By Icon controls particle motion only by animation of the icon's position. If you turn on Use Icon Orientation, Particle Flow also applies rotation of the icon to the particle motion. In essence, this motion is circular, and its extent depends on the distance between each particle and the icon. Default=off.

The best way to understand how this works is by using it. To try out Use Icon Orientation, see this procedure on page 3118.

**Steer Towards Trajectory** Particles farther away than the Distance value from the icon are moved directly toward the icon. Default=off.

**Distance** Sets the distance between the particles and the operator icon beyond which Steer Towards Trajectory takes effect. Default=10.0.
Parameters Animation group

If you animate the operator settings, Particle Flow can begin applying this animation to all particles as of the start frame of the animation or the first frame of the current event, or to each particle based on its age. For instance, if you set Sync By to Particle Age, and set Speed Variation keys at frames 0 and 30, then Particle Flow will animate the speed variation for each particle born while the event is active between its birth and its 30th frame of existence. Alternatively, if you set Sync By to Absolute Time, the speed variation is animated from frame 0 to frame 30 of the animation, even if no particles are in the event at that time. Or, if you set Sync By to Event Duration, the speed variation animation is applied to each particle as of the time that it enters the event. For further information, see Animation Offset Keying group on page 3106.

Sync By Choose the time frame for applying animated parameters:

- **Absolute Time** Any keys set for parameters are applied at the actual frames for which they’re set.
- **Particle Age** Any keys set for parameters are applied at the corresponding frames of each particle’s existence.
- **Event Duration** Any keys set for parameters are applied to each particle relative to the frame at which it first enters the event.

Icon Animation group

Particle Flow can begin applying animation of the Speed By Icon operator icon to all particles as of the start frame of the animation or the first frame of the current event, or to each particle based on its age. For an explanation, see Animation Offset Keying group on page 3106.

Sync By Choose the time frame for applying animation of the icon to the particles:

- **Absolute Time** Any keys set for icon motion are applied at the actual frames for which they’re set.
- **Particle Age** Any keys set for icon motion are applied at the corresponding frames of each particle’s existence.
- **Event Duration** Any keys set for icon motion are applied to each particle relative to the frame at which it first enters the event.
Icon Size  Sets the size of the operator icon. This setting is for visibility only; it doesn't affect particle behavior.

Uniqueness group

The Uniqueness setting enables randomization of the speed variation range.

Seed  Specifies a randomization value.

New  Calculates a new seed using a randomization formula.

**Speed By Surface Operator**

[Particle View](#) on page 3015 > Click Speed By Surface in an event or add a Speed By Surface operator to the particle system and then select it.

The Speed By Surface operator lets you control particle speed and direction with any object or objects in the scene. This is in contrast to the default Speed operator on page 3108, which uses the Particle Flow icon to control particle speed and direction. Speed By Surface also provides options for controlling speed by materials in the scene, and continuous speed control.

Typically, you use Speed By Surface to assign speed and direction characteristics based on the objects used as emitters with the Position Object operator on page 3089. That is, you assign the same objects as emitters with Position Object and as Surface Geometry objects with Speed By Surface.

**TIP**  For greater control over particle motion on the surface, apply a Speed operator on page 3108 before the Speed By Surface operator in the same event. Use the Speed operator to specify particle direction on the surface, and the Speed By Surface operator to adjust the vertical component of the speed vector to follow the contour of the surface.

- Speed By Icon Operator on page 3112
- Keep Apart Operator on page 3131
Procedures

Example: To use Speed By Surface:

The Speed By Surface operator offers a wealth of possibilities for usage. This procedure will lead you through several examples, but you're encouraged to explore the operator further on your own to learn more about it.

1. Start or reset 3ds Max, and add a Particle Flow system. Position the source icon at the world origin (X/Y/Z=0), and set the icon's Length and Width values both to 30.

2. Add a Cylinder primitive to the scene. Position it above the source icon: X/Y=0 and Z=30. Set Radius=20 and Height=40.

3. Play the animation, and then stop.
   The particles move downward, using the default starting setup.

4. Open Particle View and add a Speed By Surface operator to the end of Event 01. Click the operator in the event to display its parameters panel in Particle View.

5. In the Surface Geometry group, click Add, and then select the cylinder.

6. Play the animation again, and then stop.
   The particles still move downward.

7. Go to frame 15, so you can see the particles, and then slowly move the cylinder downward along the Z axis, while watching the particles in the Perspective and Front viewports. Stop when the emitter is above the cylinder.
   As the bottom of the cylinder passes below the emitter, more and more particles start moving on the XY plane rather than perpendicular to it. That's because they eventually become closer to one of the vertical sides of the cylinder, rather than the bottom, at which point they move perpendicular to the vertical sides. When the top becomes the closest side, the particles again move vertically, but upward instead of downward.

8. Move the cylinder back up until the emitter is at its vertical center. Then, on the Modify panel, click the lower part of the Sides spinner to decrease the number of sides, one at a time.
   Each time you click, the particle streams traveling outward change, to move perpendicular to the vertical sides as they change position. You might also try rotating the cylinder, and note that the particle streams also rotate, like the spokes of a wheel.
9 In the Speed By Surface parameters, change Direction to Out Of Surface, and then move the cylinder up and down. The overall behavior doesn't change much. Out Of Surface becomes more useful when you use the Control Speed Continuously option, as you'll observe shortly.

10 In the Speed By Surface parameters, change Direction to Parallel To Surface, and then move the cylinder up and down. Now the particle behavior is effectively opposite of that with the other two options. When the particles are closer to the top or bottom, they move along the XY plane, and when they're closer to the vertical sides, they move downward. If you want them to move upward instead, set Speed to a negative value. Next, you'll discover how the Control Speed Continuously option alters particle behavior.

11 In the Speed By Surface parameters, choose Control Speed Continuously, and then drag the time slider. The particles spread out from the emitter, and then start orbiting the cylinder in a roughly cylindrical overall formation. Particle Flow continually checks to see which side of the cylinder a particle is closest to, and, if necessary, changes its direction to make it travel parallel to that side. You can affect the size of the particles' orbits by changing their speed.

Lastly, you'll see how to contain particle motion within the cylinder.

12 Make the cylinder considerably larger: Radius=60 and Height=90. Activate the Perspective viewport, if necessary, and then press F3 to set it to Wireframe view.

13 In Particle View, click the Speed 01 operator and set Direction to Random 3D.

14 Click the Speed By Surface operator. Set Speed to 300 if necessary. In the Direction group, choose Out Of Surface, and then drag the time slider. After exiting the emitter, the particles always move away from the nearest surface, with the result that they end up milling about in the center of the cylinder.

15 Gradually increase the Speed value, up to 1,000 or so. The particles start to spread out vertically, and eventually start moving so fast that they escape the cylinder. You can make them stay inside the
cylinder by letting them accelerate more quickly, so they can turn before moving past the nearest surface.

16 Increase the Accel Limit setting until the particles no longer exit the cylinder.

17 Try giving the particles more room to move about in by increasing the size of the emitter. Also try changing other settings throughout the particle system to see their effects. The possibilities don’t end here, and the more you experiment, the more you’ll learn about how this powerful operator works.
Chapter 12  Space Warps and Particle Systems
The user interface appears in the parameters panel, on the right side of the Particle View dialog.

The first setting lets you choose whether the operator controls speed once or continuously.

**Set Speed Once** The operator sets the speed for each particle once: when the particle enters the event.

**Control Speed Continuously** The operator sets particle speed throughout the event. When you choose this option, the Continuous Speed Control group on page 3130 becomes available.

**Speed** The particle speed in system units per second. Default=300.

With the Control Speed Continuously option, you can turn off Speed. This causes Particle Flow to use the current particle speed.

Using a negative Speed value causes particles to move in the opposite direction of that effected by a positive speed.

**Variation** The amount by which particle speed can vary, in system units per second. Default=0.0.

To obtain each particle's speed, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then adds the result to the Speed value. For example, if Speed=300 and Variation=100, then each particle's speed would be between 200 and 400.

**Surface Geometry group**

Use these controls to assign objects to affect particle speed and direction. The list in this group shows the objects, or reference geometry, that the operator uses to control speed and direction.

If you don't assign any objects, the current particle speed and direction are not affected.

You can assign multiple Surface Geometry objects, but if they're not all emitters as well, the results can be difficult to interpret. In general, assign the same objects as Surface Geometry that your system uses as emitters.

**TIP** For optimal performance, when moving particles with respect to high-polygon objects, create a low-poly proxy version to use as surface geometry, link it as a child of the high-poly object if necessary, and then hide the low-poly proxy.

Use the Add and Remove buttons to edit this list.
Add Adds an object to the list. Click Add, and then click an object in the viewport.

By List Adds multiple objects to the list. Click By List to open the Select Surface Objects dialog. This works just like Select From Scene on page 206: Highlight the objects to use to control speed and direction, and then click the Select button.

Remove Removes an object from the list. Highlight the object in the list, and then click Remove.

Animated Shape Turn on to allow particles to follow the surface of an object whose form is animated by morphing or with modifiers.

Subframe Sampling When on, the operator acquires animation of the Surface Geometry shape on a tick basis (every 1/4,800th of a second) rather than a frame basis. This provides greater precision in allowing the particle positions to follow animation of the Surface Geometry object's form.

Speed by Material Varies particles' existing speed and direction based on properties of the material applied to each Surface Geometry object. For example, if an object is assigned a black-and-white checkered diffuse map and you choose the Grayscale Multiplier option, particles near the white-checked areas move faster than those from the black-checked areas.

NOTE For material-influenced speed to appear properly in the viewports, two conditions are required: at least one viewport must be set to a shaded display mode, and the material or map must have Show Map In Viewport turned on in the Material Editor.

The options are as follows:

- **Grayscale Multiplier**  Lets material luminance control speed, with darker areas producing slower particles and lighter areas producing faster ones. Particle Flow multiplies the luminance of the material near each particle, converted to a percentage, by the particle's current speed. A luminance of 0 converts to 0%, of 128 converts to 50%, and of 255 converts to 100%. For example, if the speed of a particle traveling at 50 units per second is influenced by a pixel whose luminance is 90, the resulting speed is 90/255*50, or about 17.6 units per second.

- **Signed Grayscale**  Works like Grayscale Multiplier, but the multiplier can be negative as well, causing reversal of motion. Signed Grayscale uses a material luminance value of 128 as the midpoint, and assigns it a multiplier of 0%. Luminance values from 0 to 127 result in multipliers of -100% to 100%. Luminance values above 127 produce negative multipliers.
about -1%, respectively, and values of 129 to 255 result in multipliers of about 1% to 100%, respectively.

- **RGB as World XYZ Mult.** Works like Grayscale Multiplier, but uses the intensity of the material’s red, green, and blue channels to affect particle speed on the world X, Y, and Z axes, respectively. So, for example, if the material pixel is pure red, that is, its RGB value is (255,0,0), then the particle will retain its current speed on the world X axis, but its speed on the Y and Z axes will be reduced to 0. Similarly, a medium-yellow pixel (128,128,0) will cause speed on the world X and Y axes to be reduced by half, and will cut speed on the Z axis to 0.

- **RGB as Local XYZ Mult.** Works like RGB as World XYZ Mult., but uses the object’s local coordinates rather than world coordinates.

**Use Sub-Material** When on, uses a sub-material from the Multi/Sub-Object material assigned to the Surface Geometry object to define speed. This option allows usage of “invisible” materials for controlling particle speed. If the emitter uses a Multi/Sub-Object material but its geometry doesn’t use the ID that corresponds one of the sub-materials, the sub-material doesn’t appear. However, the operator can use it to calculate the density of particle placement. Particle Flow assumes the material to be applied to the entire object surface.

**Mtl ID** Specifies the material ID of the sub-material to be used for particle speed control.

**Direction group**

The Direction drop-down list lets you specify which way the particles go after they’re born. Default=Surface Normals. In most cases, the actual direction also depends on the icon orientation. The primary exception is when Position > Location is set to Pivot.

Particle movement is always in a straight line unless influenced by other factors.

**Surface Normals** Each particle moves along a line perpendicular to the nearest face. The direction the surface faces doesn’t matter.

**Out Of Surface** Particles move away from the closest face.
**TIP** You can use this option to confine particles to the interior of an object. Position the emitter inside the object, designate the object as the Surface Geometry, choose Control Speed Continuously, and choose Out Of Surface. Each time a particle comes close to a surface, it turns to travel directly away from the surface. Control the particles' travel range with the Speed setting, but keep in mind that particles moving very fast might “escape” their container. If this happens, increase the Accel Limit setting; this lets the particles turn more quickly.

**Parallel To Surface** Each particle travels parallel to the nearest face.

To make particles orbit an object, use this with Control Speed Continuously, and set appropriate Continuous Speed Control values (see the following section).

---

**Divergence** When on, spreads out the particle stream. Use the numeric setting to define the extent of the divergence. Range=0 to 180. Default=0. The value can be animated.

This option is unavailable if Control Speed Continuously is chosen.

**TIP** For a fountain-like spray, set Position > Location to Pivot, set Direction to Along Icon Arrow, set Divergence to the desired angle, and rotate the icon so its arrow points upward.

---

**Continuous Speed Control group**

When you choose the Control Speed Continuously option, these controls become available. Basically, these controls let the particles move about within the region of the Surface Geometry object rather than in a straight line away from the emitter.

**Accel Limit** Sets the maximum acceleration. The higher this value, the more quickly particles can turn and change speed.

**TIP** Use a lower Accel Limit value for smooth motion, and a higher value when greater accuracy is needed, such as when the particles should hit a small target. You can animate this setting (use Sync By > Event Duration) to specify different appropriate values, depending on the required results.

**Unlimited Range** When on, the surface controls speed and direction of particles at any distance. When off, particles must be within a specified range. Default=on.
**Range** The maximum distance, in system units, between the particles and controlling surface. The Surface Geometry will not control particles beyond this distance.

**Falloff Zone** The distance, in system units, beyond the Range value within which the Surface Geometry exerts partial control over particles. The degree of control diminishes from 100% at the Range distance to 0% at the Range+Falloff Zone distance.

**Animation Offset Keying group**

Choose the time frame for applying animated parameters. For an explanation, see Animation Offset Keying group on page 3106.

**Absolute Time** Any keys set for parameters are applied at the actual frames for which they're set.

**Particle Age** Any keys set for parameters are applied at the corresponding frames of each particle's existence.

**Event Duration** Any keys set for parameters are applied to each particle starting when it first enters the event.

**Uniqueness group**

The Uniqueness setting enables randomization of speed variation, and randomization of direction with the Random 3D and Random Horizontal options.

**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.

**Keep Apart Operator**

**Particle View** on page 3015 > Click Keep Apart in an event or add a Keep Apart operator to the particle system and then select it.

The Keep Apart operator, a member of the Speed operator family, lets you apply forces to particles to cause them to separate, in order to prevent or minimize collisions among particles. Alternatively, you can use a negative force to keep particles from separating too much. The operator works by controlling particle speed and acceleration.
NOTE Keep Apart doesn't use particle geometry; rather, it creates a spherical force field centered on the pivot of each particle. You can adjust the size of the force field by changing the particle size.

TIP In certain cases, the default settings might not be sufficient to keep particles from interpenetrating. For increased separation, use higher values for Force and Accel Limit, choose Relative To Particle Size, and increase the Core % value.

- Speed Operator on page 3108
- Speed By Surface Operator on page 3122
- Speed By Icon Operator on page 3112

Script Wiring rollout

This rollout appears in the parameters panel below the main operator rollout after you highlight the operator, right-click it, and then choose Use Script Wiring. Thereafter, a check mark appears next to the Use Script Wiring in the right-click menu, and the rollout appears whenever you highlight the operator. To turn off script wiring, choose Use Script Wiring again from the right-click menu.

Script wiring lets you use a script to control the Force and Range parameters, which you normally specify in the operator's parameters. Place a Script operator on page 3196 before the Keep Apart operator in the event, and then use it to define values in the particleFloat and particleVector channels. For an example of a script that sets particleFloat values, see particleFloat Sample Script on page 3190.

On the Script Wiring rollout, choose either of the following:

Use Script Float As Choose either of the following:
- Not Used Particle Flow uses the Force setting on page 3135 specified in the Parameters rollout.
- Influence Particle Flow applies the script particleFloat value to the Force value.
Use **Script Vector As** Choose one of the following. Choosing Absolute Size Range or Relative Size Range makes the Range settings on the Parameters rollout unavailable.

- **Not Used** Particle Flow uses the Range on page 3135 settings specified in the Parameters rollout.

- **Absolute Size Range** Particle Flow applies the script particleVector values to the Absolute Size Range values. The X component of the vector value is used for the core radius, and the Y component for the falloff radius.

- **Relative Size Range** Particle Flow applies the script particleVector values to the Relative Size Range values. The X component of the vector value is used for the core percent, and the Y component for the falloff percent.
The user interface appears in the parameters panel, on the right side of the Particle View dialog.
**Force** The amount of force applied to the particles. Use positive values to separate particles, or negative values to move them closer together. Default=100.0

**Accel(eration) Limit** When on, lets you set a maximum acceleration value that can be applied to particles' motion. When off, Particle Flow uses any necessary acceleration. Default=on, 1000.0.

**Tip** Use a lower Accel Limit value for smooth motion, and a higher value when greater accuracy is needed, such as when the particles should hit a small target. You can animate this setting (use Sync By > Event Duration) to specify different appropriate values, depending on the required results.

**Speed Limit** When on, lets you set a maximum speed value that can be applied to particles' motion. When off, Particle Flow uses any necessary speed. Default=off, 600.0.

**Range group**

You can set a volume and falloff within which the force takes effect, either as absolute distances or relative to particle size. Default=Absolute Size.

**Absolute Size** Choose this to set the core radius and falloff zone as absolute distances, in system units.

**Core Radius** The distance from each particle's pivot point, in system units, within which the force is applied at full strength. Default=10.0

**Falloff Zone** The distance beyond the core radius, in system units, over which the force diminishes from full strength to 0. Default=10.0

**Relative to Particle Size** Choose this to set the core radius and falloff zone as percentages, relative to the radius of each particle. The particle radius is determined by measuring the distance from the pivot point to the farthest corner of its bounding box.

**Core %** The distance from each particle, as a percentage of the particle radius, within which the force is applied at full strength. Default=200.0

**Falloff %** The distance beyond the core radius, as a percentage of the radius, over which the force diminishes from full strength to 0. Default=100.0

**Variation %** The amount by which range values can vary randomly, as a percentage of the specified values. Particle Flow uses the same random variation value for both Core and Falloff values, whether absolute or relative. Default=0.0

For example, if you choose Absolute Size, set Core Radius to 40 and Falloff Zone to 20, and set Variation % to 50, then each particle's actual core radius...
will be a random number in the range 20 to 60, and the falloff zone a random number in the range 10 to 30. For each particle, Particle Flow uses the same Variation % value, so if Core Radius is determined to be 20, then Falloff Zone would be 10.

**Scope group**

By default, the Keep Apart force keeps particles only in the current event (that is, the event that contains the Keep Apart operator) apart from each other when used locally, or particles in each event in the current flow on page 8581 apart when used globally. These settings let you alternatively keep particles away from particles in other events or flows without affecting the behavior of latter. Default=Current Event.

**Current Event** Keeps particles in the current event only away from each other. When used globally, keeps particles in each event in the current flow apart from each other, but not apart from particles in other events in the flow.

**Current Particle System** Keeps particles in the current event away from each other, and away from all other particles in the current flow on page 8581. The particles not in the current event are not influenced by the Keep Apart operator. When used globally, keeps apart and influences all particles in the current flow.

**Selected Events** Keeps particles in the current event away from all particles in the events highlighted in the list below this choice. Particles not in the current event are not influenced by the Keep Apart operator. When used globally, keeps all particles in the current flow apart from all particles in the events highlighted in the list below this choice, but influences only particles in the current flow. After choosing this option, click items in the list to highlight them.

**Selected Particle Systems** Keeps particles in the current event away from all particles in the flows on page 8581 highlighted in the list below this choice. The particles not in the current event are not influenced by the Keep Apart operator. When used globally, keeps all particles in the current flow apart from all particles in the flows highlighted in the list below this choice, but influences only particles in the current flow. After choosing this option, click items in the list to highlight them.

**Uniqueness group**

The Uniqueness setting enables randomization of the Range on page 3135 > Variation % calculations.
Seed Specifies a randomization value.

New Calculates a new seed using a randomization formula.

Shape

Shape operators control the geometry of particles.

Shape Operator

Particle View on page 3015 > Click Shape in an event or add a Shape operator to the particle system and then select it.

The new Shape operator, which replaces the original version, expands the choices of ready-made geometry for use in the particle system. You can specify particles in a number of different predefined 2D and 3D shapes, such as geometric primitives, alphanumeric characters, and musical notes, as well as particle size and scale.

Primitive particles created with Shape have pivot points at their geometric centers. They also have UVW mapping assigned according to the vertex position in the local 3D particle space.

2D particles have zero thickness, and are invisible when the back of the particle faces the camera unless a double-sided material is assigned to the particles or emitter.

See also:

- Shape Instance Operator on page 3142
- Shape Facing Operator on page 3139
- Shape Mark Operator on page 3149
Interface

2D/3D Makes available a drop-down list of pre-built 2D or 3D objects for use as a particle shape. The thumbnail image is color-coded to indicate its relative complexity to other pre-built objects. Simpler shapes are blue or green, while more complex shapes are purple or red. There are 20 shapes of each type. For sequential shapes, such as digits, letters, and notes, you can turn on Multi-Shape Random Order to produce a random sequence.

Size Sets the overall size of the particles in system units. Default=10.0.

Scale Turn on to set the size of the particles as a percentage of the Size value. Use the numeric field to set the Scale percentage value. Default=100.0. Scale is animatable, while Size is not. Turning on Scale creates scale data that Scale operators later in the flow can work with.

Variation Available only if Scale is turned on. Adds variation to the overall particle scale. The resulting scale factor is set only once, when a particle enters the event. To control the scale factor continuously, use the Scale operator.

Multi-Shape Random Order When on, assigns shapes to particles in random order. This option is available only for multi-shape forms. When off, the shapes are assigned in their natural order, such as A, B, C for letters, and 1, 2, 3 for digits.
Uniqueness Group of Controls

The options in the Uniqueness group are available only when Multi-Shape Random Order is turned on.

Seed  Specifies a randomization seed.

New  Calculates a new seed using a randomization formula.

Shape Facing Operator

Particle View on page 3015 > Click Shape Facing in an event or add a Shape Facing operator to the particle system and then select it.

The Shape Facing operator creates each particle as a rectangle that always faces a particular object, camera, or direction. For effects like smoke, fire, water, bubbles, or snowflakes, use Shape Facing with a material containing appropriate opacity and diffuse maps.

By default, the particles' top and bottom sides are parallel to the horizontal plane. The Orientation setting lets you change this default alignment.

**NOTE** For the Shape Facing operator to be able to calculate the particle orientation, it must know the current particle position. For this reason, always place the Shape Facing operator *below* a Position operator in an event.

- Shape Operator on page 3137
- Shape Instance Operator on page 3142
- Shape Mark Operator on page 3149
**Interface**

![Interface Diagram]

**Look At Camera/Object group**

Use this control for defining the camera or object toward which the particle will face. This object is known as the *Look At object*. For the technically minded, the facing is maintained by keeping each particle's local Z axis pointed at the Look At object, or when Use Parallel Direction is on, aligned with the vector between the Particle Source icon and the Look At object.

**Name** After picking a Look At object, its name appears here.

**Pick Camera or Object** Click this button, and then select a camera or object in the scene to use as the Look At object. The mouse cursor changes to a cross shape when positioned over a valid object.
Use **Parallel Direction** When off, all particles continuously rotate to stay facing toward the Look At object. Each particle's orientation varies because its location differs from those of the others. When on, all particles face in the same direction, defined by an imaginary line between the Particle Source gizmo center and the Look At object. Default=off.

**Size/Width group**

Use these settings to specify the coordinate system for setting the size, as well as the size parameters. The numeric settings in this group are not animatable.

**In World Space** Sets the absolute size in system units, using the World coordinate system.

**Units** With the In World Space option, sets the particle size in system units. Range=0 to 1000000000. Default=1.

**In Local Space** Sets particle size relative to the existing size, in local space. Particle Flow uses the dimensions of the existing shape to determine the size of the “facing rectangle.”

**Inherited %** Sets the facing particles' size as a percentage of the existing size. Range=0 to 100. Default=100.

**In Screen Space** Sets the facing particles' size as a percentage of the screen width. The actual size of each particle changes as necessary throughout the animation, depending its distance from the camera, to maintain a constant size from the camera’s point of view.

This option is available only when the Look At object is a camera, and Use Parallel Direction is off.

**Proportion %** Sets the particle size as a percentage of the screen width. Default=1.

**Variation %** Sets the percentage by which particle size can vary. Default=0.

**Pivot At** Specifies the part of the particle around which rotation is performed when maintaining the facing direction. The choices, available from the drop-down list, are Top, Center, and Bottom. Default=Center.

With Top and Bottom, the center of the corresponding side is used as the particle center for rotation.
This option is useful, for example, when particles are lying on a surface, and each particle is an explosion. In this situation, you'd probably want the entire particle rectangle to appear above the surface, so you'd set Pivot At to Bottom.

**W/H Ratio** Defines the aspect (width-to-height) ratio of the shape rectangle. Adjust this ratio to that of the particle-map imagery. For the commonly used TV aspect ratio of 4:3, set W/H Ratio=1.33. The parameter is not animatable. Range=0.001 to 1000. Default=1 (square particles).

This value is not animatable.

**Orientation**

Use this drop-down list to choose how particles rotate on the axes not specified by the Look At direction. Default=Align to Horizon.

**Align to Horizon** Keeps the top edge aligned with the horizon (the world XY plane).

**Align to Speed Follow** Uses the right side of each particle as the leading edge, so the top and bottom edges are aligned with the direction of particle motion.

**Random** Orient the top edge at random.

**Allow Spinning** To spin the particles, choose this option, and in the same event use a Spin operator on page 3099. In the latter, set Rotation Axis to Particle Space and use the default axis values: X=0, Y=0, Z=1.

**Uniqueness group**

The Uniqueness setting enables changing the randomization of the size/width variation.

**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.

**Shape Instance Operator**

**Particle View** on page 3015 > Click Shape Instance in an event or add a Shape Instance operator to the particle system and then select it.

Shape Instance lets you use any reference object on page 8700 in the scene as particles. You can effectively define only one reference object per event, but the object can comprise any number of sub-objects, each of which Particle Flow can treat as a separate particle. Also, using tests, you can divide the
particle stream into multiple branches and define a different particle shape for each.

As the name of the operator indicates, reference geometry is instanced into the particle system. Thus, any physical changes you make to the original geometry are reflected instantly in the particle system. If you hide the original geometry, the particles still appear. However, if you delete the original geometry, the particles are deleted as well.

**Using Transform-Animated Reference Objects**

You can create animated particle shapes by animating the reference object with modifiers, and then turning on **Animated Shape** on page 3148. However, **Shape Instance** ignores any rotational and positional transformations applied directly to the reference object; it uses only the pure scale component. For example, if you scale an object non-uniformly using the View reference coordinate system, the result might skew the object's shape. Because the skewing is the by-product of a rotational transform, it wouldn't be reflected in the particles' shape. However, modifiers and comparable functions that contain transformations applied to the reference object are reflected in the instanced particles. For example, if you want particles to use rotational transforms applied to the reference object, use the **Reset XForm** function on the reference object. **Reset XForm** is available from the **Utilities** panel.

**TIP** Particle Flow can, however, use rotational and positional animation applied to descendant objects in a hierarchy, when you use the entire hierarchy as a single particle. To do this, create a hierarchy, animate the descendant objects, and then designate the parent as the reference object. Do not turn on **Separate Particles For > Object And Children**. You'll find a procedure illustrating this, below.

When using an animated reference object, it is recommended that you hide the reference object after instancing it in the particle system.

**See also:**
- **Shape Operator** on page 3137
- **Shape Facing Operator** on page 3139
- **Shape Mark Operator** on page 3149
Procedures

Example: To use the reference object’s rotational and positional animation in the particle system:

1. Create an object you want to use as the particle shape, such as a teapot, and a Dummy helper object.

2. Animate the teapot using the Move and Rotate tools.

3. Use the Align tool to center the teapot to the dummy.
   This step isn’t necessary, but it can help to obtain more consistent results.

4. Link the teapot as a child of the dummy (drag from the teapot to the dummy).
   You can use any object as the parent, but using a dummy, which doesn’t render, lets you animate all instanced particles visible in the final animation.

5. Create a default Particle Flow system.

6. In Particle View, delete the Rotation operator.

7. Replace the Shape operator with a Shape Instance operator.

8. In the Shape operator parameters, designate the dummy as the Particle Geometry Object.

9. Turn on Animated Shape.

10. For sequential animation, which can be more interesting visually, in Animation Offset Keying, set Sync By to Particle Age or Event Duration.
Interface

Particle Geometry group

Use this control for defining the object to be used as the particle geometry. This object is known as the reference object.

[button] Click this button, and then select a geometry object in the scene to be used as the particle shape. The mouse cursor changes to a cross shape when positioned over an object that’s valid for use as a reference object. Valid objects
include *multi-shape* objects such as groups and hierarchies; see Separate Particles For group on page 3146.

After picking a reference object, its name appears on the button.

You can use almost any geometry object as a reference object. By default, the operator automatically converts closed splines to rendering geometry by “filling in” the area defined by the shape outline. To use the shape outline instead, select the original shape and, on the Modify panel > Rendering rollout, turn on Display Render Mesh. You needn’t turn on Renderable, but changes to all other Rendering rollout settings, such Thickness and Sides, are reflected in the rendered particles.

Particle Flow does not automatically “fill in” open shapes such as Line (non-closed) and Arc. To render these shapes when using them as particles, turn on Modify panel > Rendering rollout > Display Render Mesh.

If a Shape Instance operator is in effect for which the geometry object is not defined, and the viewport display type is set to Geometry, then the particles appear in the viewports as X characters.

**NOTE** If a multi-shape object used as a reference object comprises objects both with and without materials applied, and Acquire Material is on, Particle Flow will apply the first available material to any objects without materials applied.

**NOTE** You can use a NURBS surface as a reference object, but not a NURBS curve. To use a NURBS curve as particle geometry, first convert it to a surface using a method such as the Cap function.

**TIP** For best results, when using an animated reference object, it’s highly recommended that you hide the original object before rendering, or use Object Properties to turn off its Renderable check box.

**NOTE** If using a group as a reference object, make sure the group is closed before selecting it. Selecting an open group will add only the group member you click, not the entire group.

**Separate Particles For group**

3ds Max provides a number of methods for combining disparate objects into single entities, including grouping, building hierarchies with linking, and attaching. By default, when using such a *multi-shape* object as particle geometry, each particle comprises all member objects. Alternatively, you can instruct Particle Flow to treat each member object as a separate particle with these options. When on, Particle Flow uses each member object as a single particle, in left-to-right order according to its X-axis position, by default. So, for
example, if you create text in the Front viewport, assign it as reference geometry, and turn on Object Elements, the letters come out in the proper order.

You can vary the order randomly by turning on Multi-Shape Random Order on page 3148.

You can turn on any combination of Separate Particles items. All are off by default.

**Group Members** When on, group members are treated as separate particles.

**Object and Children** When on, linked objects are treated as separate particles.

**Object Elements** When on, element sub-objects of a single mesh object are treated as separate particles.

**Vertices/Faces** Show the number of vertices and triangles per particle. If the reference geometry is multi-shape and the appropriate check boxes in the Separate Particles are on, then these displays show an average vertex/face count.

**Number of Shapes** Shows number of different particle shapes. This number is always 1 unless the reference geometry is multi-shape and the appropriate check boxes in the Separate Particles For group are on, in which case this displays the number of resulting different shapes.

**Scale (%)** Specifies a uniform scaling factor for all particles. Range=0 to 100000. Default=on, 100.

The center of scaling for multi-shape object members treated individually depends on how the objects are combined. For grouped and linked objects, the scaling is done about the objects' pivot points. For object elements, the scaling center is the geometric center of each object; that is, the averaged location of all the vertices.

This value cannot be animated. To animate particle size, use the Scale operator on page 918.

**Variation (%)** Specifies a randomized percentage of scaling variation. Use the Uniqueness setting to change the randomization. Range=0 to 100. Default=0.

This value cannot be animated. To animate scaling variation, use the Scale operator on page 3102 operator.

**Acquire Mapping** When on, all mapping data from the reference object is transferred to particles. Default=on.
**Acquire Material** When on, material data from the reference object is transferred to particles. Default=on.

If the reference object is a group, with different materials applied to the group members, Particle Flow creates a new Multi/Sub-Object material containing all of the materials and uses it as the particle material.

**TIP** Because materials are “sticky” in Particle Flow, if you turn off Acquire Material after specifying a reference object with an attached material, the material remains applied to the particles. To avoid applying the instanced shape’s material to the particles, turn off Acquire Material before specifying the reference object.

**Multi-Shape Random Order** When on, assigns shapes to particles in random order. When off, Particle Flow emits each shape in the multi-shape object as a single particle, in the order of the shape’s X coordinate. In other words, the shape with the lowest X-axis coordinate is emitted first, then the one with the next highest, and so on. The option is available only if at least one of Separate Particles For group check boxes is on. Default=off.

For example, if you want the particles to spell out a word or phrase, use extruded text created in the Front viewport as the reference object, turn on Separate Particles For > Group Elements, but leave Multi-Shape Random Order off.

**Animated Shape** When on, particles use any animation in the reference object, including cyclic animation applied with the Parameter Curve Out-of-Range Types controls. When off, the particles are not animated.

With this option, you can use the Animation Offset Keying controls to specify how to synchronize the reference-object animation with the particles. See the next section.

**NOTE** A particle that uses this option is animated only while in the event containing the Shape Instance operator. If it moves to another event that doesn’t contain a shape operator, it keeps the same shape, but the animation stops. The easiest way to keep the animation going from event to event is to place the Shape Instance operator in the global event on page 8594. Otherwise, you need to place the operator in each event in which the particle should be animated.

