Especially when working with imported motion capture data, you might find that curve editing is difficult using the standard 3ds Max tool set. This is because you might have a key on every frame, so curve manipulation becomes cumbersome and awkward. It is difficult to visually pinpoint where the trouble spots are located. The Animation Workbench offers automatic functions to reduce keys or apply filters to the motion curves to smooth animation.

*Working with the Workbench (page 2–1008)*

*Animation Workbench (page 2–1012)*

**Understanding Motion Flow**

Motion Flow is a tool that graphically arranges clips (motion files), flowing from one motion to the next. You can use a Motion Flow graph to set up a series of clips with transitions between them, which will make the biped perform the series of motions in sequence.

You can also create a network of clips on the graph, where each clip has a transition to two or more clips. With this type of graph, you can tell character studio to generate the actual motion sequence for you based on random selection.
A crowd simulation can also be used to generate a motion sequence from this type of graph. Each biped in the crowd chooses from the motions and transitions in the graph based on where they want to go and how fast they need to get there. These factors, in turn, are determined by the crowd parameters you set.

- *Motion Flow Mode* (page 2–1043)
- *Motion Flow Rollout* (page 2–1045)

**Understanding Crowds**

The Crowd system in *character studio* lets you create realistic simulations using large groups of characters, humanoid and otherwise, that behave and interact with one another by procedural means. You can use it to easily animate scenes containing hundreds of people and/or creatures, all with similar or widely varying sets of behaviors, which can vary dynamically according to other factors in the scene.

At the heart of the system are the Crowd and Delegate helper objects. A single Crowd object can control any number of delegates, which serve as stand-ins for crowd members. You can group delegates into teams, and assign behaviors such as Seek, Avoid, and Wander to individuals or teams. You can combine behaviors with weighting, so that, for example, a crowd member could seek a goal while wandering slightly.

Crowd simulations can range in sophistication from simple and straightforward to highly complex. Aiding at the latter end of the range is the Cognitive Controller feature, which lets you use the scripts to apply conditional transitions to sequences of behaviors. For example, you could tell a delegate to approach a goal until it gets within a certain distance, and then start moving away. Or you could use a Cognitive Controller to have a delegate move among a series of goals.

Another means of creating complex, dynamic crowd simulations is *motion synthesis*, which can be used in conjunction with the Cognitive Controller. The Crowd system offers two types of motion synthesis.

- When working with bipeds, you use the Motion Flow feature to allow the software to create scripts for the bipeds that match the delegate behaviors.
- When working with non-bipedal characters, such as fish or birds, you use Clip Controllers that let you apply different animation segments to various types of motion. For example, a bird might flap its wings quickly while ascending but slowly while flying level, and stop flapping its wings during descent.
Understanding character studio Workflow

One of the most important requirements of crowd simulations is avoidance; realism suffers if characters pass through each other or other objects in the scene. The Crowd system offers a number of behaviors to help achieve proper avoidance. It also provides the Vector Field, a special space warp, that, when applied to an irregularly shaped object, allows delegates to move around the object without penetrating it.

Used in combination, the Crowd-system tools described here can produce an endless variety of interesting, multi-character simulations. The Crowd topics in this manual provide detailed information about every aspect of crowd simulation.

Understanding character studio Workflow

Biped, Physique, and the Crowd system work together within 3ds Max to provide a complete set of character animation tools. Although these components can be used in a variety of ways, it is helpful to approach character studio with a basic understanding of how a typical character animation is created.

The following sections provide a brief summary of the basic workflow and related benefits to creating a character with Biped and Physique. You may not use all the following steps, but you’re likely to do them in the following order.

Create Skin Geometry
Create a basic skin shape for your character using any 3ds Max modeling tools and surface types. Be sure to place your character’s skin in a neutral pose with arms outstretched and legs spaced slightly apart. You may also want to add sufficient detail to your skin’s mesh or control points around joints to facilitate deformation during movement.

Note: Since Physique deformations are based on a volume, you can refine your geometry at a later time with minimal impact on your skin behavior. This means you can create your animation before you’ve built your model if you wish.

Create a Biped Skeleton
Biped automates the creation of bipedal character skeletons. It also lets you introduce significant changes to the skeleton’s structure and sizing at any point during your animation without adversely affecting your character’s motion. This means you can animate your character without knowing if it is short or tall, skinny or fat. It also means that if the director changes the character’s proportions, the animation will still work.

For more detail on posing a biped skeleton, see Biped (page 2–843).

Attach the Skin

- Position the biped character within its modeled skin. Use Figure mode (page 2–982) to scale bone lengths and to orient the skeleton correctly within the skin’s volume. Scale bone thickness as desired to achieve a good initial fit. Then save a figure file, so it’s easy to return to this pose.

- Use Physique to attach the skin geometry automatically to the biped or a 3ds Max bones hierarchy. The attachment is typically made to the root node in the hierarchy: the pelvis object on the biped or the root node on a bones hierarchy, not the center of mass. The attached skin is deformed as the biped or bones hierarchy moves.

- The links in the bones hierarchy are used to create a system of 3D envelopes that enclose nearby vertices. Envelopes typically overlap
at the parent and child ends of links. Vertices within overlapping envelopes are blended to create smooth skin deformation over joints as the character moves.

**Adjust Skin Behavior**

Adjust Physique parameters and introduce skin behavior effects to achieve the desired characterization.

- Change default envelope shapes by adding cross sections and control points to isolate a more specific volume of vertices for each bone. Use exclusion lists or per-vertex weighting to apply fine-tuning control over individual vertices.
- Introduce bulge angles to change muscle shape based on the angle of a particular joint. Create tendons to simulate the motion of tendons under the skin, based on link movements.
- Adjust link parameters to change skin twisting, sliding, and creasing as the biped moves. Sliding allows the skin to compress at the biceps and forearm as the elbow is bent. Twisting controls the amount of skin twisting across a joint intersection.
- Create extra links using 3ds Max bones and dummy objects for added control. Links can be added to the abdominal area to control compression, for example, or to create a link to animate the chest rising and falling as the character breathes. If a character has extra appendages, 3ds Max bones can be added to animate them. One common usage is to add a bone to animate the jaw.

Tip: Since Physique skin deformation can slow visual playback of your Biped animation, you can temporarily hide the skin object or reduce its resolution in the modifier stack to improve performance.

You can also choose to develop Biped animations in a separate scene entirely, and apply them to your final skinned character when you are satisfied with your final motion.

A biped (page 2–843) character is essentially an integrated hierarchy of bones that you can position freely using keyframes, IK goals, and footsteps. You can position a biped character using all the rotation and transformation tools found in 3ds Max.

Many of the 3ds Max coordinate systems can be used to position the biped. Local coordinates are useful to move a limb along its axis (the local X axis is always the axis along the biped limb); world coordinates are handy when there is any confusion regarding which way is up. You can use world coordinates as a home base. In 3ds Max, the world Z axis is always up.

Note: Rotations always occur about the local axis.

**Use Freeform Techniques**

Biped provides a variety of methods for creating character motion easily. You can use a purely traditional approach by manually creating keyframes in freeform mode for different poses, letting the computer interpolate between joint positions and IK goals.

**Use a Footstep-Driven Technique**

You can also choose a partially assisted approach by using footsteps and Biped dynamics to help you create a default walk, run, or jump cycle, and then adjust the biped keyframes and footsteps individually.

For further detail, see *Physique* (page 2–1076).
When using footsteps, *biped dynamics* (page 3–916) helps you by simulating gravity and balance:

- Gravity can help in a jumping motion to accelerate a character during the falling period and to bend the legs naturally on landing.
- Balance adjusts a character’s position when the spine is rotated and keyframed to retain a character’s balance.
- Dynamics can be turned off on a per-key basis or for the entire animation. The animator can override center of mass keyframes created using Dynamics calculation at any time. Simply set the dynamic properties of these keys or choose *Spline Dynamics* (page 3–1015) for keys generated by newly created footsteps.

**Convert Between Animation Types**

Once you are satisfied with a particular footstep animation and its corresponding dynamic behavior, you can *convert it* (page 2–885) to a freeform animation consisting of a simple combination of keyframes and IK goals. This intelligent conversion gives you control of animation behavior at every frame, for every joint of the character.

**Use Layers to Apply Global Changes**

*Animation layers* (page 3–910) offer you a powerful tool for introducing global changes to an existing character animation. For example, by adding a layer on top of an existing run motion, and creating a single keyframe with the biped’s spine rotated forward, an upright running motion can be turned into a crouched run. Layered changes can be stacked up, allowing you to refine your motion composition and eventually collapse your layers into a standard non-layered keyframe animation.

**Use In Place Mode to Control the View**

*In Place Mode* (page 2–930) is a tool that lets you keep your biped in view during animation playback. It offers a convenient way of adjusting and adding keyframes to a character without constantly changing your view to follow the character’s motion.

**Import Motion-Capture Files**

Motion-capture files can be imported from the BVH or CSM formats, edited, and saved as BIP files. You can import these files with or without footsteps and dynamics and combine them in Motion Flow mode with other animations.

You can use the supplied motion-capture samples as is or adjust them to suit your needs using Biped’s collection of animation tools. The ability to import motion-capture marker files directly into *character studio* using the CSM file eliminates much of the cost of post-processing optical motion capture data. You can import motion-capture files with an additional prop bone, to define the motion of an object such as a sword or club.

You can also import HTR/HTR2 motion-capture files (page 3–576), as well as TRC files (page 3–577). Motion-capture files can be imported with key reduction, making for more manageable tracks for subsequent editing.

**Use Track View for Keyframe Editing**

*Track View* (page 2–1002) allows you to edit keys and footsteps relative to the animation time line.

Footstep editing in *Track View - Dope Sheet* allows you to move footsteps in time. If you need a character to jump higher between footsteps, move the landing footsteps further down in time; dynamics automatically compensate by making the character jump higher to keep it airborne longer.
You can also specify a freeform period in a footstep animation, using Track View - Dope Sheet. This allows you to take advantage of footsteps and dynamics for part of an animation, then switch to manual keyframing during the freeform period. This approach can be particularly useful in animations where there is a mix of animation where the feet are on the ground and then off. Examples of this type of animation include running and diving, or walking and then sitting down.

Keyframe adjustment tools allow you to find the next or previous key for the selected biped body part, use the Time spinner to slide a key back and forth in time, change Tension Continuity and Bias for a key, and to display trajectories.

You can place arms and legs into the coordinate space of another object or the world to simulate interaction with fixed or moving objects. In Freeform mode, for example, putting the character’s legs into world space prevents them from sliding or moving when the animator is keyframing the character’s center of mass. Putting a character’s hand in the coordinate space of a ball allows the hand to move wherever the ball moves.

Many tools in 3ds Max can be leveraged with character studio. For example, the Select and Link tool can be used to attach objects to the biped.