**Acquire Current Shape** When on, Particle Flow acquires the particle shape from the reference object as each particle enters the event. Thus, if the reference object is animated, particles that enter at different times get different shapes. However, these shapes are not animated. When the option is off, the shape is acquired from frame 0. Default=off.

This option is available only when Animated Shape is off.
Animation Offset Keying group

These controls are available only when Animated Shape is on.

Sync By Lets you choose how to synchronize reference-object animation with the particles.

- **Absolute Time**  All particles have the same shape at any given moment.
- **Particle Age**  Animation of the reference object is synchronized with particle age: Frame 0 of the reference-object animation corresponds to the frame of each particle's birth.
- **Event Duration**  Frame 0 of the reference-object animation corresponds to the moment the particle enters the event.

Rand Offset When on, randomly varies the start of each particle's animation. Use the numeric setting to specify the number of frames by which the animation start can vary.

Update Particle Shape Refreshes instanced particle shapes from the reference object. Use this after changing an object in a hierarchical reference object. In most cases, Particle Flow automatically updates instanced particles when changes are made to the reference object. However, in some cases, when you change an object deep in a hierarchy, the particle instances might not be updated. In such a case, click Update Particle Shape to refresh the instances.

Uniqueness group

The Uniqueness setting enables changing the randomization of the scale variation, animation offset, and the multi-shape random order.

Seed Specifies a randomization value.

New Calculates a new seed using a randomization formula.

Shape Mark Operator

Particle View on page 3015 > Click Shape Mark in an event or add a Shape Mark operator to the particle system and then select it.

Use the Shape Mark operator to replace each particle with either a rectangle or a box cut out from the particle geometry with an image mapped onto it.
The image can be animated and the animation can be synchronized with particle events.

A typical application of Shape Mark would be to leave marks after particles impact objects in the scene. For example, when a torpedo hits a boat and explodes, you could use Shape Mark to leave scorch marks on the boat surface.

**TIP** By default, the mark left by Shape Mark is always rectangular, no matter what shape the particles are. To leave a differently shaped mark, choose the Shape group > Rectangle option, and use a [material](#) on page 3156 in the same event with transparent areas to define the mark's outline. For example, apply a Mask map to the material's Opacity channel, and to the map's Mask channel, apply a bitmap containing an alpha channel. On the Bitmap Parameters rollout, set Mono Channel Output to Alpha.

**NOTE** With its default settings, the Shape Mark operator can generate coplanar faces, which the mental ray renderer cannot render well. If you want to use mental ray rendering with Shape Mark, adjust the operator's settings as follows:

- In the Shape group, choose Box Intersection.
- Set Surface Offset to 0.01.
- Set Offset Variation to 0.005.
- Set Vertex Jitter to 0.002.

With these settings, faces are no longer coplanar, and the mental ray renderer gives better results.

**See also:**
- [Shape Operator](#)
- [Shape Instance Operator](#)
- [Shape Facing Operator](#)

**Procedures**

**Example: To use Shape Mark:**

1. Determine which object is to receive the marks; this will be the contact object. Apply a deflector to this object.
2 Set up your particle system with an event that causes particles to collide with the contact object deflector.

3 At the end of this event, add a Collision test on page 3236.

4 In the Collision test, designate the deflector from step 1.

5 Create a new event with the Shape Mark operator, and wire the Collision test to this event.

6 In the Shape Mark operator > Contact Object group, designate the object from step 1. Change the other Shape Mark settings as necessary.

   Now, when the particles strike the contact object, they disappear, leaving marks on the object.

   If you want the particles to bounce after leaving marks, rather than disappearing, use a Collision Spawn test on page 3241 instead, and turn off its Delete Parent check box. The spawned particles become the marks, and the original particles remain in the first event.

7 Optionally, add a Material operator to define the surface characteristics of the marks.
Contact Object group

Use this control for defining the object on which marks are to be left.

[button] Click this button, and then select an object in the scene to use as the contact object. The mouse cursor changes to a cross shape when positioned over a valid object.

After picking a contact object, its name appears on the button.

Align to Surface Animation When on, Shape Mark takes into account surface changes due to vertex animation of the contact object. If Shape on page 3154 is set to Rectangle, then the mark changes its orientation and position to appear be stuck to the surface of the contact object. If Shape is set to Box Intersection, then the mark changes shape along with that of the contact object. When off, only transformation of the contact object is taken into consideration. Default=off.

Turn this on only if there is significant vertex animation at the contact point, such as with an animated water surface.

**WARNING** This option requires significant CPU and memory resources.

Orientation group

Align To Depending on the setting for Shape on page 3154, Shape Mark creates either a rectangle or a box cutout on the contact geometry. The Orientation setting specifies how the shape is oriented. In the mark’s local coordinate system, the X axis is Length, the Y axis is Width, and with the box cutout, Z is height. The Z axis is perpendicular to the surface of the object at the contact point.

The alignment choices are as follows:

- **Speed**  The Length direction is parallel to the projection of the particles' speed vector onto the contact plane.

- **Particle X/Y/Z**  The Length direction is parallel to the projection of the particle’s local coordinate axis X, Y, or Z, respectively, as the particle moves toward the contact object.

- **Random**  Uses a random Length direction in the contact plane.

**Divergence** Applies a range of random variation, in degrees, to the orientation of the Length direction. Unavailable when using the Random option.
Size group

Use these settings to specify the coordinate system for setting the size of the mark, as well as the size parameters. The numeric settings in this group are not animatable.

In World Space Sets the absolute size of the mark in system units, using the World coordinate system.

Width/Length With the In World Space option, sets the particle dimensions in system units. Range=0 to 1000000000. Default=1.0.

In Local Space Sets the mark size relative to the existing particle size, in local space. Particle Flow uses the dimensions of the existing shape to determine the size of the “facing rectangle.”

Inherited % Sets the percentage of the mark size, relative to the existing particle size. Range=0 to 100. Default=100.0.

Variation % Sets the percentage by which particle size can vary. Default=0.0.

Impact Angle Distortion When on, increases the Length value of the mark according to the particle's angle of approach. This effectively stretches the mark shape if particle approaches the contact geometry at a low angle. Available only when Align To is set to Speed. Default=off.

For example, if a drop of paint hits a surface perpendicularly, it creates a circular mark, but if it hits the surface at a lower angle, the resulting shape is an ellipse.

Distortion Max % Sets the maximum percentage by which Particle Flow may stretch the mark. Available only when Impact Angle Distortion is on. Default=1000.

With very low angles of approach, the stretching factor can become very high. For example, value 500% means that the stretching factor cannot exceed 5.

Shape group

These settings let you specify the mark-making object as a rectangle or a box. Default=Rectangle.

Rectangle The mark shape is a two-faced rectangle.

When using a material with Shape Mark, always choose this option.

Box Intersection With this option, Particle Flow creates a box for each particle that leaves a mark, and derives the mark shape from a Boolean intersection between the contact object and the box.
**Box Height** Sets the height of the box used with the Box Intersection method. Available only with Box Intersection. Default=10.0.

**Allow Multiple Elements** When on, particles can leave marks on all parts of contact objects that contain multiple elements. When off, a particle marks only the first element it collides with. Available only with Box Intersection. Default=off.

Particles falling onto a two-element cylinder
Left: Allow Multiple Elements is off; Right: Allow Multiple Elements is on.

**Continuous Update** When on, the shape of the mark is recalculated at each frame, according to the current positions of the particle and the contact surface. This option can consume a great deal of CPU time. Available only with Box Intersection.

**Generate Mapping Coords.** Allows correct application of the shape mark when using a mapped material. Default=on.

If you're not using a mapped material, you can save memory by turning this off.

**Pivot Offset %** Shifts the position of the shape mark along its length dimension with respect to the pivot of the impacting particle. Default=0.0. Range=-50.0 to 50.0.

By default, the center of the mark's length dimension coincides with the point where the particle's pivot strikes the contact object. This setting lets you offset the mark's position to anywhere along its length.

**NOTE** The width dimension and the Box Intersection's height dimension are always centered at the intersection of the particle pivot and the contact object's surface.
**Surface Offset**  Specifies the distance of the shape mark above the contact object's surface. Default=0.001.

The mark is slightly elevated above the contact geometry to achieve the visual effect of the mark spot overlapping the contact geometry. This parameter is not animatable.

**Offset Variation**  Specifies the maximum extent of a random variation in the actual surface offset among particles. Default=0.0.

Adjusting this value can help to alleviate rendering artifacts with overlapping marks.

**Vertex Jitter**  Specifies the maximum extent of a random variation in the positions of vertices of marks created using the Box Intersection method. Available only with the Box Intersection method. Default=0.0.

Adjusting this value can help to alleviate rendering artifacts with overlapping marks.

**Uniqueness group**

The Uniqueness setting enables changing the randomization of the size/width variation.

**Seed**  Specifies a randomization value.

**New**  Calculates a new seed using a randomization formula.

**Materials and Mapping in Particle View**

Particle Flow provides three operators for applying materials to particles. To give the same appearance to all particles throughout an event, use **Material Static Operator** on page 3163. If you're using a compound material such as **Multi/Sub-Object** on page 6120, you can assign different sub-materials to different particles with the **Material Frequency operator** on page 3166. And to assign materials that change in appearance over time, use the **Material Dynamic operator** on page 3168.

Related to this is the **Mapping operator** on page 3175, which lets you give the same mapping coordinates to the entire surface of each particle in an event, thus using a single pixel from a material to color the particles. By animating the mapping coordinates, you can cause the particles to change color over time. This is particularly effective with a gradient material.
The Bitmap map on page 6213, used in conjunction with Material Dynamic, lets you assign different frames from an image sequence to particles based on the particle age, among other effects.

Following are some items to keep in mind when using materials with Particle Flow:

- A material is a static property of an event. It does not travel along with the particles from one event to the next. A particle's material ID does, but its material does not. If you want particles always to use the same material, define the material in the global event on page 8594 with a Material operator or a Shape Instance operator on page 3142. Otherwise, you need to define it in each local event.

- The primitive particle shapes available with the Shape operator on page 3137 do not have mapping coordinates. The Mapping operator on page 3175 applies the same mapping coordinates to each particle's entire surface, so it's not suitable in this situation. If you want to apply image-based materials to particles, use Shape Instance on page 3142 instead.

- If you use a Material operator with Shape Instance on page 3142, be sure to apply mapping coordinates to the reference object(s) on page 8700. You can do this by making sure the object's Generate Mapping Coords option is on (if available), or applying a UVW Map modifier on page 1932 or Unwrap UVW modifier on page 1837. If you don't apply mapping coordinates, the system generates a Missing Map Coordinates warning when you render the scene.

- If you use an object with a material already applied as a reference object on page 8700 for instanced particles, you don't need a Material operator in the same event. However, the material appears only in the event containing the Shape Instance operator on page 3142; it does not persist from event to event.

- If you use the Cache operator on page 3178 with Update set to Always, toggling the Material Editor > Show Map In Viewport switch causes Particle Flow to recalculate the cache.

- You can drag a material from the Material Editor to a Particle Flow source icon, but the material will not have any effect on the system. You must use a Material operator or Shape Instance to apply materials to particles in Particle Flow.

- Once you've assigned a material to a Material operator, the material shows up in the Material Editor as “hot”; that is, triangles appear in the corners of its sample slot. However, because of the nature of the Particle Flow data
structure, the Material Editor functions Select By Material and Get Material > Browse From Selected do not work correctly with Particle Flow systems. You can, however, use Get Material > Browse From Scene.

**Mapping Object Operator**

*Particle View* on page 3015 > Click Mapping Object in an event or add a Mapping Object operator to the particle system and then click it.

The Mapping Object operator assigns mapping to particles by taking mapping values from one or more reference objects. For every particle, the Mapping Object operator finds the closest point on reference geometry, takes the mapping values and material ID from this point, and then assigns these values to the particle.

If a particle enters the event with mapping already assigned, you can blend the mapping values to avoid a jump in color. Blending can occur either by time or by distance from the reference geometry.
**Type** Defines the timing used to acquire and apply the mapping. The options are:

- **Once on Event Entry**  Acquires the mapping once, from the closest point on the reference object geometry when the particle enters the event. Use this option if particles are locked to the reference surface.

- **Continuous**  Acquires the mapping continuously during the time a particle is in the current event. If a particle changes location with regard to the reference object, mapping values change according to the closest point at any given time because, in this case, the closest point on the surface is not constant. This option takes significantly longer to calculate, as the closest point has to be computed for every particle on every frame. Use this option only when necessary.

**Acquire Sub-Material Index** When on, the Mapping Object operator assigns the material ID from the nearest face to each particle. If the current event or a previous event has a material operator that uses the reference surface material, this option matches particle coloring to the reference surface. This allows you to blend particles to the reference surface for Multi/Sub-Object materials.

**TIP** Place the Mapping Object operator below a Material operator in the same event. This way, Mapping Object has the final word in assigning the sub-material index to a particle.

**Uniform Color Per Particle** When on, the whole particle gets the same mapping coordinates. As a result, the whole particle is of the same color since the mapping coords are the same across the particle shape. The mapping coordinates are taken from the surface point on the reference geometry nearest the particle pivot point.

When off, a mapping for a particle is a linear approximation of the mapping at the nearest surface point. It's as though mapping from the reference geometry is projected onto the particle. As a result, vertices of a particle have different mapping coordinates, and a texture on a particle represents a patch of texture from the reference geometry. This method is slower because it requires more complex analysis of the reference geometry.

**Mapping From Objects group**

These controls let you assign reference objects, from which particles acquire mapping or material IDs.

[List] Lists reference objects.
Add Adds an object to the list.

By List Displays a dialog where you can select multiple objects from a list.

Remove Removes a highlighted object from the list.

Static Objects Indicates that reference geometry is not animated in any way. In this case, the Mapping Object operator acquires mapping and material IDs only once.

Animated Surface When on, the Mapping Object operator updates the surface data at every frame, which is necessary if the reference geometry has surface animation that causes it to change shape. If the object has transform animation only (move, rotate, scale), leave this option off. This option is available only when Static Objects is off.

Mapping Channels Choose mapping channels to acquire from the reference surface and assign to particles. You can choose up to 32 channels.

Vertex Color Channel Acquires the Vertex Color channel from reference geometry and assigns it to particles.

Mapping Variation group

U/V/W Var % Enables variation of the mapping values assigned. The variation value is a percentage of the standard 0.0-1.0 mapping space. For example, if the U Var % value is 20.0, then the U mapping assigned to a particle can vary by up to 0.2 from the reference geometry mapping U value.

Exclude Tiling Clamps mapping values to the 0.0-1.0 range. Variations set by U/V/W Var % can cause mapping values to go below 0.0 or above 1.0. With non-tiling textures, this can cause a visual jump in coloring. When this option is on, if the original mapping value is below 1.0, then adding the variation won’t make it larger than 1.0. If the original mapping is above 0.0, adding the variation won’t make it smaller than 0.0.

By default, the acquired mapping values are assigned to a particle as soon as it enters the event. If particles have been assigned mapping values in a previous event, a visual color jump can result. Use Blend Mapping By Time or Blend Mapping By Distance to cause particles to smoothly blend between previous mapping and mapping assigned by the Mapping Object operator in the current event.

Blend Mapping By Time Causes particles to blend smoothly between previous and current mapping by time.
NOTE When Blend Mapping By Time is on, Blend Mapping By Distance is unavailable.

Type This option defines the timing used for map blending. It is available only when Blend Mapping By Time is on.

The types are:

- **Absolute Time**  Particles finish the blending process by the time they reach the frame specified by the Finish At Time parameter.

- **Particle Age**  Particles finish the blending process by the time they reach the age specified by the Finish At Age parameter.

- **Event Duration**  Particles will finish the blending process after they spend a specific period of time in the current event, as specified by the Finish At Time parameter.

- **Limited Change Rate**  Limits the rate at which a particle can change its mapping. The Turnaround Time parameter defines the time interval required to change the mapping value from its previous value to the current value. The greater the Turnaround Time value, the longer it takes for a particle to change to the current mapping.

**Blend Mapping By Distance** Causes particles to blend smoothly between previous and current mapping based on the distance from the reference geometry. At every frame, the operator calculates the distance to the closest surface point. As a particle approaches the reference surface, the blending process occurs. The blending is finished when a particle reaches the Finish Distance in relation to the reference surface. Use this option if particles are directed toward the surface upon entry into the event, as with a Find Target operator.

NOTE When Blend Mapping By Distance is on, Blend Mapping By Time is unavailable.

**Show Map In Viewport** Displays map coloring in viewports.

**Uniqueness Group of Controls**

The settings in this group change the randomization of the U Var, V Var, and W Var parameters in the Mapping Variation group.

**Seed** Specifies a randomization value.

**New** Generates a new seed using a randomization formula.
Material Static Operator

Particle View on page 3015 > Click Material Static in an event or add a Material Static operator to the particle system and then select it.

The Material Static operator lets you give particles material IDs that remain constant throughout the event. It also lets you assign a material to each particle based on its material ID. The operator can assign the same material ID to all particles, or different IDs to successive particles on a cyclical or random basis. The most common usage of this latter capability is with a Multi/Sub-Object material, for applying a different material to each particle.

■ Materials and Mapping in Particle View on page 3156
■ Material Frequency Operator on page 3166
■ Material Dynamic Operator on page 3168

Interface

![Material Static Operator Interface](image-url)
The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Assign Material** When on, the operator assigns a material to the particles. Default=on.

**button** Use this button to assign a material to the operator. Click the button and then use the Material/Map Browser to choose the material. Alternatively, drag the material from a Material Editor sample slot to the button. After you assign a material to the operator, its name appears on the button.

**Assign Material ID** When on, the operator defines a material ID number for each particle. Default=off.

**Show In Viewport** When on, the material is shown applied to the particles in the viewports.

**Assignment Method**

The Material Static operator gives you a choice of three different methods for assigning Material IDs to particles:

**Material ID** Assigns the same material ID to all particles. Use the numeric field to set the ID value.

**Cycle** Assigns each particle a material ID in the range 1 to N, where N=# Sub-Materials, in increasing sequential order. The first ID assigned is 1, then 2, then ..., then N, then 1 again, and so on.

**Random** Assigns each particle a random material ID in the range 1 to N, where N=# Sub-Materials.

# Sub-Materials The highest ID number assigned to particles using the Cycle or Random option.

In general, set this to the same number of sub-materials in the Multi/Sub-Object material. If you set it to a smaller number, the operator will use only that many sub-materials, starting with the first and counting upward.

**NOTE** Particle Flow automatically sets this value to the number of sub-materials in the material, once only, the first time you apply the material to the operator. Any subsequent changes in the material itself, or applying a different material to the operator, will not change or update the setting.
Rate group

These settings let you choose the basis on which the operator changes material ID assignments, and specify the rate of change.

Per Second Sets the number of times per second that the assigned material ID is incremented. If this value is the same as the rate at which particles enter the event, then one ID is assigned per particle. If it's lower, then multiple particles are given the same ID, or if it's higher, then Particle Flow increments the assigned ID faster than 1 per particle.

For instance, if particles enter the event at intervals of 1/60 of a second, and Per Second=30, then each pair of particles will be assigned the same ID. Or if particles enter the event at intervals of 1/15 of a second, and Per Second=30, then the ID is incremented (or changed randomly) twice per particle.

Per Particle Sets the number of particles that must appear before material ID assignment changes. For example, If you set Per Particle=3, the material ID changes every three particles.

If you set Per Particle to a number less than 1.0, Particle Flow then moves through the sub-material list more rapidly than one (or more) particle per ID. That is, Particle Flow divides this value into 1.0, and adds the result to the current material ID to obtain the next one. For example, with eight sub-materials, if you set Per Particle=0.33, and use the Cycle option, the following series of IDs will result: 1, 4, 7, 2, 5, 8, 3, 6, 1, ... In general, this option is useful only with the Cycle option.

Loop When on, and the last ID has been assigned, Particle Flow loops back around to the first ID and continues the cycle. When off, Particle Flow assigns the last cycle ID to all subsequent particles. Available only with the Cycle assignment method. Default=on.

For example, say you want the first eight particles that enter the event to use different materials, and all subsequent particles to use a ninth material. To do so, you would create a nine-sub-material Multi/Sub-Object material and assign it to the Material Static operator. Turn on Assign Material ID, choose the Cycle assignment method, and set # Sub-Materials=9. For Rate, use the default settings of Per Particle and 1.0. Lastly, turn off Loop.

Uniqueness group

The Uniqueness setting varies the sequence of assigned IDs with the Random option.
**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.

---

**Material Frequency Operator**

[Particle View](#) on page 3015 > Click Material Frequency in an event or add a Material Frequency operator to the particle system and then select it.

The Material Frequency operator lets you assign a material to an event, and specify the relative frequency with which each sub-material appears on the particles. Typically, the material is a Multi/Sub-Object or other compound material, and you specify the frequency by setting a percentage for each of up to 10 different sub-materials (or material ID). Particle Flow assigns IDs to particles in a random sequence, based on these percentages. You can also use other materials that use sub-materials, such as Double Sided and Top/Bottom.

See also:

- [Materials and Mapping in Particle View](#) on page 3156
- [Material Static Operator](#) on page 3163
- [Material Dynamic Operator](#) on page 3168
Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Assign Material** When on, the operator assigns a material to the particles. Default=on.

[button] Use this button to assign a material to the operator. Click the button and then use the Material/Map Browser to choose the material. Alternatively, drag the material from a Material Editor sample slot to the button. After you assign a material to the operator, its name appears on the button.

**Assign Material ID** When on, the operator defines a material ID number for each particle, and enables the remaining parameters. Default=on.

In general, this should remain on. Particle Flow uses the material ID with compound materials to know which sub-material to assign to a particle.
Show In Viewport  When on, the material is shown applied to the particles in the viewports.

# Sub-Materials  Displays the number of sub-materials in the assigned material.

Material ID #1–10  Specifies the relative likelihood of particles to be assigned the corresponding material ID. Assign values for all IDs, or sub-materials, in the material that you want to have applied to the particles. So, for example, with a Multi/Sub-Object material containing five sub-materials, you'd set values for Material IDs #1-5.

This value is not absolute, but relative to the other settings. To follow the previous example, if you wanted all five materials to appear with equal frequency, you'd set the same nonzero value for Material IDs #1-5; the actual value wouldn't matter. On the other hand, if you wanted the materials to appear with decreasing frequency, you'd set the lower Material ID settings to relatively higher values; say 100, 80, 50, 33, and 10. In this case, each particle would twice as likely to be assigned material ID 1 as it would material ID 3, and one-tenth as likely to be assigned ID 5 as it would ID 1.

The actual sequence of material ID assignments is random, and can be varied by changing the Uniqueness Seed setting.

Uniqueness group

The Uniqueness setting varies the random sequence of assigned IDs.

Seed  Specifies a randomization value.

New  Calculates a new seed using a randomization formula.

Material Dynamic Operator

Particle View  on page 3015 > Click Material Dynamic in an event or add a Material Dynamic operator to the particle system and then select it.

The Material Dynamic operator lets you give particles material IDs that can vary during the event. It also lets you assign a different material to each particle based on its material ID. When used with an animated texture  on page 8505, this lets you assign a different frame or map to each particle based on its total age or the amount of time it has spent in the current event. In this context, one example of an animated texture is a material that uses a multi-frame bitmap, such as an AVI file, as the Diffuse Bitmap map  on page 6213. Other examples of animated textures are materials that use the Particle Age map on
page 6306 or the Particle MBlur map on page 6308. Alternatively, you can use different sub-materials from a compound material such as Multi/Sub-Object.

**NOTE** When using Object Motion Blur, if an event contains a Material Dynamic operator that uses a material with a Particle Age/MBlur/Bitmap map, the event should not also contain a Delete operator, or a Spawn or Collision Spawn test. Also, the event should not contain any tests that are wired to another event. The only exception to this is the Age Test operator when set to Absolute Time without any variation; that is, all particles leave the event at the same time. This applies to the use of Object Motion Blur only; there are no restrictions with Image Motion Blur.

- Material Frequency Operator on page 3166

**Procedures**

**Example: To assign animation frames to particles based on age:**

1. Prepare a file to be used as the animated bitmap. This can be a multiple-frame format such as AVI, or an image file list (IFL file) that points to a sequence of still images. With the latter, you can use images in a format such as Targa that contain predefined alpha channels to specify particle opacity selectively.

2. Open the Material Editor, and assign a Bitmap map as the Diffuse map.

3. Use the Select Bitmap Image File dialog to assign the file from step 1 as the bitmap. This dialog appears automatically when you first assign a Bitmap map; alternatively, click the Bitmap button on the map's Bitmap Parameters rollout.

4. On the map's Time rollout, turn on Sync Frames To Particle Age.

5. If you want to use the image background or alpha channel to define transparency, on the Maps rollout, copy this map to the Opacity slot, and set the parameters accordingly.
At the material level, turn on Show Standard Map In Viewport.

Add a camera to the scene and set it up as desired. Activate the Perspective viewport and press the C key to set the viewport to show the camera view.

Create a default Particle Flow system.

Open Particle View.

Replace the Shape operator with a Shape Facing operator. Using this operator makes it easier to see the animation.

Click the Shape Facing operator, and in its rollout, click the Look At Camera/Object button, and then select the camera.

In the Size/Width group, increase In World Space > Units to about 15.

Add a Material Dynamic operator to Event 01, and assign it the material from the beginning of this procedure.

Turn on Show In Viewport.

In the Animated Texture group, make sure Same As Particle ID is chosen, and turn on Reset Particle Age.

Always choose Same As Particle ID with an animated texture, and one of the Sub-Material Rotoscoping options when using a compound material. Turning on Reset Particle Age causes Particle Flow to set particles to age 0 as they enter the event. In this example, the particles are born in the event, so technically it's not necessary to turn on Reset Particle Age. However, it's a good habit to get into to ensure that the animation always plays from the first frame.

Play the animation.

In the viewport, the bitmap animation advances as the particles move, but all the particles show the same frame, regardless of age. This is anomalous behavior related to the limitations of viewport interactivity. The particles render correctly, however.

Render the animation.

As each particle is born, it begins displaying the animation from the first frame. At each frame, each particle's age is incremented, and it displays the next frame from the applied map.
Example: To use the Particle Age map:

The Particle Age map on page 6306 applies up to three different colors or maps to particles throughout their life span, gradually changing from one to the next as the particles age. This effect can be used, for example for sparks flying from a fire: At first they're yellow; then, as they cool down, they turn red, and finally they become gray ashes. In order for Particle Age to know how far a particle has progressed through its life span, the particle has to be given a finite life. You do this using the Delete operator on page 3067.

1. Start or reset 3ds Max, and add a Particle Flow system.
2. Open Particle View and the Material Editor. Position them side by side.
3. In Particle View, add a Material Dynamic operator and a Delete operator to Event 01.
   For Particle Age to work, the Delete operator must be in the same event as the Material Dynamic operator. Alternatively, you can add the Delete operator to the global event on page 8594 so that it affects every event.
4. Click the Delete operator, and in the parameters panel, choose By Particle Age, and set Life Span=100 and Variation=0.
   This gives each particle a life span of 3 1/3 seconds.
5. Click the Material Dynamic operator.
6. In the Material Editor, assign a Particle Age map as the Diffuse map. On the Particle Age Parameters rollout, set three different colors, such as red, green, and blue. Also change the Age percentage values as necessary. For example, if you want each particle to show the second color a third of the way through its life instead of halfway, change Age #2 to 33.
7. Drag the active material from its sample slot to the material button on the Material Dynamic parameters rollout in Particle View. When the Instance (Copy) dialog appears, click OK to accept the default choice: Instance.
8. In the Material Dynamic parameters, make sure Assign Material ID is on.
   If it isn’t, the particles all change color at the same time.
   There’s no need to turn on Show In Viewport; the Particle Age map doesn’t appear in the viewports.
9. Render the animation, or a few representative frames.
   As each particle falls, it gradually changes color, with the oldest particles changing first.
TIP You needn't actually delete the particles to use this method. There are several ways to avoid this. You could set Life Span to a higher number than the length of the animation, and then, in the Particle Age map parameters, lower the Age #2 and Age #3 settings. Or, if you're using a local Delete operator, you could use an Age test on page 3235 to move the particles into another event just before they're scheduled to be deleted. In that case, to avoid an abrupt color change, you might want to add to subsequent events a Material Static operator on page 3163 with a material that uses the same final color or map as the Particle Age map.

Interface

![Interface illustration](image-url)
The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Assign Material** When on, the operator assigns the specified material (see next parameter) to the particles. Default=on.

[button] Use this button to assign a material to the operator. Click the button and then use the Material/Map Browser to choose the material. Alternatively, drag the material from a Material Editor sample slot to the button. After you assign a material to the operator, its name appears on the button.

**Assign Material ID** When on, the operator defines a material ID number for each particle. Default=on.

In general, this should remain on. Particle Flow uses the material ID with the Particle Age map to find the particle's other properties, including its life span and current age. And it uses the material ID with compound materials to know which sub-material to assign to a particle.

**Show In Viewport** When on, the material is shown applied to the particles in the viewports when the particles are displayed as geometry.

**Assignment Method**

The Material Dynamic operator lets you assign Material IDs to particles in several different ways, depending on whether you're using an animated texture or a compound material. Default=Same As Particle ID.

**Animated Texture group**

**Same As Particle ID** Assigns the same material ID to a particle as its particle ID. Choose this when using a material containing an animated texture, such as a Bitmap, Particle Age, or Particle MBlur map.

**NOTE** Particle Flow assigns Particle IDs consecutively to particles at birth, starting with 0. Although the highest possible Particle ID is over 2,000,000,000, the highest possible material ID is 65535. Thereafter, the numbering sequence starts again at 0. Thus, when using a Particle Age map in a material assigned to the Material Dynamic operator, for best results, use a total of 65,536 particles or fewer.

**Reset Particle Age** When on, sets each particle's age to 0 when it enters the event.

When using an animated material with a Bitmap map, turn this on to ensure that the animation always plays from the first frame.
Randomize Age Offset When on, Particle Flow varies the difference between the particle age and the starting material ID at random. The maximum difference is determined by the Max Offset parameter.

Max Offset The maximum number of frames by which Particle Flow can randomly vary particle age.

Sub-Material Rotoscoping group

These settings let you choose the basis on which the operator changes material ID assignments when using a compound material such as Multi/Sub-Object, and specify the rate of change.

Material ID Assigns the same material ID to all particles. Use the numeric field to set the ID value.

Cycle Assigns each particle a material ID in the range 1 to N, where N=# Sub-Materials, in increasing sequential order. The first ID assigned is 1, then 2, continuing to increment each by 1 until N; then 1 again, and so on.

Random Assigns each particle a random material ID in the range 1 to N, where N=# Sub-Materials.

# Sub-Materials The highest ID number assigned to particles using the Cycle or Random option.
In general, set this to the same number of sub-materials in the Multi/Sub-Object material. If you set it to a smaller number, the operator will use only that many sub-materials, starting with the first and counting upward.

NOTE 3ds Max automatically sets this value to the number of sub-materials in the material, once only, the first time you apply the material to the operator. Any subsequent changes in the material itself, or applying a different material to the operator, will not change or update the setting.

Rate Per Sec(ond) Sets the number of times per second that the assigned material ID is incremented. If this value is the same as the rate at which particles enter the event, then one ID is assigned per particle. If it's lower, then multiple particles are given the same ID, or if it's higher, then Particle Flow increments the assigned ID faster than 1 per particle.
For instance, if particles enter the event at intervals of 1/60 of a second, and Per Second=30, then each pair of particles will be assigned the same ID. Or if particles enter the event at intervals of 1/15 of a second, and Per Second=30, then the ID is incremented (or changed randomly) twice per particle.
Loop When on, and the last ID has been assigned, Particle Flow loops back around to the first ID and continues the cycle. When off, Particle Flow assigns the last cycle ID to all subsequent particles. Available only with the Cycle assignment method. Default=off.

For example, say you want the first eight particles that enter the event to use different materials, and all subsequent particles to use a ninth material. To do so, you would create a nine-sub-material Multi/Sub-Object material and assign it to the Material Dynamic operator. Choose the Cycle assignment method, and set # Sub-Materials=9. Set the Rate Per Sec value to the rate at which particles enter the event. Lastly, turn off Loop.

Sync By Choose the time frame for applying animated parameters. Available only with the Material ID and Cycle options.
- Absolute Time Any keys set for parameters are applied at the actual frames for which they're set.
- Particle Age Any keys set for parameters are applied at the corresponding frames of each particle's existence.
- Event Duration Any keys set for parameters are applied to each particle starting when it first enters the event.

Rand Offset When on, Particle Flow varies the difference between the particle age and the assigned material ID at random. The maximum difference is determined by the numeric parameter. Available only with the Material ID and Cycle options.

Uniqueness group
The Uniqueness setting varies the sequence of assigned IDs with the Random option, and the offset with the Randomize Age Offset option.
Seed Specifies a randomization value.
New Calculates a new seed using a randomization formula.

Mapping Operator
Particle View on page 3015 > Click Mapping in an event or add a Mapping operator to the particle system and then select it.

The Mapping operator lets you assign a constant UVW mapping to the entire surface of the particles. It works in conjunction with a map specified in a material operator in the current event. By animating the mapping coordinates,
you can vary the location on the material map from which the particle color is taken, thus changing the particle color in a predictable way over time.

The Mapping operator was designed primarily to be used with gradient maps, although you can use it with any map you like. The procedure below describes a recommended method for using the Mapping operator.

See also:

- Material Static Operator on page 3163
- Material Frequency Operator on page 3166
- Material Dynamic Operator on page 3168

Procedures

Example: To animate particle coloring using the Mapping operator:

1. Open the Material Editor, and create a material that uses Gradient Ramp as the Diffuse map.
2. On the map’s Gradient Ramp Parameters rollout, make sure Gradient Type is set to Linear.
3. Create a colorful gradient. The Mapping operator uses the colors in left-to-right order as the U value increases from 0.0 to 1.0.
4. Add a Particle Flow Source object to the scene.
5. Open Particle View.
6. In Event 01, click the Speed operator and set Speed to 100.
7. In Event 01, click Display and set Type to Geometry.
8. Add a Material Static operator to Event 01, and then click the operator in the event.
9. Drag the material you created from its Material Editor sample slot to the button (labeled “None”) on the Material Static parameters rollout in Particle View.
10. Add a Mapping operator to Event 01, and then click the operator in the event.
11. On the Mapping rollout in Particle View, turn on Show Map In Viewport.

12. Go to frame 100 and turn on Auto Key.

13. On the Mapping rollout in Particle View, set Map Values > U=1.0.

14. For Sync By, choose Particle Age.

15. Turn off Auto Key, and click Play Animation.

As each particle is born and falls, its U mapping coordinate gradually changes from 0.0 to 1.0, while its color changes to match the corresponding position across the Gradient Ramp map.

To vary the effect, try changing the Gradient Type setting, and animate the V and W values as well. Or, for more sophisticated effects, assign animation controllers such as Noise Float to the Mapping coordinate values, or wire them to other changing parameters in the scene (Animation menu > Wire Parameters > Parameter Wire Dialog).

**TIP** In the Material Editor, it’s easier to see the result of the Gradient Type choice if you set Sample Type to Cube.

**Interface**

The user interface appears in the parameters panel, on the right side of the Particle View dialog.
Map Values group

U/V/W Set the coordinates on the map from which the particle color is taken. One pixel from this location is used to color the entire particle.
In general, U and V represent the horizontal and vertical dimensions, respectively, beginning at the upper-left corner of the map, and W is useful only with three-dimensional maps, in which context it specifies depth.

Sync By Choose the time frame for applying animated parameters. For further information, see Animation Offset Keying group on page 3106.
- Absolute Time Any keys set for parameters are applied at the actual frames for which they’re set.
- Particle Age Any keys set for parameters are applied at the corresponding frames of each particle’s existence.
- Event Duration Any keys set for parameters are applied to each particle starting when it first enters the event.

Channel group

The Channel setting determines whether the mapping is applied to a map channel or to a vertex color channel.

Map Channel The mapping is applied to the specified map channel.

Vertex Color Channel The mapping is applied to the particles’ vertex color channel.

Show Map In Viewport The map coloring is visible in the viewports.

Additional Operators

The operators described in this section are utilities to help you manage Particle Flow systems.

Cache Operator

Particle View on page 3015 > Click Cache in an event or add a Cache operator to the particle system and then select it.
The Cache operator records and stores particle states to memory. This is particularly useful with large or complex particle systems, where playback, and particularly backtracking, are slow because of the large amount of processing required.

When Cache is in effect, the first time you play or go to a frame, the particle motion up to and including the frame is calculated and recorded in the cache. Thereafter, playing the frame or any previous frames uses the data in the cache, rather than recalculating the particle action. With caching on, the particle system needs to be calculated only once for each frame, and thereafter playback and moving among frames is significantly faster.

To cache an entire flow, add a Cache operator to the global event. To cache an individual local event, add a Cache operator to it.

To determine how best to implement caching in your particle system, turn on Particle View > Track Update > Update Progress, and then play the animation or go to a frame relatively distant from the current frame. Observe the particle diagram, and watch for events with actions that highlight longer than a fraction of a second, or events with more activity than the rest. Any such events could benefit from caching.

**NOTE** Use no more than one Cache operator per event, unless you’re using two: one set up for viewports, and the other for rendering. Similarly, don’t use global and local Cache operators in the same flow, unless one is set up for viewports, and the other for rendering.

**TIP** When using real-time playback, if playback isn’t fast enough, you can use the Cache operator to speed it up. For best results, set the Viewport integration step to the same value as the real-time playback speed, and set cache sampling to Integration Step. For example, if the real-time playback speed is set to 1/4x, then the Viewport Integration Step for viewport should be also set to 1/4 Frame, and the Cache operator Sampling parameter should be set to Integration step. Thus, because real-time playback is showing four times as many frames per second, and the Cache operator has stored four times as many frames per second, the two are synchronized. If the real-time playback speed is set to 2x or 4x, set the Viewport Integration Step to Frame.

**Procedures**

**Example: To use the Cache operator:**

1. Start or reset 3ds Max, and then add a Particle Flow system.
2. Open Particle View.
3 In Particle View, go to Options menu > Track Update and turn on Update Progress.
This lets you monitor calculation of the particle system by highlighting actions in Particle View as the system executes them.

4 In Particle View, Add a Keep Apart operator on page 3131 to Event 01. Keep Apart is a fairly calculation-intensive operator.

5 Go to frame 100 by clicking the right end of the time slider track. There is a delay as the system calculates all particle motion between frames 0 and 100. This is necessary because Particle Flow is a history-dependent system. At the same time, the actions in the system highlight briefly in Particle View as they're executed at each frame.

6 Go to frame 50 by clicking the center of the time slider track. There is another delay as the system calculates all particle motion between frames 0 and 50.

7 In Particle View, drag a Cache operator from the depot to Event 01. Insert it anywhere in the event. When you release the mouse button, there is a delay as the Cache operator automatically caches particle motion from the start of the animation to the current frame. Meanwhile, each action highlights briefly at each frame.

8 Go to frame 20 or so. The only operators that highlight are Cache (very fast) and Display; there is no delay for calculation. All frames between 0 and 50 have been cached.

9 Go to frame 100. The delay this time is a result of caching particle motion for frames 50 to 100.

10 Jump to different frames, and drag the time slider. All particle motion is now cached, so no delays occur. But if you change a setting's value, the Cache operator automatically recalculates and stores the particle motion.

11 Go to frame 100, and then, in Particle View, click the Keep Apart operator and use the keyboard to change the Falloff Zone value to 8.0. By default, the Cache operator automatically updates the cache when you change any parameters it stores. Thus, when you change the Falloff Zone value at frame 100, it recalculates and recaches the entire animation.
Next, you'll briefly explore how manual caching works.

12 Click the Cache operator and set Update to Manually.
   The Cache operator no longer updates the stored data automatically when you change a parameter.

13 Click the Keep Apart operator, change the Falloff Zone value to 9.0, and then drag the time slider.
   There is no delay, because the animation is still playing back from the cached data. However, the cached data is now invalid, because you changed a parameter in the particle system.

14 Click the Cache operator, and in the Manual Update group, click Update.
   3ds Max closes Particle View, updates the cache for the active segment, and then reopens Particle View. The cached data is now accurate.
   Other manual update options let you update the cache for the entire animation or a custom frame range.
   As you can see, the Cache operator is quite powerful. When present and active, by default it overrides recalculation of the particle system, except when you change any action parameters, whereupon it automatically updates the cached data. Used appropriately, it can save a good deal of time in setting up and testing particle systems.
The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Use At** Caches particle motion when playing back in the viewports, or at render time, or both. Default = Viewport.

**IMPORTANT** Choose the Viewport/Render option only when using the same number of particles in the viewports and for rendering (see Quantity Multiplier group on page 3038). Otherwise, unpredictable results can occur.
Update If you change a parameter in the particle system, the cached data might become invalid. This setting determines whether Particle Flow should update the cache automatically, or let you do it manually. Default=Always.

- **Always** Changing any parameter under the Cache operator's purview causes it automatically to update stored data from the start of the current range (see next parameter) to the current frame.

- **Manually** Updating occurs only when you click the Update button, or clear the cache and then move to a different frame.

**Range** Sets the frame range within which the Cache operator operates. Default=Active Segment.

- **Complete** Particle Flow caches the entire animation.

- **Active Segment** Particle Flow caches only frames in the active segment, as defined by the Start Time and End Time settings on the Time Configuration dialog. This is the frame range shown on the track bar. You can also change the active segment by holding down Alt and Ctrl and dragging the track bar with the left, middle, or right mouse button.

- **Custom** Particle Flow caches only frames in the custom range, as defined by the Cache operator's Start Time and End Time settings (see following).

**NOTE** If you cache only part of the animation, Particle Flow calculates particle behavior in subsequent, non-cached frames using the cached data. For example, if you cache frames 0 to 50, and then jump to frame 60, Particle flow will calculate frame 51 based on the cached data, and frames 52 to 60 based on each previous frame.

**Start/End Time** The first and last frames of the range considered for caching when Range=Custom (see above). Default=0, 30.

**NOTE** The frame range time frame is in absolute time; that is, in terms of the entire animation. If you use a Cache operator locally, and specify a frame range during which no particles are present in the event, Particle Flow won’t use the cache.

**Sampling** Determines how often the Cache operator samples and caches the animation. Default=Every Frame.

- **Every Frame** Particle Flow caches animation data once per frame.

- **Integration Step** Particle Flow caches animation data at each integration step, using the Integration Step setting as specified in the Use At setting.
(see above). If Use At is set to Viewport/Render, it uses lower of the two Integration Step values. For example, if Viewport is set to Half Frame, and Render to 1/8 Frame, the sampling rate would be eight per frame.

■ **Every Nth Frame**  Particle Flow caches animation data at frame intervals specified by the N value, below.

N Determines the frame interval for caching when Sampling (above) is set to Every Nth Frame. Default=5.
For example, with N set to the default value of 5, the cache stores animation data for every fifth frame.

**Cache Test Results**  When caching particle data, this caches the results of test actions as well. Default=on.
This is important if Cache is used as a local operator, and the next event doesn’t have a Cache operator. For the next event to work properly, it should receive particles from the current event. Those particles result from the activity of a test action. The Cache operator can record the test activity to play it back later.
If the Cache operator is used as a global operator, there is no need to cache the test results. This is because the system has cache data for every event, and is able to jump to an arbitrary frame without the need for test results.

**Save Cache with File**  When on, Particle Flow Includes the cached data with scenes that you save to disk. This can significantly increase the size of saved files, but saves the time of recalculating the particle motion upon reloading the file. Default=off.
Normally, the cached data is saved only in disk files that you create with the Save or Save As commands. You can also instruct 3ds Max to include cached data with other types of files using the two following options.

**Save Cache with Hold**  Saves cached data in the Hold file, created with Edit menu > Hold. Default=off.

**Manual Update group**

These controls let you update or clear the cache manually within a frame range, or clear the entire cache.

**Update**  Calculates particle motion within the current range (defined below) and stores it in the cache, replacing any existing cached data. Available only when Range is set to Active Segment or Custom.
During the update, 3ds Max temporarily closes Particle View and displays a Cache Update Progress bar, while moving the time slider through the cached
range. At the same time, by default, the animation plays in the viewports. To prevent this, and speed calculation, turn off Update Viewports.

If the cache runs out of memory during a manual update, Particle Flow halts the update operation and displays an alert. Click OK to continue, and then, if possible, increase the Limit value before updating the cache again.

**Clear** Deletes any cached data.

After you clear the cache buffer, if you go to a different frame or change any action parameters, Particle Flow automatically caches particle motion even if Update is set to Manually.

**Range** Sets the frame range within which the Cache operator recalculates data when you click Update. Default=Active Segment.

- **Complete** Particle Flow clears the cache for the entire animation. Choosing Complete makes the Update button unavailable; this option is for clearing the cache only.
  
  To update the entire animation, set the active segment or the custom range to encompass all frames, and then use the corresponding choice and click Update.

- **Active Segment** Particle Flow updates the cache only for frames in the active segment, as defined by the Start Time and End Time settings on the Time Configuration dialog. This is the frame range shown on the track bar. You can also change the active segment by holding down Alt+Ctrl and dragging the track bar with the left, middle, or right mouse button.

- **Custom** Particle Flow updates the cache only for only frames in the custom range, as defined by the Start Time and End Time settings (see following).

**Start/End Time** The first and last frames of the range that’s updated when Range=Custom (see above). Defaults=0, 30.

**Update Viewports** When on, the animation plays in the viewports during manual updating of the cache. Turn this off to disable playing the animation in the viewports during manual caching; this can speed up the caching process, especially with large or complex particle systems. Default=on.

**Memory Used (K) group**

The Cache operator stores data in system memory; you can specify an upper limit for the amount of memory it uses. If the Limit setting and the amount of cached data exceeds the available free memory, the computer system might
use virtual (hard disk-based) memory instead, which slows down the caching. If Particle Flow fills the cache, any remaining frames are calculated on the fly. This group also lets you monitor the amount of memory used for caching data.

**Limit** The maximum amount of system memory used to cache particle data, in kilobytes. Default=100,000, or 97.6 MB.

**Total** The amount of memory currently used by the cached data, in kilobytes. Read-only.

**NOTE** Even animation frames with no particles will probably consume a certain amount of cache memory. The reason for this is that the cache also stores states for randomly calculated values such as Variation, to ensure that particle activity is consistent across a rendering network, and with machines that might not have regular access to all frames.

**Current Frame** The amount of memory used by the data cached for the current frame, in kilobytes. Read-only.

### Display Operator

**Particle View** on page 3015 > Click Display in an event or add a Display operator to the particle system and then select it.

The Display operator lets you specify how particles appear in the viewports. The default display mode is Ticks, which is the simplest, and thus the fastest to display. It’s useful for animations that use a large number of particles. At the opposite end of the complexity spectrum is the Geometry option, which lets 3ds Max depict particles as their actual shapes. In addition, the Display operator provides a variety of simple shapes that provide fast feedback in testing animation, as well as the ability to easily distinguish among particles in different events. It also lets you set the percentage of visible particles.

By default, Particle Flow automatically inserts a new Display operator in each local event you add to the system. Alternatively, you can choose Particle View > Options menu > Default Display > Global. With this option, Particle Flow automatically inserts a Display operator in new global events, but does not add one to new local events.

Particles in any local event that doesn’t contain a Display operator don’t appear in the viewports, unless an associated global event contains a Display operator (that is, a global Display operator). If a particle is affected by multiple Display
operators (for example, both global and local operators) simultaneously, 3ds Max generates all viewport particle representations at the same time.

See also:

- Render Operator on page 3194

Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

Type Choose how particles appear in the viewports. The two-dimensional particle markers depict position only. Geometry shows how particles will actually render, in three dimensions; Lines shows speed and direction of motion; and Bounding Boxes reflects scale and orientation.

In the following list, each choice's description is preceded by the number of dimensions used by each particle representation:

- **None**  
  Particles do not appear in the viewports.

- **Dots** (0D)  
  Each particle appears as a single pixel.

- **Ticks** (2D)  
  Each particle appears as a + sign.

- **Circles** (2D)  
  Each particle appears as a small circle.

- **Lines** (1D)  
  Each particle appears as a line, one pixel thick. The line's length indicates particle speed, and its orientation reflects the direction of motion. Use this option for fast, accurate feedback when experimenting with the Speed operators.
TIP When using the Lines display type with the OpenGL display driver, slow-moving particles might not appear properly in the viewports. In such cases, to see all particles, add a second Display operator in the same event and set its Type to Dots.

- **Bounding Boxes** (3D) Each particle appears as a bounding box. Use this option for a good representation of the final animation, at a slight cost in computational speed.
- **Geometry** (3D) Each particle appears as its actual geometry. Use this option for the best representation of the final animation, at the greatest cost in computational speed.
- **Diamonds** (2D) Each particle appears as a diamond.
- **Boxes** (2D) Each particle appears as a small square.
- **Asterisks** (2D) Each particle appears as an asterisk (*).
- **Triangles** (2D) Each particle appears as a small triangle.

**Visible %** Specifies the percentage of particles visible in the viewports. This option lets you speed up viewport redrawing by reducing the number of visible particles.

**Show Particle IDs** When on, each particle's unique index number is visible in the viewports. Particles are numbered in the order of their birth, starting with 1 for the first particle born.

[**[color swatch]**] Shows the color for particles displayed using options other than Geometry, as well as for the particle IDs. Particle Flow chooses a different color at random for each Display operator added to the system. In addition to the Type options, using different colors helps to distinguish among particles in different events.

To change the color, click the color swatch and use the Color Selector dialog to choose a new color.

If a system has a global Display operator, and you select its Source icon in a viewport, then you can change the color of the global Display operator from the color swatch on the Modify panel. However, changing the global Display operator's color in Particle View does not change the color of the swatch on the Modify panel.
NOTE When a Particle Flow source icon is selected, all of its non-selected particles, other than those shown as geometry, are colored white in the viewports. To see all assigned particle colors, deselect the particle system.

Selected Choose how selected particles appear in the viewports. The choices are the same as for Type, above.

**Force Operator**

**Particle View** > Click a Force operator in an event or add a Force operator to the particle system and then select it.

The Force operator lets you influence particle motion with one or more space warps from the Forces category. Use this operator along with different forces to simulate the effects of wind, gravity, and so on.

The following force space warps work with the Force operator:

- **Displace** on page 2930
- **Drag** on page 2908
- **Gravity** on page 2923
- **Motor** on page 2898
- **PBomb** on page 2914
- **Push** on page 2894
- **Vortex** on page 2903
- **Wind** on page 2926

**NOTE** By default, the influence of these space warps on Particle Flow particles is equivalent to their influence on the 3ds Max 2 particle systems: PArray, Super Spray, Blizzard, and PCloud. To obtain an influence on Particle Flow particles equivalent to that of the 3ds Max 1 particle systems Snow and Spray, set **Influence** on page 3192 to **100.0**.

**TIP** To make the particles follow a path, use the **Speed By Icon operator** on page 3112 and use Path Constraint to assign its icon to the path. For a procedure, see **Example: To send particles along a path** on page 3114.
To employ deflectors for particle dynamics, with or without the Force operator, use the Collision test on page 3236 and Collision Spawn test on page 3241.

**Script Wiring rollout**

This rollout appears in the parameters panel below the main operator rollout after you highlight the operator, right-click it, and then choose Use Script Wiring. Thereafter, a check mark appears next to the Use Script Wiring in the right-click menu, and the rollout appears whenever you highlight the operator. To turn off script wiring, choose Use Script Wiring again from the right-click menu.

Script wiring lets you use a script to control parameters that you normally specify in the operator's parameters. Place a Script operator on page 3196 before the Force operator in the event, and then use it to define values in the particleFloat channel. You'll find an example script below.

**Use Script Float As** Choose either of the following:

- **Not Used**  Particle Flow uses the Influence setting on page 3192 specified in the Parameters rollout.

- **Influence**  Particle Flow applies the script to the Influence setting.

**particleFloat Sample Script**

**NOTE**  See this topic in the online User Reference for the particleFloat sample MAXScript code.

**Procedures**

**To affect particle motion with force space warps:**

1. Add one or more force space warps to the scene, and set them up as necessary.

2. In Particle View, add a Force operator to any events in which particles are to be affected by the forces. To affect particles in all events, add the Force operator to the PF Source instead.

3. Highlight the Force operator, and then use the Add or By List button to apply the force space warps to the operator.
Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Force Space Warps group**

This group displays the forces currently in effect, and let you add and remove forces.

[List] Shows the forces that apply to this operator. If more than three forces apply, a scroll bar appears at the right side of the list.

If you delete a listed space warp from the scene, its name is replaced in the list by the entry “<deleted>”.

**NOTE** Particle Flow applies the forces to particle motion in the order in which the space warps appear in the list; the effect is cumulative in top-to-bottom order. First, the topmost space warp is applied to particle motion, then the second space warp is applied to the result of the first space warp, and so on. Changing the order can alter the final result.

Add Click this button, and then select a force space warp in the scene to add it to the end of the list.
By List  Click this button, and then use the Select Force Space Warps dialog to add one or more space warps to the list. The space warps must already exist in the scene.

Particle Flow adds space warps to the list in same order in which they appear in the dialog. To effect a different order, use the Add button to add them one at a time.

Remove  Highlight a space warp in the list, and then click this button to remove it from the list. Any removed space warps remain in the scene.

Force Field Overlapping  Determines how multiple forces that occupy the same volume of space affect the particles. With Additive, the forces are combined according to their relative strengths. With Maximum, only the force with the greatest strength affects the particles.

For example, you might apply Wind and Gravity space warps to particles, and set their Strength parameters to 1.5 and 1.0, respectively. If you choose Additive, the Wind space warp will have approximately 50 percent more influence over the particles than the Gravity space warp. But if you choose Maximum, only the Wind space warp will affect the particles.

Influence  Specifies the strength with which the force or forces are applied to the particles as a percentage. Default=1000.0.

A negative Influence value reverses the force effects.

NOTE  By default, the influence of the Force space warps on Particle Flow particles is equivalent to their influence on the 3ds Max 2 particle systems PArray, Super Spray, Blizzard, and PCloud. To obtain an influence on Particle Flow particles equivalent to that of the 3ds Max 1 particle systems Snow and Spray, set Influence=100.0.

Offset Influence group

Choose the time frame for applying animated parameters. For an explanation, see Animation Offset Keying group on page 3106.

Sync By  Choose the time frame for applying animated parameters:

■ Absolute Time  Any keys set for parameters are applied at the actual frames for which they’re set.

■ Particle Age  Any keys set for parameters are applied at the corresponding frames of each particle’s existence.

■ Event Duration  Any keys set for parameters are applied to each particle starting when it first enters the event.
Notes Operator

Particle View on page 3015 > Click Notes in an event or add a Notes operator to the particle system and then select it.

The Notes operator lets you add a textual comment to any event. It doesn’t have any direct effect on the particle system, but it helps you keep track of the overall function of each event.

NOTE You can also add a comment directly to an event or action by right-clicking it and choosing Comments.

Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

The interface is a simple text box. Click in the box and enter your text.
Render Operator

Particle View on page 3015 > Click a Render operator in an event or add a Render operator to the particle system and then select it.

The Render operator provides controls related to rendering particles. You can specify the form that rendered particles are to take, and how to convert the particles to individual mesh objects for rendering purposes.

**Interface**

![Render Operator Interface](image)

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Type** Lets you render particles as bounding boxes or geometry, or disable the particle system at render time, or enable the particle system but prevent it from sending renderable particles to the 3ds Max renderer. Default=Geometry.

- **None**  The particle system (or event, if used locally) is considered non-renderable, and therefore is never evaluated during render.

- **BoundingBox**  Particles render as boxes whose sizes represent the particle geometry extents. Use this option with complex particle systems to speed up test renders.

- **Geometry**  Particles render with their actual geometry. Use this option with simpler particle systems, and for the final render.

- **Phantom**  Use this option when you want Particle Flow to function normally, calculating the animation at each frame, but not to render geometry directly. An example would be when you're using a Final Step...
Update script on page 3043 to pass data from the particle system to other objects in the scene.

Visible % The percentage of particles that render. Range=0 to 100. Default=100. Lower this value for faster rendering of complex particle systems. You can also reduce the number of particles in the system at render time with the Quantity Multiplier > Render setting on page 3038.

**Render Result group**

These settings determine how the system converts particles to mesh format for rendering. By default, 3ds Max renders all particles as a single mesh per event, which provides for the most efficient operation under most conditions. However, in some situations each particle should be converted to an individual mesh object by turning on Mesh Per Particle. For example, with particles each of whose face count exceeds 10,000, it’s most efficient to render a mesh per particle. Alternatively, you can opt to combine particles into multiple meshes by specifying a face count and number of particles per mesh.

Certain renderers might require a non-default setting for Render Result. Consult the renderer documentation for further information.

---

**NOTE** The number of particles Particle Flow can handle per frame is limited only by system resources, but each single mesh is allowed a maximum of 5,000,000 faces or vertices. If the total number of faces or vertices in a mesh exceeds 5,000,000, Particle Flow ignores particles beyond this limit.

**Single Mesh** Sends the renderer one mesh object comprising all particles in the system.

**Multiple Meshes** Sends the renderer the specified number of mesh objects, each containing the specified number of particles. If the result of dividing the total number of particles by the Particles p/Mesh value is less than the specified Mesh Count value, some of the meshes might contain few or no faces. This is a compromise method of operation, and can be used with renderers that cannot handle all particles in a single mesh, but can deal with groups of particles of a certain size.

**Mesh Count** The maximum number of mesh objects that Particle Flow will send to the renderer.

**Particles p/Mesh** The number of particles that each mesh object will comprise.

**Mesh Per Particle** Sends the renderer a separate mesh for each particle.
This is the least efficient method of operation, but might be required by certain renderers.

NOTE With the default scanline and mental ray renderers, this method does not support rendering of particles born after the start of the rendered frame sequence. In general, use Mesh Per Particle only with renderers that require it.

**Script Operator**

*Particle View* on page 3015 > Click Script Operator in an event or add a Script Operator to the particle system and then select it.

The Script operator enables control of particles within the Particle Flow system using a MAXScript script. The script can use any program functionality available to MAXScript.

When you add a new Script operator, it contains a default script that slows particles, and then, when they are slow enough, splits off the first 50 particles into a stream traveling in a negative direction on the world X axis, and the remainder traveling in the opposite direction.

**TIP** You can use MAXScript to align particle scale with the underlying bitmap, thus providing a “scale bitmap” function. This requires a sandwich with three operators: two Script operators, and a Speed By Surface operator in between. The first Script operator reads the current speed vector into the MXVector channel, thus caching the current speed. The Speed By Surface operator changes the speed according to the underlying bitmap. And the second Script operator reads the speed channel into a temporary variable, restores the speed from the MXVector channel (the cached value), and uses the temporary variable to define the scale. This way, the original speed is restored, and the scale value is defined by the bitmap.

**Interface**

![Script Operator Interface](image)
The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Edit Script** Click this button to open the current script in a MAXScript Editor window.

For detailed information about the MAXScript utility, open the MAXScript Help, available from Help menu > MAXScript Help.

**Uniqueness group**

The Uniqueness setting provides a randomization seed that the script can use or ignore.

**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.

**Painting Particles**

New in Particle Flow is the ability to generate particles from specific locations by “painting” particle generators, or seeds, on object surfaces. The toolset for doing so includes the Particle Paint helper and the Placement Paint operator.

**Particle Paint**

The Particle Paint toolset lets you use a spray-paint metaphor to specify arbitrary areas of object surfaces for emitting particles. To paint particles, you first apply particle “seeds” to one or more objects with the Particle Paint helper, and then use other controls to specify how the seeds should generate particles.

**Particle Paint Helper**

Create panel > Helpers > Particle Flow > Particle Paint

The Particle Paint helper enables you to apply particle seeds with a specific pattern and timing onto the surface of one or more objects.
Particle seeds painted with the Particle Paint helper are not particles, but are seeds that can be turned into particles with the Birth Paint or Placement Paint operators in Particle Flow.

You can spray particle seeds with a freehand painting tool, or by using 3ds Max splines to define the pattern. Particle Paint works in any orthogonal viewport such as a Front or Top view. It sprays directly into the viewport (that is, perpendicular to the plane of view), and plants particle seeds on the surface of first object that it hits.

**Particle Paint Icon**

To create the Particle Paint icon, click Create panel > Helpers > Particle Flow > Particle Paint, and then drag in a viewport.

The Particle Paint icon is composed of two parts: a circle and a spray can icon.

The Particle Paint helper uses the metaphor of a real-world airbrush to spray-paint particle seeds onto a surface. When you use the Freehand paint tool, particle seeds are sprayed through a virtual nozzle, as with an airbrush. The circle in the Particle Paint icon represents the size of the nozzle. If, on the other hand, you use stroke splines, the particle seeds are sprayed along the spline.

The Particle Paint icon does not have to sit in front of or on the objects on which you plan to paint particle seeds, nor does it have to be created in the viewport in which you plan to paint.

Deleting the Particle Paint icon deletes all particle seeds and strokes associated with it.
Strokes

The Particle Paint helper works with particle groupings called *strokes*. With a real-world airbrush, each time you depress the nozzle, spray, then release the nozzle, you create a stroke. With the freehand tool, you can drag across objects several times to create strokes. With the spline method, you can pick several splines to create different strokes.

Each set of strokes stored with the Particle Paint helper can be used as a series of birth instructions with the “Birth Paint” on page 3222 and “Placement Paint” on page 3224 operators in Particle Flow. You can work with each stroke separately to adjust its timing, delete some of its particles, and perform other operations. To edit particle seeds and strokes after creating them, select the Particle Paint helper and then access the Editing rollout on the Modify panel.

You can undo the creation of strokes, and you can also delete particle seeds or change particle seed timing with the options on the Editing rollout. You can also restart by deleting the Particle Paint helper and creating a new one.

Procedures

**Example: To create strokes with freehand painting:**

1. Create a sphere in the Top viewport.
2. Click Create panel > Helpers > Particle Flow > Particle Paint, and drag in any viewport to create the Particle Paint helper.
3. With the Particle Paint helper selected, go to the Modify panel.
4. On the Setup rollout, click Freehand Paint.
5. In the Front viewport, position the mouse cursor over the sphere. A set of nozzle crosshairs appear, indicating that Particle Paint is ready to paint.

   **NOTE** You can create freehand strokes only in orthographic viewports.

6. Drag the nozzle crosshairs over the sphere for a few seconds, then release. After you release, the particle seeds appear as +-shaped tick marks on the object surface.
   
   You have just created one stroke.
7. Move the time slider to a later frame.
8. Drag the nozzle over a different part of the sphere to create another stroke.
9. Click the Freehand Paint button to turn it off.
10  On the Editing rollout, turn on Show Particle Timing.
11  Drag the time slider to see the particle timing.

   As you drag the time slider, the particle seeds change color as they become eligible for birth. You will see the second stroke begin at the frame to which you moved the time slider before making the stroke.

To create strokes with splines:

1  Create a 3D object in any viewport.
2  In the Front viewport, create two splines, such as a line and a circle. Place the splines so they overlap the 3D object when viewed in the Front viewport.

   The splines don’t have to actually be in front of the 3D object in 3D space. But because Particle Paint will project the splines onto the object to create particle seeds, the splines must overlap the 3D object when viewed in the viewport.
3  Click Create panel > Helpers > Particle Flow > Particle Paint, and create the Particle Paint helper in any viewport.
4  With the Particle Paint helper selected, go to the Modify panel.
5  On the Setup rollout, click Pick Stroke Spline.
6  Activate the Front viewport.
7  With the time slider at frame 0, click one of the splines in the Front viewport.

   This creates the first stroke.
8  Move the time slider to a later frame, and click another spline.

   This creates a second stroke, starting at the current frame.
9  Click Pick Stroke Spline again to turn it off.
10  On the Editing rollout, turn on Show Particle Timing.
11  Drag the time slider to see the particle timing.

   As you drag the time slider, the particle seeds change color as they become eligible for birth. You will see the second stroke begin at the frame to which you moved the time slider before picking the second spline.
Interface

The controls on the Setup, Orientation, and Mapping rollouts set parameters for particle seeds upon creation. These settings go into effect when you create the particle seeds with the freehand or spline tool. Changing the parameter values after you create particle seeds has no effect on the seeds. After particle seed creation, you can change some aspects of seeds and strokes with the Editing rollout settings.

The Particle Paint rollouts are as follows:

Setup Rollout (Particle Paint) on page 3201
Layout Rollout (Particle Paint) on page 3208
Orientation Rollout (Particle Paint) on page 3212
Mapping Rollout (Particle Paint) on page 3213
Editing Rollout (Particle Paint) on page 3215

Setup Rollout (Particle Paint)

Select a Particle Paint helper. > Modify panel > Setup rollout

The parameters on the Setup rollout determine the density and placement of particle seeds as well as stroke timing.

**IMPORTANT** For these parameters to affect the strokes or seeds, you must set them before you create particle seeds. Changing values after creating particle seeds has no effect on the existing strokes or seeds.
**Freehand Paint** Activates a freehand paint tool, allowing you to drag anywhere in an orthographic viewport to set particle seeds. The timing of the drag across an object determines the base timing for particle birth when used with the Birth Paint or Particle Paint operators. This option is available only on the Modify panel.

**IMPORTANT** To use the freehand paint tool, you must work from one of the orthographic viewports such as Top or Front. You cannot use this tool in Perspective, Camera, or Spotlight viewports.

Each time you release the mouse while using this tool, you create an individual stroke. You can create as many strokes as you like for each Particle Paint helper. Particle timing and other options for each stroke are governed by the other settings on the Setup rollout.

To stop creating strokes, right-click in the active viewport or click the Freehand Paint button again.

**Pick Stroke Spline** Allows you to pick one or more standard splines as paths for the particle seeds. Particles are then placed along this spline, but are projected on to 3D surfaces into the orthogonal viewport. The splines do not have to be in front of the surfaces in the orthographic viewport; Particle Paint will project from splines to surfaces as if the splines were in front of the objects regardless of their actual positions in 3D space.

The picked splines can be either open or closed splines. NURBS curves cannot be used as spray splines.

You can pick as many splines as you like, and each spline picked is considered to be a separate stroke. The stroke starts from the spline's first vertex, and continues along the spline until it reaches the end of the spline (or the first vertex, in the case of closed splines).

**Total Particle Seeds** The total number of particle seeds that have been generated.

**Strokes** The number of strokes created by the Particle Paint helper.

**Brush Radius** Adjusts the spray emitter's nozzle size. The change in size is reflected in the Particle Paint icon. This value determines the distance around the center of the nozzle by which particle seeds spread when using either method to generate particle seeds. This value can be animated over time.

**Paint Density group**

These controls set the particle seeds’ area of distribution within the emitter nozzle.
Center (%) Percentage of particle seeds that spray at the center of the nozzle.

Sides (%) Percentage of particle seeds that spray at the edges of the nozzle. Higher percentages result in wider bands of particles.

**Paint Flow Rate group**

These controls determine how many particle seeds are emitted and how fast they are emitted over the course of a single stroke. For the freehand paint method, a stroke is defined by the time you press the mouse button to start the stroke, until you release the mouse button. For a spline, one stroke is distributed over each spline picked.

**Stroke Limit** Sets the overall number of particle seeds that can be emitted per stroke when using the freehand or spline methods. So if Seeds p/sec is 25.0 and Stroke Limit is 100.0, you can spray for four seconds before running out of particle seeds with that one stroke. This parameter is overridden by the Stroke spray rate type, selected under Type (see following).

**Type** Sets the spray rate type. The available choices are Time, Length, and Stroke. Each one works with one of the later parameters to set the spray rate.