If a character is to pick up and carry an object and then put it down, the Link controller can be used to animate the duration of the attachment. 3ds Max bones can be used to animate character subassemblies, like pistons, and to create extra links for Physique.

**Use the Motion Mixer to Mix Animations**

You can use the Motion mixer to combine motions on a biped. For example, you could combine a walking motion with a cheering motion, and cause the biped to walk while cheering.

**Use Motion Flow to Combine Animations**

After you have created and modified various animation sequences, and stored them in biped motion files (BIP format), you can use Motion Flow mode to combine various motion files into longer animations that can be quickly previewed and edited. Motion Flow mode automatically places the animations end-to-end, allowing you to mix and match both freeform and footstep-driven motion files. Transitions between successive motions are automatically created for you, to provide a first-pass blending between overlapping frames of animation.

The Motion Flow transitions use velocity interpolation to create seamless transitions between clips. You can use the Transition Editor to modify a variety of blending parameters, including transition start frame, length, and angle between clips.

**Refining Your Character**

Great character animation is a result of many refinements that tune the overall personality of your character. You will find the need to refine progressively both the skinning behavior and the animation timing of your character. Biped and Physique make this iteration process straightforward by fully using the 3ds Max modifier stack and undo methods.

In addition, Biped’s ability to map motions between characters makes it easy to interchange great animations with existing characters, and tune their behaviors to achieve true integration of motion with character motivation and personality.
Use Crowds to Animate Groups of Characters

Once you’ve created animation sequences for characters or other models (such as a bird flapping its wings), you can replicate the models or characters and apply the motions to these groups using the Crowd system (page 2–1154). You can also combine them with a wide range of supplied behaviors to create lifelike activities in crowds, such as people streaming through a doorway, street traffic, or birds and fish flocking and avoiding obstacles. You can use Motion Flow mode to create motion clip networks so that characters perform animation sequences appropriate to their current movement and transition smoothly between sequences. And you can use Crowd’s cognitive controllers to transition between behaviors based on a variety of criteria. For more on crowd behaviors, see Creating a Crowd System (page 2–1155).

Biped

To work most efficiently with bipeds, it is important to follow the general workflow described in this topic.

Create Skin Geometry

Before you create a skeleton for a character, you should already have a character skin to put the skeleton into.

Create a basic skin shape for your character using any of the 3ds Max modeling tools and surface types. Be sure to place your character’s skin in a neutral pose with arms outstretched and legs spaced slightly apart. You may also want to add sufficient detail to your skin’s mesh or control points around joints to facilitate deformation during movement.

Tip: Before adding a biped skeleton, freeze your character mesh. When the mesh is frozen, you can still see it, but you can’t select or alter it, reducing the chance for error or frustration.

Create a Biped Skeleton

Once you have a character mesh, you can create a biped skeleton to fit inside. Use Figure mode (page 2–982) to set up your biped.

Before you position the skeleton, use controls on the Structure rollout (page 2–984) to alter the biped to match your mesh, setting the number of links for the spine, arms, neck, or fingers, or adding props to represent weapons or tools.

Tip: You can use ponytails to create animated jaws, ears, or horns.

Note: Certain biped body parts, including fingers, tails, ponytails, props, and clavicles, can be repositioned in Figure mode to suit different characters.

When you position the biped inside your mesh, start with the center of mass (COM), which is the parent of all objects in the biped hierarchy. The COM should be positioned in line with the hips of the mesh character. Scale the pelvis so that the legs fit properly in the mesh, and then use Move and Scale on the 3ds Max toolbar to position your biped skeleton.
Note: In addition to the standard move, rotate, and scale operations, you can also use modifiers to adjust the parts of the biped.

Note: Biped body parts cannot be removed, however unwanted parts can be hidden. If you delete a part the entire biped will be deleted.

The following list includes some tips for positioning your skeleton:

- Use the [Page Up] and [Page Down] keys to cycle through links.
- Use Rubber Band mode (page 3–1003) to move and scale the arm and leg links on your skeleton simultaneously.
- Use tools from the Bend Links rollout (page 2–952), such as Bend Links Mode (page 3–915) and Twist Links Mode (page 3–1028) to adjust tail, neck, spine, and ponytail links.
- The head, toes, and fingertips should extend slightly beyond the mesh extents to fulfill the requirements of Physique.
- Use the minimum number of fingers and toes. You need extra fingers or links only if you are planning on complex hand or foot animation. If your character is wearing gloves or shoes, then you probably only need one finger or toe, with one link.
- To create a biped with knees that bend backwards, rotate the biped calves or thighs of both legs 180 degrees about their local X-axis (along the length of the limb). When you exit Figure mode, the biped walks, runs, and jumps with reversed knees.
- When working with a mesh in a symmetrical pose, pose one side of the skeleton, and use controls on the Copy/Paste rollout (page 2–966) to paste the posture to the opposite side of the biped.

When you are satisfied with your pose, check the alignment in all viewports to make sure that the skeleton is positioned correctly in the mesh.

Once you have successfully positioned a skeleton inside your character mesh, you are ready to attach the mesh with Physique. For more on this workflow, see Understanding Physique (page 2–834).

Creating a Biped
A biped model is a two-legged figure: human or animal or imaginary. Each biped is an armature designed for animation, created as a linked hierarchy. The biped skeleton has special properties that make it instantly ready to animate. Like humans, bipeds are especially designed to walk upright, although you can use bipeds to create multi-legged creatures. The joints of the biped skeleton are limited to match those of the human body. The biped skeleton is also specially designed to animate with character studio footsteps, which help solve the common animation problem of locking the feet to the ground.

The parent object of the biped hierarchy is the biped’s center of mass object, which is named Bip01 by default.

Creating a Biped

A button for creating a Biped appears in the Create panel under Systems. You create a biped by clicking this button and then dragging in the active viewport. You interactively define the height of the biped as you move the cursor.

During biped creation, you can change any of the default settings that are used to define its basic structure. The default settings, for Arms, Neck Links, Spine Links, and so on, are for a human figure.

If you turn on Most Recent .fig File, the biped you make will use the parameters stored in the last FIG (figure) file you’ve loaded.

Changing Biped Parameters

Like other 3ds Max objects, you can change biped parameters on the Create panel at creation time. However, to modify or animate a biped, you use parameters on the Motion panel. For more information on changing biped parameters, see Structure Rollout (page 2–984).

Creating a Biped Using AutoGrid

The AutoGrid feature lets you create objects on the surface of other objects, rather than on the home grid. AutoGrid automatically creates a grid for construction. When you turn AutoGrid on, a tripod cursor is displayed in the viewport. As you move your mouse over the geometry in the scene, the tripod cursor rotates to match the orientation of the face it’s touching. A grid is created at that spot and is used to create the biped.

By turning on AutoGrid in the Create Panel > Object Type rollout, biped creation will respect the AutoGrid, letting you build bipeds with their feet on top of geometry.

Procedure

To create a biped on a surface:

1. On the Create panel > Systems, click Biped.
2. Turn on AutoGrid.
3. Move your cursor over any geometry in the viewport.
   A Transform gizmo moves with your cursor to indicate the location of the AutoGrid.
4. Drag out a biped.
The biped feet will be in contact with the geometry.

Understanding Biped Anatomy

The geometry of a biped is a linked hierarchy of objects that by default resemble those of a human. The parent or root object of the biped is its center of mass (COM) (page 3–920). This object is displayed as a blue octahedron near the center of the biped’s pelvis. Moving the COM positions the entire biped.

You can select the center of mass by choosing Bip01 from the Select Objects dialog (page 1–78). You can also select the center of mass by clicking Body Horizontal, Body Vertical or Body Rotation in the Track Selection rollout (page 2–945).

Changing the Biped Hierarchy

The biped Hierarchy is a little different than a standard 3ds Max hierarchy in that you can’t delete any of the components of the skeleton. If you try to delete any part of the biped skeleton, you delete the entire hierarchy. If you want to create a partial biped, for example a biped with no head, simply hide the objects you don’t want to use.

Repositioning Biped Body Parts

Certain Biped body parts can be repositioned in Figure mode to suit different characters. You can move entire arm assemblies by selecting the clavicles and moving them up or down. You can also reposition the fingers, tail and ponytails as you like. See Posing the Biped (page 2–847).

Biped’s structure also includes an option to add forearm twist. This uses two to four forearm links to transfer twisting animation into the biped’s associated mesh via Physique or Skin.

Props

The biped structure includes an option to add up to three props. Props appear next to the biped’s hands and body by default, but can be modified or animated throughout the scene like any 3ds Max object.

Adding Extra Biped Body Parts

To add extra legs, arms, or other body parts you need to create 3ds Max geometry for those parts, then link them to the biped hierarchy. You can use Snapshot to duplicate biped body parts to create these as well. In either case you will need to animate them with standard 3ds Max rotations, because biped IK will not be available on these extra parts.

Changing Initial Biped Anatomy

Use the body parameters to change initial biped anatomy. The Body parameters are in the Create Biped rollout that appears in the Create panel when you create a biped.

Note: You can change body parameters in the Create panel immediately only after creating a biped. Once you leave the Create panel, these settings are still available, but from the Structure rollout in the Motion panel. The body parameters
in the Structure rollout are enabled when the biped is selected and Figure mode is active.

See also
Creating a Biped (page 2–844)
Structure Rollout (page 2–984)

Naming the Biped

If your scene is going to contain more than one biped, it’s a good idea to give the biped a unique name. By default, the first biped in a scene is called Bip01. Succeeding bipeds have the same name except that the two-digit number is replaced by another number in sequence: 02, 03, 04, and so on.

Since the parent of the biped hierarchy is the biped’s center of mass object, that is also the object selected when you choose Bip01. You can link the biped center of mass to other objects or dummies for additional animation control. For more information on the biped’s hierarchy, see Understanding Biped Anatomy (page 2–846).

Procedure

To change the biped name upon creation:

- Immediately after creating the biped and before moving to another panel, enter the new name in the Root Name field in the Create Biped rollout.

  The center of mass is renamed and the entire biped hierarchy inherits the new name.

To change the biped name after creation:

1. Select any part of the biped and go to the Motion panel.
2. In the Biped rollout, click the expander bar to display the Modes and Display groups.
3. Enter a new name in the Name field and press Enter

Warning: Do not use the usual Name And Color rollout to rename a biped. This changes only the name of the biped’s root object (its center of mass) without updating the names of other biped parts in the hierarchy.

To create a Named Selection for the biped center of mass:

1. Select the biped center of mass (diamond shaped object in the pelvis) in the viewports.
2. Type a name in the Named Selection Sets field on the 3ds Max toolbar.
3. Press Enter

You can now choose this selection if the biped is hidden and you want to view the biped and edit biped parameters on the Motion panel.

Tip: Give the center of mass selection the same name as your character in the Named Selection Sets field, "John," for example. With multiple characters, you can quickly select the character you want to edit by choosing the character’s name in the Named Selection Sets dropdown.