- **Time** Sets the spray rate by particle seeds per second.
- **Length** Sets the spray rate by spatial movement of the nozzle.
- **Stroke** Sets the spray rate with a specific number of particle seeds per stroke, regardless of stroke length. This option overrides the Stroke Limit parameter (see preceding).

[rate value] Depending on the Type setting (see preceding), one of these is available to set the number of seeds created when painting.

- **Seeds p/sec** The number of particle seeds emitted per second as you draw in viewports. Higher values cause more seeds to be emitted. This option is available only for the Time spray rate type (see preceding).
- **Paint Step** The distance the nozzle center must move between emitting individual particle seeds. Higher values cause fewer seeds to be emitted during a stroke. This option is available only for the Length spray rate type.
- **Total Amount** Determines the total number of particle seeds per stroke, regardless of the stroke length in units or time. Seeds are evenly distributed over the stroke time. This option is available only for the Stroke spray rate type.
Brush Adjustment group

These controls are used for fine-tuning the Brush Radius and Flow Rate with regard to stroke timing.

**Radius** Provides for varying the seed-painting radius over the course of each stroke. Alternatively, you can animate the Brush Radius parameter to vary the brush size, but that animation occurs in absolute time (that is, within a specific frame range). Use this option to adjust the brush radius within a single stroke regardless of its start and end times.

Clicking Radius opens the “Brush Radius Graph (Particle Paint)” on page 3218. The settings on the graph are in effect when the Radius option is on.

**Rate** Provides for varying the seed-painting rate over the course of each stroke. Alternatively, you can animate the Seeds p/sec parameter to vary the rate, but this animates the rate in absolute time (that is, within a specific frame range). Use the Rate option to adjust the seed painting rate within a single stroke regardless of its start and end times.

Clicking Rate displays the “Paint Flow Rate Graph (Particle Paint)” on page 3220. The settings on the graph are in effect when the Rate option is on.

Display Type

This drop-down list gives you the choice of how to display the particles in the viewports. You can choose Ticks or Flags as the display type. The Flags type gives more information about each seed's rotational data. The pole of a flag marker is aligned with its seed's local Z axis, while the banner points in the direction of the local X axis.

**Particle Size** Sets the size of the flag markers. Available for the Flags type only.

Stroke Start group

The settings in this group determine the start frame for particle seeds generated by a stroke. These timing values can be used later by the Birth Paint on page 3222 and Placement Paint on page 3224 operators for precise timing of every particle emitted.

**Stroke Start** Choose either of the following:

- **Current Frame** Starts the stroke timing at the current frame.
- **Fixed** Starts the stroke timing at the indicated frame.
Stroke Stop group

These settings specify the method for determining the duration or stop frame of the stroke.

Stroke Stop Choose one of the following:

- **Real-Time Offset**  Defines stroke time by the actual time taken for drawing the stroke. If you created a stroke by picking a spline, then the default time for the stroke is one second.
  Use the Time Scale % parameter to define the correspondence between the animation time (frames of animation) and the real-world time when a stroke is drawn. For example, a value of 100.0 means that one second of actual time corresponds to 30 frames of animation (for NTSC), while a value of 50.0 means that one second of stroke drawing corresponds to 15 frames of animation.

  **NOTE** Adjusting the Time Scale % value changes the effective flow rate of the painting, since the Seeds p/sec on page 3205 parameter uses animation time, not drawing time.

- **Fixed**  Stops the stroke at the specified frame, in absolute time.

- **Duration**  Sets the stroke length in frames.

Auto Adjust Current Frame Aligns the start of each successive stroke automatically with the stop time of the previous one. If you turn on this option for an existing stroke, the time slider is adjusted to the stop moment of the stroke. This option is available only if Stroke Start is set to Current Frame and Stroke Stop is set to either Real-Time Offset or Duration.

Auto Adjust Global Timing Adjusts emission timing of the related Birth Paint operator automatically.

The Birth Paint operator has its own parameters that define when particles start and stop emission. When this switch is off, Particle Flow fits the timing of the strokes into the Birth Paint operator’s Start/Stop interval. However, when this option is on, Particle Paint allows the related Birth Paint operator to adjust its emission timing to the timing of the strokes.

Icon Size Adjusts the overall size of the helper icon, but does not affect the nozzle radius.
**Paint Spread Uniqueness group**

These settings randomize particle-seed distribution over a stroke. If you pick the same spline for a stroke, the helper generates the same placement for seeds. To generate varied particle placement for the same spline, change the Seed value.

**Seed** Specifies a randomization value. Not otherwise related to particle seeds.

**New** Generates a new Seed value.

**Layout Rollout (Particle Paint)**

Select a Particle Paint helper. > Modify panel > Layout rollout

The settings on this rollout determine how the particles are placed on objects in the scene. The Layout settings affect all particle seeds associated with the Particle Paint helper, either before or after they are created.
Interface

Layout

- Paint on All Objects
- Paint on Objects Listed

Add | By List | Remove

- Animated Objects
- Include Children
- Include Group Members

- Use Mask Objects

Add | By List | Remove

- Include Children
- Include Group Members

Selection Filter:

None

Particle Location:

- At Surface

  Distance: 10.0
  Variation %: 0.0

- Separation: 1.0

- Max Attempts: 100
- Stack Up For Separation
Choose a painting option:

- **Paint on All Objects**  Allows particle painting on any object in your scene.
- **Paint on Objects Listed**  Allows particle painting only on listed objects. Click Add to pick objects from viewports, or By List to choose from a dialog. The names of paintable objects appear in the list. To delete an object from the list, highlight it and then click Remove.

**Animated Objects**  If the object on which particle seeds are placed is animated, the original stroke placement might not be at the same place as the animated surface at the time particles are born. If you want particles painted on animated objects to be born from the animated surface regardless of the surface's position, orientation, or shape by the time the particles are born, turn on this option. The Particle Paint helper works with any animated object, whether animated by transforms or another method, such as sub-object animation, morphing, or skinning operations. If the surface animation involves a change in the number of faces (as with the Optimize modifier), Particle Paint might fail because the seeds are linked to specific faces by face indices.

**Include Children**  Allows painting on linked children of listed objects.

**Include Group Members**  For groups in the list, allows painting on all group members.

**Use Mask Objects**  Lets you use a mesh or patch object as a mask or frisket to block particles from being sprayed in that area. Click Add to pick objects from viewports, or By List to choose from a dialog. The names of selected objects appear in the list. To delete an object from the list, highlight it and then click Remove.

**NOTE**  Mask objects block painting only where their geometry is above (or closer to the viewpoint than) the painted surface in the viewport in which the painting occurs. Also, mask objects cannot receive particle seeds.

**Include Children**  Linked children of listed objects also mask the painting.

**Include Group Members**  For groups in the list, all group members mask the painting.

**Selection Filter**  Restricts painting to selected areas of geometry. Choose one of the following:

- **None**  No restriction.
- **Selected Faces Only**  Paints particle seeds only at the geometry's selected faces.
■ **Soft Selection**  Uses Soft Selection on a selection of the geometry's vertices or faces. Fewer particle seeds will be placed areas where the selection falls off.

**Particle Location group**

These controls determine how to distribute particle seeds on the geometry.

**Particle Location**  This drop-down list lets you choose where particle seeds will be deposited. The choices are:

■ **At Surface**  Particle seeds will reside on the surface of any objects on which they are painted.

■ **Above Surface**  Particle seeds will be placed above the surface of objects on which they are painted. Set the distance above the surface with the Distance parameter.

■ **Below Surface**  Particle seeds will be placed below the surface of any objects on which they are painted. Set the distance below the surface with the Distance parameter.

■ **Above And Below Surface**  Particle seeds will be placed both above and below the surface of any objects on which they are painted. Set the distance from the surface with the Distance parameter.

**Distance**  The distance above or below the surface that particles seeds are placed. This value is expressed in units.

**Variation**  Adds variation to the distance from the surface that particle seeds are placed.

**Separation**  When on, Particle Paint attempts to keep particle seeds apart by the specified distance, expressed in 3ds Max units.

**Max Attempts**  When Separation is on, Particle Paint attempts to separate particles by generating seeds repetitively until the desired separation is achieved. The Max Attempts parameter sets the number of times Particle Paint will generate seeds to attempt separation. If the Distance value is low and Separation is high, the desired separation might not be achieved even after many attempts. In this case, turn on Stack Up For Separation (see following).

**Stack Up For Separation**  When on, instead of using repetitive seed generation to attempt to separate particles, the separation conflict is resolved by moving the conflicting seed away in the direction of the surface normal.
Orientation Rollout (Particle Paint)

Select a Particle Paint helper. > Modify panel > Orientation rollout

The Orientation rollout controls the way particle seeds are oriented on surfaces. The orientation information can be used by the Birth Paint and Placement Paint operators to rotate particles in space. These options are useful when you plan to use instanced shapes with a visible orientation as particles.

**IMPORTANT** To have these settings affect the particle seeds, set these parameters before you create the seeds. Changing these parameter values after creating particle seeds has no effect on the existing seeds’ orientation.

**Interface**

Generate Rotational Comp. Enables control over the orientation of particle seeds. The remaining settings on this rollout are available only when this check box is on.

X-Axis and Z-Axis groups

Priority Axis Sets the axis as the primary axis. When the X axis is chosen as the Priority Axis, each particle first aligned by its local X axis in the manner specified in the drop-down list, and then the local Z axis is used. If the Z axis is chosen as the Priority Axis, each particle is aligned first by its local Z axis, and then its X axis.
Reverse Reverses the direction of the Priority Axis. This has the effect of rotating particles by 180 degrees so they point in the opposite direction.

[orientation list] Use this drop-down list to specify how Particle Flow orients particles with respect to the surface of the painted object.

- Random Orients the particles on the surface at random, according to the chosen axis.
- Align to Surface Normal Aligns particles to the surface normal of the object upon which they were painted. For example, if X is selected as the Priority Axis, the local X-axis for a particle is aligned with the surface normal. This option is suitable for placing instanced grass or hair objects on a surface.
- Align to World X/Y/Z-Axis Aligns the particles along the respective world axis.
- Look at Viewport Forces all particles to align with the active viewport.
- Look at Particle Paint Icon Forces all particles to face the Particle Paint Icon.
- Follow Stroke Aligns particles along the spray path in the direction in which the stroke was drawn.
- Align to U/V/W Map Vector Aligns particles along the U/V/W mapping direction on the surface of the painted object.

Divergence Sets the maximum degree of variation off the chosen Priority Axis, expressed in degrees.

Mapping Rollout (Particle Paint)

Select a Particle Paint helper. > Modify panel > Mapping rollout

The Mapping rollout determines how particles are mapped. To use mapping with particle seeds, add a Material operator to the event, and assign a material that has mapping.

IMPORTANT To have these settings affect the particle seeds, set these parameters before you create the seeds. Changing the parameter values after creating particle seeds has no effect on existing seeds’ mapping.
**Interface**

[Image: A small diagram illustrating the interface with checkboxes for "Acquire Sub-Material Index," "Generate Mapping Coords," and a dropdown menu for "Assign To Mapping Channels." Below this, there are options for "Type" and two input fields for "Start Value" and "End Value".]

**Acquire Sub-Material Index** Causes each particle seed to acquire the sub-material index (Material ID) of the nearest point of the surface painted.

**Generate Mapping Coords.** Creates mapping coordinates for each particle seed according to the Type selection. If you use this option, do not use a Mapping operator with the Birth Paint or Placement Paint operator, because doing so will override the mapping generated by the Particle Paint helper.

**Assign To Mapping Channels** Defines the mapping channels to which mapping values are assigned. You can choose more than one channel for assignment. Available only when Generate Mapping Coords. is on.

**Type** Lets you specify how Particle Paint assigns mapping to particles. These mapping types work with numeric parameters to set mapping on particle seeds. For example, with a planar map the bottom-left corner has UVW values of 0,0,0, while the top-right corner has UVW values of 1,1,0. These mapping types correlate these values to the stroke.

- **Stroke Dependent** Spreads mapping values from the Start Value to the End Value over the course of the stroke. The first particle in the stroke receives the Start Value, the last particle of the stroke receives the End Value, and intervening particles receive values interpolated between the two. The same value is assigned to U, V, and W.

- **Time Dependent** Assigns mapping values according to time. The first particle in the stroke is given the Start Value, and the timing of each successive particle (in relation to the first particle) receives an incremented value according to the Offset p/Sec parameter and the number of seconds elapsed. For example, if Offset p/Sec is 0.25 (the default value), then a four-second stroke covers the 0-1 range of UV mapping values.
Index Dependent  Assigns mapping values incrementally regardless of the stroke time. The first particle in the stroke is given the Start Value, and each successive mapping value increments by the Offset p/Particle value. For example, if Offset p/Particle is 0.01 (the default value) and a stroke has 101 particles, then particles in the stroke receive the incremental mapping values 0.0, 0.01, 0.02, 0.03, ... 0.98, 0.99, 1.0.

From Object Painted  Particle seeds take their mapping from their placement on the painted object. A particle acquires the mapping values at the nearest point of the object surface. To acquire mapping values from several mapping channels of the object, activate multiple buttons in the Assign To Mapping Channels group.

Editing Rollout (Particle Paint)

Select a Particle Paint helper. > Modify panel > Editing rollout

The Editing rollout lets you delete unwanted particle seeds or whole strokes, adjust stroke/particle timing, and select particles/strokes and pass the selection data to the Birth Paint and Placement Paint operators. You cannot directly manipulate selected particle seeds with standard 3ds Max tools such as Move and Rotate.

This rollout appears only on the Modify panel.
Two levels of sub-objects are available for selection: Particles and Strokes. As with other sub-object types in 3ds Max, each level remembers its selection. Selected particles are red.

- **Particle** Lets you select particle seeds by clicking them or dragging a region.

- **Event** Lets you select entire strokes. At this level, you can select all particle seeds in one or more strokes with standard selection methods.

**Show Particle Timing** When on you can scrub the time slider to see particle timing in the viewports. Particles start out with the color specified by the
Show Particle Timing color swatch. As you scrub the time slider, each particle turns white when it reaches its emission time.

The particle timing displayed with this option is taken from the current stroke timing settings stored in the Particle Paint helper. This timing might differ from the timing set by a Birth Paint operator.

Available only when not at a sub-object level (Particles or Strokes).

**Delete Selected Items** Deletes selected particles or strokes. You can also use the Delete key.

**Combine Into Single Stroke** Combines selected strokes into a single stroke. The particle seeds are intermixed according to their relative timing. You can use this tool to combine short or single-particle strokes into a larger stroke.

Available only at the Stroke sub-object level when multiple strokes are selected.

**Equalize Particle Timing** Evens out the distribution of particle timing within a stroke. This tool is useful for evening out strokes where some particles have been deleted.

Available only at the Stroke sub-object level.

**Auto Sync Timing by Sel.** When on, sets Start At, Stop At, and Duration (see following) to the current start frame, stop frame, and duration of the currently selected stroke. This option takes effect only if a single stroke is selected.

**Current Start** Shows the start frame of the currently selected stroke(s). If multiple strokes with different start times are selected, then the value shown is <multiple>.

**Start At** The start time for selected strokes. If you change this value, the new time goes into effect when you click Adjust Stroke Timing.

**Current Stop** Shows the end frame of the currently selected stroke(s). If multiple strokes with different end times are selected, then the value shown is <multiple>.

**Stop At** The end time for selected strokes. If you change this value, the new time goes into effect when you click Adjust Stroke Timing. You can choose either this method or the Duration method for changing the length of the stroke.

**Cur. Duration** Shows the duration of the currently selected stroke(s). If multiple strokes with different durations are selected, then the value shown is <multiple>.
**Duration** The duration of selected strokes. A change to this value goes into effect when you click Adjust Stroke Timing. You can choose either this method or the Stop At method for changing the length of the stroke.

**Auto-Adjust Global Timing** When on, changing the stroke timing automatically changes the timing in any related Birth Paint operators on page 3222 in Particle Flow. This option has an effect only if a Birth Paint operator that references the Particle Paint helper is present in the scene.

**Adjust Stroke Timing** Adjusts the timing of selected strokes to match the values for Start At, and Stop At or Duration.

**Total Particles** Displays the total number of particle seeds associated with the Particle Paint helper.

**Total Strokes** Shows the total number of strokes in the Particle Paint helper.

**Selected Particles** Shows the number of selected particles. At the Particles sub-object level, it shows the number of selected particles. At the Strokes sub-object level, it show the total number of particles in the selected strokes. At the object level, it displays the number of selected particles at the Particles sub-object level.

**Selected Strokes** Shows the number of selected strokes. The value changes for different sub-object levels. At the Particles level it shows the number of strokes that have selected particles. At the Strokes level it shows the number of directly selected strokes. At the Object level it shows the same amount as in the Strokes level.

**Selected Stroke #** Shows the sequence number of the currently selected stroke. Strokes are stored in the order in which they are made.

---

**Brush Radius Graph (Particle Paint)**

Select a Particle Paint helper. > Modify panel > Setup rollout > Brush Adjustment group > Turn on Radius. > Click Radius.

The Brush Radius Graph appears when you click the Radius button on the Setup rollout of a “Particle Paint helper” on page 3197. It allows you to animate the brush radius over the time of a single stroke.
The left end of the graph represent the start of the stroke, while the right end represents the end of the stroke. The values in the left column represent the brush radius in units.

Move the existing control points, or add and move more control points, to change the curve over the length of the stroke.

The controls on this dialog are similar to those on the loft deformation dialogs in 3ds Max.

Moves control points in any direction. The exceptions are the start and end control points, which can be moved only vertically.

Moves control points horizontally only. This button is available from the main Move button flyout.

Moves control points vertically only. This button is available from the main Move button flyout.

Scales selected control points with respect to the 0 value.

Inserts a Corner point on the graph.
Inserts a Bezier point on the graph. This type of point has handles that you can adjust for a smooth curve. This button is available from the Corner point button flyout.

Deletes a control point.

Pans the graph.

Zoom Extents, Zoom Horizontal Extents, and Zoom Vertical Extents zoom the graph in or out to fit in the window.

Interactive zoom controls zoom horizontally or vertically, zoom the entire window, or zoom to a selected region.

**Paint Flow Rate Graph (Particle Paint)**

Select a Particle Paint helper. > Modify panel > Setup rollout > Brush Adjustment group > Turn on Rate. > Click Rate.

The Paint Flow Rate Graph appears when you click the Rate button on the Setup rollout of a “Particle Paint helper” on page 3197. It allows you to animate the particle paint rate over the time of a single stroke.
The left end of the graph represents the start of the stroke, while the right end represents the end of the stroke. The values in the left column represent particles per second.

To change the curve over the length of the stroke, move control points, or add and move control points.

The controls on this dialog are similar to those on the loft deformation dialogs in 3ds Max.

- Moves control points in any direction. The exceptions are the start and end control points, which can be moved only vertically.
- Moves control points horizontally only. This button is available from the main Move button flyout.
- Moves control points vertically only. This button is available from the main Move button flyout.
- Scales selected control points with respect to the 0 value.
- Inserts a Corner point on the graph.
- Inserts a Bezier point on the graph. This type of point has handles that you can adjust for a smooth curve. This button is available from the Corner point button flyout.
- Deletes a control point.
- Pans the graph.

Zoom Extents, Zoom Horizontal Extents, and Zoom Vertical Extents zoom the graph in or out to fit in the window.

Interactive zoom controls zoom horizontally or vertically, zoom the entire window, or zoom to a selected region.
Birth Paint Operator

Particle View on page 3015 > Click Birth Paint in an event or add a Birth Paint operator to the particle system and then click it.

The Birth Paint operator uses a Particle Paint helper on page 3197 as a reference for creating particles. With the Particle Paint helper, you place particle seeds on an object with a specific pattern and timing. The Birth Paint operator creates particles from these seeds, initializing particle position, rotation, mapping and selection status.

**TIP** If the Particle Paint helper does not generate a sufficient number of particles, but you want to use the overall particle birth pattern and rate set by the Particle Paint helper, use the Spawn test on page 3281 after Birth Paint in the event to spawn additional particles at each particle seed's location.

See also:

- Placement Paint Operator on page 3224
Interface

Particle Paint Helper group

[button] Choose a Particle Paint helper as the source for particle seeds by clicking the button, labeled “None” by default, and then selecting a helper. After doing so, the helper name appears as the button label.

Total Particles Shows the total number of particles in the Particle Paint helper. The amount of particles actually generated depends on the Quantity Multiplier of the master PF Source object. If the multiplier value is less than 100%, the Birth Paint operator samples the particles from the helper. If the multiplier is greater than 100%, some particle seeds from the helper generate multiple particles.

Total Strokes The total number of strokes in the Particle Paint helper.

Emit Start The frame number at which particles start to emit, beginning with particle seeds at the start of the first stroke.
**Emit Stop/Duration** Choose either of two methods of setting the length of time particles are emitted:

- **Emit Stop** Sets the frame number at which particles stop emitting. The time to emit all strokes in the Particle Paint helper is scaled to fit the time between Emit Start and Emit Stop.

- **Duration** Sets the duration of the emission in frames. If the Duration value is not the same as the stroke time, particle emission timing is scaled to fit the Duration value.

**Reset To Stroke Time** Adjusts the Emit Start, Emit Stop, and Duration values to the timing of the Particle Paint helper's strokes. The Emit Start value is set to the earliest start time of the strokes, and the Emit Stop time is set to the latest stop time of the strokes.

**Subframe Sampling** When on, particles are emitted on the sub-frame timing as defined by the strokes timing and the Emit Start and Emit Stop values. This can help avoid particle clumps. When off, the particle creation time is clamped to the nearest whole frame value.

**Lock At Painted Objects group**

This group of controls tells the Birth Paint operator how to continue controlling particle position/rotation after particles are born. These options apply only if objects painted with the Particle Paint helper are animated, and the Animated Objects on page 3210 option on the Particle Paint helper's Layout rollout is on.

- **Position** Causes all particle pivot points to stick firmly to the painted objects.

- **Rotation** Causes all particles to retain their original orientations. Even if the painted object has surface animation, particles retain the same normal orientation they had at the moment of generation.

- **Acquire Selection** Uses the Particle Paint helper selection. This selection overwrites the PF Source particle selection, if any. Choose the sub-object selection Particles or Strokes (see Editing Rollout (Particle Paint) on page 3215).

**Placement Paint Operator**

Particle View on page 3015 > Click Placement Paint in an event or add a Placement Paint operator to the particle system and then click it.
The Placement Paint operator uses a **Particle Paint helper** on page 3197 to acquire particle seeds from which to generate particles. Placement Paint sets particle positions, rotation, and mapping.

For more information about painting particles, see **Particle Paint** on page 3197.

**Using Placement Paint**

Both Placement Paint and Birth Paint allow placing particles as painted with the Particle Paint helper. Birth Paint combines Birth operator functionality with limited placement options. If you prefer to use birth options not provided in Birth Paint, you can use a different Birth operator with Placement Paint placed immediately after the Birth operator in the event.

Another case for using Placement Paint would be a situation in which you would like to paint particle positions to which particles should be sent by the Find Target operator. In that case the event would look something like this:

- Birth (any)
- Placement Paint
- Script operator (to copy particle positions to Script Vector)
- Position operator (any)
- Find Target (set to use Script Vector)

This the way particles are directed to the positions defined by the painted particle seeds.

**See also:**

- **Birth Paint Operator** on page 3222
Particle Paint Helper Click the button to specify a Particle Paint helper on page 3197 as the reference for particle seeds.

Total Particles The total number of particles in the Particle Paint helper. How the particles seeds correspond to the particles in the current event depends
on the Quantity Multiplier of the PF Source object and the option Obey Quantity Multiplier.

Total Strokes The total number of strokes in the Particle Paint helper.

Data Update Lets you choose how the operator controls positions and rotation:
- Once Sets the positions and rotation for each particle once, when the particle enters the event.
- Continuous Sets particle positions and rotation throughout the event.

Acquire Paint Data group

These controls tell the Placement Paint operator which data to get from the Particle Paint helper, how to interpret the data, and how to use it for particle control.

Paint Position To When on, Particle Flow uses position data from the Particle Paint helper to control particle position or speed. Choose either of the following:
- Position The particle seeds’ position data is translated into particle position. If Data Update is set to Continuous, particle speed is controlled to ensure that particles are locked to the particle seeds location. This is similar to the Lock On Emitter option of the Position Icon operator.
- Script Vector The particle seeds’ position data is translated into the particle script vector channel (as used by the Script operators and Find Target test). If Data Update is set to Continuous, the script vector channel is updated continuously while the particles are in the event. Most commonly, the Find Target test uses the Script Vector data to direct particles at the target defined by the script vector. However, Find Target controls particles only until they reach the target. To overcome this and keep particles on target, you can use the following option.

Snap If Close Available for the Script Vector option only. If a particle is directed close to the target point as defined by the Paint Position value (written to the Script Vector channel), then the operator starts controlling the particle position directly, as with the option Position. With this technique you can use the Find Target test to direct particles to the Paint seeds’ location, and then switch back to direct control of particle position (similar to Lock On Emitter operation). Keep in mind that the operator continues to write the data into the script vector channel even after the snap moment.
Snap Distance Defines distance in 3ds Max units when control shifts from
directing particles toward a target to snapping to the target, as defined in the
Snap If Close description.

Rotation When turned on, Particle Flow uses rotation data from the Particle
Paint helper to control particle rotation or spin.

- Blend-in Rotation Available when Data Update is set to Continuous,
  Paint Position To is set to Script Vector, and Rotation is on. In this case,
  particles move toward the position as defined by the Particle Paint helper.
  When on, the operator modifies particle rotation to allow smooth blending
  from the current particle rotation to the rotation by Particle Paint while
  particles are approaching their target position.

- Near/Far Distance Available when Blend-in Rotation is On. The Far
  Distance value indicates the distance from the target point to the current
  particle position when the blend-in rotation process starts. The Near
  Distance value indicates the distance when the blend-in process should
  be finished, meaning a particle eventually assumes the rotation value as
  defined by the Particle Paint helper.

Mapping When on, uses the mapping data from the Particle Paint helper for
particle mapping.

Material ID When on, defines a material ID for each particle. The ID is defined
by the Particle Paint operator as sub-material index at the closest face of the
painted object to the particle seed.

Selection When on, uses the Particle Paint helper selection to set up the
selection qualities of particles. Any selection made at a PF Source sub-object
level is overwritten by the selection from the helper. Since selection in the
helper can be done at two different sub-object levels, you must choose the
selection level: Particles or Strokes.

Index Order group

These controls associate particle quantity and timing in the event with particle
seeds in the Particle Paint helper.

Type Indicates the method the operator uses to select particle seeds from the
Particle Paint helper for conversion to particles. The choices are:

- Random Selects particle seeds for conversion to particles at random,
  without regard to stroke timing. If the number of particles exceeds the
  number of particle seeds and Stop If Count Overflow is off, all particle
  seeds are used each time Placement Paint cycles through the seeds.
- **Paint Timing**  Uses the timing of particles and strokes in the Particle Paint helper to define the order of emission.

**Stop If Count Overflow**  Causes Placement Paint to stop controlling particles when the number of particles in the event reaches the number of particle seeds in the Particle Paint helper. When this option is turned off, Placement Paint cycles through the particle seeds as many times as necessary to create the required quantity of particles.

**Obey Quantity Multiplier**  Uses the Quantity Multiplier parameter from the PF Source object to adjust the correspondence between particles in the event and particle seeds in the helper. For example, if Quantity Multiplier is set to 50%, then only half the particle seeds in the Particle Paint helper are used. If Quantity Multiplier is greater than 100%, then some or all particle seeds will be used to generate more than one particle.

**Separate Streams Indexing**  Causes particles from different events to be treated as separate streams with regard to particle seed correspondence. When on, particles retain their correspondence to their original seeds. When off, particles coming into the event can be associated with any seed from the entire pool of seeds.

**Uniqueness group**

These parameters initialize randomness for particle sequence when Random is selected as the Type in the Index Order group.

- **Seed**  Specifies a randomization value.
- **New**  Generates a new randomization value.

**Flows**

The flows category contains operators for creating three different kinds of initial particle-system setups. These are: Preset, Empty Flow, and Standard Flow.

**See also:**

- **Operators** on page 3050
- **Tests** on page 3233
Preset Flow

Particle View on page 3015 > depot > Preset Flow

Particle View > Edit menu > New > Particle System > Preset Flow

Preset Flow merges a previously saved Particle Flow setup into the current scene. It allows you to use the flow as an event within your current flow, or as a starting point for a new particle system.

Before you can merge a scene with Preset Flow, you must save it with the Preset Manager on page 3026. A preset can include Particle Flow elements as well as standard 3ds Max objects.

To add a Preset Flow, drag Preset Flow into the event map of Particle View. The Select Preset Flow dialog opens. Highlight a preset and then click OK, or simply double-click a preset name.

When you drag a Preset Flow in Particle View, the global event appears where you drop the flow, and additional events appear in the same spatial relationship as when they were saved in the preset (if you add the Preset Flow from the Edit menu, it appears where it was saved from). All items that were added by Preset Flow are selected in the scene and in Particle View.

To revert the merge, activate the 3ds Max window (by clicking outside a viewport, right-clicking a viewport, or closing Particle View) and then press the Delete key.

If the Preset Flow contains geometry, operators, or other items with names identical to those in your current scene, the standard 3ds Max Duplicate Name dialog appears and prompts you to change the names or skip the items. If you skip the PF source item, the preset will not merge.

NOTE Preset Flow flushes the Undo/Redo buffer.

See also:

- Empty Flow on page 3232
- Standard Flow on page 3232
Interface

**Presets** Lists the current presets in the system. Add a preset either by double-clicking its name or by highlighting it and then clicking OK.

**Preset Description** Displays the description for the highlighted preset. To scroll a description that is too long to fit into the visible space, place the cursor in the description area and use the Down Arrow and Up Arrow keys.
OK Adds the selected preset.
Cancel Cancels the merging of presets.

Empty Flow

Particle View on page 3015 > depot

Empty Flow provides a starting point for a particle system consisting of a single global event containing a Render operator. This lets you build a system completely from scratch, without having first to delete the default operators provided by the Standard Flow system.

To use Empty Flow, drag it from the depot to the event display. In Particle View, this creates a global event containing a single Render operator. If the Global default display option is active in the Particle View > Options menu, the global event will also contain a Display operator. Adding an Empty Flow also creates a Particle Flow Source icon in the viewports, at the world origin (0,0,0).

NOTE If an orthographic viewport is active when you add an Empty Flow to the system, 3ds Max orients the new source icon parallel to the plane of the active viewport, with the default emission direction pointing forward. For example, if the Front viewport is active, the icon is oriented parallel to the XZ plane in the world coordinate system, with the default emission direction along the positive Y axis. If a Camera or Perspective viewport is active, Particle Flow uses the default orientation: parallel to the XY plane, pointing in the negative Z direction.

See also:
- Preset Flow on page 3230
- Standard Flow on page 3232

Standard Flow

Particle View on page 3015 > depot

Standard Flow provides a starting point for a particle system consisting of a global event containing a Render operator, wired to a birth event containing a Birth, a Position, a Speed, a Rotation, a Shape, and a Display operator, with
all parameters set to default values. This is the same system that 3ds Max creates automatically when you add a Particle Flow icon to the viewport.

To use Standard Flow, drag it from the depot to the event display. In Particle View, this creates the particle system described above. If the Global default display option is active in the Particle View > Options menu, the global event will also contain a Display operator. Adding a Standard Flow also creates a Particle Flow Source icon in the viewports, at the world origin (0,0,0).

**NOTE** If an orthographic viewport is active when you add a Standard Flow to the system, 3ds Max orients the new source icon parallel to the plane of the active viewport, with the default emission direction pointing forward. For example, if the Front viewport is active, the icon is oriented parallel to the XZ plane in the world coordinate system, with the default emission direction along the positive Y axis. If a Camera or Perspective viewport is active, Particle Flow uses the default orientation: parallel to the XY plane, pointing in the negative Z direction.

- Empty Flow on page 3232
- Preset Flow on page 3230

**Tests**

The basic function of a test in Particle Flow is to determine whether particles satisfy one or more conditions, and if so, make them available for sending to another event.

When a particle passes a test, it is said to “test True.” To send eligible particles to another event, you must wire the test to that event. Particles that don’t pass the test (“test False”) remain in the event and are repeatedly subjected to its operators and tests. Or, if the test isn’t wired to another event, all particles remain in the event. You can use several tests in an event; the first test checks all particles in the event, and each test after the first checks only particles that remain in the event.

One test, Spawn, doesn’t actually perform a test, but simply creates new particles from existing ones, and sets the new particles’ test result to True so they’re automatically eligible for redirection to another event. And the Send Out test simply sends all particles to the next event by default.
Some tests can also serve as operators, in that they contain parameters that modify particle behavior. If you don’t wire a test to another event, it functions only as an operator; the test aspect doesn’t affect particle flow.

**TIP** Always place a test at the end of its event, unless you have specific reasons for placing it elsewhere. That way, all preceding actions can take effect during each integration step before the test is evaluated.

All the tests are grouped together in the Particle View depot, and are listed in alphabetical order. The icon for all tests is a yellow diamond, usually containing a simplified diagram of an electrical switch.

---

- **Split Group Test** on page 3084
- **Operators** on page 3050
- **Flows** on page 3229
Age Test

Particle View on page 3015 > Click Age Test in an event or add Age Test to the particle system and then select it.

Age Test lets the particle system check whether a specific amount of time has passed since the start of the animation, or how long a particle has existed, or how long a particle has been in the current event, and branch accordingly.

Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

The first interface element is a drop-down list that lets you choose the type of age to test. Default=Particle Age.

- **Absolute Age** Tests the current frame number in the animation.
- **Particle Age** Tests the current age of each particle in frames. This is the default test type.
- **Event Age** Tests the current duration of the current event in frames.