Posing the Biped

After creating the default biped, you will often need to change the proportions of the skeleton to fit your model. Use Figure mode to change the biped structure in its rest pose.

Activating Figure mode returns the biped to its original location and orientation. With the biped in Figure mode, you can use the transform tools to change the proportions and positions of body parts. For instance, you might apply a non-uniform scale to shorten the legs or lengthen the arms.
Once you have a default biped, you'll need to match its proportions to the character’s geometry. It is quite typical to find the character’s geometry with the arms outstretched. The common workflow is to freeze the character and then in Figure mode, reposition the biped, so the center of mass is at the base of the torso. The spine objects, legs, and feet are scaled and rotated to fit within the confines of the mesh, then the arms and hands, neck and head. The tail and ponytail objects can be used for animating wings, fins, jaws, ears, horns, or hair.

Once your biped proportions are correct, you can save them in a .FIG file. Since biped saves the character in the .FIG file, and then animation in the .BIP file, you can change the character’s proportions without affecting the animation.

**Changing the Biped Structure**

Bipeds don’t have to appear human. You can change their elements and form to create other kinds of characters. Although you can change some initial aspects of the biped’s structure in the
Create panel, you use Figure mode to change all aspects of the biped’s structure after its creation.

Bipeds don’t have to be human ... or even walk on two legs.

Any number of bipeds can be in Figure mode at the same time, though you can only work on one biped at a time. When you select a biped, the Figure mode button indicates whether or not the biped is in Figure mode.

In Figure mode you can:

- Define the position of the feet relative to the ankles.
- Define the default pose of the biped before animation is applied to it, for example define a hunchback.
- Scale the biped and its various parts.
- Simultaneously scale and position biped parts using Rubber Band mode (page 3–1003). See Rubber-Banding Arms and Legs (page 2–852).
- Create natural links for Physique using Triangle Pelvis.
- Use forearm links to transfer twisting animation to the biped’s associated mesh.

For more information on adjusting the biped’s proportions see Posing the Biped (page 2–847).

**Working with Both Arms or Legs**

As you pose your biped, there are two different methods for posing both arms or legs symmetrically.

The first method involves using Symmetrical on the Track Selection rollout (page 2–945) to select both limbs simultaneously. With both limbs selected, you can rotate and scale the objects, and they will maintain a mirror-image relationship. You can also move the limbs, however they will not retain a symmetrical pose (with respect to the body) if you move them laterally.

The second method involves posing only one side of the biped, then copying the posture to the corresponding limbs on the other side.

*Note: You can scale biped limbs only in Figure mode (page 2–982).*

**Procedures**

**To work in Figure mode:**

1. Select the biped you want to pose, and then go to the Motion panel.
The Motion panel doesn't show Biped controls unless the biped is selected.

2. On the Biped rollout, click Figure mode. The button turns blue to indicate a special edit mode.

The biped’s pose and location change to the one last specified when the biped was in Figure mode. If the biped was just created and, therefore, was never in Figure mode before, it changes to the pose and location it had when you created it. When you turn off Figure mode, the biped returns to its animated pose and location in the scene.

Note: Biped disables all keyframe editing tools when Figure mode is active. Adjustments made in Figure mode are not animatable.

To fit biped legs to the skin:

1. Turn on Figure mode on the Biped rollout.
2. Use the Scale Transform gizmo to scale the Z-axis of the biped’s pelvis so the biped’s leg links are centered in each leg of the skin.
3. Select the biped’s two thigh links (LLeg and RLeg) and scale the X-axis of the thigh links so they end at the knees of the skin.
4. Select the biped’s two lower leg links (LLeg1 and RLeg1), and scale the X-axis of the lower leg links so the biped’s ankles are level with the ankles of the skin.

Tip: When the two upper legs are selected, you can press Page Down to select the lower legs.

5. In a left or right viewport, scale the biped’s feet so their profile roughly matches the profile of the feet of the skin.
6. Scale toes or move them along their local X-axis so each toe is aligned with the corresponding toe in the skin.

The ends of the final toe links should go through the tips of the skin’s toes.

You might have to change the number of biped toes to match the number of skin toes. A biped must have at least one toe on each foot. If the skin has no toes or the character is wearing footgear, the position and number of biped toes doesn’t matter—but they should still extend beyond the skin.

Tip: During the fitting process, try Freezing the skin object to prevent accidental selection.

To fit the spine to the skin torso:

1. On the Biped rollout, turn on Figure mode.
2. Select the lowest link of the spine (Bip01 Spine). Choose the Move transform, constrain movement to the spine link’s local X-axis, and move it vertically to the waist of the skin, just below the navel.
3. Scale the other spine links in their local X-axis so they fit the upper part of the skin’s torso.

The neck link should begin where the skin’s neck begins.

If the torso of the skin curves, you should also rotate spine links about their local Z-axes, to align the spine with the longitudinal center of the torso.

4. Scale the biped’s neck in its local X-axis to match the length of the neck of the skin. The top of the last neck link (also the base of the head link) should be where you want the head to pivot. This is usually just below the ears, centered with the spine.

Leave the head in its default position relative to the spine and neck links.
**To fit both arms using copy/paste:**

1. On the Biped rollout turn on Figure mode.

2. Rotate one upper arm (R Arm1 or L Arm1) in its local Y-axis to center its link in the upper arm of the skin.

3. Scale the upper arm so its link ends at the elbow of the skin.

4. Scale the lower arm (RArm2 or L Arm2) so its link ends at the wrist of the skin.
   
   If the skin’s arms are bent, rotate the lower arm to center its link as well.

5. Scale fingers, or move them along their local X-axis so each finger is aligned with the corresponding finger of the skin.
   
   The ends of the final finger links should go through the tips of the skin’s fingers. You might have to change the number of biped fingers to match the number of skin fingers.

6. When the arm is completely fitted to the skin, select all of it and on the Copy/Paste rollout, click Copy Posture.

7. On the Copy/Paste rollout, click Paste Posture Opposite to pose the opposite arm.

**To pose both arms simultaneously:**

1. On the Motion Panel > Biped rollout, turn on Figure mode.

2. Select the biped’s left or right hand.

3. On the Track Selection rollout, click Symmetrical.
   
   The opposite hand is also selected.

4. Move, rotate, and scale the hands until you have the position and size you want. Use PAGE UP and PAGE DOWN to move the different parts of the arm.

**Note:** If you move limbs laterally, they will both move in the same direction, and will no longer be symmetrical about the body.

**To create a symmetrical pose by copying one side of the biped to the other:**

1. On the Motion Panel > Biped rollout, turn on Figure mode.

2. Move, rotate, and scale the left arm and leg of the biped until you have the position and size you need.

3. Select all of the bones in the left arm and leg.

4. On the Copy/Paste Rollout, create a collection, then turn on Posture and click Copy Posture.

5. On the Copy/Paste Rollout, click Paste Posture Opposite.

   The right arm and leg assume the position and scale of their corresponding bones on the left.

*Biped Rollout (page 2–936)*

*Creating a Skin (page 2–1076)*

---

**Scaling Links**

Use standard 3ds Max scale transforms to adjust a biped’s posture by scaling the size of its links. You must be in Figure mode to scale the biped links. If you try to scale a biped without going into Figure mode, nothing happens.

As with rotation, when you scale biped links, Biped constrains the transform to use the link’s Local coordinate system. The position of other biped links can change so they remain attached to the resized link. If you shorten the thigh, the...
calf and ankle will maintain their size, but change their position.

To scale a link, select any scale icon from the Scale flyout on the Main Toolbar. When you select a body part to scale, use the Transform gizmo to scale along one axis at a time.

Use Scale and the Transform gizmo to scale links.

If your character is symmetrical, select body parts in pairs and scale them at the same time.

Select one body part and then click Symmetrical in the Track Selection rollout. Now both are selected.

You can also scale one and then use Copy Posture and Paste Posture Opposite from the Copy/Paste rollout. This approach ensures symmetry in your character.

Tip: Use the Page Up and Page Down keys to move through your hierarchy as you work. For example, after you scale the thighs, press Page Down to select the calves.

Scaling the biped limbs to fit snugly to the mesh will help when Physique is used to associate the mesh with the biped. The Bounding Box option uses biped limb dimensions to size the envelopes. This saves time when you adjust envelopes in Physique.

Rubber-Banding Arms and Legs (page 2–852)

Rubber-Banding Arms and Legs

Rubber Band mode provides a way to proportion the arm and leg links simultaneously. Rubber Band mode works with the Move transform rather than the Scale transform. When you move an arm or leg with Rubber Band mode turned on, both the link and its child are scaled in a single step.

Rubber-banding the upper arm rescales the upper and lower arm objects and moves the elbow link without affecting the position of the shoulder or the wrist. If you’ve spent a lot of time getting the fingers in the right place, you can reposition the elbow by rubber-banding, without affecting the hands.
Using Rubber Band to resize an arm without changing the hand position

Procedures
To rubber band an arm or leg link:

1. On the Motion panel > Biped rollout, turn on Figure mode.
2. Select the arm or leg link you want to rubber band.
3. Turn on the Move transform.
4. On the Biped rollout > Modes group, turn on Rubber Band mode.

Note: This button is unavailable if you are not in Figure mode or if a part of the biped other than the upper or lower arm or leg or if the center of mass is selected.

Note: The Modes group is hidden by default. To display it, click the expansion bar on the Biped rollout.
5. Move the selected arm or leg link.

As you move the arm or leg link, the hands and feet are stationary as the knees or elbows are positioned.

To adjust the biped center of mass with Rubber Band:

1. On the Motion panel > Biped rollout, turn on Figure mode.
2. Select the center of mass object (diamond shape) on the biped.
3. Turn on the Move transform.
4. On the Biped rollout > Modes group, turn on Rubber Band mode.

This button is unavailable if you are not in Figure mode or if a part of the biped other than the upper or lower arm or leg or if the center of mass is selected.
5. Move the center of mass.

While Rubber Band mode is active, the center of mass moves independently from the rest of the biped, which remains in the same position.

Tip: Another way to adjust the biped’s balance is to change the value of Balance Factor. Balance Factor displays on the Key Info rollout when a Body Horizontal key is current. Balance Factor can be keyframed.

Biped Display Options
For greater speed in displaying bipeds, or to make your viewports less cluttered while you edit your scene, Biped lets you turn off the display of some biped elements. These display controls are found in the Motion panel > Biped rollout (page 2–936) > Display group, rather than in the Display panel.
These controls allow you to quickly turn on and off the biped bones, objects and footsteps, twist links and leg states, as well as footstep numbers and trajectories. There is also a Display Preferences dialog accessed from here that lets you control which bipeds are visible during Biped Playback.

Note: The Display group is hidden by default. To display the group, click the expansion bar on the Biped rollout.

**Procedure**  
To change biped display:  
1. Go to the Motion panel.  
2. On the Biped rollout > Display group, click a button corresponding to the display choices you want.  
   
   Note: The Display group is hidden by default. To display the group, click the expansion bar on the Biped rollout.

---

### Deleting a Biped

You can quickly and easily delete an entire biped from a scene.

**Procedure**  
To delete a biped:  
1. Use any selection tool to select the entire biped or any part of the biped.  
2. Press [Del] or [Delete] on your keyboard.

---

### Linking Character Body Parts to the Biped

With the Physique component, you can use Biped to animate a deformable skin, usually a mesh object. However, some animations don’t require deformation. For example, a knight clad entirely in rigid metal armor doesn’t need to deform as skin does. Also, figures seen from a distance don’t require the same degree of realism as figures seen close up.

Characters available commercially often come in two varieties: jointless andjointed. Jointless characters have a seamless mesh at limb joints. Jointless characters should be attached to the biped using Physique. A jointed character has separate objects with ball joint geometry for the limbs, and lends itself to the linking technique described in this topic.

Linking objects and other geometry to the biped can also be used in cases such as the following:

- Link a weapon or a flower to the biped hand.  
- Link eyeballs or teeth to the biped head.
• Link extra 3ds Max bones or splines to the biped to create extra envelopes when Physique is applied.
• Link 3ds Max bones to the biped to automate mechanical assemblies when the biped is keyframed.
• Link particle emitters to the biped hands or feet to create smoke or dust.

Note: If you’ve linked particle emitters or 3ds Max bones (with the IK controller) to the biped, the Animate button must be on when you reposition the biped.

Procedure

To link a mechanical character to the biped (without Physique):

With mechanical or jointed characters, you can simply link objects to the biped without using the Physique modifier.

1. Load or create a mechanical or jointed model. Body parts in this model should be separate 3ds Max objects.
2. Create a biped.
3. On the Biped rollout turn on Figure mode, then position and fit the biped to your mesh objects.
4. Go through the mesh objects and use Select and Link on the 3ds Max toolbar to link each object to its corresponding part on the biped.

Note: If you plan to use 3ds Max linking and Physique together, link the body parts to the biped after applying Physique. In this way, Physique will not create superfluous links from the biped to the mechanical body parts when it is applied.

Saving and Loading FIG Files

Select a biped. > Motion panel > Biped rollout > Load File (in Figure Mode)

Select a biped. > Motion panel > Biped rollout > Save File (in Figure Mode)

Figure files save all information about a biped’s anatomy: links, link positions, twist links, and Figure mode posture, and the scale of geometric elements. Figure (FIG) files have a .fig file name extension.

Figure files do not contain the actual biped skeleton, or any animation. They are used strictly for setting or saving a biped’s pose in Figure mode.

Figure files are useful for quickly setting poses for similar or identical characters.

Clicking Load File brings the Open dialog, from which you can pick a FIG file and choose from the following twist poses (page 2–950) options:

• **Load Twist Poses**: Loads both the twist links (page 2–984) and twist poses data. (Default=on).

• **Don’t Load Twist Poses**: Loads only the twist links data.

  Note: The pose presets are always available.

• **Load Twist Poses Only**: Loads only the twist poses data without the twist links.

  Note: The Twist and Bias values are not used without twist links. Refer to the Twist Poses rollout (page 2–950) for details.
Procedures

To save a biped's figure information to a file:
1. Select the biped to save.
2. On the Motion panel, activate Figure mode.
3. On the Motion panel > Biped rollout, click Save File.
4. In the file dialog, enter a name for the figure file, and then click OK.
   Tip: While you work on creating a biped pose, save your work frequently in a figure file.

To load a biped figure:
1. Select the biped to replace with a saved figure.
2. Activate Figure mode in the Motion panel.
3. On the Motion panel > Biped rollout, click Load File.
4. In the file dialog, choose the figure file to load.
5. Choose one of the three loading options, depending on whether or not you want to load twist poses, or to load twist poses only.
6. Click OK.

Warning: Loading a figure file replaces the selected biped's pose and base parameters. If you have created a new pose or a new biped structure, save it in a figure file before you load a different biped figure.

Figure Mode (page 2–982)

Footstep Animation

Footstep animation is a central compositional tool in Biped. Footsteps are biped sub-objects, similar to gizmos (page 3–949) in 3ds Max. In viewports, footsteps look like the diagrams often used to illustrate ballroom dancing. Each footstep’s position and orientation in the scene controls where the biped steps.

Footsteps

The language of footsteps allows you to more directly describe and compose the complex time and space relationships that are found in different forms of locomotion.

While the placement of footsteps appears in viewports, the timing appears in Track View - Dope Sheet Editor. There, each footstep appears as a block of time, with each block representing the time when the foot is planted in a footstep.
Footsteps are appropriate for animation where the biped is on the ground or uses the ground a great deal, such as walking, standing, jumping, running, dancing, and athletic motion. For movement that does not require the biped to interact with the ground, such as swimming or flying, freeform animation (page 2–886) is more appropriate.

Footsteps are used to lock the foot to the ground. You can create the same result in freeform animation by simply creating planted keys for the feet.

Workflow

In general, you compose a footstep pattern with these actions:

1. Select the biped and access the Motion panel.
2. Click Biped rollout > Footstep Mode.
3. In the Footstep Creation rollout, click Walk, Run or Jump to choose the gait (a method or pattern of moving on foot). The gait sets the initial timing for footsteps you create. When you first create them, footsteps are inactive. They exist in the scene but don’t yet control the biped’s motion.

4. Create the footstep pattern in viewports. You can create footsteps in a few different ways, each available in the Footstep Creation rollout:
   - Automatically create a number of footsteps with Create Multiple Footsteps, or
   - Individually place each footstep with Create Footsteps (append) or Create Footsteps (at current frame). Use Auto Grid to create footsteps on a surface of a mesh.
5. Edit footstep placement by moving or rotating footstep icons in viewports.
6. Edit footstep timing in the Track View - Dope Sheet mode.
7. Activate the footsteps to create keys for the biped. The biped will now move through the footsteps using the placement and timing you set up.
8. Play the motion to test it out, looking only at the leg and foot motion and disregarding the upper body for now. If the footstep motion isn’t right, deactivate the footsteps, make changes to footstep placement or timing, reactivate the footsteps and play it again. Do this until the foot and leg motions are correct.

When footsteps are activated, keys are created for each of the tracks of the figure: the head, spine, pelvis, arms, legs, and, if appropriate, tail and ponytails. These keys form an initial sketch of your animation. The default keys, when interpolated (page 3–958), form the basic, minimal motion required to animate the figure according to the footstep pattern. Most likely you will want to adjust or replace these keys.

9. Edit the animation of the upper body using ordinary 3ds Max animation methods: Turn on Auto Key and move or rotate the biped parts. You can also use the character studio Set Key tools on the Key Info rollout (page 2–954).
10. Play the animation again and make any corrections to the upper body motion.

**Footstep Method**

In the viewports, footsteps represent support periods in space for the biped feet. You can move and rotate footsteps in viewports. In Track View, each footstep appears as a block that represents a support period in time for each of the biped’s feet. You can move footsteps in time in Track View. The footstep position and orientation in the viewport controls where the biped will step.

There are three ways to create footsteps for the biped:

- Place footsteps individually.
- Use the footstep tools to automatically create a walking, running or jumping animation.
- Import motion-capture data to footsteps.

A key advantage of the footstep method is the natural adaptation of the biped that occurs when the footsteps are edited in time and space. Editing footsteps in the viewports allows you to reposition all of the footsteps to move the entire animation. In Footstep mode, stride, length, width, and direction can be changed quickly for an entire animation and the biped automatically adapts.

Using the Footsteps Show/Hide button on the Display rollout, all footsteps can become visible. Move the footsteps in the viewports to position them for proper ground collision with the terrain object. For example, if the biped toes are rotated for the Lift key at the last frame of a footstep (to create more toe curl as the character walks) the leg automatically repositions itself to maintain foot contact with the ground (footstep).

These adaptations speed up the process of creating and editing animation for the biped. If necessary, the animator can prevent biped adaptation by using the Adapt Locks parameters (page 3–905) on the Dynamics & Adaptation rollout (page 2–980).

**Foot States**

Within a footstep animation, there can be four foot states (page 3–943): move, touch, plant, and lift. These correspond to the state of the biped feet in relationship to the footsteps. Use the foot state displays in the Biped rollout to determine the state of the biped feet when you are editing the biped foot or leg keys. The foot states can be displayed in the viewport by turning on Leg states in the Display group of the expanded Biped rollout. The Foot states are represented as colored keys in Track View - Dope Sheet.

**Footstep Mode**

When Footstep mode is active, footstep creation controls appear in the Motion panel.
Footstep Animation

Footstep controls in Motion panel

Footstep Animation

Using the default keyframes as a starting point, you can interactively insert, replace, or delete keyframes in order to refine the motion of the biped and fill in the details of movement that are unique to your animation.

Note: By default, when Biped Dynamics (page 3–916) is turned on in the Dynamics and Adaptation rollout, gravity (Dynamics Blend) and ballistic tension calculate the trajectory of the center of mass for all newly created keys in a footstep animation containing a running or jumping motion. If Spline Dynamics (page 3–1015) is turned on in the Dynamics and Adaptation rollout before footsteps are created and activated, the center of mass uses spline dynamics to calculate vertical motion, which does not take gravity into consideration. Using spline dynamics, you must set keys for the top of a jumping motion or the dip when the character lands; this trajectory is automatically calculated with biped dynamics.

Footstep Editing

At any point in the design process, you can choose to interactively edit your footstep’s spatial pattern in the scene or the timing of footsteps in Track View. The keyframes adapt to each edit: changes to footstep location retain the details of all your keyframe positions. Keyframe timing remains synchronized with changes to footstep timing,
except in cases where default leg keys must be regenerated to account for timing edits that alter the basic gait pattern, such as creating a hop in the middle of a walk.

Use Footstep mode to create and edit footsteps. Use Keyframe mode (Footstep mode off) to create and edit your character’s keys. You can always edit the timing of both footsteps and keyframes in Track View.

While the biped’s feet are airborne, you can animate its legs as you do its upper body. Biped does not create keys based on physics while the biped is off the ground, so animating the legs might be necessary to make long leaps realistic. Alternatively, you might want to make the biped appear to be floating in midair, or underwater, or have it ride a bicycle. See Freeform Editing Between Footsteps (page 2–883).

You can make the biped interact with other objects in the scene: throwing or kicking a ball, opening a door, and so on. You do this by attaching a biped limb to an object in the scene.

An animatable IK Blend parameter lets you store the anchored position and combine inverse with forward kinematics. After you’ve set keys, be sure to remove the anchors.

Tip: You can often get good results by loading an existing biped motion and then varying it. You’ll find a set of sample motion files on the program disc in the \Samples\Motions directory.

Note: On the time slider or in Track View, you can move one Biped key past another. See Moving Keys (page 2–1004).