**Test True if Particle Value** Lets you specify whether the test passes particles on to the next event if the age test succeeds or fails. Default=Is Greater Than Test Value
By default, Age Test returns True if the value tested for exceeds the Test Value quantity, but you can alternatively choose Is Less Than Test Value. For example, if you use the Absolute Age test type and set Test Value=60 and Variation=0, and choose Is Less Than Test Value, then particles will move to the next event only until frame 60. After frame 60, any remaining particles stay in the current event unless another test returns True.

**Test Value** The specific frame number, particle age (in frames), or event duration (in frames) to test for. Default=30.
This value cannot be animated.

**Variation** The number of frames by which the value tested for can vary randomly. Default=5.
This value cannot be animated.
To obtain the actual test value for each particle, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then adds the result to the Test Value setting. For example, if Test Value=300 and Variation=10, then tested value for each particle would be between 290 and 310.

**Subframe Sampling** Turning this on helps avoid particle "puffing" when passing particles to the next event by testing the time at a much higher subframe resolution (that is, throughout each frame), rather than using the relatively coarse frame resolution. Default=on.
"Puffing" is the effect of creating separate "puffs" or clusters of particles, rather than a continuous stream.
Turn off Subframe Sampling to cause the test to be executed exactly at frame times.

**Uniqueness group**
The Uniqueness setting enables randomization of the test value variation.

**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.

**Collision Test**

Particle View on page 3015 > Click Collision in an event or add Collision to the particle system and then select it.
Collision tests for particles that collide with one or more specified Deflector space warps. It can also test whether a particle has slowed down or sped up after one or more collisions, has collided more than once, and even whether it will collide with a deflector in a specified number of frames.

The Collision test supports all deflector space warps except the DynaFlect defectors:

- POmniFlect on page 2935
- SOmniFlect on page 2946
- UOmniFlect on page 2948
- SDeflector on page 2953
- UDeflector on page 2956
- Deflector on page 2959

**TIP** When testing for collisions with multiple deflectors, for best results, place all the deflectors in a single Collision test. This tests for collisions with all the deflectors simultaneously, and helps avoid possible missed collisions.

See also:

- Collision Spawn Test on page 3241

**Procedures**

**Example: To test for particles slowing down after one or more collisions:**

In the real world, particles bouncing repeatedly against a surface lose kinetic energy at each collision, and slow down gradually. Rather than testing for a specific number of bounces, you can use the Is Slow After Collision(s) to test whether particle speed has sunk below a specific level.

1. Start or reset 3ds Max. Set the animation length to 500 frames.
2. Add a Gravity space warp and a Deflector space warp. Decrease the deflector’s Bounce setting below 1.0, and increase the Variation and Chaos values above 0.0. Set the deflector’s Width and Length to 500.
3. Create a default Particle Flow system. Position the emitter directly above the deflector.
4 Add a **Force operator** on page 3189 to the end of Event 01 and add the Gravity space warp to the Force operator.

5 Create a new event with a **Display operator** on page 3186, and change the display type to a different choice than is used in Event 01.

6 Add a Collision test to Event 01, below the Force operator, and wire it to the new event.

7 In the Collision test settings, add the deflector. Choose **Is Slow After Collision(s)**, and set **Speed Min=100** (assuming you're using the default initial speed of 300).

8 Play the animation. You might need to adjust one or more settings before seeing the expected behavior.

   After several bounces, the particles change in appearance and move steadily away from the deflector, indicating that they've entered the second event. Of course, you can set any behavior you like in this event. In the next step, you'll see what happens when actions in an event are not in the right order.

9 In Event 01, move the Collision test above the Force operator, and then play the animation.

   Quite a few particles leak through the deflector. This happens because Particle Flow first tests the particles for a collision, and then applies the Gravity force. The particles that are approaching the deflector and are very close to it are being tested for a collision, which tests False because they haven't actually struck the deflector yet. Particle Flow then applies the gravity, which pushes them past the deflector, making them no longer eligible for testing for collision. Generally speaking, it is best to keep Force operators above Collision tests in each event to ensure that particles don't leak through the deflector.
Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

Deflectors group

This group displays the deflectors currently in effect, and let you add and remove deflectors.

[list] Shows the deflectors that apply to this operator. If more than three deflectors apply, a scroll bar appears at the right side of the list.

If you delete a listed space warp from the scene, its name is replaced in the list by the entry “<deleted>”.

Particle Flow | 3239
Add Click this button, and then select a Deflector space warp in the scene to add it to the list.

By List Click this button, and then use the Select Deflectors dialog to add one or more space warps to the list. The space warps must already exist in the scene.

Remove Highlight a deflector in the list, and then click this button to remove it from the list. Any removed space warps remain in the scene.

Test True If Particle group

Choose the condition under which the test will pass particles on to the next event, and then adjust the associated setting or settings. Default=Collides.

Collides Choose this option, and then set Speed according to how particle speed should be affected by the collision.

Speed Choose one of the following. Default=Bounce.

■ Bounce The speed and direction after collision is determined by the deflector properties.

■ Continue Particle speed and direction are unaffected by the collision.

■ Stop Particle speed is set to 0 after the collision.

■ Random Particles bounce off the deflector in random directions.

Is Slow After Collision(s) The test succeeds if, after collision, particle speed is less than the Speed Min value.

With this choice, particle behavior with respect to the deflector(s) is the same as with the Collides > Bounce option.

Speed Min Particles traveling at less than this speed, in system units per second, test True and become eligible for moving to the next event. Default=1.0.

Is Fast After Collision(s) The test succeeds if, after collision, particle speed is greater than the Speed Max value.

With this choice, particle behavior with respect to the deflector(s) is the same as with the Collides > Bounce option.

Speed Max Particles traveling faster than this speed, in system units per second, test True and become eligible for moving to the next event. Default=1000.0.
Collided Multiple Times  The test becomes True after a particle collides a specific number of times. The particle is moved to the point of the last collision and then redirected to the next event.

# Times  The number of times a particle must collide in order to test True.

Speed  Determines speed and direction after the specified number of collisions. See above for explanations of the choices.

Will Collide  Particle Flow extrapolates particle motion in a linear fashion, based on the current direction and speed, and the test becomes True if the results suggest that the particle will collide with the deflector during a specified time interval. The particle is redirected to the next event without updating its speed or position.

# Frames  The number of frames ahead during which Particle Flow looks for an impending collision.

Uniqueness group

The Uniqueness setting enables randomization of the Random options in the Speed drop-down lists.

Seed  Specifies a randomization value.

New  Calculates a new seed using a randomization formula.

Collision Spawn Test

Particle View on page 3015 > Click Collision Spawn in an event or add Collision Spawn to the particle system and then select it.

Collision Spawn creates new particles from existing ones that collide with one or more Deflector space warps.

You can specify different post-collision behavior for the colliding particles and their offspring. Each spawned particle is born at the same location as its parent, and has the same orientation and shape. Collision Spawn can give the spawned particles a different speed and scaling factor. If you wire the Collision Spawn test to another event, spawned particles are sent to that event, where you can specify different properties for the new particles.

Examples of Collision Spawn usage include marks or explosions resulting from collisions between particles and objects. To achieve these effects, you can use Collision Spawn in conjunction with the Shape Mark on page 3149 and Shape Facing on page 3139 operators.
The Collision Spawn test supports all deflector space warps except the DynaFlect deflectors:

- **POmniFlect** on page 2935
- **SOmniFlect** on page 2946
- **UOmniFlect** on page 2948
- **SDeflector** on page 2953
- **UDeflector** on page 2956
- **Deflector** on page 2959

**TIP** When testing for collisions with multiple deflectors, for best results, place all the deflectors in a single Collision Spawn test. This tests for collisions with all the deflectors simultaneously, and helps avoid possible missed collisions.

**See also:**

- **Collision Test** on page 3236
- **Spawn Test** on page 3281
The user interface appears in the parameters panel, on the right side of the Particle View dialog.

In the context of Collision Spawn, a parent is the original particle from which new particles are spawned.

**Test True for group**

These check boxes let you specify which particles, if any, should become eligible for redirection to the next event upon satisfaction of the test conditions.

**NOTE** After a particle tests True, the Collision Spawn test no longer tests the particle for collision. If you simply want particles to spawn every time they collide, turn either or both of these off and use a different test for redirection.

**Parent Particles** When on, parent particles qualify for redirection when the test conditions are met. Default=on.

When using the Spawn On First Collision option on page 3245, Parent Particles is available only when Delete Parent is off.

This option is also available when using the Spawn On Each Collision option on page 3245. In this case, parent particles test True only after colliding the number of times specified by the Until # value.

**Spawn Particles** When on, spawned particles qualify for redirection when the test conditions are met. Default=on.

**Deflectors group**

This group displays the deflectors currently in effect, and let you add and remove deflectors.

**[list]** Shows the deflectors that apply to this operator. If more than three deflectors apply, a scroll bar appears at the right side of the list.

If you delete a listed space warp from the scene, its name is replaced in the list by the entry “<deleted>”.

**Add** Click this button, and then select a Deflector space warp in the scene to add it to the list.

**By List** Click this button, and then use the Select Deflectors dialog to add one or more space warps to the list. The space warps must already exist in the scene.
Remove Highlight a deflector in the list, and then click this button to remove it from the list. Any removed space warps remain in the scene.

**Spawn Rate And Amount group**

Use these settings to specify when particles are to spawn and other values related to how many particles are spawned.

**Spawn On First Collision** Particles spawn only the first time they collide with a deflector.

**Delete Parent** When on, deletes each original particle from which a new one is spawned. Available only with the Spawn On First Collision option.

**Spawn On Each Collision** Particles spawn on each of multiple collisions, up to a limit specified with the Until # parameter.

**Until #** The maximum number of collisions by the parent particles that produce spawned particles. Available only with the Spawn On Each Collision option. Default=3.

When Test True For > Parent Particles is on, parent particles test True only after colliding the number of times specified by the Until # value.

**Spawnable** The percentage of particles in the current event that will spawn new particles. This is determined once for each particle, when it enters the event. However, the parameter is animatable. Default=100.0.

For values other than 100.0, Spawnable uses a randomized selection process, which is affected by the Uniqueness Seed value. For example, with five parent particles, Offspring #=1, and Spawnable=80.0, you might get any number of spawned particles between two and five for each collision. The average per spawning would be four, however.

**Offspring #** The number of new particles the system creates from each parent particle for each spawning event. Default=1.

**Variation** The amount by which the Offspring # value can vary randomly. Default=0.0.

To obtain the actual test value for each particle, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then applies the result as a percentage of the Offspring # setting. For example, if Offspring#=20 and Variation=10, then the actual number of offspring for each particle would be between 18 and 22.
Sync By Choose the time frame to use when animating Offspring # and Variation:

- **Absolute Time**  Any keys set for parameters are applied at the actual frames for which they're set.
- **Particle Age**  Any keys set for parameters are applied at the corresponding frames of each particle's existence.
- **Event Duration**  Any keys set for parameters are applied to each particle starting when it first enters the event.

---

**Restart Particle Age** When on, sets the age of each newly spawned particle at 0. When off, each spawned particle inherits its parent's age. Default=on.

**Speed group**

Lets you specify the behavior of spawned particles, as well as their speed in absolute terms or relative to the parents' speed, with optional random variation. The direction of a spawned particle is always in relation to that of its parent, but you can set a Divergence so they eventually spread out. Default=Inherited.

**Parent** Specify the parent's behavior. Available only when Delete Parent is off.
- **Bounce**  The speed and direction after collision is determined by the deflector properties.
- **Continue**  Particle speed and direction are unaffected by the collision.

**Offspring** Specify the behavior of the newly spawned particles.
- **Bounce**  The speed and direction of offspring after collision is determined by the deflector properties.
- **Continue**  Speed and direction of offspring are unaffected by the collision.

**In Units** Choose this to specify the speed of spawned particles in system units per second. Default=100.0.

A positive value inherits the parent's direction; a negative value reverses it.

**Inherited** Choose this to specify each spawned particle's speed as a percentage of its parent's speed. Default=100.0

A positive value inherits the parent's direction; a negative value reverses it.
Variation The amount by which a spawned particle's speed can vary randomly. Default=0.0.
To obtain the actual speed for each spawned particle, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then adds the result to the particle's speed as specified or inherited. For example, if a particle's speed is 100 units/second and Variation=20, then the tested value for each particle would be between 80 and 120 units/second.

Divergence When on, spreads out the stream of spawned particles. Use the numeric setting to define the extent of the divergence in degrees. Range=0 to 180. Default=12.0.

Size group

Scale Factor The amount of uniform scaling to apply to each spawned particle, as a percentage of its parent's size. Default=100.0.
Variation The amount by which a spawned particle's scale can vary randomly. Default=0.0.
To obtain the actual scaling for each spawned particle, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then adds the result to the Scale Factor value. For example, if Scale Factor=100 and Variation=20, then each spawned particle would be between 80 and 120 percent of its parent's size.

Uniqueness group

The Uniqueness setting enables randomization of the Spawnable result, when less than 100.0, as well as of the Variation values.
Seed Specifies a randomization value.
New Calculates a new seed using a randomization formula.

Find Target Test

Particle View on page 3015 > Click Find Target in an event or add Find Target to the particle system and then select it.
Select a Find Target icon in the viewport. > Modify panel > Parameters rollout Create panel > Helpers > Particle Flow > Find Target
By default, Find Target sends particles to a specified target or targets. Upon reaching a target, the particles become eligible for redirection to another event. You can specify that the particles should use a particular speed or time frame in moving toward the target. You can also specify where on the target the particles should go.

Alternatively, you can use Find Target as a simple proximity test: If a particle comes within a certain distance of its target, it becomes eligible for redirection to the next event.

When you add a Find Target test to the particle system in Particle View on page 3015, a spherical Find Target icon, or helper, appears in the scene at the world origin (0,0,0). You can use this icon as a target, or you can use one or more mesh objects in the scene as targets. To display the Find Target parameters on the Modify panel, select the icon. If you delete the icon, Particle Flow also deletes the test.

**NOTE** If you add Find Target from the Create panel, Particle Flow creates a separate event for the test in the particle diagram.

**TIP** In a particle loop, all particles end up at their respective starting positions, enabling seamless repetition of the resulting animation. You can make particle loops with Particle Flow using a Script operator and a Find Target operator. At the start of the loop, the Script operator should read all particle positions and write them into the MXS Vector channel. Then, at the end of the loop, set the Find Target operator to Control by Time, set Timing to Absolute Time, set Time to the end of the loop, and in the Target group, set Point to By Script Vector. Particle Flow will direct particles to the previously cached position at the specified frame.
Script Operator Example

NOTE See this topic in the online User Reference to view the script operator sample MAXScript code.

3250 | Chapter 12  Space Warps and Particle Systems
The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Control By ...** The drop-down list at the top of the parameters panel lets you choose whether to send particles to a target by specifying the speed and acceleration, or by specifying the amount of time they should take. Alternatively, by choosing No Control, you can test particles' distance from a target.

- **Control By Speed** Specify speed and acceleration settings for the particles to follow while traveling to the target. Use the Control By Speed group to set the parameters.

- **Control By Time** Specify time-based settings for the particles to follow while traveling to the target. Use the Control By Time group to set the parameters.

- **No Control** With this option, Find Target functions only as a proximity test. When a particle comes within the specified distance of the target, the particles become eligible for redirection to the next event.

**NOTE** When you choose No Control, the Find Target test does not affect particle speed or direction.

**Test True If Distance To group**

These settings let you choose which distance the Find Target test measures and specify the measured distance. You can choose Target Pivot or Target Point, and specify a distance with the Is Less Than setting.

- **Target Pivot** Measures the distance between the particle and the target pivot. If the particles are directed to the outside of the target and the Is Less Than value is small, this condition might never be satisfied.

- **Target Point** Measures the distance between the particle and the target point on page 3255.

- **Is Less Than** When particles are closer than this distance from target pivot or point, they test True and become eligible for redirection to the next event. Measured in scene units.

**NOTE** If you set Is Less Than to 0, the particles might never test True. This might be desirable for an animation of, for example, bees buzzing around a flower but not landing on it. In this case, you might want to use a low value for Accel Limit so the bees don’t circle too close to the flower.
Control By Speed group

Use these settings to specify speed and acceleration parameters when using Control By Speed or Speed Then Time. This group is available only when using Control By Speed.

Use Cruise Speed When on, Particle Flow gives you explicit control over particle speed and speed variation. When off, Particle Flow calculates particle speed automatically using the Accel Limit value. Default=on.

Speed Particle speed in scene units per second. Default=300.0.

Variation The amount by which the actual Speed value can vary randomly. Default=0.0.

To obtain the actual speed for each particle, the system multiplies the Variation value by a random number between –1.0 and 1.0, and then applies the result as a percentage of the Speed setting. For example, if Speed=200 and Variation=10, then the actual speed for each particle would vary randomly between 190 and 210.

Accel Limit Sets the acceleration limit. This value impacts the inertia and speed of the particles. Default=1000.0.

The default acceleration limit value is based on the default Speed value of 300.0. If you change the Speed value, it is recommended that you also change the Accel Limit value proportionately.

TIP Use a lower Accel Limit value for smooth motion, and a higher value when greater accuracy is needed, such as when the particles should hit a small target. You can animate this setting (use Sync By > Event Duration) to specify different appropriate values, depending on the required results.

Ease In % Controls the rate by which particles slow down when it approaches the target point.

Particle Flow calculates the final speed with this formula: (100% – Ease In) * Speed. Therefore, if the Ease In value is 100%, a particle should approach the target with a speed of 0, and if Ease In is 0%, the particle doesn't slow down at all when approaching the target. At intermediate values, the speed is calculated according to the distance to the target point, as linear interpolation between the initial (cruise) speed, and the final speed. When a particle enters the event, the distance to the target point is calculated and later used for the interpolation. Default=0.0.
Sync By  Choose the time frame to use when animating Speed, Variation, and Accel Limit:

- **Absolute Time**  Any keys set for parameters are applied at the actual frames for which they're set.

- **Particle Age**  Any keys set for parameters are applied at the corresponding frames of each particle's existence.

- **Event Duration**  Any keys set for parameters are applied to each particle starting when it first enters the event.

**Control By Time group**

```
Control By Time:

Timing: [Event Duration]

Time: 48
Variation: 4

Subframe Sampling
Use Docking Speed

Speed: 100.0
Variation: 0.0
```

Lets you specify the amount of time particles should take to reach the target. This group is unavailable when using Control By Speed.

**Timing** Determines how Particle Flow applies the specified timing, defined by the Time and Variation values. The possible options are:

- **Absolute Time**  Time refers to the overall time of the system. Each particle will reach its target at the frame number specified by Time.

- **Particle Age**  Time refers to the time elapsed since the birth of the particle. Each particle will reach its target when its age reaches the value specified by Time.

- **Event Duration**  Time refers to the time elapsed since the particle entered the current event. Each particle will reach its target when it has been in the current for the number of frames specified by Time.

**Time** The number of frames particles should take to reach the target. Default=60.
Variation. The number of frames by which Time can vary randomly. Default=5.
To obtain the actual time to the target for each spawned particle, the system multiplies the Variation value by a random number between –1.0 and 1.0, and then adds the result to the Time value. For example, if Time=60 and Variation=20, then the time to target for each particle would be between 40 and 80 frames.

Subframe Sampling. Turning this on helps avoid particle "puffing" by timing particles at a much higher subframe resolution (that is, throughout each frame), rather than using the relatively coarse frame resolution. Default=on. "Puffing" is the effect of clustering particles, rather than producing a continuous stream. This effect is especially noticeable when the emitter is animated.

Use Docking Speed. Lets you specify particles' speed when they reach the target.
A particle might be required to reach the target from a specific direction at a specific speed. When Use Docking Speed is off, Particle Flow calculates a path for particles to reach the target in the shortest distance with the least acceleration along the path. When Use Docking Speed is on, Particle Flow calculates particles' final speed when they reach the target using the Speed and Variation parameters. Therefore if you want a "smooth landing," set Speed to 0.0. Default=off.

Speed. The speed of particles when they reach the target in scene units per second. Default=100.0.

Variation. The amount by which the actual Speed value can vary randomly. Default=0.0.

Target group
By default, Find Target uses its own target icon, but you can use these controls to designate other scene objects as targets instead.

Icon. Use the Find Target icon as the target.
Each Find Target test has its own target icon. Even if you don't use it as a target, it still influences particle behavior if you set the docking type to Parallel, Spherical, or Cylindrical.

Mesh Objects. Use one or more scene mesh objects as targets. Choose this to make the list and list-management buttons available.
If you designate more than one target, the target used by each particle is determined by the choice in the Object drop-down list on page 3256 in this group.
[list] Shows the mesh objects used as targets. If more than three target objects apply, a scroll bar appears at the right side of the list.

**Add** Click this button, and then select a mesh object in the scene to add it to the list as a target.

**By List** Click this button, and then use the Select Target Objects dialog to add one or more mesh objects to the list. The objects must already exist in the scene, and the dialog shows only eligible objects.

**Remove** To remove a target object from the list, first highlight it and then click this button. Any removed objects remain in the scene.

**Sync By** Choose the time frame to use when sending particles toward animated objects when using Animated Shape or Follow Target Animation:

- **Absolute Time** Animation derived from the target is applied to particles immediately.
- **Particle Age** Animation derived from the target is applied to particles at the corresponding frames of each particle’s existence.
- **Event Duration** Animation derived from the target is applied to particles is applied to each particle starting when it first enters the event.

**Animated Shape** Turn on to allow particles to target the surface of an object whose form is animated by scaling, by morphing, or with modifiers. This requires more computation, because the destination must be updated at every integration step.

**Follow Target Animation** Turn on to allow particles to follow a moving target; that is, a target whose location is animated. This requires more computation, because the destination must be updated at every integration step.

**Point** Lets you specify where on its target a particle should land.

- **Random** Each particle targets a random point on the target.
- **Closest Surface** Each particle targets the nearest point of the target’s surface.
- **By Script Vector** The target point or points are defined using a Script operator that defines values in the particleVector channel. The Script operator can be anywhere upstream of the Find Target test.
NOTE When using By Script Vector to target absolute positions, such as vertex locations, be sure to set Target to Icon. If you set it to Mesh, the positions specified by the script will be relative to the position of the mesh object. This latter option is useful for placing scripted targets on the surface of a moving object.

Object With multiple mesh targets, lets you specify how Particle Flow should choose among them. Available only when targeting more than one object.

- **Random** For each particle, Particle Flow chooses a target object at random.
- **Closest Pivot** For each particle, Particle Flow chooses as its target the object whose pivot is nearest to the particle.
- **Closest Surface** For each particle, Particle Flow chooses as its target the object whose surface is nearest to the particle.
- **Least Deviation** For each particle, Particle Flow chooses as its target the object that requires the least change in its current direction (or resteering) to reach.
- **By Script Integer** For each particle, the choice of a targeted object is defined by a script operator that sets an index. This index corresponds to a target-object entry position in the target list. See Script Operator Example on page 3249.

Lock On Target Object When on, Particle Flow calculates each particle's target object once: when the particle enters the event. Thereafter, the particle is "locked on" to its target object. When off, Particle Flow can continually recalculate the target object for each particle. Available only when multiple target objects are designated.

For example, if you set particles to target the closest surface, due to the target animation and particle movement, the definition of the closest surface is constantly changing. Thus the particle may change the target object due to the circumstances.

NOTE Each time Find Target sets a target object, it "locks on" to a specific point on that object. This point can change only if the target object changes. Thus, with a single target object, the target point always remains constant relative to the target object. That is, if the target object or its surface is animated, and Follow Target Animation or Animated Shape is on, the absolute coordinates of the target point may change.
NOTE When Lock On Target Object is off, more calculation is required because the system might have to recalculate each particle’s optimal target point in each frame.

Docking Direction group

Docking type Lets you specify from which direction particles should approach targets.

- **None Specified**  No docking constraints. Particles reach their targets in the most efficient way, based on their assigned parameters and their current attributes.

- **Along Icon Arrow**  The final direction is the same as the Find Target icon arrow.

  NOTE When using this option, arrows appear on the Find Target icon to indicate the direction particles will use for docking. You can change the docking direction by reorienting the icon. This applies even when using mesh objects as targets.

- **Icon Spherical**  The final direction points toward the center of the operator icon.

  NOTE When using this option, arrows appear on the Find Target icon to indicate the directions particles will use for docking. You can change the docking directions by reorienting the icon. This applies even when using mesh objects as targets.

- **Icon Cylindrical**  The final direction points toward the icon arrow as a line, thus forming a cylindrical field with the arrow as the cylinder's main axis.

  NOTE When using this option, arrows appear on the Find Target icon to indicate the directions particles will use for docking. You can change the docking directions by reorienting the icon. This applies even when using mesh objects as targets.

- **Surface Normals**  Each particle reaches its target point from a direction perpendicular to the surface at that point.
NOTE When using this option, arrows appear on the Find Target icon to indicate that particles will use surface normals for docking; the actual directions they will use depends on the target surface. This applies even when using mesh objects as targets.

**Distance** The distance from the target at which particles begin docking behavior. This includes the docking direction, and, when using Control By Time, the docking speed.

**Icon Size** Set the size of the Find Target icon. This affects particle behavior when using the icon as the target.

**Color Coordinated** When on, the Find Target icon uses the color of the event containing the test as defined by its local Display operator, if one exists. This applies even if the Display operator is turned off. When off, the Find Target icon uses the default Test Gizmos color as defined in Customize User Interface > Colors > Particle Flow. Default=on.

Turn on Color Coordinated to make it easier to spot the Find Target icon, because the particles in the event use the same color as the icon.

**Uniqueness group**

The Uniqueness setting enables randomization of the Random options and the Variation options.

**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.

### Go To Rotation Test

**Particle View** on page 3015 > Click Go To Rotation in an event or add Go To Rotation to the particle system and then select it.

The Go To Rotation test enables a smooth transition in the rotational component of a particle, so that the particle can gradually rotate to a specific orientation over a specific period. An example of its usage would be with falling leaves, which spin chaotically as they fall, but land on a flat side rather than an edge. The test aspect lets you direct the particle to a new event when the transition period ends.
To set a target orientation, place the Go To Rotation test *before* an orientation-type operator (*Rotation* on page 3097 or a *Script operator* on page 3196 if it defines the rotation channel) in the same event. In this situation, the Go To Rotation test can grab the particle rotational component before the orientation-type operator overwrites it. The Go To Rotation operator modifies the particle orientation and spinning in the post-evaluation cycle. For an example, see the procedure below.

**WARNING** The Go To Rotation test is not compatible with the Spin, Shape Facing, and Shape Mark operators. Do not use any of these operators in the same event with a Go To Rotation test.

**NOTE** You can define the transition period only in terms of time. You cannot set the test to come to a specific rotation by the time of another test, such as a collision test. Also, limited control is provided over the axis of spinning when a particle comes to the final rotation.

**Procedures**

**Example: To make falling particles land smoothly, face up:**

This procedure assumes a basic knowledge of Particle Flow usage.

1. In the Perspective viewport, add a Particle Flow system and raise its icon about 80 units on the Z axis.

2. In Event 01, make the following changes:
   - Birth > Amount=50
   - Speed=100
   - Shape=Cube (or use Shape Instance with a custom object, such as a coin-shaped cylinder)
   - Display > Type=Geometry

   This reduces the number of particles and slows them down, making it easier to see what's going on.

3. Add a Spin operator on page 3099 to Event 01, and set both Spin Rate and Variation to **150**.
   - This gives the particles random spinning behavior as they fall.

4. Add an Age test to the end of Event 01, and set Test Value=15.
This allows each particle to fall and tumble for 15 frames before Go To Rotation takes effect.

5 From the Depot, drag a Go To Rotation test to an empty area in Event Display. Set Duration=15 and keep all other default settings.

6 Insert a Rotation operator immediately after the Go To Rotation test. Choose Random Horizontal as the orientation matrix. Keep the other default settings.
   The Go To Rotation test will use this as the final orientation for the particles.

7 Use a Speed event to create a third event. Set Speed=0.0. This stops the particles at the end of the animation.

8 In both new events, set Display > Type=Geometry.

9 Wire the Age Test in Event 01 to Event 02, and then wire the Go To Rotation test in Event 02 to Event 03.

10 Play the animation.
   The particles tumble chaotically as they fall for about 30 frames, and then come to a smooth stop, facing up.
The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Test True When group**

**Transition Period Ends** When on, the particles test True at the end of the specified transition period, and become eligible for redirection to the next event. When off, particles will not go to the next event, even if wired. Turn off to disable the test aspect of Go To Rotation. Default=on.

**Transition By group**

Determines how Particle Flow applies the specified timing, defined by the Time and Variation values. Default=Event Duration.
The possible options are:

- **Absolute Time**  Time refers to the overall time of the system. Each particle will reach its target orientation at the frame number specified by Time.

- **Particle Age**  Time refers to the time elapsed since the birth of the particle. Each particle will reach its target orientation when its age reaches the value specified by Time.

- **Event Duration**  Time refers to the time elapsed since the particle entered the current event. Each particle will reach its target orientation when it has been in the current for the number of frames specified by Time.

**Duration**  The number of frames particles should take to reach the target orientation. Default=30.

**Variation**  The number of frames by which Duration can vary randomly. Default=0.

To obtain the actual time to the target orientation for each particle, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then adds the result to the Duration value. For example, if Duration=60 and Variation=20, then the time to target orientation for each particle would be between 40 and 80 frames.

**Target Rotation group**

When you use an orientation-type operator with Go To Rotation, this setting lets you determine whether the test sets the target orientation on a one-time or ongoing basis. Default=Constant.

**Constant**  Defines that the orientation-type operator sets a constant orientation for a particle. For example, when using a Rotation operator set to an orientation matrix other than Speed Space Follow, the Go To Rotation operator would acquire the target orientation only once, and then use it as its goal.

**Changing**  Defines that the orientation-type operator sets a changing rotation for a particle. At each frame the desirable final rotation may be different. For example, if you use the test with a Rotation operator set to Speed Space Follow, the test will adjust the particle rotation constantly to aim at the changing final rotation.
**Target Rotation Spin group**

Defines the angular velocity for each particle when it reaches the target orientation.

**Match Initial Spin** Sets the angular velocity at the end of the transition period to the same as the angular velocity when particle enters the event.

**NOTE** The axis of rotation might still be different, because it is calculated on the fly to let the particle come to the target orientation.

**Spin Rate** Defines each particle's angular velocity, in degrees per second, when it reaches the target orientation. Available only when Match Initial Spin is off. Default=0.0.

For a smooth transition to the target orientation, set to **0.0**.

**Variation** Defines a random variation in the Spin Rate value when a particle reaches the target orientation. Default=0.0.

To obtain the final angular velocity for each particle, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then adds the result to the Spin Rate value. For example, if Spin Rate=6.0 and Variation=1.0, then the final angular velocity for each particle would be between 5.0 and 7.0 degrees per second.

**Ease In %** Defines a curve in achieving the final spin rate. Default=0.0

When set to 0.0, the test produces a linear interpolation between the initial and final spin rate, and when set to 100.0, the final spin rate is achieved earlier. For the smoothest approach to the target orientation, set Spin Rate and Variation to 0.0, and Ease In to 100.0.

**Transition End group**

**Stop Spinning** When on, halts particle rotation when it reaches the target orientation. Default=on.

Even with Spin Rate spinner set to 0.0, we recommend that you keep this check box on to avoid slow spinning at the end, due to computational averaging and marginal errors.

**Uniqueness group**

The Uniqueness setting enables randomization of the Variation options.

**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.
Lock/Bond Test

Particle View on page 3015 > Click Lock/Bond in an event or add a Lock/Bond test to the particle system and then click it.

The Lock/Bond test attaches particles to objects, and can keep them attached even as the object animates. Particles can move over an object’s surface and the bond can be broken, causing particles to fly or break off from the object.

The standard Position Object operator is also able to lock particles to an object, but because it chooses particle positions at random on the object’s surface, particles can drift when the object is animated. The Position Object operator’s main limitation is that it cannot be applied to particles that have already established their positions. Because the Position Object operator generates new particle positions regardless of the old ones, it can create the illusion that each particle shifts to a new location instantaneously. With Lock/Bond, you can force particles to maintain their original positions with respect to an animated surface.

Lock/Bond can also fix particle orientation. This means that particles with a perceivable orientation, such as darts or arrows, can maintain their orientation to the object even as it rotates. You can also limit particles’ rotation from their original orientations for fine control over wind and gravity effects.

You can also dampen particle motion to simulate air, fluid, or friction as particles move across a surface or through the air.

While Lock/Bond functions mainly as an operator, applying various attributes to particles while they’re in the same event, it also serves as a test for particles breaking off from the object. For information on the test performed, see the parameter Break Off When Exceeds on page 3270.

For more information on Lock/Bond, see Using the Lock/Bond Test on page 3271.
Interface
Lock On Objects group

The controls in this group set the starting point for the Lock/Bond test. Here you specify the objects to which to attach the particles, and choose the method for placing particles as they enter the event.

When the Lock/Bond test starts, each particle is locked to a specific point in the scene, usually on the object's surface. This point is referred to as the particle's lock point. If the object is animated, the lock points animate along with the object. When Snap to Surface is turned on, the lock point is on the surface. When Snap to Surface is off, the lock point is exactly at the point where the particle is located at the moment when it enters the event. This location is translated to the local coordinates of the reference object, and maintained throughout the animation of the reference object.

[list] Shows all objects referenced by the test.

Add  Adds an object to the list.

By List  Allows you to add multiple objects to the list.

Remove  Removes highlighted objects from the list.

[locking method] Choose a method for locking particles to objects in the list:

■ **Lock To Object**  Locks particles to the object's local coordinate space. This option takes less processing time than Lock To Surface.

■ **Lock To Surface**  Locks particles to the closest point of the object's surface at the moment when the particle enters the event. By default, this option maintains the distance each particle had from the surface upon entering the event. When used in conjunction with Snap To Surface, this option locks particles to the actual object surface.

Lock to Surface takes more processing time than Lock to Object because the software has to find the closest point on the surface for each particle.