- Editing Footstep Motion (page 2–868)

---

**Planning for Footstep Placement**

- How are the footsteps going to be positioned in viewports? Draw a sketch of their positions.
Choosing a Gait

A gait is a method or pattern of moving on foot. When you create new footsteps, the timing is determined by the gait you have chosen (Walk, Run, or Jump) and the parameters for that gait. You must choose the gait before parameters can be set.

Choose the gait that most closely approximates the type of movement you want to create. You can alter or adjust the gait after footsteps have been created.

Walk Gait

In a walk, at least one foot is always in contact with the ground. A period where one or both feet are in contact with the ground is called a support period. If both feet are on the ground, this is known as a double support period.

Planning for Footstep Timing

- What is the sequence of the footsteps? This will determine the footstep numbers. Footsteps always begin with the number 0. Number them in your diagram if you can.
- Is each footstep a left or right footstep?

Planning for Footstep Timing

- What is the support relationship between left and right footsteps? In other words, does the timing of the footsteps resemble a walk, run or jump pattern? A character doing a foxtrot or waltz, for example, is actually moving with “walk” timing – the character shifts weight from one foot to the other.
- How long, in frames, should each footstep be? How long are the biped’s airborne periods?
- Are there any periods of time where the biped is standing on two feet for a while?

Choosing a Gait

The gait parameters of a walk are:

Walk Footstep—The number of frames that each footstep remains on the ground.

Double Support—The number of frames in a double support period, that is, when both feet are on the ground.

Run Gait

With running, both feet are never on the ground at the same time. Either one foot is on the ground during the support period, or the body is airborne. While it is airborne, the body moves forward horizontally at a constant speed. In general, the longer the body is in the air, the higher it must fly after lifting off from the supporting foot to stay airborne for the specified period of time.

The gait parameters of a run are:

Run Footstep—The number of frames that each footstep remains on the ground.

Airborne—The number of frames that the biped is airborne, that is, when neither foot is on the ground.

Jump Gait

Jumping is a special case of running. Both feet are in contact with the ground at the same time, or airborne at the same time. As with running, forward motion is horizontal and constant, but vertical motion depends on the length of the jump.

The gait parameters of a jump are:
Feet Down—The number of frames in which both feet are on the ground.

Airborne—The number of frames that the biped is airborne, that is, when neither foot is on the ground.

Changing these values changes the biped’s jump behavior.

Setting Gait Parameters
Gait parameters can be found in two areas:

- If creating footsteps automatically with Create Multiple Footsteps, the gait parameters appear on the Create Multiple Footsteps dialog (page 2–992).
- If creating footsteps manually with Create Footsteps (append) or Create Footsteps (at current frame), the gait parameters on the Footstep Creation rollout (page 2–988) are used.

Changing these values changes the timing for any footsteps placed after the values are set.

Changing the Gait After Creating Footsteps
After creating the footsteps, you can change the gait by editing footstep timing in Track View’s Dope Sheet mode. See Editing Footstep Timing (page 2–869).

Gait parameters are only one way to define the timing and nature of the biped’s gait. For a more complete description of gaits and other parameters that alter the nature of the biped’s motion, see Adjusting Vertical Motion (page 2–878).

Creating Footsteps Automatically
Automatic footstep creation is the easiest way to create a walk or run cycle. You can use this method to make the biped climb or descend a flight of stairs, hop repeatedly, and do a variety of motions. Automatic footstep creation places the footstep for you, generating perfectly timed and spaced footsteps.

Procedure
To create footsteps automatically:

1. Select any part of the biped.
2. On the Motion panel > Biped rollout, click Footstep Mode.
   You are now in Footstep mode, where you can create, activate, or edit footsteps.
3. In the Footstep Creation rollout, choose the gait you want to use for the footsteps: Walk, Run, or Jump.
   The selected gait determines the timing pattern of the automatically placed footsteps.
4. In the Footstep Creation rollout, click Create Multiple Footsteps.
   The Create Multiple Footsteps dialog (page 2–992) appears. This dialog determines various aspects of the footstep sequence, such as how far each footstep will be placed from the previous footstep.
5. Set the multiple footstep parameters, and then click OK.
   This places footstep icons in the scene. To make the biped move through the footsteps, you must create keys for the footsteps.
6. Click Create Keys For Inactive Footsteps on the Footstep Operations rollout.
   Keys have now been created for the footsteps.
7. Click Play Animation to see the animation.
Creating Footsteps Manually

Creating footsteps manually is useful for complicated footwork, such as dancing. Manual footstep creation allows you to place each new footstep carefully where you want it.

Multiple footsteps can also be generated automatically. To quickly generate a simple walking, running, or jumping footstep patterns, see Creating Footsteps Automatically (page 2–862).

There are two ways to create footsteps manually:

- You can start creating footstep at the current frame with Create Footsteps (at current frame) in the Footstep Creation rollout (page 2–988). Any footsteps added subsequently will extend in time from the first footstep. If you attempt to create a footstep at the same time as an existing footstep on the same side, an alert appears and you are not allowed to create the footstep.

- You can also append footsteps onto the end of the existing footsteps with Create Footsteps (append) in the Footstep Creation rollout (page 2–988). Then Biped computes the frame at which the first footstep should be created based on the chosen gait and the existing footsteps. This option is disabled if there are no existing footsteps.

As with all footsteps, any footsteps you create with these methods are inactive upon creation. You must activate them with Create Keys for Inactive Footsteps in order to make the biped move through them.

Preparing to Create Footsteps Manually

Before placing footsteps, you must choose the gait, then set parameters for the gait in the Footstep Creation rollout (page 2–988).

When you select the Walk, Run, or Jump gait, parameters for that gait appear on the Footstep Creation rollout. See Choosing a Gait (page 2–861) for information on gaits and parameters.

Switching Between Left and Right Footsteps

By default, manually placed footsteps alternate left, right, left, right. The footstep cursor, which appears during individual footstep creation, shows you whether a left or right footstep will be placed next.

If you want to change the footstep side that will be placed when you next click, press Q to toggle between them. Pressing Q also changes the cursor, showing you which footstep side will be placed next.

Automatic Time Extension

During manual footstep creation, your display remains at the current frame. However, footsteps are created sequentially in time. If the footsteps you create require more frames than are in the active time segment, the footstep creation process extends the active time segment, which can create new frames.
Creating New Footsteps Between Existing Footsteps

If inactive footsteps exist, you can only create new, inactive footsteps within or directly before or after the time of the inactive footsteps. If you need to add more footsteps near a time where there are only active footsteps, deactivate all footsteps first, then add footsteps and activate them again. See Deactivating Footsteps (page 2–865).

Procedures

To prepare for manual footstep creation:

1. On the Motion panel > Biped rollout, click Footstep Mode. You are now in Footstep mode, and can create, activate, or edit footsteps.

2. In the Footstep Creation rollout, choose the gait you want to use: Walk, Run, or Jump. See Choosing a Gait (page 2–861) for details on gaits and their parameters.

3. In the Footstep Creation rollout, set parameters for the chosen gait.

To create footsteps beginning at the current frame:

1. Turn on Footstep Mode.

2. Click Create Footsteps (at current frame).

3. Click in a viewport to create a footstep. Move the cursor and continue clicking to create more footsteps.

4. Move and rotate footsteps until you have achieved the desired pattern.

5. Click Create Keys For Inactive Footsteps.

6. Click Play Animation to see the animation.

To append footsteps onto the existing footsteps:

1. Make sure Footstep Mode is turned on.

2. If the existing footsteps are active, deactivate them first. Select all footsteps and click Deactivate Footsteps.

3. Click Create Footsteps (append).

4. Click in a viewport to create a footstep. Move the cursor and continue clicking to create more footsteps.

Tip: A Top viewport is usually best when you create footsteps individually.

5. Move and rotate footsteps until you have achieved the desired pattern.

6. Click Create Keys For Inactive Footsteps.

7. Click Play Animation to see the animation.

To create footsteps using AutoGrid:

The AutoGrid feature creates objects on a surface other than the default construction plane. You can use this feature to place footsteps on an irregular surface.

1. Using any 3ds Max modeling method, create a surface as the terrain for the biped to step on.

2. On Create panel > Systems, click Biped. In the Object Type rollout, turn on AutoGrid.

3. If you already have a biped to use, return to the Motion panel without creating a biped. If you
need a biped, create the biped at this time, then access the Motion panel.

4. Turn on Footstep Mode.

5. Click Create Footsteps (at current frame). Move the cursor over the terrain. A transform gizmo moves with your cursor to indicate the location and orientation of the gizmo. Click to place a footstep, then move the cursor and click again to place more footsteps.

6. When you have finished placing footsteps, click Create Keys For Inactive Footsteps. Keys have now been created for the footsteps.

7. Click Play Animation to see the animation. The biped steps on the terrain, following the footsteps.

Choosing a Gait (page 2–861)
Creating Footsteps Automatically (page 2–862)
Editing Footstep Placement (page 2–869)

Activating Footsteps

When footsteps are created, they are inactive. To make the biped move through the footsteps, you must activate them by clicking Create Keys for Inactive Footsteps on the Footstep Operations rollout (page 2–990).

When you activate footsteps, keys are created for the biped’s legs and feet, causing the biped to step through the footsteps. In addition, keys are created for the spine, arms, hips, and tail (if the biped has one) to make the biped move naturally through the footsteps. Keys are not created for the head, ponytails or props.

When keys are created for footsteps, a generic type of motion is generated for the biped’s body based on footstep placement and timing. This movement is intended as a starting point for your own animation, not as a final setup.

There are times when it is appropriate to deactivate footsteps, make changes, and activate footsteps again. See Deactivating Footsteps (page 2–865).

Procedure
To activate footsteps:

1. While in Footstep mode, create footsteps using the automatic or manual method.

2. Move, rotate, delete and edit footsteps as desired.

3. Click Create Keys for Inactive Footsteps in the Footstep Operations rollout.

4. Click Play Animation to see the animation.

Creating Footsteps Manually (page 2–863)

Deactivating Footsteps

When you change the position or timing of active footsteps, the biped’s animation changes accordingly, causing the biped to step into the footsteps in their new positions with the new timing.

Deactivating footsteps temporarily suspends changes to animation when footsteps are changed. When you move deactivated footsteps or change their timing, the biped still continues to do the same motion it did before footsteps were deactivated.
Footsteps should be deactivated when you make substantial changes to footstep timing or placement.

Footsteps are deactivated by selecting footsteps and clicking Deactivate Footsteps in the Footstep Operations rollout (page 2–990).

After making changes to the footsteps, click Create Keys for Inactive Footsteps in the Footstep Operations rollout (page 2–990). This will recreate keys for the biped and cause it to follow the footsteps.

Active footsteps are pale in color, while inactive footsteps are brightly colored. This coloring appears both on footstep icons in viewports and on footstep keys in the Dope Sheet.

Note: Deactivating and reactivating footsteps causes all biped keys to be replaced with default animation keys for the current footstep pattern and timing.

Procedure

To deactivate footsteps:

1. Select the footsteps to deactivate.
   The footsteps you select must be in sequence; you cannot deactivate a nonsequential set of footsteps.

2. Click Deactivate Selected Footsteps in the Footstep Operations rollout.
   The footsteps are deactivated. Viewports and the Dope Sheet display them in bright colors again.

When to Deactivate Footsteps

There are many situations where you will want or need to deactivate footsteps after activating them.

- When you move or rotate active footsteps substantially, you might find that the original keys generated are no longer appropriate for your animation. If this happens, deactivate footsteps, move the footsteps into the correct locations, and activate footsteps again.

- When changing footstep timing in the Curve Editor’s Dope Sheet mode, you might receive an error message stating that what you are trying to do violates one of the rules of biped key placement. If this occurs, deactivate footsteps, make timing changes in the Dope Sheet, then activate footsteps again.

- If you have a large number of active footsteps in the scene, moving footsteps and making timing changes can cause delays as all keys are adapted and updated. You might find your work is faster if you deactivate footsteps while making your changes.

- If you have activated footsteps then changed the default animation, then find you want to return to the default animation, you can deactivate footsteps and activate them again to recreate the default animation.

Activation/Deactivation Workflow

The fastest workflow with footsteps is to deactivate footsteps and make changes, reactivate footsteps, and play the animation to check your work, and repeat this process until the footstep timing and placement are correct. However, deactivating and reactivating footsteps replaces any biped keys with the default animation for the current footstep pattern and timing.

For this reason, it is recommended that you work with footsteps exclusively first, ignoring the upper body animation, and deactivate and reactivate footsteps as needed. When the motion of the feet is perfect or near-perfect, only then should you adjust the biped animation manually. Otherwise, you will lose all your manual animation work every time you deactivate and reactivate footsteps.
Tip: Alternatively, you can use layers (page 2–974) to store any upper body animations you want to preserve while you proceed with changes in your biped’s footsteps.

Rules for Inactive Footsteps

When you click deactivate footsteps, only selected footsteps are deactivated. If you haven’t made any changes to the default animation, it is recommended that you deactivate all footsteps. However, if you’ve changed or added animation keys to part of the animation, you might want to deactivate only a portion of the footsteps.

When some but not all footsteps are currently deactivated, limitations are imposed on the changes you can make to footsteps:

- You cannot set, delete, move, or edit keys in any way; footstep tracks are disabled in the Dope Sheet.
- You can create footsteps only when the new footsteps are among and adjacent to existing inactive footsteps.
- You can delete only inactive footsteps, and at least one inactive footstep must remain.
- You cannot deactivate a set of nonsequential footsteps.

See also
Activating Footsteps (page 2–865)

Leg States

A leg moving through a footstep has four states, beginning with the foot on the ground. Then the foot lifts, moves through the air, and returns to the ground again. These leg states are labeled by character studio to help you work with footsteps and leg/foot keys more easily when editing footsteps.

These states are referred to in these topics to aid in understanding more advanced footstep concepts, so it’s important that you become familiar with them.

- **Touch** occurs at the leg keyframe where the foot first touches the footstep, and always corresponds with the start frame of a footstep in Track View. The Touch state is always one frame long.

- **Plant** occurs after touching, and before lifting. It is always in between the start and end frames of a footstep in Track View. The Plant state is usually more than one frame long.

- **Lift** occurs at the keyframe where the foot lifts off the ground, and always corresponds with the end frame of a footstep in Track View. The Lift state is always one frame long.

- **Move** occurs while the foot is in the air, and is always in the intervals between footsteps in Track View. In walking, while one foot moves, the body is supported by the other leg. In running or jumping, there are periods where the body is not supported and moves in midair.

For more information on these keys, see Editing Footstep Timing (page 2–869).

You can display the current state of each leg by turning on Leg States in Biped rollout > Display group. The state name appears in viewports near the foot, corresponding to the state at the current frame.

Understanding Footstep and Body Keys

When you activate footsteps, keys are created for biped body parts. Before you work with footstep placement and timing, it’s essential that you understand the default keys generated and how they relate to footstep editing.
Note: State names appear only on footsteps that have been previously activated. If active footsteps have been deactivated and edited, the state names that appear will correspond to states the legs were in before deactivation. For this reason, leg states displayed between deactivation and reactivation might not be accurate.

Regardless of the footstep pattern, activating footsteps will always cause leg keys to be generated at each lift and touch frame. Although you can alter these keys to some degree by going to a touch or lift keyframe, turning on Auto Key and changing the leg positions or rotations, you cannot delete these keys.

To change the foot/leg animation after footsteps are activated, see Allocating Legs and Feet (page 2–874) and Adjusting Body Keys in Track View (page 2–875).

**Body Keys**

When footsteps are activated, keys are also generated for the center of mass (COM) object, the blue tetrahedron at the center of the biped’s pelvis. The position and rotation of the COM determines the horizontal and vertical position of the biped body, as well as its rotation.

Unlike other biped parts or 3ds Max objects, the COM has three separate animation tracks, two for motion and one for rotation. You select these tracks by clicking the appropriate button on the Track Selection rollout (page 2–945):

- ![Body Horizontal](image)
- ![Body Vertical](image)
- ![Body Rotation](image)

Keys for these tracks are generated automatically when you activate footsteps. You can view the keys for each track on the Track Bar by turning off Footstep Mode and clicking the corresponding button listed above. These tracks are also visible in Track View’s Dope Sheet mode.

Note: When you select the COM, only the keys corresponding to the selected track are displayed. If you select the COM and do not select a track, no keys are displayed on the Track Bar, even if the COM is animated. You can find out which COM track is selected by checking the status of the buttons displayed above. When a button is turned on, the track is selected.

You can animate the COM or change existing keys after footsteps are activated. To change COM keys after footsteps are activated, see Allocating the Upper Body (page 2–874) and Adjusting Body Keys in Track View (page 2–875).

---

**Editing Footstep Motion**

The topics in this section deal with the editing of footstep motion when animating bipeds. They are:

Editing Footstep Placement (page 2–869)

Editing Footstep Timing (page 2–869)

Editing Active Footsteps (page 2–871)

Splicing Footsteps (page 2–872)

Allocating Legs and Feet (page 2–874)

Allocating the Upper Body (page 2–874)

Adjusting Body Keys in Track View (page 2–875)

Shifting the Biped’s Balance (page 2–876)

Adjusting Vertical Motion (page 2–878)

Saving Footstep Animation (page 2–882)
Editing Footstep Placement

After you’ve created footsteps, there are several ways to edit their placement in the scene.

- You can use standard 3ds Max controls to select, move, rotate, or delete footsteps.
  Note: The 3ds Max scale transform will not scale the footprint icons themselves; the size of the icons is set by the size of the biped’s feet. The biped foot size is originally set by the biped’s height, then later by any scaling you perform on the feet in Figure Mode. See Posing the Biped (page 2–847).

- You can use the Bend and Scale controls in the Footstep Operations Rollout (page 2–990) to edit the footsteps. The Bend value curves a selection of footsteps, while Scale changes the distance between selected footsteps.

Selecting Footsteps

To change footstep placement, you must first select the footsteps to change.

When Footstep Mode is turned on, footsteps can be selected with the same methods used to select 3ds Max objects:

- Click footstep icons while holding down the Ctrl key.
- Click and drag to draw a bounding box around footsteps you want to select.
- Unselect footsteps by holding down the Alt key and clicking footsteps.

You can also select footsteps in Track View’s Dope Sheet mode. See Editing Footstep Timing (page 2–869).

Biped Key Adaptation

When you move, rotate, delete, bend, or scale active footsteps, the software automatically alters biped keys to account for changes in balance and motion. This change is called adaptation (page 3–905). For information on how adaptation occurs, see Editing Active Footsteps (page 2–871).

Editing Footstep Timing

You can edit footstep timing in Track View.

Footstep keys have their own display in Track View’s Dope Sheet mode. Footstep keys are displayed as blocks of color, each indicating a period of time when one of the biped’s feet is in a footstep.

The footstep key colors match the colors of footprint icons in viewports. Just as with footprint icons, inactive footsteps are brightly colored, while active footsteps are displayed with pale colors.

The footstep key display relates directly to the different states (page 2–867) the leg and foot can be in at any given time. The left edge of each footstep key indicates the foot is in the Touch state, while the right edge indicates the Lift state. The duration of the footstep key between Touch and Lift indicates the time the foot is in the Plant state. The space between footstep keys indicates a time when the foot is completely out of a footstep, a Move state.

You can change footstep timing in Track View by:

- Moving footstep keys to an earlier or later time.
• Moving footstep keys to change the time relationships between footsteps.
• Changing the lengths of footstep keys.
• Deleting footstep keys.

You must select footstep keys before you can change their timing.

**Selecting Footsteps for Time Editing**

Selecting footstep keys is the same as selecting footstep icons; when one is selected, the other is selected as well. Footstep keys can be selected in a number of ways for editing in Track View.

**Note:** To select footsteps, you must have Footstep Mode turned on.

• Select footsteps in viewports as you would any 3ds Max object. Click a footstep to select it, and hold down the Ctrl key and click additional footsteps to select them. You can also draw a selection box around footsteps to select them.

Selecting footsteps also selects the footsteps in Track View. A selected footstep in Track View has a white border and a dot on both the left and right edges of the footstep key.

• Click the center of a footstep key in Track View to select it. Hold down the Ctrl key and click the center of additional footstep keys to select multiple footsteps.

• To select several footsteps at once, draw a selection box around the footstep keys in Track View.

• You can also select one edge of a footstep key by clicking the left or right edge in Track View. A single white dot appears at the selected edge. You can change the duration of the footstep by increasing or decreasing the length of the key on the selected edge.

![Footstep key selected in Track View](image)

• To select an edge, right-click the footstep track in Track View to display the Footstep Mode dialog (page 2–1000). Select one or more footstep keys, and use the controls in the Footstep Edge Selection group to select an edge.

**Editing Footstep Timing**

Editing the timing of footsteps is a simple matter of moving selected footsteps or selected edges in time.

Moving an entire footstep changes the time at which it starts and ends, but not its duration. Moving a footstep edge changes the duration of the footstep.

**Restrictions on Footstep Time Editing**

The timing for both active and inactive footsteps can be changed. Editing timing for active footsteps also changes keys for the center of mass and leg keys, but not the spine, arm or tail keys. This can cause the resulting animation to look different from the way you intended. For this reason, you might prefer to deactivate footsteps before editing timing. See Deactivating Footsteps (page 2–865).

When editing footstep timing in Track View, the following limitations apply to both inactive and active footsteps:

• There must be at least one frame between footstep keys for the same foot.
• Footstep keys cannot start in negative frames.
Editing Active Footsteps

Every footstep must be at least two frames long.