**Animated Surface**  Locks particles to a changing surface. Use this option when the object's surface changes shape or detail over time, such as with animated sub-objects or parameters, morphing, or a skinning modifier. If the object is animated through transforms only (position/rotation/scale), you can save processing time by leaving this option off.

When on, the operator acquires the surface data at every frame. When off, the operator acquires the surface data only once, and uses transformation data as needed to calculate the surface location at every frame.

Available only when Lock To Surface is on.
Snap To Surface  Causes particles to jump to the object's surface as they enter the event. This option differs from Lock To Surface, which locks particles to the surface but maintains each particle's distance from the surface upon entering the event. Snap To Surface forces particles to lie on the object's surface.

If you turn on Snap To Surface but not Restrict To Surface (see following), particles jump to the surface upon entering the event, but don't stay on the surface if Force in the Position Lock/Bond group is less than 100% and other forces such as the Speed operator or Force operator are applied.

Available only when Lock To Surface is on.

Position Lock/Bond group

These options control the movement of particles from their lock points after they enter the event.

Restrict To Surface  Forces particles to stay on the object's surface as they move. When the Force parameter is less than 100%, particles can move from their original positions based on Speed and Force operators within the event. In this case, turning on Restrict to Surface forces the particles to move only to other parts of the surface without leaving the surface itself.

For more information on how Restrict to Surface works with the Force parameter, see Force, following.

Offset Limit  The maximum distance a particle can move from its lock point, in units. When off, particles are not limited in their movement.

If the object or surface is animated, particles might need to move quickly to keep up with the lock point's animation and stay within the Offset Limit distance. If Offset Limit is on and particles cannot keep up with the lock point's movement, particles will be limited to be within the Offset Limit distance to the lock point (to the Offset Limit) even if Force is less than 100%. In addition, if Speed Limit is on, particles can exceed the speed limit to maintain the specified offset. In other words, the Offset Limit parameter, when on, overrides the Speed Limit parameter.

Speed Limit  The maximum speed a particle can travel, in units per frame. If Speed Limit is on and particles cannot keep up with lock points on an animated object, particles are limited to the Speed Limit even if Force is 100%. In other words, the Speed Limit parameter, when on, overrides the Force % parameter.

Force %  Sets the amount of force holding the particle to its lock point. A Force % value of 100.0 attempts to keep particles stuck to their lock points. If the Force % value is less than 100.0, particles can move off their lock points based on Speed and Force operators in the event. The lower the Force % value, the more influence Speed and Force operators have on the particles.
If Force % is less than 100.0 and Restrict To Surface is on, particles move along the object’s surface. If Force % is less than 100.0 and Restrict To Surface is off, particles move off the surface but retain their relationships to lock points. In either case, particle movement is based on Speed and Force operators, and is restricted by Offset Limit and Speed Limit if those parameters are on.

When Force % = 100.0 and Restrict To Surface is on, particles are locked strictly to the object or surface, and do not move. If Force % = 100.0 and Restrict To Surface is off, particles are locked to the object unless Break Off When Exceeds is on and the object is animated at a sufficient speed to break off particles.

**NOTE** Offset Limit and Speed Limit, when enabled, can override a 100% Force setting.

**Dampening** Defines how particles are slowed down, whether moving on the object’s surface or off it. Dampening simulates the effect of various resistance forces.

- **None**
  No dampening is applied, other than the default dampening on oscillating forces from Speed and Force operators.

- **Friction**
  Simulates a surface friction effect, which gradually slows particles until they stop moving. The total slowdown is proportional to the travel distance of a particle. The number of seconds in which a particle loses its speed is equal to initial speed divided by the Friction value. For example, if the initial speed of a particle is 300.0 and the Friction value is 100.0, then the particle gradually comes to a halt over three seconds.

- **Air/Fluid**
  Simulates the resistance of a medium such as air or water, which slows particles but never stops them completely. The resistance is proportional to the speed squared, making the resistance very high for fast-moving particles, but quite low for slow-moving particles. For example, if one particle is moving at a speed of 100.0 and another at 200.0, the resistance for the faster particle will be four times larger than for the slower particle. The Resistance value defines the resistance force for a particle with speed equal to the Speed Unit value.

- **Both**
  Combines both forces: Friction and Air/Water. If you want the overall effect of air resistance, but you want particles to stop moving eventually, use this option. In this case, a small Friction value stops slow-moving particles.

**No Force In Central Zone group**

The central zone is a volume around a lock point. Each particle has its own central zone defined by the Radius parameter in this group.
When Force % is less than 100.0, particle movement is influenced by Force and Speed operators, where forces are oscillated and particles gradually slow down until they come to rest. If you want particles to wander around the lock point rather than coming to rest, you can use these settings to disable forces in each particle's central zone. This will keep a particle wandering indefinitely if its location is within the Radius of its lock point.

**Acceleration** When on, turns off acceleration forces in each particle's central zone. This prevents the particle from slowing down to a stop.

**Dampening** When on, turns off dampening in each particle's central zone. This prevents particles from being slowed by friction and coming to a stop.

**Rotation Lock/Bond group**

Use these options to control the rotation of particles. In this section, mentions of the Force % parameter refer specifically to the one in this group.

**Offset Limit** The maximum number of degrees by which a particle can deviate from its lock point's rotation. For example, the maximum number of degrees a particle can lean or bend when affected by Wind or Gravity.

If the object or surface is animated, particles might need to rotate quickly to keep up with the lock point's rotation and still remain within the Offset Limit. If Offset Limit is on and particles cannot keep up with the lock point's rotation, particles will be limited to the Offset Limit even if Force % is less than 100.0. In addition, if a Spin Limit is set (see following), particles can exceed the Spin Limit to maintain the specified offset. In other words, the Offset Limit, when on, overrides the Spin Limit.

**Spin Limit** The maximum number of degrees per frame that a particle can rotate. If Spin Limit is on and particles cannot keep up with lock points that are rotating, particles will be limited to the Spin Limit even if Force %=100. In other words, the Spin Limit, when on, overrides the Force % setting.

**Force %** The amount by which the particle's rotation is forced to match its lock point's rotation. When Force % = 100.0, particles maintain their original orientations, unless limited to rotate by Spin Limit settings. When Force % is less than 100.0, particles can be rotated with Force operators. The lower the Force value, the more a particle can be influenced by Force operators and inertial properties of a particle.

**Dampening %** The amount of resistance that prevents a particle from catching up with the lock point's rotation. A value of 0.0 creates no dampening, while 100.0 keeps the particle from rotating at all. If Offset Limit is on, Dampening cannot cause the particle rotation to deviate from the lock point's rotation by
more than the Offset Limit amount, even if Dampening % is set to 100.0. In other words, the Offset Limit setting overrides the Dampening value.

**Induced By Speed Change** Causes particle rotation to occur even when particles' positions are locked to their lock points. For example, a field of grass particles would not move, but could rotate when wind is applied to them. This option also works with particles locked to animated surfaces, such as hair or fur particles on an animal's body. Usually particles are rotating because the underlying surface is rotating, and particles are trying to catch up with the "lock" orientation. This option lets you simulate the effect of a particle with a springy attachment to a surface. Since the center of gravity of a particle doesn't coincide with the lock point, any movement of the underlying surface initiates a rotational movement of a particle.

**Inertial Size** The distance between the pivot point of a particle and the particle's center of gravity. For example, the inertial size of a blade of grass is half the length of the strand. Smaller values induce a stronger rotation. Available only when Induced By Speed Change is turned on.

**Break Off When Exceeds** Causes particles to be released from an object's surface when they achieve a specific speed or acceleration. This option works only when particles are glued to the object's surface and have no speed of their own, and any speed or acceleration comes from animation of the object itself. Particles that break off from the object become available to the Lock/Bond test output, which you can wire to another event.

You can use either of the following settings with this option:

- **Speed** The particle speed at which a particle breaks off the object.
- **Accel.** The particle acceleration at which a particle breaks off the object.

**Break If Outwards Only** Causes particles to break off only when the particle's motion is directed away from the object's surface, in the direction of the nearest surface normal. Particles that would penetrate the object when breaking off are not released from the object. Available only when Lock to Surface is chosen and Break Off When Exceeds is on.

**Parameters Animation group**

You can animate Lock/Bond parameters. When you do, Particle Flow can begin applying the animation to particles at different times, depending on the settings in this group.
Sync By
Choose the time frame for applying animated parameters:

- **Absolute Time** Any keys set for parameters are applied at the actual frames for which they're set.

- **Particle Age** Any keys set for parameters are applied at the corresponding frames of each particle's existence. For example, suppose you set keys for the Offset Limit parameter at frames 0 and 30. With the Particle Age option, the settings for the first key would be applied to particles at birth, and the second key would be applied 30 frames later.

- **Event Duration** Any keys set for parameters are applied to each particle relative to the frame at which it first enters the event. Use this option when particles are entering from another event. If particles are born in the current event, this option has the same effect as the Particle Age option.

**Uniqueness Group**

These controls set randomization for the Randomly Selected and Select By Particle Property selection conditions.

- **Seed** Specifies a randomization value.

- **New** Calculates a new seed using a randomization formula.

**Using the Lock/Bond Test**

The Lock/Bond test is a versatile tool for locking particles to objects. By combining its controls in different ways, as described in this topic, you can create a variety of effects.

**How Lock/Bond Works**

Lock/Bond has three main functions:

- Attaching particles firmly to an object, either at the start of an animation or as a result of a collision

- Moving particles along or near an object's surface with a flexible attachment

- Ejecting particles from an animated object

In setting up these effects, you will find that the four most important parameters are Lock To Surface, Snap To Surface, Restrict To Surface, and Force.
Different settings for these parameters, along with a few other parameters and operators, can create a variety of effects with Lock/Bond.

**Attaching Particles to an Object**

When particles enter an event containing a Lock/Bond test with the Snap To Surface option enabled, each particle is locked to a specific point on the selected object's surface. This point is referred to as the particle's lock point. If the object is animated, the lock points animate along with the object.

With Lock/Bond, particle attachment is controlled largely by the Force % parameter in the Position Lock/Bond group. In general, when Force %=100.0, particles stay firmly stuck to their lock points, even on an animated object. For firm attachment, the Lock/Bond test should be the last action in the event. If there are other operators below Lock/Bond that modify speed, then the overall attachment might not be as firm as desired.

All parameters in the Lock/Bond test are animatable. Therefore, you can animate Force % to lock down particles gradually or loosen them from their locked positions.

**Position Object vs. Lock/Bond**

The standard Position Object operator can generate particles randomly on the surface of an object. Position Object is useful for some types of animation, but is limited in its functionality. The Lock/Bond test overcomes many of these limitations, as described in the following points:

- When an object to which particles are attached is rotated, the Position Object operator does not rotate the particles along with it. The effects of this limitation are not necessarily visible with tiny or round particles, but it becomes obvious when using directional-type particle instances such as arrows or darts. Lock/Bond rotates the particles along with the object to which they are locked.

- When particles are passed to a new event that has a Position Object operator and the particles are meant to land on the object's surface, particles do not necessarily lock to the exact spot on which they land. This is because Position Object generates particles randomly on the surface, and they are not "glued down" to a specific spot on a specific face or vertex. Lock/Bond attaches each particle to a specific location on the object's surface so particles don't drift in relation to the surface.
The Position Object operator can be useful in conjunction with the Lock/Bond test. For example, you can use Position Object to cover an object with particles before locking them down with Lock/Bond, as described in the following section.

Covering an Object in Particles

To cover an object in particles, add a Position Object operator to the same event as the Lock/Bond test. The Position Object operator places particles randomly on the surface, while the Lock/Bond test locks or animates them with Lock/Bond forces and parameters.

To cover the object with particles, make sure the Amount setting in the Birth operator is high enough to create the necessary quantity of particles. The Birth Texture operator generates complete, even coverage when using Face subdivision.

After the object is covered in particles, you can lock them to the surface as the object animates, make them drift over the surface, or fling them off the object.

Locking Particles to an Animated Surface

An animated surface is one that deforms, or changes shape, over time. Examples of animated surfaces are objects with:

- Parameter animation
- Sub-object animation (animated vertices or faces)
- Morphed objects
- Surfaces animated with skinning modifiers such as Skin and Physique

Transform animation (position, rotation, scale) at the object level is not considered an animated surface.

Use these parameters to lock particles to an animated surface:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lock To Surface</td>
<td>On</td>
</tr>
<tr>
<td>Animated Surface</td>
<td>On</td>
</tr>
</tbody>
</table>
When Force % = 100.0, particles stay firmly stuck to their lock points. The exception is when Speed Limit is on and the object is animated. In that case, particles stick to their lock points only if they can keep up with them without exceeding the specified velocity (Speed Limit). If this parameter is off, there is no distance or speed limit, and particles stay firmly stuck to their lock points.

A Force % value of 100.0, coupled with Offset Limit and Speed Limit off, forces the particles to stay on the surface.

**Moving Particles Along or Near an Object’s Surface**

To allow particles to move along an object’s surface, Restrict To Surface must be on and the Force % parameter in the Position Lock/Bond group must be set to a value lower than 100.0.

Any Speed or Force operators in the event will then act on the particles to move them along the surface. These forces are applied in such a way that they cause the particles to oscillate with and against the force, gradually slowing down (damping). You can control the amount of damping in the particles’ motion with the Dampening parameters in the Position Lock/Bond group.

When Restrict To Surface is on, all Force and Speed operators should be above the Lock/Bond test, while Collision and Spawn tests should be below the Lock/Bond test.

**Moving Particles Along a Surface**

If you want particles to drift along the surface of an object, use the following settings:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lock To Surface</td>
<td>On</td>
</tr>
</tbody>
</table>

---

3274 | Chapter 12  Space Warps and Particle Systems
Add Speed and Force operators to the event to make the particles move in a particular direction. For example, you can use a Wind space warp with a Force operator to push all the particles onto one end of the object.

**Drifting Particles**

Lock/Bond can also cause particles to drift slightly but always stay a short distance from their lock points. The area around each particle's lock point is called the central zone. Each particle has its own central zone, which extends to a specified radius around the lock point.

**Ejecting Particles from an Animated Object**

Lock/Bond can also cause particles to be ejected, released, or flung from an object's surface when they achieve a specific speed or acceleration.
**Ejecting Particles from a Fast-Moving Object**

Use this technique when particles are glued to the object's surface and have no speed of their own, and any speed or acceleration comes from animation of the object itself. Examples include a fast-spinning or fast-moving object, or one with sub-object animation that moves one part of the object at a fast speed.

Use these parameters to cause particles to break off a fast-moving object:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lock To Surface</td>
<td>On</td>
</tr>
<tr>
<td>Snap To Surface</td>
<td>On</td>
</tr>
<tr>
<td>Restrict To Surface</td>
<td>Off</td>
</tr>
<tr>
<td>Force %</td>
<td>100.0</td>
</tr>
<tr>
<td>Break Off When Exceeds</td>
<td>On</td>
</tr>
</tbody>
</table>

Under Break Off When Exceeds, choose either Speed or Acceleration, and set the speed or acceleration where particles should break off. Use the Acceleration method to simulate an object shaking off particles. When the object suddenly stops shaking the particles will fly off the object.

Particles that break off pass the Lock/Bond test and can be passed to another event. Use a Force operator in the next event to specify how the particles will behave after they are released from the object.

**Ejecting Particles When They Reach a Specific Speed**

To cause particles to break off an object as they move along the surface and achieve a specific speed of their own, use the settings described in the preceding section Moving Particles Along a Surface, and use a Speed Test operator to test particle speed and break to a new event.
Scale Test

*Particle View* on page 3015 > Click Scale Test in an event or add Scale Test to the particle system and then select it.

Scale Test lets the particle system check particle scaling, or particle size before or after scaling, and branch accordingly. The test provides a variety of axis options for measuring scale or size.

You can use this test to cause a change in behavior based on size. For example, a bubble could grow to a certain size, and then pop. Or an object could shrink in size until it falls under the influence of a force, like wind.

**Interface**

The user interface appears in the parameters panel, on the right side of the Particle View dialog.
Type Choose the type of measurement to test. You can test actual scaling, or the size before or after scaling. Default=Scale.
For example, if the X-axis size of a particle's bounding box starts out at 10 system units, and you then use the Scale operator to scale it by 150% on the X axis, the pre-scale size is 10, and the post-scale size is 15. And, of course, the scale is 150.

NOTE Particle Flow measures particle size based on each particle’s bounding-box dimensions in the particle’s local coordinate space. With the low-polygon Shape options Tetra and Sphere, the result of this measurement might not be the same as the Shape operator’s Size value.

- **PreScale Size** Tests the size before scaling.
- **PostScale Size** Tests the size after scaling.
- **Scale** Tests the scaling percentage.

Axis Choose the axis to measure. Default=Average.
- **Average** Obtains an average measurement by adding the sizes on all three axes and then dividing by three.
- **Minimum** Uses the smallest dimension.
- **Median** Uses the middle dimension in order of size. For example, if the particle dimensions are X=5, Y=6, Z=12, then the number compared to Test Value would be 6.
- **Maximum** Uses the largest dimension.
- **X/Y/Z** Uses the specified dimension.

Test True if Particle Value Lets you specify whether the test passes particles on to the next event if the speed test succeeds or fails. Available for all tests except True When Accelerates/Decelerates. Default=Is Greater Than Test Value. By default, Scale Test returns True if the value tested for exceeds the Test Value quantity, but you can alternatively choose Is Less Than Test Value. For example, if you set Type to Scale and set Test Value=150 and Variation=0, and choose Is Less Than Test Value, a particle will move to the next event only when its scaling factor is less than 150%.

Size group

These settings are available when Type is set to PreScale Size or PostScale Size.
**Test Value** The specific size to test for. Default=10.0.

**Variation** The amount by which the value tested for can vary randomly. Default=0.0.

To obtain the actual test value for each particle, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then adds the result to the Test Value setting. For example, if Test Value=10 and Variation=5, then the tested value for each particle would be between 5 and 15.

**Scale group**

These settings are available when Type is set to Scale.

**Test Value** The specific scaling factor to test for. Default=100%.

**Variation** The amount by which the value tested for can vary randomly. Default=0.0%.

To obtain the actual test value for each particle, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then adds the result to the Test Value setting. For example, if Test Value=100% and Variation=10%, then the tested value for each particle would be between 90% and 110%.

**Test Value Offset Keying group**

**Sync By** Choose the time frame to use when animating Test Value and Variation:

- **Absolute Time** Any keys set for parameters are applied at the actual frames for which they’re set.

- **Particle Age** Any keys set for parameters are applied at the corresponding frames of each particle's existence.

- **Event Duration** Any keys set for parameters are applied to each particle starting when it first enters the event.

**Uniqueness group**

The Uniqueness setting enables randomization of the test value variation. Available only when either Variation value exceeds 0.0.

**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.
Script Test

Particle View on page 3015 > Click Script Test in an event or add a Script Test operator to the particle system and then select it.

Script Test lets you test particle conditions using a MAXScript script. The script can use any program functionality available to MAXScript.

The default test script tests for the presence of all particles within a spherical volume of radius 20.

Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

Edit Script Click this button to open the current script in a MAXScript Editor window. For detailed information about the MAXScript utility, open the MAXScript Help, available from Help menu > MAXScript Help.

Uniqueness group

The Uniqueness setting provides a randomization seed that the script can use or ignore.

Seed Specifies a randomization value.

New Calculates a new seed using a randomization formula.

Send Out Test

Particle View on page 3015 > Click Send Out in an event or add Send Out to the particle system and then select it.
The Send Out test simply sends all particles to the next event, or, conversely, keeps all particles in the current event. Use Send Out when you simply want to send particles to another event without any conditions.

**TIP** You can temporarily convert any test to Send Out. To specify that a test should send all particles out without any conditions, click the left side of its icon in Particle view; the icon changes to a green light bulb to indicate that all particles automatically test True. Or, if you click the right side of the icon, it changes to a red light bulb, indicating that all particles test False and thus will stay in the current event. To revert to the test's original function, click its icon again.

### Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Test True For** Lets you specify whether the test passes all particles on to the next event or keeps them in the current event. Default=All Particles.

- **All Particles** All particles are passed on to the next event.
- **No Particles** All particles are retained in the current event.

**Spawn Test**

Particle View on page 3015 > Click Spawn in an event or add Spawn to the particle system and then select it.

Spawn creates new particles from existing ones. Each spawned particle is born at the same location as its parent, and has the same orientation and shape. Spawn can give the spawned particles a different speed and scaling factor. If you wire the Spawn test to another event, spawned particles are sent to that event, where you can specify different properties for the new particles.

Spawn is a test only in that it sends the spawned particles to another event (if wired); it doesn't actually test any properties. All particles that encounter Spawn are immediately affected by it. Thus, if you want particles to spawn based on the results of a test, use a different test that branches to an event.
containing the Spawn. In such a case, you might want to then send the spawned particles to yet another event, or the particles will continually respawn. Alternatively, to spawn particles after a collision, use Collision Spawn Test on page 3241.

See also:

- Collision Spawn Test on page 3241

Interface

![Particle System Interface Diagram](image)
The user interface appears in the parameters panel, on the right side of the Particle View dialog.

In the context of Spawn, a *parent* is the original particle from which new particles are spawned.

**Spawn Rate And Amount group**

Use these settings to specify how often particles are to spawn, the measurement system to use, and other values related to how many particles are spawned.

**Once** Particles spawn one time only. For each existing particle, one new one is born.

**Delete Parent** When on, deletes each original particle from which a new one is spawned. Available only with the Once option.

**Per Second** Lets you specify a number of particles to spawn every second. For example, if you use the default Rate setting of 10.0, at 30 fps a new particle is born every three frames.

**Rate** The number of particles to spawn per second. Available only with the Per Second option.

**By Travel Distance** Lets you spawn new particles at regular intervals over the path of a moving parent particle.

**Step Size** The system spawns a new particle every time the parent moves this distance, in system units.

**Spawnable** The percentage of particles in the current event that will spawn new particles. This is determined once for each particle, when it enters the event. However, the parameter is animatable. Default=100.0. For values other than 100.0, Spawnable uses a randomized selection process, which is affected by the Uniqueness Seed value. For example, with five parent particles, Offspring #=1, and Spawnable=80.0, you might get any number of spawned particles between two and five. The average per spawning would be four, however.

**Offspring #** The number of new particles the system creates from each parent particle for each spawning event. Default=1.

**Variation** The amount by which the Offspring # value can vary randomly. Default=0.0.

To obtain the actual test value for each particle, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then applies the result as a percentage of the Offspring # setting. For example, if Offspring
#=20 and Variation=10, then the actual number of offspring for each particle would be between 18 and 22.

**Sync By** Choose the time frame to use when animating Rate, Step Size, Offspring #, and Variation:

- **Absolute Time** Any keys set for parameters are applied at the actual frames for which they're set.

- **Particle Age** Any keys set for parameters are applied at the corresponding frames of each particle's existence.

- **Event Duration** Any keys set for parameters are applied to each particle starting when it first enters the event.

**Restart Particle Age** When on, sets the age of each newly spawned particle at 0. When off, each spawned particle inherits its parent's age. Default=on.

**Speed group**

Lets you specify the speed of spawned particles in absolute terms or relative to the parents' speed, with optional random variation. The direction of a spawned particle is always in relation to that of its parent, but you can set a Divergence so they eventually spread out. Default=Inherited.

**In Units** Choose this to specify the speed of spawned particles in system units per second. Default=100.0.

A positive value inherits the parent's direction; a negative value reverses it.

**Inherited** Choose this to specify each spawned particle's speed as a percentage of its parent's speed. Default=100.0

A positive value inherits the parent's direction; a negative value reverses it.

**Variation** The amount by which a spawned particle's speed can vary randomly. Default=0.0.

To obtain the actual speed for each spawned particle, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then adds the result to the particle's speed as specified or inherited. For example, if a particle's speed is 100 units/second and Variation=20, then the tested value for each particle would be between 80 and 120 units/second.

**Divergence** When on, spreads out the stream of spawned particles. Use the numeric setting to define the extent of the divergence in degrees. Range=0 to 180. Default=20.0.
Size group

Scale Factor The amount of uniform scaling to apply to each spawned particle, as a percentage of its parent's size. Default=100.0.

Variation The amount by which a spawned particle's scale can vary randomly. Default=0.0.

To obtain the actual scaling for each spawned particle, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then adds the result to the Scale Factor value. For example, if Scale Factor=100 and Variation=20, then each spawned particle would be between 80 and 120 percent of its parent's size.

Uniqueness group

The Uniqueness setting enables randomization of the Spawnable result, when less than 100.0, as well as of the Variation values.

Seed Specifies a randomization value.

New Calculates a new seed using a randomization formula.

Speed Test

Particle View on page 3015 > Click Speed Test in an event or add Speed Test to the particle system and then select it.

Speed Test lets the particle system check particle speed, acceleration, or the rate of circular travel, and branch accordingly. The test provides a number of variants that let you test speed or acceleration on specific axes, or simply whether the particle is accelerating or decelerating.
The user interface appears in the parameters panel, on the right side of the Particle View dialog.

The first interface element is a drop-down list that lets you choose the type of measurement to test:

- **Velocity Magnitude** Tests the particle velocity, in system units per second, without consideration of direction. This is the default test type.

- **Velocity X/Y/Z** Tests the particle velocity on the specified axis, in system units per second, using the world coordinate system.
  An example of this option would be with fireworks: As the particles move upward, their velocity on the world Z axis is positive. When the reach the top of their trajectory and begin to move downward, their velocity on the world Z axis slows to 0, and then becomes negative. If you choose Velocity Z and Is Less Than Test Value, and set Test Value to 0.0, you can send particles to another event at the moment they begin to move downward.

- **Acceleration Magnitude** Tests the particle acceleration (change in velocity), in system units per second per second, without respect to direction.

- **Acceleration X/Y/Z** Tests the particle acceleration (change in velocity) on the specified axis, in system units per second per second, using the world coordinate system.

- **Steering Rate** Tests the circular component of particle travel in degrees per second, without consideration of rotation or spinning.
For example, if a particle travels along a parabolic path, its motion has both linear and circular components. The circular component is greatest at the top of the parabola. If a particle travels in a full circle in one second, the rate is 360; if it travels in a half circle, the rate is 180.

Potential usage: When a particle is forced to turn too sharply, it might explode or change its type of movement. For example, missiles chase a jet fighter, which maneuvers to elude the missiles. The missiles are forced to change their course rapidly, but the missile construction cannot stand the fast change in steering, so the missiles blow up or disintegrate.

**TIP** You can test steering rate by setting the particle speed with Speed By Icon on page 3112, and linking the Speed By Icon operator icon to a circular path.

- **True When Accelerates** Returns a True value when the particle velocity is increasing in value.
- **True When Decelerates** Returns a True value when the particle velocity is decreasing in value.

**Test True if Particle Value** Lets you specify whether the test passes particles on to the next event if the speed test succeeds or fails. Available for all tests except True When Accelerates/Decelerates. Default=Is Greater Than Test Value.

By default, Speed Test returns True if the value tested for exceeds the Test Value quantity, but you can choose Is Less Than Test Value as well. For example, if you use the Velocity Magnitude test type and set Test Value=200 and Variation=0, and choose Is Less Than Test Value, then particles will move to the next event only when they travel faster than 200 units per second. Any particles traveling 200 units per second or slower stay in the current event unless they later exceed that speed or another test returns True.

**Test Value** The specific speed or acceleration to test for. The unit of measurement depends on the type of test; see above. Default=300.0.

**Variation** The amount by which value tested for can vary randomly. Default=0.0.

To obtain the actual test value for each particle, the system multiplies the Variation value by a random number between -1.0 and 1.0, and then adds the result to the Test Value setting. For example, if Test Value=300 and Variation=10, then tested value for each particle would be between 290 and 310.
Sync By Choose the time frame to use when animating Test Value and Variation. For further information, see Animation Offset Keying group on page 3106.

- **Absolute Time** Any keys set for parameters are applied at the actual frames for which they’re set.

- **Particle Age** Any keys set for parameters are applied at the corresponding frames of each particle’s existence.

- **Event Duration** Any keys set for parameters are applied to each particle starting when it first enters the event.

**Uniqueness group**

The Uniqueness setting enables randomization of the test value variation.

**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.

**Split Amount Test**

**Particle View** on page 3015 > Click Split Amount in an event or add Split Amount to the particle system and then select it.

The Split Amount test lets you send a specific number of particles to the next event, keeping all remaining particles in the current event. You can split the particle stream by a specific number or percentage, or by every Nth particle. With a specific number of particles, the splitting takes place once per event, but you can animate the percentage and “every Nth” values to vary the amount of split-off particles over time.
Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Test True For group**

Lets you choose how to split the particle stream. Default=Fraction Of Particles, 50%.

**Fraction Of Particles** Split the particle stream on a percentage basis, specified with the Ratio value. With Ratio greater than 0.0, whether a particular particle is split off depends on a randomization factor; change this with the Uniqueness Seed value.

**Ratio** Specify the percentage of particles that will test True. Animatable. Default=50.0.

Available only with the Fraction Of Particles option.

**Every Nth Particle** Splits off a regular sample of particles.

**N** Specify how often to split off a particle. Animatable. Default=3.

For example, enter 8 to split off every eighth particle.

Available only with the Every Nth Particle option.

**First N Particles** Splits off the number of particles specified as the N value (below), starting with the first particle to enter the event, and retains the rest.
**Particles After N First** Splits off all particles starting with the first one after N particles, as specified with the N parameter (below). All particles starting with the first to enter the event up to N are retained in the event.

N Specify the number of particles to split off, with First N Particles, or to retain in the event, with Particles After N First.
Available only with the First N Particles or the Particles After N First option.

**Per Emission Source** When on, Particle Flow applies the N value for the options First N Particles and Particles After N First separately for each emission source.
Use this option with multiple Particle Flow sources converging into a single Split Amount test.

**Uniqueness group**

The Uniqueness setting enables randomization of particle retention with the Fraction Of Particles option.

**Seed** Specifies a randomization value.

**New** Calculates a new seed using a randomization formula.

**Split Selected Test**

**Particle View** on page 3015 > Click Split Selected in an event or add Split Selected to the particle system and then select it.

The Split Selected test lets you split the particle stream based on particles' selection status. For information about selecting particles, see **Selection rollout** on page 3039.

**NOTE** This test considers only particles selected at the Particle sub-object level. To use all particles in an event at a specific frame, go to that frame, go to the Event sub-object level, and highlight the event. Then go to the Particle sub-object level, and on the Selection rollout, click Get From Event Level.
Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

Test True If Particle group

Lets you choose how to split the particle stream. Default=Is Selected.

Is Selected All selected particles are eligible for redirection to another event.

Is Not Selected All non-selected particles are eligible for redirection to another event.

Split Source Test

Particle View on page 3015 > Click Split Source in an event or add Split Source to the particle system and then select it.

The Split Source test lets you split the particle stream based on particles' origin. You can specify that particles from one or more specific Particle Flow sources should or should not be eligible for redirection to the next event.
Interface

The user interface appears in the parameters panel, on the right side of the Particle View dialog.

**Test True If Particle group**

Lets you choose how to split the particle stream. Default=Is From Selected Source.

- **Is From Selected Source** All particles from sources highlighted in the Selected Emission Sources list are eligible for redirection to another event.

- **Is Not From Selected Source** All particles from sources not highlighted in the Selected Emission Sources list are eligible for redirection to another event.

---

**Selected Emission Sources** Lists all emission sources in the system. Highlight the sources to be considered by the test.

**Non-Event-Driven Particle Systems**

Create panel > Geometry > Particle Systems

Create menu > Particles

Non-event-driven particle systems provide relatively simple, straightforward methods for generating particle sub-objects over time for the purpose of simulating snow, rain, dust, and so on. You use particle systems primarily in
animations. 3ds Max provides six built-in, non-event-driven particle systems: Spray, Snow, Super Spray, Blizzard, PArray, and PCloud.

**Fountain spray created as a particle system**

**TIP** You can take advantage of the AutoGrid feature to orient and position new particle systems with respect to existing objects. For details, see AutoGrid on page 2792.

- Particle Flow on page 2997
Interface

Snowstorm created as a particle system

This topic describes only the general properties of particle systems. Other plug-in particle systems might be available in your configuration.

The built-in particle systems share these controls:

**Emitter** Specifies where in the scene the particles are generated. The emitter is the particle system's main sub-object. It doesn't render. Particles appear on the surface of the emitter and fall (or drift, drop, flurry, spray) from the emitter in a particular direction.

**Timing** The timing parameters control the dynamics of particles in the system. They specify how quickly particles appear, how quickly they disappear, whether the emission rate is constant, and so on.

**Particle-specific parameters** These parameters are specific to the kind of particle system. Examples are particle size and speed.

**Rendering properties** These parameters are also specific to the kind of particle system. There are options for displaying particles in viewports and rendering them in scenes and animations. Particles do not necessarily appear the same in renderings as they do in viewports.

You can modify and animate particle system parameters. You can also affect particle system behavior with space warps on page 2887. In addition, you can deform particle systems with the Mesher compound object on page 794.

**NOTE** Particles can participate in dynamics simulations.
Particle System Usage

You create particle systems when you want to model an object or effect that can best be described as a large collection of similar objects behaving in a similar fashion. Obvious examples of such effects include rain and snow, but other equally valid examples include water, smoke, ants, and even crowds of people.

On the Create panel, click Spray, Snow, Super Spray, Blizzard, PArray, or PCloud to create a particle system. Spray and Snow exist primarily for compatibility with earlier releases of 3ds Max, and are superseded by Super Spray and Blizzard.

To create a particle system, first choose Create menu > Particles > Spray or Snow.

These are the basic steps for creating a particle system:

1. Create a particle emitter. All particle systems require an emitter. Some particle systems use the particle system icon as the emitter while others use an object you select from the scene as the emitter.

2. Determine the number of particles. You set parameters such as birth rate and life span to control how many particles can exist at any given time.

3. Set particle shape and size. You can select from many standard particle types (including metaballs) or you can select an object to be emitted as a particle.

4. Set initial particle motion. You can set the speed, direction, rotation, and randomness of particles as they leave the emitter. Particles can also be affected by animation of the emitter.

5. Modify particle motion. You can further modify the motion of particles after they leave the emitter by binding the particle system to a space warp in the Forces group, such as Path Follow, or make them bounce off a deflector in the Deflectors space warp group, such as UDeflector.

**IMPORTANT** When you use forces and deflectors together, always bind the forces before the deflectors.

**TIP** If the particles don't follow the emitter after it's moved, then change any Path Follow parameter on page 2919. The motion will be applied to the particles.
Rain and Snow

Create rain and snow using Super Spray on page 3315 and Blizzard on page 3319. These particle systems are optimized for droplet (Super Spray) and tumbling flake (Blizzard) effects. Add space warps such as Wind on page 2926 to create spring rains or winter storms.

Bubbles

Create bubbles by using the Bubble Motion options of Super Spray on page 3315. If you require good rendering speed, consider using constant or tetra particles. If you require bubble detail, consider using opacity-mapped facing particles, instanced spheres, or metaparticles.

Flowing Water

You generate flowing liquid effects by setting Super Spray on page 3315 to generate closely packed metaparticles. The metaparticles blob together forming a stream. Add a Path Follow on page 2919 space warp to send the stream down a trough.

Explosions

Particle Array (PArray) on page 3331 uses another object as its particle emitter. You can set the particle type to use fragments of the emitter object to simulate the object exploding.

Volume Effects

Particle Cloud (PCloud) on page 3324 constrains its particles within a specified volume. You can use Particle Cloud to generate bubbles in a glass of soda, or bees buzzing inside a jar.

Crowds

Super Spray on page 3315, Blizzard on page 3319, Particle Array on page 3331, and Particle Cloud on page 3324 can use instanced geometry as their particle type. You can create a stream of ants, a flock of birds, or a cloud of dandelion seeds using instanced geometry particles.
Creating a Particle Emitter

After you choose a particle system type to add, you create the particle system icon in the scene. The icon serves different purposes depending on the type of particle system.

As an emitter: The icon defines the starting location and direction of the particles. Spray, Snow, Super Spray, Blizzard, and Particle Cloud use the icon as the particle emitter.

As a placeholder: The icon serves only to hold the parameters for the particle system. The particles are emitted from another selected object. Particle Array and Particle Cloud use the icon as a placeholder.

You can choose whether Particle Cloud uses its icon or another selected object as the emitter.

Procedures

To create emitter icons:

- Drag in a viewport to set the size and orientation of the particle emitter icon for Spray, Snow, Super Spray, Blizzard, and Particle Cloud. Spray, Snow, Blizzard, and Particle Cloud use the icon size as the area of particle emission. Super Spray emits particles from its center regardless of its icon size.
  
  All particle systems align the particle direction with the Z axis of the creation grid.

To create placeholder icons:

1. Drag in a viewport to set the size of the placeholder icon for Particle Array and Particle Cloud. The size and location of the particle system icon has no effect on the particles.

2. After placing the particle system icon, click Pick Object on the Basic Parameters rollout to select the object to use as the particle emitter.

Using Materials with Particle Array

There are a few different options for applying a material to a particle system.
The material that appears on the particles comes from one of three places:

- The particle system itself
- The material assigned to the distribution object (PArray only)
- The material assigned to the instanced objects
Particles with various materials assigned to them

You make this choice in the Material Mapping and Source group near the bottom of the Particle Type rollout. Choose Icon to use the material assigned to the particle system, choose Picked Emitter to use the material assigned to the distribution object, or choose Instanced Geometry to use the material assigned to the instanced objects. Note that this third option is available only when Instanced Geometry is the current particle type (selected in the Particle Types group at the top of the Particle Type rollout).

**NOTE** SuperSpray and Blizzard don’t have distribution objects. PCloud has a distribution object but you can’t get the material from it. In these cases, a radio button lets you use the material from the instanced geometry. Only PArray lets you get the material from the distribution object.

**IMPORTANT** A particle-system object, like any other object, can carry only a single material at any time. Thus, if you choose either Picked Emitter or Instanced Geometry, an instance of the chosen material is actually copied to the particle system, overwriting the material assigned to the emitter. If you want to restore the emitter material, choose Icon, and then reassign the material from the Material Editor or the Browser.

No matter what choice you make, if the material used is not mapped, then all particles take on the surface properties of the material, regardless of which object is used as the source of the material.
Achieving Particle Motion Blur

Particle motion blur is actually the result of varying the opacity and the length of particles based on their speed. To accomplish this requires coordination between material assignment and the settings in the particle systems.

Follow these instructions:

■ Use the Particle MBlur map on page 6308 in the material that you assigned to the particles. For best results, assign it as an opacity map.

■ Make sure that the particle system, PArray, PCloud, and Super Spray, or Spray, supports the Particle MBlur map.

■ Choose Rotation and Collision rollout > Spin Axis Controls group > Direction of Travel/Mblur option.

■ In this same group, set the Stretch spinner greater than 0 to stretch the particles as a percent of their length based on the particle Speed setting.

■ Use the correct type of particle. MBlur works on all particle types except Constant and Facing.

NOTE Instanced objects with multi/sub-object materials cannot be image motion blurred.

Using Mapped Materials with Particle Systems

Mapped materials affect particles differently, depending on the source of the material.
When you choose Icon, the mapping coordinates of the material are applied across the V (vertical) axis, from \( V=0 \) (the bottom edge of the map) to \( V=1 \) (the top edge of the map). The bottom edge of the map is applied at the birth of the particle, and the top edge at either the death of the particle (if Time is on) or the distance of the particle at its death (if Distance is on).

The Time spinner specifies the number of frames from birth that it takes to complete one mapping of a particle. Thus, if set to 15, the particle uses the bottom edge of the map at its birth, and moves through to the top edge of the map at frame 15.

The Distance spinner specifies the distance, in units, from birth that it takes to complete one mapping of a particle. Thus, if set to 50, as the particle moves along the normal vector, it displays the bottom edge of the map at birth, and the top edge at 50 units along the normal vector.

The one exception to this is when you use the Tetra particle type. In this case, each particle is always constantly mapped with \( V=0 \) at the head and \( V=1 \) at the tail.

When you choose Picked Emitter, the particles take on the color of the object at the point at which they're created. If the mapped surface is yellow where the particle emerges, then the particle is yellow.

Again, Tetra particles are an exception and the distribution-object material is mapped from head to tail.
Fragment particles use the same technique, with additional options when the Thickness setting is greater than 0.

When Thickness is 0, all faces in the fragment are mapped the same as the portion of the object surface from which they're derived.

When Thickness is greater than 0, the outer faces of the fragment copy the surface of the distribution object, and are assigned the material ID specified in the Outside ID spinner in the Particle Type rollout > Fragment Materials group. The thickness edges use the Edge ID number, and the inner faces use Backside ID. Thus, by assigning a multi/sub-object material to the object-based emitter, you can specify a different material for the outer fragment surfaces, the edges, and the inner surfaces. Note that the Outside ID spinner defaults to a value of 0, which means “use whatever material is currently assigned.” Change this to a specific sub-material number to assign a sub-material to the outside edges of the fragments.

**Using Multi/Sub-Object Materials with Particle Systems**

If the assigned material is a Multi/Sub-Object material, the source of the material affects how particles are rendered.

- **Icon:** In most cases, each particle, at its birth, is assigned a different sub-material, cycling through each available sub-material. For example, if there are only three sub-materials, the first particle receives sub-material #1, the second #2, the third #3, the fourth #1, and so on. The exceptions to this are as follows:
  - MetaParticles use only the first sub-material.
  - Object fragments are born at once, so all of them use only the first sub-material.
  - **Picked Emitter:** When used with object fragments as particles, each particle uses the three ID numbers in the Fragment Materials group. If this source is used with the other particle types, the particles are assigned sub-materials in the same way as when Icon is chosen.
  - **Instanced Geometry:** When used with Instanced Geometry particles, each particle is assigned a sub-material in exactly the same way as the source object, so each particle looks just like the source object. When used with other particle types, the particles are assigned sub-materials in the same way as when Icon is chosen.
NOTE: Instanced objects with Multi/Sub-Object materials cannot be image motion blurred.

Particles with a Multi/Sub-Object material

Using Spawned Particles

The examples in this topic demonstrate a very simple spawning using the Super Spray particle system.

Example: Setting up the particle system:

1. In the Perspective viewport, create a pyramid that's 5 units in all dimensions.
2. Create a cylinder with a radius and height of 3, and 6 sides.
3. In the center of the Perspective viewport, create a Super Spray emitter.
4. Set Speed in the Particle Motion group (Particle Generation rollout) to 3.0.
5. On the Particle Type rollout, choose Instanced Geometry, then in the Instancing Parameters group click Pick Object, and select the pyramid.
In the Viewport Display group of the Basic Parameters rollout, choose Mesh and set the Percentage of Particles to 100.

On the Particle Generation rollout, choose Use Rate, and set the spinner to 1.

Set Emit Start and Emit Stop to 0, set Display Until to 100, set Life to 10, and leave Variation at 0.

Under Particle Size, set Grow For and Fade For to 0.

Drag the time slider between frames 0 and 15.

A single pyramid particle emerges from the emitter, moves up, and then dies and disappears at frame 10.

**Example: Adding spawning effects:**

1. On the Particle Spawn rollout, choose Spawn on Death.
2. Leave Spawns spinner at 1, and set the Multiplier to 2.
3. Set the Direction Chaos spinner to 50.
4. Drag the time slider slowly over frames 8 to 25 (approximately).
   At frame 10, two pyramids appear at the death of the original particle (because of the Multiplier setting), and move off in different directions (because of the Direction Chaos setting). All particles die after frame 20 because only one generation of spawned particles is specified.
5. Set Spawns to 4, and the Multiplier to 4.
6. Drag the time slider over frames 8 to 50.
   With each spawned generation the particles increase exponentially.

**Example: To mutate the objects:**

1. In the Object Mutation Queue group, click Pick Object, and then select the cylinder.
   The name of the cylinder appears in the list window.
2. Click Pick Object and select the pyramid. Then click Pick Object again, and select the cylinder. Your list now reads: Cylinder01, Pyramid01, Cylinder01.
3. Drag the time slider over frames 0 to 50.
The pyramid appears over frames 0 to 10, then changes to four cylinders at frame 11, then 16 pyramids at the next spawning, and so on.

**Using Interparticle Collision**

You can set up particles to detect collisions with each other. This can be useful when the particles are meant to model solid objects such as marbles.

![Particles colliding and then rebounding](image)

**Procedures**

**Example: To create particles that collide with each other:**

1. Create a Super Spray particle emitter, and place a Deflector space warp on page 2959 a short distance from it with the surface of the deflector perpendicular to the stream of the particles. Bind the deflector to the Super Spray.
2 Set the Super Spray values as follows:
   ■ Off Axis: 1, Spread: 1, Off Plane: 180, Spread: 180
   ■ Mesh: chosen, Percent of Particles: 100
   ■ Particle Quantity: Use Rate chosen and set to: 1
   ■ Speed: 3, Variation: 100%
   ■ Emit Start: 0, Emit Stop: 5, Display Until: 100, Life: 100
   ■ Size: 4.0, Grow For: 0, Fade For: 0
   ■ Particle Type: Sphere

3 Drag the time slider so you can see the particle spheres bounce off the deflector. Note that the rebounding particles move through each other.

4 On the Rotation & Collision rollout, turn on Enable in the Interparticle Collisions group. View the animation again. This time, the particles bounce off each other.

**TIP** InterParticle Collisions, Deflector Binding, and Bubble Noise do not get along well together. Particles may leak through the deflector when these three are used together. Instead of bubble motion use animated mapping. Use facing particles with an animated map of a bubble, where the bubble is smaller than the map size. The bubble is animated moving around the map. This simulates bubble motion at the map level.

**Spray Particle System**

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > Spray

Create menu > Particles > Spray

Spray simulates water drops such as rain, a fountain, the spray from a garden hose, and so on.
Kinds of Spray

NOTE SuperSpray on page 3315 is a more powerful and advanced version of Spray. It provides all the functionality of Spray, plus additional features.

TIP To animate particles following a path through space, use the Path Follow space warp on page 2919.

Procedures

To create spray:

1. On the Create panel, make sure the Geometry button is active and Particle Systems is chosen in the object category list, then click Spray.

2. Drag in a viewport to create the Spray emitter; see Creating a Particle Emitter on page 3297.

The emitter's direction vector points in the negative Z direction of the active construction plane. For example, if you create the emitter in the Top viewport, the particles will move downward in the Front and Left viewports.
Interface

Particles group

Viewport Count  Maximum number of particles displayed in viewports at any given frame.

TIP  Setting the viewport count less than the render count can improve viewport performance.
**Render Count** Maximum number of particles that can appear in a single frame when you render it. Works in combination with the particle system's timing parameters.

- When the number of particles reaches the Render Count value, particle creation is suspended until some particles die.
- When enough particles die, particle creation resumes until Render Count is reached again.

**Drop Size** Size of a particle in the active units.

**Speed** Initial velocity of each particle as it leaves the emitter. Particles travel at this speed unless they are affected by a particle system space warp.

**Variation** Varies the initial speed and direction of particles. The greater the Variation, the stronger and broader the spray.

**Drops, Dots, or Ticks** Choose how particles are displayed in viewports. The display setting does not affect how particles are rendered. Drops are streaks that appear like raindrops, dots are points, ticks are small plus signs.

**Render group**

**Tetrahedron** Particles are rendered as long tetrahedrons, with the length you specify in the Drop Size parameter. Tetrahedron is the default setting for rendering. It provides a basic simulation of water drops.

**Facing** Particles are rendered as square faces whose width and height equals the Drop Size. Facing particles always face the camera (or the user's perspective). They are provided especially for use with material maps. Use with an appropriate opacity map for bubbles or snowflakes.

**NOTE** Facing works correctly only in a perspective or camera view.

**Timing group**

Timing parameters control the "birth and death" rates of emitted particles.

At the bottom of the Timing group is a line that displays the maximum sustainable rate. This value is based on the Render Count and the lifetime of each particle. To be precise:

maximum sustainable rate=Render Count/Life

Because the number of particles in a frame never exceeds Render Count, if the Birth Rate exceeds the maximum rate, the system will run out of particles,
pause until some die off, and then start again, generating particles in bursts or spurts.

**Start** Number of the first frame where particles appear.

**Life** The lifetime of each particle, in number of frames.

**Birth Rate** The number of new particles born per frame. If this is less than or equal to the maximum sustainable rate, the particle system generates an even flow of particles. If it is greater than the maximum rate, the particle system generates particles in bursts.

You can animate the Birth Rate parameter.

**Constant** When on, Birth Rate is unavailable and the birth rate used equals the maximum sustainable rate. When off, Birth Rate is available. Default=on. Turning Constant off does not mean that the birth rate varies automatically; the birth rate remains constant unless you animate the Birth Rate parameter.

**Emitter group**

The emitter specifies the area where particles appear in the scene. It has a geometry you can display in viewports, but it isn’t renderable.

The emitter is displayed as a rectangle with a vector pointing out of one side. The vector shows the direction in which the system emits particles.

**Width and Length** You implicitly set the initial value of these parameters when you drag in a viewport to create the emitter. You can adjust the values in the rollout.

The space occupied by the particle system at any given time is the result of a combination of its initial parameters (such as size of the emitter, and speed and variation of emission) and any space warps that have been applied.

**Hide** Turn on to hide the emitter in viewports. When Hide is off, the emitter is displayed in viewports. The emitter is never rendered. Default=off.

**Snow Particle System**

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > Snow

Create menu > Particles > Snow
Snow simulates falling snow or confetti. The snow system is similar to Spray, but it has additional parameters to generate tumbling snowflakes, and its rendering options are different.

Kinds of Snow

NOTE Blizzard on page 3319 is a more powerful and advanced version of Snow. It provides all the functionality of Snow, plus additional features.

TIP To animate particles following a path through space, use the Path Follow space warp on page 2919.

Procedures

To create snow:

1. In the Create panel, make sure the Geometry button is active and Particle Systems is selected from the object category drop-down list, then click Snow.

2. Drag in a viewport to create the Snow emitter; see Creating a Particle Emitter on page 3297.

   The emitter's direction vector points in the negative Z direction of the active construction plane.
Interface

Particles group

**Viewport Count** Maximum number of particles displayed in viewports at any given frame.
TIP Setting the viewport count less than the render count can improve viewport performance.

**Render Count** Maximum number of particles that can appear in a single frame when you render it. Works in combination with the particle system’s timing parameters.

- When the number of particles reaches the Render Count value, particle creation is suspended until some particles die.
- When enough particles die, particle creation resumes until Render Count is reached again.

**Flake Size** Size of a particle in the active units.

**Speed** Initial velocity of each particle as it leaves the emitter. Particles travel at this speed unless they are affected by a particle system space warp.

**Variation** Varies the initial speed and direction of particles. The greater the Variation, the broader the area of snowfall.

**Tumble** Amount of random rotation for snowflake particles. This parameter can range from 0 to 1. At 0, flakes do not rotate; at 1, they rotate the most. The axis of rotation is generated randomly for each particle.

**Tumble Rate** Speed at which snowflakes rotate. The greater the Tumble Rate, the faster the rotation.

**Flakes, Dots, or Ticks** Select how particles are displayed in viewports. The display setting does not affect how particles are rendered. Flakes are star-shaped snowflakes, dots are points, ticks are small plus signs.

**Render group**

**Six Point** Each particle is rendered as a six-pointed star. Each side of the star is a face to which you can assign a material. This is the default setting for rendering.

**Triangle** Each particle is rendered as a triangle. Only one side of the triangle is a face to which you can assign a material.

**Facing** Particles are rendered as square faces whose width and height equals the Drop Size. Facing particles always face the camera (or the user’s perspective). They are provided especially for use with material maps. Use with an appropriate opacity map for bubbles or snowflakes.

**NOTE** Facing works correctly only in a perspective or camera view.
Timing group

Timing parameters control the "birth and death" rates of emitted particles.

At the bottom of the Timing group is a line that displays the maximum sustainable rate. This value is based on the Render Count and the lifetime of each particle. To be precise:

maximum sustainable rate=Render Count/Life

Because the number of particles in a frame never exceeds Render Count, if the Birth Rate exceeds the maximum rate, the system will run out of particles, pause until some die off, and then start again, generating bursts or spurts of particles.

Start Number of the first frame where particles appear.

Life The lifetime of a particle, in number of frames.

Birth Rate The number of new particles born per frame.

If this is less than or equal to the maximum sustainable rate, the particle system generates an even flow of particles. If it is greater than the maximum rate, the particle system generates particles in bursts.

You can animate the Birth Rate parameter.

Constant When on, Birth Rate is unavailable and the birth rate used equals the maximum sustainable rate. When off, Birth Rate is available. Default=on.

 Turning Constant off does not mean that the birth rate varies automatically; the birth rate remains constant unless you animate the Birth Rate parameter.

Emitter Group

The emitter specifies the area where particles appear in the scene. It has a geometry you can display in viewports, but it isn't renderable.

The emitter is displayed as a rectangle with a vector pointing out of one side. The vector shows the direction in which the system emits particles.

You set emitter parameters in the Emitter group of the particle system's Parameters rollout.

Width and Length You implicitly set the initial value of these parameters when you drag in a viewport to create the emitter. You can adjust the values in the rollout.

The space occupied by the particle system at any given time is the result of a combination of its initial parameters (size of the emitter, and speed and variation of emission) and any space warps that have been applied.
**Hide** Turn on to hide the emitter in viewports. When off, the emitter is displayed in viewports. The emitter is never rendered. Default=off.

**Super Spray Particle System**

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > Super Spray

Create menu > Particles > Super Spray

Super Spray emits a controlled spray of particles. This particle system is like the simple Spray particle system with the added power provided by all the newer particle systems.
To animate particles following a path through space, use the Path Follow space warp on page 2919.
Procedures

To create a super spray particle system:

1. On the Create panel, make sure the Geometry button is active and Particle Systems is chosen in the object category list, then click Super Spray.

2. Drag in any viewport to create the Super Spray emitter icon; see Creating a Particle Emitter on page 3297. The icon appears as an intersecting plane and circle with an arrow. The initial direction of the spray (based on the orientation of the emitter icon and indicated by the icon arrow) depends on the viewport in which you create the icon. Generally, the particles spray toward you when created in an orthographic viewport, or spray upward when created in a Perspective viewport.

3. Adjust the various parameters to alter the spray effect.

Interface

NOTE This section describes the Particle Formation group in the Basic Parameters rollout, and the Particle Motion group in the Particle Generation rollout. These are the only controls unique to Super Spray. The other Super Spray rollouts and their contents are identical with those in Particle Array, except that Object Fragments and associated settings are not available on the Particle Type rollout. See PArray Particle System on page 3331 for details or choose from the following list for rollout information.

- Particle Generation Rollout (PArray) on page 3338
- Particle Type Rollout (PArray) on page 3342
- Rotation and Collision Rollout (PArray) on page 3352
- Object Motion Inheritance Rollout (PArray) on page 3355
- Bubble Motion Rollout (PArray) on page 3356
- Particle Spawn Rollout (PArray) on page 3358
- Load/Save Presets Rollout (PArray) on page 3364
These items control the direction and spread of particles.

**Off Axis** Affects the angle of the particle stream off the Z axis (along the plane of the X axis).

**Spread** Affects the spread of the particles away from the emission vector (along the plane of the X axis).

**Off Plane** Affects the angle of emission about the Z axis. This has no effect if Off Axis is set to 0.
**Spread** Affects the spread of the particles about the Off Plane axis. This has no effect if Off Axis is set to 0.

**Particle Generation rollout > Particle Motion group**

**Speed** The speed of the particle at birth, in units per frame.

**Variation** Applies a percentage of variation to the speed of emission for each particle.

**Blizzard Particle System**

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > Blizzard

Create menu > Particles > Blizzard

This is an advanced version of the original Snow particle system.
To animate particles following a path through space, use the **Path Follow space warp** on page 2919.

Blizzard viewport icon (emitter)

Snowflake particles in a blizzard
Procedures

To create a blizzard particle system:

1. On the Create panel, make sure the Geometry button is active and Particle Systems is chosen in the object category list, then click Blizzard.

2. Drag in a viewport to create the Blizzard emitter; see Creating a Particle Emitter on page 3297.
   The icon appears as a plane with a perpendicular line pointing in the direction of emission.

3. Adjust the various parameters on the command panel.

Interface

This section describes the Display Icon group in the Basic Parameters rollout, the Particle Motion group in the Particle Generation rollout, and the Material Mapping and Source group in the Particle Type rollout. These are the only controls unique to Blizzard. The other Blizzard rollouts and their contents are identical with those in Particle Array, except that Object Fragments and associated settings are not available on the Particle Type rollout. See PArray on page 3331 for details or choose from the following list for rollout information.

- Particle Generation Rollout (PArray) on page 3338
- Particle Type Rollout (PArray) on page 3342
- Rotation and Collision Rollout (PArray) on page 3352
- Object Motion Inheritance Rollout (PArray) on page 3355
- Particle Spawn Rollout (PArray) on page 3358
- Load/Save Presets Rollout (PArray) on page 3364
The emitter specifies the location where particles are generated in the scene. It has a geometry you can display in viewports, but it isn’t renderable.

The emitter is displayed as a rectangle with a vector pointing out of one side. The vector shows the direction in which the system emits particles.

You set emitter parameters on the particle system’s Basic Parameters rollout, in the Display Icon group.

**Width and Length** You implicitly set the initial value of these parameters when you drag in a viewport to create the emitter. You can adjust the values on the rollout.

The space occupied by the particle system at any given time is the result of a combination of its initial parameters (such as size of the emitter, and speed and variation of emission) and any space warps that have been applied.

**Emitter Hidden** Hides the emitter in viewports. When off, the emitter is displayed in viewports. The emitter is never rendered. Default=off.
Particle Generation rollout > Particle Motion group

Specifies the number, size, and motion of particles.

**Speed** The speed of the particle at birth, in units per frame.
Variation Applies a percentage of variation to the speed of emission for each particle.

Tumble Amount of random rotation of the particles.

Tumble Rate Speed at which the particles rotate.

Particle Type rollout > Mat'l Mapping and Source group

Emitter Fit Planar Maps particles at birth, based on their point of emission from the rectangular Blizzard emitter icon. The UV range of the mapped material runs from 0 to 1 over the width and length of the emitter.

PCloud Particle System

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > PCloud
Create menu > Particles > PCloud

Use the PCloud (or Particle Cloud) particle system when you want a "cloud" of particles that fill a specific volume. PCloud can provide a flock of birds, a starfield, or a troupe of soldiers marching over terrain.

You can confine the particles using basic supplied volumes of a box, sphere, or cylinder, or you can use any renderable object in the scene as a volume as long as that object has depth. Two-dimensional objects do not work with PCloud.

**TIP** There is no automatic way to hide the object chosen as the object-based emitter. Hide it by using Hide Selected on the Display panel, or by applying a Hide key in Track View.
PCloud viewport icon (object-based emitter)

PCloud used to form a school of fish (each fish is a particle)
Procedures

To create a particle cloud:

1 On the Create panel, make sure the Geometry button is active and Particle Systems is chosen in the object category list, then click PCloud.

2 Drag in a viewport to create the PCloud emitter; see Creating a Particle Emitter on page 3297. Adding a PCloud emitter works the same way as creating a box primitive: First drag out the length and width, then release the mouse button and move the mouse vertically to set the height, and then click to finish.

3 The emitter appears with a letter "C" representing the particle cloud.

3 Adjust the various parameters on the command panel.

Interface

This section describes the Object-Based Emitter, Particle Formation, and Display Icon groups in the Basic Parameters rollout, and the Particle Motion group in the Particle Generation rollout. These are the only controls unique to PCloud. The other PCloud rollouts and their contents are identical with those in Particle Array, except that Object Fragments and associated settings are not available on the Particle Type rollout. See PArray on page 3331 for details or choose from the following list for rollout information.

Particle Generation Rollout (PArray) on page 3338
Particle Type Rollout (PArray) on page 3342
Rotation and Collision Rollout (PArray) on page 3352
Object Motion Inheritance Rollout (PArray) on page 3355
Bubble Motion Rollout (PArray) on page 3356
Particle Spawn Rollout (PArray) on page 3358
Load/Save Presets Rollout (PArray) on page 3364
Basic Parameters rollout

Object-Based Emitter group

This button lets you select a renderable mesh object to use as a particle emitter. This object is used only when the Object-Based Emitter option is chosen in the Particle Formation group.

Pick Object Click this, and then select a renderable mesh object to be used as a custom emitter.

Object Displays the name of the picked object.
Particle Formation group

These options let you specify the shape of the emitter.

**Box Emitter** Chooses a box-shaped emitter.

**Sphere Emitter** Chooses a sphere-shaped emitter.

**Cylinder Emitter** Chooses a cylindrical emitter.

**Object-Based Emitter** Chooses the object selected in the Object-Based Emitter group.

**NOTE** With regard to animation of the object-based emitter, the particles will properly fill a deformed object at frame 0, but they can't stay with the emitter while it's moving. If the emitter moves in a straight line, this can give the appearance of the cloud moving with the emitter.

Display Icon group

These options let you adjust the dimensions of the emitter icon when a custom object is not used as an emitter. When a custom object is used you can still resize the "Fill" icon using these options.

**Rad/Len** Adjusts the radius of a spherical or cylindrical icon, and the length of a box icon.

**Width** Sets the width of a box emitter.

**Height** Sets the height of a box or cylindrical emitter.

**Emitter Hidden** Hides the emitter.
Particle Generation rollout > Particle Motion group

Speed The speed of the particle at birth along the normal, in units per frame.

NOTE For the correct volume effect, Speed should be set to 0.

Variation Applies a percentage of variation to the speed of emission for each particle.

Random Direction One of three options that affect the direction of the particles. This option emits particles in random directions.

Direction Vector Specifies the direction of the particles by a vector defined by the three X, Y, and Z spinners.

X/Y/Z Displays the particle direction vectors.

Reference Object Emits particles in the direction of the local Z axis of a specified object.

Object Displays the name of the picked object.
**Pick Object** Click this, and then select an object in the scene to use as a reference object. This button is available only when you choose Reference Object.

**Variation** Applies a percentage of variation to the direction when you choose either the Direction Vector or Reference Object option. This spinner is unavailable and has no effect when you choose Random Direction.

---

**PArray Particle System**

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > PArray

Create menu > Particles > PArray

The PArray (Particle Array) particle system can distribute particles on a geometric object. You can also use it to create sophisticated object explosions.

**TIP** A good way to create explosions with PArray is to set the particle type to Object Fragments and then apply a PBomb space warp on page 2914.

When you use PArray to emit particles using a selected geometric object as the emitter template (or pattern) for the emission, the object is referred to as the *distribution object.*
Basket used as a distribution object for random particles over its surface

How particles can be distributed on an object:
Left: Edges
Center: Vertices
Right: Faces

See also:
- Particle System Usage on page 3295
- Using Materials with Particle Array on page 3297
- Achieving Particle Motion Blur on page 3300
- Using Mapped Materials with Particle Systems on page 3300
- Using Multi/Sub-Object Materials with Particle Systems on page 3302
- Using Spawned Particles on page 3303
- Using Interparticle Collision on page 3305

Procedures

To set up a particle array:

1. Create an object that will become the distribution object, providing the emitter pattern (or exploded object) for the particle array.

2. On the Create panel, make sure the Geometry button is active and Particle Systems is chosen in the object category list, then click PArray.

3. Drag anywhere in a viewport to create the particle-system object; see Creating a Particle Emitter on page 3297.

4. On the Basic Parameters rollout, click Pick Object, and then click the object to use as the distribution object.

5. Adjust the various options in the Particle Array rollouts to achieve the effect you want. The distribution object can be any object containing renderable faces. The particle-system object does not appear in the rendered scene. Its placement, orientation or size in the scene has no influence on the particle effect. To access the Particle Array parameters after creation, open the Modify panel and select the particle-system object (or click any visible...
particles in the viewport). To transform or otherwise modify the distribution object, select the distribution object itself.

Also, you can share a single distribution object among more than one particle-system object. The distribution object merely provides the template for the particles, which are actually generated by the particle system.

Example: To assign three different mapped materials to fragments:

1. Apply mapping coordinates to the distribution object, either by turning on Generate Mapping Coords, if necessary, or by applying a UVW Map modifier on page 1932.

2. Assign a Multi/Sub-Object material on page 6120 to the distribution object.

3. Set up the first three sub-materials to be mapped materials.

4. Select the PArray icon.

5. On the Particle Type rollout in the Mat'l Mapping And Source group, choose Picked Emitter.

6. In the Particle Type rollout > Particle Types group, turn on Object Fragments.

7. Make sure the three spinners in the Fragment Materials group are set to 1, 2, and 3, respectively (or match the numbers with the sub-materials you've assigned in your multi/sub-object material).

TIP Using a complex distribution object for object-fragment particles can really slow down viewport interaction. You can use a simple stand-in object as the distribution object, and then later use the File/Replace command to replace the distribution object with a more complex object of the same name.

Basic Parameters Rollout (PArray)

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > PArray > Basic Parameters rollout

The items on the Basic Parameters rollout let you create and adjust the size of the particle system, and pick the distribution object. In addition, they let you specify the initial distribution of the particles in relation to the geometry of the distribution object, and the initial velocity of the particles from the
distribution object. From here, you can also specify how the particles appear in the viewport.

**Interface**

**Object-Based Emitter group**

**Pick Object** After you create the particle-system object, the Pick Object button becomes available. Click this button, and then click to select an object in your scene. The selected object becomes the object-based emitter, and is used either
as the source geometry over which particles form, or the source geometry used to create particles that appear to be fragments of the object.

**Object text field** Displays the name of the picked object.

**Particle Formation group**

These options determine how standard particles are initially distributed over the surface of the object-based emitter. These controls are available only when the picked object is used as a distribution grid for standard particles, MetaParticles, or instanced geometry; see Particle Type rollout on page 3342. When Object Fragments is chosen in the Particle Type rollout, these controls are unavailable.

**Over Entire Surface** Emits particles randomly over the entire surface of the object-based emitter. This is the default choice.

**Along Visible Edges** Emits particles randomly from the visible edges of the object.

**At All Vertices** Emits particles from the vertices of the object.

**At Distinct Points** Places a specified number of emitter points randomly over the surface of the object.

**Total** Specifies the number of emitter points used when At Distinct Points is chosen.

**At Face Centers** Emits particles from the center of each triangular face.

**Use Selected SubObjects** With mesh-based emitters, and to a limited extent with patch-based emitters, limits the source of the particle stream to the sub-object selection passed up the modifier stack in the object-based emitter. For example, if your emitter object is a cylinder converted to an editable mesh, and the top cap of that cylinder is selected at the Face or Polygon sub-object level, if Use Selected SubObjects is on and Particle Formation group > At Face Centers is on, the particles will stream only from the top cap of the cylinder. Default=off.

The type of particle formation you specify determines the type of sub-object geometry used, as follows:

- **Over Entire Surface** Faces
- **Along Visible Edges** Edges
- **At All Vertices** Vertices
- **At Distinct Points** Faces
At Face Centers
Faces
If you've converted your object to an editable mesh, and selected different sub-object sections of it with vertex, edge, and face selection, as you switch particle formation options, you'll see the particles emit from different areas of the object.

NOTE Use Selected SubObjects is applicable to patch object emitters only at the patch and element sub-object levels, and is not applicable NURBS objects used as emitters.

TIP You can best see the emission patterns by first setting Speed on the Particle Generation rollout > Particle Motion group to 0. Move to a frame in which the particles appear, and then choose the various particle formation options.

Display Icon group

Adjusts the display of the particle-system icon in the viewports. (The particle-system icon is usually called the "emitter." In this case, however, it doesn't actually emit particles, so we're avoiding the term.)

Icon Size Sets the overall size of the icon, in units.

Icon Hidden When on, the PArray icon is hidden in the viewports. Note that the icon does not render, in any case. Default=off.

Viewport Display group

Specifies how the particles are displayed in the viewports.