If you want to add footstep keys, use the tools on the Footstep Creation rollout. See *Creating Footsteps Automatically* (page 2–862) and *Creating Footsteps Manually* (page 2–863).

Footsteps cannot be cloned.

To scale time of footsteps and body keys together, you can use Scale Time on the Track View toolbar.

**Warning:** Do not use the Re-scale Time option in the Time Configuration dialog to scale an animation that contains active footsteps. If you do so, biped keys might not adapt appropriately. Instead, use Scale Time on the Track View toolbar.

If you attempt to perform an illegal footstep timing change in Track View, an error message appears and the footstep timing pattern returns to the state it was in before you made edits.

**Procedures**

**To display footstep keys in Track View:**

1. Choose Graph Editors menu > Track View > Dope Sheet.
2. If necessary, expand the Objects listing to display footstep keys.

**To move selected footsteps in time:**

- In Track View, drag any selected footstep key to drag all selected footstep keys in time.

**To change the duration of a footstep:**

1. In Track View, click the left or right edge of a footstep key.
   In addition to a white border, a small white dot appears to indicate the edge is selected.
2. Drag the selected edge to make the footstep key longer or shorter.

You can adjust a selection of multiple footsteps this way.

You can also adjust any combination of left edge, right edge, and center selections. Dragging in Track View adjusts any combination of edge or center selection.

**To change the display of numbers of footstep keys:**

1. In Track View, right-click the footstep track to display the Footstep Mode Dialog (page 2–1000).
2. Choose the values to display from the Footstep Number Display group.

**To scale keys in time:**

1. On the Track View toolbar, click Scale Time.
2. In the Track View window, click and drag to indicate the beginning and end of the time period you want to scale.
3. Move the cursor over the selection region until a scale cursor appears. Drag to the left to reduce time, or drag to the right to increase time.

*Adjusting Body Keys in Track View* (page 2–875)

---

**Editing Active Footsteps**

One of the most powerful features of footsteps is the ability to adapt keyframes automatically to edits you make to your footstep pattern. By analogy, the footsteps become a kind of *gizmo* (page 3–949) for manipulating the keyframes of your character’s animation. In most cases, edits you make to footsteps act upon your keys in an intuitive fashion.

In order to understand what happens when active footsteps are edited, you must first understand what happens to biped keys when footsteps are activated. See *Understanding Footstep and Body Keys* (page 2–867).
Key Adaptation for Footstep Placement Edits

When you move or rotate active footsteps as described in Editing Footstep Placement (page 2–869), the biped’s keys are immediately influenced by the edit. The following keyframe tracks are influenced in the vicinity of the edited footsteps:

- Body Horizontal keys change to step or hop within range of new footstep locations
- Body Vertical keys change to match possible changes in stride length, since the center of mass must move lower to step longer distances
- Body Turning (Body Rotation) keys change to bank into turns created by changes in path curvature or body speed
- Right or left leg keys in a Move state (when the leg is not in a footstep) are adapted to step between new locations

Other keys are preserved in the adaptation process. For example, if you animate the body to kneel while turned to the right, altering a nearby footstep will maintain the biped’s height and turning motion as much as possible.

Key Adaptation for Footstep Timing Edits

To edit active footsteps in time, follow the methods described in Editing Footstep Timing (page 2–869). Keyframes affected by the edit are updated immediately.

A fundamental factor in how your keyframes are adapted is whether the sequence of leg support transitions has changed. Changing the relationship between opposite leg keys effectively changes the gait, which causes entirely new keyframes to be generated at that point.

- If you move footstep keys in such a way that you remove an overlap or create a new overlap between opposite legs, you have changed the gait, and new keys will be generated for legs.
- If you do not change the overlap relationship between opposite legs, existing legs keys are retained.

Warning: Editing a jumping sequence so that the feet hit or leave the ground slightly out of phase rather than at the same time introduces a change in the leg support sequence. Hence, even in this case, the leg keys will be locally replaced with default keys.

Note: If you scale the biped’s feet in Figure mode after activating footsteps, then turn off Figure mode, character studio will recalculate the footstep display size and the footstep dynamics automatically.

Locking Keys

You can lock specified tracks to prevent them from adapting automatically when you move active footsteps. The controls in the Footstep Adapt Locks group on the Dynamics & Adaptation rollout (page 2–980) lock specified tracks.

Procedure

To prevent keys from changing when active footstep agents are edited:

1. On the Motion panel, on the Dynamics & Adaptation rollout, in the Footstep Adapt Locks group, select the types of keys you want to lock.
2. Move, rotate, scale, or bend active footsteps.

The tracks you lock are unaffected by footstep editing.

Splicing Footsteps

You can copy the motion of a biped footstep sequence, and paste it either at the end or into the middle of another footstep sequence. This technique is called splicing (page 3–1015).
You can use splicing to build an extended, or cyclic, motion sequence out of shorter sequences. You can also copy footsteps from one biped and paste them onto another biped with this technique.

Splicing footsteps makes use of a **footstep buffer** to store footstep positions and keys. The buffer is a temporary area in memory where footsteps are stored.

Tip: Use motion splicing when you want to edit segments of a single footstep-based animation. To build longer animations by connecting finished .bip files, use **Motion Flow** (page 2–1026) or the **Motion Mixer** (page 2–604).

**Procedures**

**To copy footsteps to the buffer:**

1. Turn on Footstep mode.
2. Select a series of footsteps.
3. In the Footsteps Operations rollout, click Copy Footsteps.

**To edit the footstep buffer:**

You can edit the footstep buffer only when footsteps have been copied to the buffer, as described in the previous procedure.

1. On the Biped rollout > Modes group, click Buffer Mode. This button is active only when there are footsteps in the buffer.

   The viewports now display the footsteps in the footstep buffer, rather than the footsteps in the currently activated footstep sequence.

2. Edit footsteps or motion keys as you normally would – by moving and rotating footsteps, or turning on Auto Key and moving and rotating parts of the biped skeleton.

   Note: You can’t splice (copy and paste) footsteps while in Buffer mode.

If you load a BIP file by clicking Load File on the Biped rollout while Buffer mode is active, the footstep buffer is replaced with the motion in the BIP file.

3. Click Buffer Mode to turn it off.

   Now you can splice the edited buffer by pasting footsteps.

**To splice the footstep buffer:**

1. Click Paste Footsteps on the Footstep Operations rollout.

   The footsteps from the buffer appear in their saturated colors.

2. Use Select and Move from the 3ds Max toolbar to position the first pasted footstep at the point where you want to splice. When you move the first pasted footstep over an activated footstep of the same side, right or left, the activated footstep turns red to indicate splicing is possible.

   This step is usually easiest to do in a Top viewport.

   Note: If you deselect the pasted footsteps by clicking elsewhere in a viewport, no paste occurs and the pasting process ends.

3. When you have moved the buffer footsteps to the desired location, release the mouse.

   The contents of the footstep buffer are placed over the active footsteps. The first footstep in the buffer replaces the footstep that turned red, and the rest of the buffer footsteps follow.

4. The footstep that turned red and the remaining original footsteps now appear in the viewports. They will be near the activated footsteps, in their saturated colors. They can now be moved and pasted onto the end of the spliced motion, which will, in effect, perform an insert of the buffer motion. The red footstep and is
following footsteps can also be pasted anywhere in the footstep sequence. If you pasted onto the last footstep, this step does not occur.

If you don’t want to append the leftover footsteps, simply click anywhere in the viewport to dismiss them.

**Warning:** If any footstep in the buffer overlaps in time with a footstep previous to the one onto that you are pasting, a message appears and the paste will not be performed.

**Tip:** To create a cycle of a motion with alternating footsteps, you must copy and paste at least three footsteps.

*Footstep Operations Rollout (page 2–990)*

---

**Animating Legs and Feet**

When you activate footsteps, keys are created for the legs and feet according to the footstep pattern and timing. Leg and foot keys are set at each Touch and Lift frame, and between footsteps.

Although the parts of the leg (thigh, calf, foot, toes) can move and rotate separately, one key dot appears on the Track Bar and in Track View for each leg structure unless you have turned on separate tracks in the *Keyframing Tools rollout* (page 2–962).

When the foot is not in a footstep, you can move or delete keyframes, and animate or reposition any part of the leg or foot. Simply turn on Auto Key and move or rotate the leg or foot to its new position.

**Animating Legs and Feet in Footsteps**

The leg keys created at either end of each footstep are *locked*, meaning they cannot be moved or deleted. You can, however, change the animation at these frames, or add new keyframes within the timespan of the footstep key.

When the foot is in a footstep, you can animate or reposition the leg and foot to some degree:

- You can rotate the foot around its pivot point within the footstep.
- You can animate the pivot point with the Select Pivot option in Key Info rollout > IK bar. See *Animating Pivots (page 2–905).*
- You cannot move a foot out of a footstep. If you do not want the foot to be in the footstep at a particular frame, change the timespan of the footstep key so it does not include that frame. See *Editing Footstep Timing (page 2–869).*

---

**Animating the Upper Body**

When you use footsteps to animate the legs and feet, animating the spine, neck, head, arms, and other upper body parts is accomplished in the same way as for freeform animation. Simply turn on Auto Key and start moving and rotating body parts. See *Animating by Moving Links (page 2–890)* and *Animating by Rotating Links (page 2–891).*

>You can also click the Set Key button on the *Key Info rollout (page 2–954)* to set keys for selected body parts at the current frame. This option allows you to move body parts as you like, setting keys only when you have decided to do so.

**Warning:** Do not use the 3ds Max Set Key button to set keys for the biped.

Animation on the center of mass (COM) works differently, depending on whether the biped is in a footstep at that particular frame.

- If at least one foot is in a footstep, moving or rotating the COM will animate the entire body along with the COM, except a foot that is in a footstep. A foot in a footstep will stay planted in
the footnote and the leg will bend or straighten as the COM is moved up or down.

- If the biped is airborne (no footsteps at that frame), the COM can be moved horizontally and can be rotated, but cannot be moved vertically. This is because character studio automatically calculates how high the biped can go based on the biped’s height and the current gravity setting. To make the biped jump higher or lower during airborne periods, see Freeform Animation Between Footsteps (page 2–883).

**Working with Existing Keys**

Because keys are created for the spine, arms, and tail when footsteps are activated, you will want to take care when creating new keyframes. As with 3ds Max animation, placing keyframes one or two frames apart creates jerking or popping motions.

To avoid placing keyframes on upper body parts too close together, you can do one of the following:

- Turn on the 3ds Max Key Mode toggle, select the body part, and use Next Key and Previous Key to move in time from one keyframe to another. Animate only on existing keyframes.

- Delete all the body part keys except the key at frame 0, and create entirely new keys throughout the animation.

**Warning:** If you delete all keys, including the key at frame 0, be sure to set a key at frame 0 before animating on other frames. character studio does not automatically place a key at frame 0 when you animate on frames other than 0, as 3ds Max does.