Dots Displays the particles as dots.

Ticks Displays the particles as crosses.

Mesh Displays the particles as mesh objects. This results in slower viewport redraws.

BBox For instanced geometry only, this displays each instanced particle, whether a single object, a hierarchy, or a group, as a bounding box.

Percentage of Particles This spinner specifies the number particles displayed in the viewports as a percentage of the number of rendered particles. Default=10 percent.

Set the display percentage to 100 percent if you want to see the same number of particles as will be rendered in your scene. However, this can considerably slow viewport display.
Particle Generation Rollout (PArray)

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > SuperSpray/Blizzard/Parray/PCloud > Particle Generation rollout

Select a SuperSpray/Blizzard/Parray/PCloud emitter. > Modify panel > Particle Generation rollout

Items on this rollout control when and how quickly particles form, how particles move, and the size of the particles over time.
Interface

Particle Quantity group

In this group, you can choose one of two methods by which the number of particles is determined over time. These settings are unavailable if you set Particle Type (in the Particle Type rollout on page 3342) to Object Fragments.
Use Rate Specifies a fixed number of particles emitted per frame. Use the spinner to set the number of particles formed per frame.

Use Total Specifies a total number of particles formed over the life of the system. Use the spinner to set the number of particles formed per frame.
The life of the system, in frames, is specified by the Life spinner in the Particle Timing group, described later in this topic.

**TIP** Generally, Use Rate is best for a continuous flow of particles, like a trail of pixie dust, while Use Total is better for bursts of particles over a short period of time.

**Particle Motion group**

These spinners control the initial particle velocity, which is directed along the surface, edge, or vertex normals (interpolated for each emitter point).

**Speed** The velocity of the particle at birth, along the normal, in units traveled per frame.

**Variation** Applies a percentage of variation to the speed of emission for each particle.

**Divergence** Applies an angular degree of variation by which each particle's velocity can vary from the emitter normal.

**NOTE** The initial direction for a fragment cluster is the normal of the cluster's seed face. Clusters are created by choosing a single face (the seed face), and then creating a cluster outward from that face, depending on the method chosen in the Object Fragment Controls group on the Particle Type rollout.

**Particle Timing group**

These options specify when particle emission starts and stops, and the lifespan of the individual particles.

**Emit Start** Sets the frame at which particles begin to exist in the scene.

**Emit Stop** Sets the last frame at which particles are emitted. This setting has no effect if you choose the Object Fragments particle type.

**Display Until** Specifies the frame at which all particles will disappear, regardless of other settings.

**Life** Sets the lifespan in number of frames of each particle from the frame of creation.
Variation Specifies the number of frames by which the life of each particle can vary from the norm.

Subframe Sampling Turning on any of the three check boxes below helps avoid particle "puffing" by sampling particles at a much higher subframe resolution, instead of the relatively coarse frame resolution. Depending on your needs, you can do this over time, over motion, or over rotation. "Puffing" is the effect of emitting separate "puffs" or clusters of particles, rather than a continuous stream. This effect is especially noticeable when the emitter is animated.

- **Creation Time** Enables the addition of a time offset to the equations of motion that prevents puffing in time. This setting has no effect with the Object Fragments particle type. Default=on.

- **Emitter Translation** If the object-based emitter is moving in space, particles are created at integral times at positions along the geometry's path between renderable positions. This prevents puffing in space. This setting has no effect if Object Fragment particle type is on. Default=on.

- **Emitter Rotation** If the emitter is rotating, turn this on to avoid puffing and produce smooth spiral effects. Default=off.

**IMPORTANT** Each additional subframe sampling check box that you turn on progressively increases the necessary computation. In addition, the methods are listed in order of least amount of computation to most. Thus, Emitter Rotation is more costly than Emitter Translation, which is more costly than Creation Time.

---

**Particle Size group**

These spinners specify the size of the particles.

**Size** This animatable parameter specifies the target size for all particles in the system, depending on the type of particle:

- **Standard Particles** The major dimension of the particle.

- **Constant** The dimension, in rendered pixels, of a Constant type of particle.

- **Object Fragments** No effect.

**Variation** The percentage by which the size of each particle may vary from the norm. This is applied to the Size value. Use this parameter to get a realistic mix of large and small particles.
Grow For  The number of frames over which the particle grows from being very small to the Size value. The result is subject to the Size/Variation value, since Grow For is applied after Variation. Use this parameter to simulate natural effects such as bubbles growing as they reach the surface.

Fade For  The number of frames over which the particle will shrink to 1/10th its Size setting prior to its death. This is also applied after Variation. Use this parameter to simulate natural effects such as sparks fading to ash.

Uniqueness group

By changing the Seed value in this spinner, you achieve different results using otherwise identical particle settings.

New  Randomly generates a new seed value.

Seed  Sets a specific seed value.

Particle Type Rollout (PArray)

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > SuperSpray/Blizzard/Parray/PCloud > Particle Type rollout

Select a SuperSpray/Blizzard/Parray/PCloud emitter. > Modify panel > Particle Type rollout

The controls on this rollout let you specify the type of particle used and the type of mapping performed on the particles.
Left: A stream from a fountain
Right: The same stream with various types of particles
Chapter 12  Space Warps and Particle Systems
Particle Types group

These options specify one of four categories of particle type. Depending on which option you choose, different controls become available in the lower portion of the Particle Type rollout.

**Standard Particles** Uses one of several standard particle types, such as triangle, cube, tetra, and so on.

**MetaParticles** Uses Metaball particles. These are particle systems in which the individual particles blend together in blobs or streams.

**Object Fragments** Creates particles out of fragments of an object. Object Fragments is available only with Particle Array. Choose it when you want to fracture the particle emitter object and use the pieces as particles. This option is useful for animating explosions and shattering collisions. The fragments are created at the Emit Start frame. The Use Rate, Use Total, Emit Stop, and Particle Size parameters are unavailable.

**Instanced Geometry** Generates particles that are instances of either an object, a linked hierarchy of objects, or a group. The object is selected in the Instancing Parameters group on the Particle Type rollout. Choose Instanced Geometry when you want particles to be identical instances of another object in your scene. Instanced geometry particles are extremely effective for creating crowds, flocks, or flows of very detailed objects. Here are a few examples:

- Instance a red blood cell and use Super Spray to animate blood flowing in an artery.
- Instance a bird and use Particle Cloud to animate a flock of birds flying.
- Instance a rock and use Particle Cloud to animate an asteroid field.

**NOTE** Only one type of particle can be used for the particle system. However, you can have more than one particle array bound to a single object, and each particle array can emit a different type of particle.

**TIP** Image motion blur, described in Object Properties on page 283 > Motion Blur group, is known not to work properly with instanced particles. Use object motion blur with instanced particles, or use image motion blur with standard particles.
Standard Particles group

When you choose Standard Particles in the Particle Types group, the options in this group become available. Choose one of the following options to specify the particle type:

Triangle Renders each particle as a triangle. Use Triangle particles with noise opacity for steam or smoke.

Cube Renders each particle as a cube.

Special Each particle consists of three intersecting 2D squares. These are effective when you use a face-map material, described in Shader Basic Parameters Rollout on page 5969, optionally along with an opacity map, to create the effect of a three-dimensional particle.

Facing Renders each particle as a square that always faces the view. Use with an appropriate opacity map for bubbles or snowflakes.

Constant Provides a particle that remains the same size, in pixels, specified in the Size spinner. This size never changes, regardless of its distance from the camera.

**IMPORTANT** You must render either a camera or a perspective view for Constant particles to render correctly.

Tetra Renders each particle as a mapped tetrahedron. Use Tetra particles for raindrops or sparks.

The default alignment of the tetra particles depends on the particle system type and emitter setup. To specify an alignment, use controls in the Rotation and Collision rollout on page 3352.

SixPoint Renders each particle as a six-pointed, two-dimensional star.

Sphere Renders each particle as a sphere.

MetaParticle Parameters group

When you choose the MetaParticles option in the Particle Types group, the options in this group become available, and metaballs are used as particles. Metaparticles take extra time to render but are very effective for spraying and flowing liquid effects.

Tension Determines the tightness of the particles, with regard to their tendency to blend with other particles. The higher the Tension, the harder the blobs, and the harder it is for them to merge.
Variation Specifies the percent of variation of the Tension effect.

Evaluation Coarseness Specifies how accurately the metaparticle solution is calculated. The higher the coarseness values, the less calculation. However, if the coarseness is too high, there may be little or no metaparticle effect at all. Conversely, if the coarseness is set too low, the time for calculation can become extremely long.

Render Sets the coarseness for metaparticles in the rendered scene. This option is unavailable when Automatic Coarseness is on.

Viewport Sets the coarseness for the viewport display. This option is unavailable when Automatic Coarseness is on.

Automatic Coarseness A general rule is to set the Coarseness value between 1/4 and 1/2 the size of the particles. When this item is on, the rendering coarseness is automatically set, based on the size of the particles, and the viewport coarseness is set to about twice that of the rendering coarseness.

One Connected Blob When off (the default), all particles are calculated; when on, a shortcut algorithm is used that calculates and displays only those particles that are adjoining or contiguous to each other.

NOTE One Connected Blob mode speeds particle calculations, but you should use it only when your metaparticles form one connected blob, as the label indicates. That is, all particles’ blobs must be touching. For example, if you were to use One Connected Blob on a stream of particles containing a mass of 10 contiguous particles followed by a space, then 12 contiguous particles followed by another space, and finally 20 contiguous particles, one of the particles will be chosen, and only the mass connected to that particle will be displayed and rendered.

TIP When in doubt, leave this option off. If you think all your particles are contiguous and want to save time, turn on One Connected Blob, and then display various frames to see if everything appears.

Object Fragment Controls group

With a particle array, when you choose the Object Fragments particle type, the items in this group become available, and the object-based emitter is exploded into fragments, rather than being used to distribute particles.

NOTE To see the fragments in the viewports, choose Mesh in the Viewport Display group near the bottom of the Basic Parameters rollout on page 3334.
The items in this group include a Thickness spinner, along with three option buttons that determine how the fragments are formed.

**TIP** There is no automatic way to hide the distribution object that explodes into fragments. To create the illusion that an object is exploding, you must either set the original object to be invisible at the start of the explosion, as described in Add Visibility Track on page 3910, or move or scale the original object so it doesn't remain in view.

**Thickness** Sets the thickness of the fragments. At 0, the fragments are single-sided with no thickness. When greater than 0, the fragments are extruded, at fragmentation time, by the amount specified. The outer and inner surfaces of the fragment use identical smoothing, which is picked up from the object-based emitter. The edges of the fragments are not smoothed.

The three options that follow specify how the object fragments.

**All Faces** Each face of the object becomes a particle. This results in triangular particles.

**Number of Chunks** The object breaks into irregular fragments. The Minimum spinner, below, specifies the minimum number of fragments that will appear. The method of calculating the chunks may result in more fragments than specified.

**Minimum** Determines a number of "seed" faces in the geometry. Each seed face collects connecting faces surrounding it until all available faces are exhausted. Any leftover faces become unique particles, thus increasing the minimum number of fragments.

**Smoothing Angle** The fragments are broken based on the angles between face normals, as specified in the Angle spinner. Generally, the higher the Angle value, the fewer the number of fragments.

**Angle** Sets the amount of smoothing angle.
Instancing Parameters group

100.0

Get Material From:

- Icon
- Picked Emitter
- Instanced Geometry

Fragment Materials

Outside ID: 0
Edge ID: 2
Backside ID: 3
These options are used when you specify Instanced Geometry in the Particle Types group. They let you generate each particle as an instance of either an object, a linked hierarchy of objects, or a group.

**NOTE** Instanced objects can be animated, providing the animation incorporates one or more of the following types:

- Animation of object geometry parameters, such as a sphere's Radius setting.
- Animation of object-space modifiers, such as the Angle setting of a Bend modifier on page 1165.
- Transform animation of a hierarchical object's children. Transform animation of the top-level parent and non-hierarchical objects is not supported. For example, if you use the toolbar Select and Rotate function on page 915 to animate a box rotating, and then use the box as instanced geometry with a particle system, the system will not use instanced box's keyframed animation.

**Object** Displays the name of the picked object.

**Pick Object** Click this, and then select an object in the viewport to be used as a particle. If you select an object that's part of a hierarchy and Use Subtree Also is on, then the picked object and its children become a particle. If you pick a group, all objects in the group are used as a particle.

**Use Subtree Also** Turn this on when you want to include the linked children of the picked object in the particle. If the picked object is a group, all children of the group are included. Note that you can turn this on or off at any time to alter the particles.

**Animation Offset Keying** Because the instanced objects can be animated, the options here let you specify the timing of the animations for the particles.

**None** Each particle duplicates the timing of the original object. As a result, the animation of all particles will be identically timed.

**Birth** The firstborn particle is an instance of the current animation of the source object at the moment of that particle's birth. Each subsequent particle then uses the same start time for the animation. For example, if the animation of the source object is a bend from 0 to 180 degrees, and the first particle is born at frame 30, when the object is at 45 degrees, then that particle, and all subsequent particles will be born starting at a bend of 45 degrees.

**Random** This option is the same as None when Frame Offset is set to 0. Otherwise, each particle is born using the same animation as the source object.
at the time of birth, but with a random offset of frames, based on the value in the Frame Offset spinner.

**Frame Offset** Specifies an offset value from the current timing of the source object.

**Mat'l Mapping and Source group**

Specifies how a mapped material affects the particles, and lets you specify the source of the material assigned to the particles. A detailed description of how materials affect particles is in the topic Using Mapped Materials with Particle Systems on page 3300.

**Time** Specifies the number of frames from the birth of the particle that it takes to complete one mapping of the particle.

**Distance** Specifies the distance, in units, from the birth of the particle that it takes to complete one mapping of the particle.

**NOTE** Tetra particles are an exception. They always have their own local mapping from head to tail, as described in the following section.

**Get Material From** Updates the material carried by the particle system, using the source specified by the option buttons below this button.

**IMPORTANT** Remember to click Get Material From whenever you choose a different source option button, or whenever you assign a new material to the specified source. Only a single material (or multi/sub-object material) is carried by the particle-system object at any time. Thus, when you change sources, you actually overwrite the currently assigned material with an instance of the source material.

**Icon** The particles use the material currently assigned to the particle system icon.

**NOTE** The Time and Distance options are available only when you choose this option.

**Picked Emitter** The particles use the material assigned to the distribution object.

**Instanced Geometry** The particles use the material assigned to the instanced geometry. This option is available only when you choose Instanced Geometry in the Particle Types group.
IMPORTANT When you turn on either Picked Emitter or Instanced Geometry, an instance of the material from the chosen source is copied to the emitter icon, overwriting the material originally assigned to the icon. Thus, if you've assigned a material to the particle emitter, and then switch to Picked Emitter, the material originally assigned to the icon is replaced by an instance of the material carried by the picked object. If you then return to the Icon option, the particle system does not revert to the material that was assigned the icon, but retains the material taken from the picked object.

Fragment Materials group

These spinners let you assign different material ID numbers to outside surfaces, the edges and the back sides of fragment particles. You can then assign different materials to the front, edge and back of the fragments by using a multi/sub-object material.

Outside ID Specifies which face ID number is assigned to the outside faces of the fragments. This spinner defaults to 0, which is not a valid ID number, forcing the outside of the particle fragments to use whatever material is currently assigned to the associated faces. Thus, if your distribution object already has several submaterials assigned to its outer faces, these materials are retained by using ID 0. If you want a single, specific submaterial, you can assign it by changing the Outside ID number.

Edge ID Specifies which submaterial ID number is assigned to the edges of the fragments.

Backside ID Specifies which submaterial ID number is assigned to the back sides of the fragments.

Rotation and Collision Rollout (PArray)

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > SuperSpray/Blizzard/Parray/PCloud > Rotation and Collision rollout

Select a SuperSpray/Blizzard/Parray/PCloud emitter. > Modify panel > Rotation and Collision rollout

Particles often move at high rates of speed. In such cases, you might want to add motion blur to the particles to enhance their motion. Also, real-world particles typically rotate as they move, and collide with each other.
The options on this rollout affect the rotation of the particles, provide motion blur effects, and control inter-particle collisions.

**Spin Speed Controls group**

**Spin Time** The number of frames for one rotation of a particle. If set to 0, no rotation takes place.

**Variation** The percent of variation of the Spin Time.
Phase Sets the initial particle rotation, in degrees. This has no meaning for fragments, which always begin with zero rotation.

Variation The percent of variation of the Phase.

Spin Axis Controls group

These options determine the spin axis for the particles, and provide a partial method of applying motion blur to the particles.

Random The spin axis for each of the particles is random.

Direction of Travel/Mblur (Not available with the Blizzard particle system.) Rotates the particles about a vector formed by the direction in which they're moving. This option also lets you apply a form of motion blur to the particles by using the Stretch spinner. For further information, see Achieving Particle Motion Blur on page 3300.

Stretch When greater than 0, the particles stretch along the travel axis, depending on their speed. Specifically, the Stretch value specifies the percent of their length per each unit of the Speed setting (in the Particle Motion group). Thus, if you set Stretch to 2 while Speed is set at 10, the particles are stretched 20 percent longer than their original size along the axis of their travel. This spinner is available only when you choose Direction of Travel/Mblur.

NOTE For best results when using Stretch, you should also assign the Particle MBlur map as an opacity map of the material assigned to the particle system.

User Defined Uses a vector defined in the three X, Y, and Z axis spinners.

X/Y/Z Axis Specifies the spin vector of the X, Y, or Z axis, respectively. These spinners are available only when User Defined is chosen.

Variation The amount, in degrees, by which the spin axis of each particle may vary from the specified X Axis, Y Axis, and Z Axis settings. This spinner is available only when you choose User Defined.

Interparticle Collisions group

These options enable collisions between particles, and control how the collisions occur. Note that this involves intensive calculation, particularly when large numbers of particles are involved.

Enable Enables inter-particle collisions in the calculation of the particle movements.
Calc Intervals Per Frame The number of intervals per rendering interval, during which an inter-particle collision test is conducted. The higher the value, the more accurate the simulation, but the slower the simulation will run.

Bounce The degree to which speed is recovered after a collision.

Variation The percentage of random variation of the Bounce value, applied to the particles.

Object Motion Inheritance Rollout (PArray)

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > SuperSpray/Blizzard/PArray/PCloud > Object Motion Inheritance rollout

Select a SuperSpray/Blizzard/PArray/PCloud emitter. > Modify panel > Object Motion Inheritance rollout

Each particle's position and direction of movement are determined by the position and orientation of the emitter at the time the particle is created. If the emitter is moving through the scene, particles are scattered along the emitter's path.

Use these options to affect the motion of the particles by the motion of the emitter.

Procedures

Example: To observe object motion inheritance:

1. Create a Super Spray particle system.

2. Animate the emitter moving sideways (perpendicular to the direction of the particle stream) between frames 1 and 15.

3. Play the animation while observing it from the Top viewport.
   The emitter stops at frame 15, while the particles it has emitted up to that point continue moving along the diagonal between the emitter's path and that of the particles. The remaining particles move straight out from the emitter.

4. On the Object Motion Inheritance rollout, set Influence to 50.

5. Play the animation again.
This time, only some of the particles inherit the emitter’s motion, while the rest move straight out from the emitter. Note that the latter form a diagonal stream because each particle emerges at a subsequent point on the emitter path.

**Interface**

<table>
<thead>
<tr>
<th>- Object Motion Inheritance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Influence: 100.0%</td>
</tr>
<tr>
<td>Multiplier: 1.0</td>
</tr>
<tr>
<td>Variation: 0.0%</td>
</tr>
</tbody>
</table>

**Influence** The percent of particles that inherit the motion of the object-based emitter at the moment of particle formation. For example, when this is set at 100 (the default), all particles travel along with a moving object; when it’s set at 0, none of the particles are affected by the translation of the object and fall behind its movement.

**Multiplier** Modifies the amount by which the emitter motion affects the particle motion. This can be a positive or negative number.

**Variation** Provides a percentage of variation of the Multiplier value.

**Bubble Motion Rollout (PArray)**

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > SuperSpray/Parray/PCloud > Bubble Motion rollout

Select a SuperSpray/Parray/PCloud emitter. > Modify panel > Bubble Motion rollout

Bubble motion provides the wobbling effect you see in bubbles rising underwater. Typically, it’s used when the particles are set to rise in thin streams. Bubble motion is similar to a waveform, and the Bubble Motion parameters let you adjust the amplitude, period, and phase of the bubble “wave.”

**NOTE** The bubble motion is not affected by space warps, so you can use a space warp to control the direction of the particle flow without altering the local, wobbling bubble effect.
TIP InterParticle Collisions, Deflector Binding, and Bubble Noise do not get along well together. Particles may leak through the deflector when these three are used together. Instead of bubble motion, use animated mapping. Use facing particles with an animated map of a bubble, where the bubble is smaller than the map size. The bubble is animated moving around the map. This simulates bubble motion at the map level.

Interface

<table>
<thead>
<tr>
<th>Bubble Motion</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amplitude: 0.0</td>
</tr>
<tr>
<td>Variation: 0.0 %</td>
</tr>
<tr>
<td>Period: 100000</td>
</tr>
<tr>
<td>Variation: 0.0 %</td>
</tr>
<tr>
<td>Phase: 0.0 deg</td>
</tr>
<tr>
<td>Variation: 0.0 %</td>
</tr>
</tbody>
</table>

Amplitude The distance the particle moves off its usual velocity vector as it travels.

Variation The percent of Amplitude variation applied to each particle.

Period The cycle time for one complete oscillation of a particle through the bubble "wave." A recommended value might be 20 to 30 intervals.

NOTE Bubble motion is measured in time, not in rate, so a very large Period value means the motion takes a long time to complete. Thus, there is no motion, effectively. Period is therefore set to a very large default value so that the default motion of this type is none.

Variation The percent of Period variation for each particle.

Phase The initial displacement of the bubble pattern along the vector.

Variation The percent of Phase variation for each particle.
Particle Spawn Rollout (PArray)

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > SuperSpray/Blizzard/Parray/PCloud > Particle Spawn rollout

Select a SuperSpray/Blizzard/Parray/PCloud emitter. > Modify panel > Particle Spawn rollout

The options on the Particle Spawn rollout let you specify what happens to particles when they die, or when they collide with a particle deflector. Using the options on this rollout, you can have particles generate additional generations of particles upon collision or death.

- **Use Fixed Value:**
  - Value: No
None Uses none of the spawning controls, and the particles act as they normally would. That is, upon collision, they either bounce or stick, depending on Particle Bounce settings in the deflector, and on death they disappear.

Die After Collision Particles disappear when they strike a deflector to which they're bound, such as the SDeflector.

Persist The life, in frames, that the particle will persist after the collision. Setting this to 0 (the default) causes particles to vanish immediately after the collision.

Variation Varies the Persist value of each particle, when Persist is greater than 0. This lets you "feather" the dying off of particle density.

Spawn on Collision Spawn effects take place upon collision with a bound deflector.

Spawn on Death Spawn effects take place at the end of each particle's life.

Spawn Trails Particles are spawned from existing particles at each frame of that particle's life. The Multiplier spinner specifies the number of particles that are spawned from each particle. The base direction of the spawned particles is opposite that of the parent's velocity. The Scale, Direction, and Speed Chaos factors are applied to that base direction.

NOTE If the Multiplier is greater than 1, at least one of the three Chaos factors must be greater than 0 in order to see the additional spawned particles. Otherwise, the multiples will occupy the same space.

WARNING This option can produce many particles. For best results, begin by setting Particle Quantity on the Particle Generation rollout to Use Rate and to 1.

Spawns The number of spawns beyond the original particle generation. For example, if this is set to 1, and you're spawning at death, one spawning will occur beyond the original lifespan of each particle.

Affects Specifies the percentage of particles that will spawn. Reducing this reduces the number of particles that produce spawned particles.

Multiplier Multiplies the number of particles spawned at each spawning event.

Variation Specifies a percentage range by which the Multiplier value will vary, frame by frame.
Direction Chaos group

Chaos Specifies the amount by which the direction of the spawned particle can vary from the direction of the parent particle. A setting of 0 means no variance. A setting of 100 causes the spawned particle to travel in any random direction. A setting of 50 causes the spawned particle to deviate from its parent's path by up to 90 degrees.

Speed Chaos group

These options let you vary the spawned particles' speed randomly in relation to their parents' speed.

Factor This is the range of a percentage of change in the speed of the spawned particle relative to its parent. A value of 0 means no change.

Slow Applies the speed factor randomly to slow the speed of the spawned particles.

Fast Randomly speeds up particles based on the speed factor.

Both Some particles speed up, while others slow down, based on the speed factor.

Inherit Parent Velocity Spawned particles inherit the speed of their parents, in addition to the effect of the speed factor.

Use Fixed Value Uses the Factor value as a set value, rather than as a range applied randomly to each particle.
Scale Chaos group

These options apply random scaling to the particles.

**Factor** Determines a random percentage range of scaling of the spawned particles relative to their parents, and dependent on the options below.

**Down** Randomly scales down spawned particles to be smaller than their parents, based on the Factor value.

**Up** Randomly scales up spawned particles to be larger than their parents.

**Both** Scales spawned particles both larger and smaller than their parents.

**Use Fixed Value** Uses the Factor value as a fixed value, rather than a range of values.

Lifespan Value Queue group

These options let you specify a list of alternative lifespan values for each spawned generation of particles. The spawned particles use these lifespans.
rather than the lifespan specified for the original particles in the Life spinner on the \textit{Particle Generation rollout} on page 3338.

\textbf{List window} Displays a list of lifespan values. The first value on the list is used for the first generation of spawned particles, the next value is used for the next generation, and so on. If there are fewer values on the list than there are spawnings, then the last value is used repeatedly for all remaining spawnings.

\textbf{Add} Adds the value in the Lifespan spinner to the list window.

\textbf{Delete} Deletes the currently highlighted value in the list window.

\textbf{Replace} Lets you replace a value in the queue with a value in the Lifespan spinner. To use, first place a new value in the Lifespan spinner, then select the value in the queue you want to replace, and click the Replace button.

\textbf{Lifespan} Use this to set a value, and then click the Add button to add the value to the list window.

\textbf{Object Mutation Queue group}

The options in this group let you switch between instanced-object particles with each spawning (as set with the Spawns spinner). These options are available only if Instanced Geometry is the current particle type.

\textbf{List window} Displays a list of objects to be instanced as particles. The first object on the list is used for the first spawning, the second for the second spawning, and so on. If there are fewer objects on the list than there are spawnings, then the last object on the list is used for all remaining spawnings.

\textbf{Pick} Click this, and then select an object in the viewport to add to the list. Note that the type of object you use is based on the settings in the Instancing Parameters group of the Particle Type rollout. For example, if you've turned on Subtree in that group, you can pick object hierarchies. Likewise, if you've picked a group, you can use groups as your spawned particles.

\textbf{Delete} Deletes the currently highlighted object in the list window.

\textbf{Replace} Replaces an object in the queue with a different object. Select an object in the queue to enable the Replace button. Click Replace, and then pick an object in the scene to replace the highlighted item in the queue.
Load/Save Presets Rollout (PArray)

Create panel > Geometry button > Choose Particle Systems from the drop-down list. > Object Type rollout > SuperSpray/Blizzard/Parray/PCloud > Load/Save Presets rollout

Select a SuperSpray/Blizzard/Parray/PCloud emitter. > Modify panel > Load/Save Presets rollout

These options let you store preset values that can be used in other, related particle systems. For example, after setting parameters for a PArray and saving it under a specific name, you can then select another PArray system, and load the preset values into the new system.

Interface

| Preset Name | An editable field in which you can define a name for your settings. Click the Save button to save the preset name.
| Saved Presets | Contains all the saved preset names. A number of presets are included with 3ds Max; to see what they do, create a particle system, load a preset, and play back the animation. Some of the presets, such as Particle Array's Shimmer Trail, are most effective with moving particle systems.

- Load | Loads the preset currently highlighted in the Saved Presets list. Alternatively, double-click the preset name in the list to load it.

- Save |
Save Saves the current name in the Preset Name field and places it in the Saved Presets window.

Delete Deletes the selected items in the Save Presets window.

NOTE Animated parameter values subsequent to frame 0 are not stored.
3ds Max gives you a variety of different ways to create animation, and a wealth of tools for managing and editing animation.

A spacefighter model is animated by following a path.

Animation Concepts and Methods

With 3ds Max, you can create 3D computer animation for a variety of applications. You can animate characters or vehicles for computer games, or you can animate special effects for film or broadcast. You can create animation for serious purposes such as medical illustration or forensic presentation in the courtroom. Whatever reason you have to animate, you'll find 3ds Max a capable environment for achieving your goals.

The basic way to animate is quite simple. You animate the transform parameters of any object to change its position, rotation, and scale over time. Turning on the Auto Key button, then moving the time slider places you in a state in which any changes you make will create animation for the selected objects in the viewport.

Animation is used throughout 3ds Max. You can animate the position, rotation, and scale of an object, and almost any parameter setting that affects an object's shape and surface. You can link objects for hierarchical animation, using both forward and inverse kinematics, and you can edit your animation in Track View.

This section discusses the basics of creating animation. It looks briefly at a comparison between computer animation and classic hand-drawn animation, and then describes the creation of keyframed animation.

Animation Concepts

Animation is based on a principle of human vision. If you view a series of related still images in quick succession, you perceive them as continuous motion. Each individual image is referred to as a frame.
A frame is a single image in an animated film.

**Traditional Animation Method**

Historically, the main difficulty in creating animation has been the effort required of the animator to produce a large number of frames. One minute of animation might require between 720 and 1800 separate images, depending on the quality of the animation. Creating images by hand is a big job. That’s where the technique of keyframing comes in.

Most of the frames in an animation are routine, incremental changes from the previous frame directed toward some goal. Traditional animation studios realized they could increase the productivity of their master artists by having them draw only the important frames, called keyframes. Assistants could then figure out what belonged on the frames in between the keyframes. The in-between frames were called tweens.

Once all of the keyframes and tweens were drawn, the images had to be inked or rendered to produce the final images. Even today, production of a traditional animation usually requires hundreds of artists to generate the thousands of images needed.
The frames marked 1, 2, and 3 are key frames. The other frames are tweens.

**The 3ds Max Method**

This program is your animation assistant. As the master animator, you create the keyframes that record the beginning and end of each animated sequence. The values at these keyframes are called keys. 3ds Max calculates the interpolated values between each key to produce the completed animation. 3ds Max can animate just about any parameter in your scene. You can animate modifier parameters, such as a Bend angle or a Taper amount, material parameters, such as the color or transparency of an object, and much more.

Once you have specified your animation parameters, the renderer takes over the job of shading and rendering each frame. The result is a high-quality animation.
The object’s position at 1 and 2 are the keyframed models at different times. The computer generates the in-between frames.

Comparing Frames and Time

Traditional animation methods, and early computer animation programs, are rigidly locked to the concept of producing animation frame by frame. This is okay if you always work in a single format or do not need to specify an animated effect at a precise time. Unfortunately, animation comes in many formats. Two of the more common formats are film at 24 frames per second (FPS) and NTSC video on page 8654 at 30 FPS. Also, the need for accurate time-based animation versus frame-based animation is critical as animation becomes more common for scientific and legal presentation.
Different animation formats have differing frame rates.

3ds Max is a time-based animation program. It measures time, and stores your animation values, with an internal precision of 1/4800 of a second. You can configure 3ds Max to display time in a format best suited for your work, including traditional frames format. See Time Configuration on page 8106.

Many of the examples in the following sections describe time using the frames method for the sake of tradition and familiarity. Keep in mind that you are really animating using a very precise time-based method, and frames aren’t created until you instruct 3ds Max to render your animation.

**Identifying Animation Tools**

You can locate the basic animation tools in the following areas of the interface:
Track View Provides detailed animation editing capabilities in several floating or dockable windows. See Track View on page 3790.

Track Bar Provides quick access to keyframes and interpolation controls. Can be expanded for function curve editing. See Track Bar on page 8071.

Motion Panel Use this panel to adjust transform controllers that affect all position, rotation, and scale animation. See Working with Controllers on page 3391.

Hierarchy Panel Use this panel to adjust all parameters governing the linkage of two or more objects. These include inverse kinematics parameters and pivot point adjustments. See Hierarchy Panel on page 8213.

Time Controls Use these controls to move through time in the viewport displays. You can move to any point in time, and play animations in the viewports. The time controls, documented in Animation and Time Controls on page 8089, include:

- Time slider on page 8068
- Auto Key button on page 8090
- Set Key buttons on page 8093
- Animation playback buttons on page 8102
- Current frame field on page 8104
- Key Mode toggle on page 8105
- Time Configuration button on page 8106

To get started with animation, see Using Auto Key Mode on page 3373.

Using Auto Key Mode

Start creating an animation by turning on the Auto Key button, setting a current time, and then changing something in your scene. You can change the position, rotation, or scale of an object, or change almost any setting or parameter.

When you make a change, a key storing the new value for the changed parameter is created at the current time. If that key was the first animation key created for the parameter, a second animation key is also created at time 0 to hold the parameter's original value.
Keys are not created at time 0 until you create at least one key at another time. After that, you can move, delete, and re-create keys at time 0.

Turning Auto Key on has the following effects:

- The Auto Key button, the time slider, and the border of the active viewport turn red to indicate you are in animation mode.
- Whenever you transform an object or change an animatable parameter, 3ds Max creates keys at the current frame, as indicated by the time slider position.

To begin animating an object:

1. Click Auto Key to turn it on.
2. Drag the time slider to a time other than 0.
3. Do one of the following:
   - Transform an object.
   - Change an animatable parameter.

For example, if you have a cylinder that has not been animated yet, it has no keys. If you turn on Auto Key, and at frame 20 you rotate the cylinder 90 degrees about its Y axis, rotation keys are created at frames 0 and 20. The key at frame 0 stores the original orientation of the cylinder, while the key at frame 20 stores the animated orientation of 90 degrees. When you play the animation, the cylinder rotates 90 degrees about its Y axis over 20 frames.