**Interdependencies Between Legs and Upper Body**

When footstep animation is used, animation of the upper body and animation of the legs are interdependent. Any time you change the position of the body’s center of mass, leg positions are automatically updated to ensure the feet still move from footstep to footstep.

Interdependencies between the upper body and legs are updated after a key has been set, sometimes causing the appearance of a pop in the leg position. However, in playing the animation you will find the motion to be smooth.

When you set a leg key while the foot is on the ground, the location of the foot is automatically recalculated based on the natural roll of the foot from its point of initial contact with the ground. The pivot points are based on collisions between the footstep plane, the two corners of the heel, and the bones that connect the toes’ links.

This ability to preserve interdependent relationships allows you easily to experiment and improvise with motion, since you are assured that edits to one body part will not corrupt the integrity of other parts.

In general, changes to the center of mass, spine, and pelvis cause the legs to adjust. Changes to the legs do not affect the center of mass’s vertical position.

---

**Adjusting Body Keys in Track View**

When you activate footsteps, keys are created for biped body parts. After activating footsteps, you can also create keys by turning on Auto Key and animating body parts. All these keys can be viewed in Track View – Dope Sheet mode.

In general, editing biped body keys in Track View is the same as editing keys of any sort in 3ds Max, with a few restrictions.

Before reading this section, please read Understanding Footstep and Body Keys (page 2–867) for terms and definitions used in this section.
Note: The information in this section applies only to biped body keys for the arms, legs, spine, neck, and other parts of the upper body. For rules for editing footstep keys, see Editing Footstep Timing (page 2–869).

Locked Keys
Some biped keys are locked, meaning they cannot be moved in time. Locked keys are colored red in Track View.

Locked keys for the COM Body Vertical track are created at each footstep’s lift and touch frames. These are the only keys that are locked. These keys can be moved in time by changing footstep duration in Track View.

Although you cannot move or delete a locked key in Track View, you can sometimes change the animation on the frame by going to the frame, turning on Auto Key and manually animating the key.

Restrictions on Biped Body Key Editing
All options available for editing biped body key timing are available only when Edit Keys on the Track View toolbar is turned on.

The following rules apply to the editing biped body key timing in Track View:

- You cannot move existing keys outside the area between the first and last footsteps, or to negative frames.
- You can use Add Keys to add keys to any biped body track. You cannot add keys outside the area between the first and last footsteps, or to negative frames.
- You can clone keys the same way you clone 3ds Max object keys, by selecting keys and holding down Shift as you drag them. You can also clone keys by copying and pasting postures. See Copying and Pasting Postures and Poses (page 2–910).
- The Track View – Curve Editor can be used to view and edit curves showing the interpolation between body keys. You can also use the Workbench to analyze, edit and fix biped motion curves. See Working with the Workbench (page 2–1008).
- You can use Scale Keys to scale selected keys, except for locked keys.

Tip: If you want to animate a biped performing movements with its upper body while standing, extend the length of the standing footsteps to cover the length of the standing animation, then add keys for the upper body.

See also
Animating the Upper Body (page 2–874)

Shifting the Biped’s Balance
After footsteps are activated, you can adjust the biped’s overall balance in either of two ways:

- In the Biped rollout (page 2–936), turn on Rubber Band Mode and move the biped’s COM, or
- Change or animate the Balance Factor parameter in the Key Info rollout (page 2–954).

Rubber-Banding the COM
When Rubber Band mode is active, you can move the biped’s center of mass in relation to the rest of the body, changing the biped’s overall balance. Rubber-banding the center of mass defines your character’s balance point in at-rest pose and in any resulting motion.

When a character is standing at rest, with feet side by side, the center of mass should be directly above the area where the feet touch the ground. The center of mass determines the center of your character’s distribution of weight. For most
characters, the physical center of mass is located near the pelvis.

Typical placements for the center of mass are:

- Characters that stand erect, such as humanoids, use the default location of the center of mass within the pelvis.
- Characters that naturally lean forward, such as some dinosaurs and birds, should have the center of mass moved slightly forward of the pelvis. This is also good for robots and droid soldiers.
- Characters that are holding a heavy weight out in front of them, or overweight characters, might need their center of mass moved slightly behind the pelvis.
- Characters that are pushing or pulling objects might need their center of mass moved slightly behind the pelvis.

Note: If you place the center of mass too far in front of the pelvis, the character unnaturally compensates for balance. As each step is taken, the legs and body move in an awkward fashion, as if there was an invisible weight attached to the front of the character.

Center of mass moved behind the biped in rubber-band mode

For a tutorial that uses this technique, see “Creating the Illusion of Weight”.

**Balance Factor**

The balance factor is an animatable parameter that determines how the biped’s hips and spine will compensate when the biped bends forward or backward.

The balance factor determines the degree and direction in which the head and/or hips swing out from their original vertical alignments when the biped bends over.

The Balance Factor parameter can have any value from 0 to 2:
When Balance Factor is 1 (the default value) and you rotate the spine forward, both the hips and head swing out from their original vertical alignment to a similar degree to compensate for the shift in weight. This value is suitable for times when the biped leans forward while standing.

When Balance Factor is 0 and you rotate the spine forward, the COM keeps its original vertical alignment, and the head swings forward. There is no movement in the hips to compensate for the shift in body weight. This setting is good for animating a sitting biped who leans forward, to prevent its hips from shifting backward. It can also work well for characters with tails; the tail provides weight in back of the biped, so the hips don’t have to shift backward to compensate when the character bends over.

When Balance Factor is 2 and you rotate the spine forward, the head retains its original vertical alignment while the COM swings backward. The hips compensate strongly for the shift in body weight. This setting can be useful for violent or acrobatic motions.

In order to affect the animation, the balance factor must be set before you animate the biped. The balance factor can be animated to give the biped different reactions to bending motions over the course of the animation.

The Balance Factor parameter appears in the Key Info rollout > Body section.

Procedure

To set the balance factor:
1. On the Motion panel, turn off Footstep Mode if it is turned on.

   Note: The Key Info rollout is accessible only when Footstep Mode is turned off.

2. Expand the Body bar on the Key Info rollout.

3. Go to the frame where you want to set the Balance Factor.

4. Click Body Horizontal to select this track (page 3–1023).

5. If no Body Horizontal key exists at the frame where you want to set the Balance Factor, create one by clicking Set Key in the Key Info rollout.

6. Change the Balance Factor parameter.

   There is no need to click Set Key again after setting the Balance Factor parameter.

7. Rotate the biped’s spine.

   The biped’s hips and/or head shift position based on the Balance Factor value.

Adjusting Vertical Motion

A ballistic gait is any footstep pattern in which there are periods with no feet on the ground, causing the biped to become airborne, or ballistic. Running and jumping are ballistic gaits, while walking is not.

When Biped Dynamics is turned on in the Dynamics & Adaptation rollout (page 2–980) and you activate footsteps, the Body Vertical keys that are automatically generated during a ballistic gait period will take gravity and landing speed into account. The parameters described in this section affect Body Vertical keys created in this manner.

Airborne Dynamics

With footsteps, each airborne period always begins and ends with Body Horizontal and Body Vertical keys. These keys define the position of the biped at lift-off and touchdown.

When the biped is airborne and Biped Dynamics is turned on, the vertical motion is governed by physically based dynamics. Its airborne trajectory
is based on the current gravity setting, the height of the Body Vertical key at lift-off and touchdown, and the amount of time in the air.

By default, there is no Body Vertical key at the peak of the biped’s trajectory; the biped’s peak airborne height is calculated and enforced automatically. You cannot, for example, set a Body Vertical key at the peak of an airborne trajectory and move the biped up or down. If you attempt to do so, the biped will snap back to its original airborne height. Although this will cause a Body Vertical key (page 2–867) to appear on the Track Bar and in Track View, the key will have no effect on the biped’s airborne height.

Gravity and Timing

In reality, the length of time a person, animal or insect stays in the air during a jump is based on two factors:

- How high the creature jumps, which in turn is based on how hard the creature pushes with its legs at the start of the jump. The creature’s weight has no bearing on the height of the jump, except to affect its ability to give a good push at the start. A very light character might be taken by the wind and thus stay in the air longer, but that circumstance is not part of the gravitational equation.
- The gravitational pull of the planet from which the creature jumps.

From these two factors, you can calculate how long the creature will stay in the air. You can also perform this calculation backward; if you know how long the creature was in the air and the gravitational equation for the planet, you can figure out how high it jumped.

Jump height increases with time in air

character studio uses the latter method for calculating the height of a biped’s jump. It knows from footstep timing how long the biped will be in the air, and it has a method for determining the “gravitational pull” in your scene.

The default gravity setting in character studio is based on the standard equation for calculating the Earth’s gravitational pull, which is an acceleration of approximately 32 feet/sec/sec. Because this equation depends on an accurate measure of distance, the biped’s height is used as a guide to actual distances in the scene. For the purpose of gravitational computation, the biped is considered to be about 5’10” tall, the average height for a male human being.

Of course, some of your characters will not be the same height as the average man, so airborne periods between footsteps for these characters will appear inaccurate, with the biped jumping too high or too low for your purposes.

There are two solutions to this problem. You can change the amount of time the character is airborne between footsteps (see Editing Footstep Timing (page 2–869)), or you can accelerate gravity with the GravAccel parameter.
Accelerating Gravity

The GravAccel parameter on the Dynamics & Adaptation rollout (page 2–980) alters the degree of gravitational pull imposed on the biped during its airborne periods between active footsteps.

The GravAccel default value is based on the standard calculation for the Earth’s gravity and its effects on a man of average height. When the GravAccel parameter is increased, the effects of gravity are decreased, and the biped jumps higher. The GravAccel parameter can be set separately for each biped in the scene.

GravAccel values increase height of jump.
(Left=500, Middle=1000, Right=1500).

You can change GravAccel at any time during the animation process to affect the biped’s vertical airborne motion, both for keys already created and for animation not yet created. This value cannot be animated; the current GravAccel value is used throughout the biped’s footstep sequence.

Changes to the GravAccel parameter have no effect whatsoever on the amount of time the biped spends in the air.

Tip: If you want to change GravAccel back to its default value but don’t remember what that was, you can find out by creating another biped of the same height and noting its GravAccel value.

Note: If there is not enough gravitational acceleration or time in the air to account for differences in vertical height (such as a biped falling from footsteps on a ledge in slow motion), the biped is placed on the ground at the touchdown frame, causing a discontinuity. You can fix this by either increasing GravAccel or increasing the amount of time between footsteps in Track View. See Editing Footstep Timing (page 2–869).

Touch and Lift Dynamics

When footsteps are activated for a footstep pattern that includes airborne periods, Body Vertical keys are set at each Touch and Lift keyframe.

Based on the time in the air and the biped’s height, character studio calculates the height to which the biped will jump. From this, the software figures out how hard the biped’s legs would have to push at the Lift frame to reach this height, and how much the legs would have to bend to absorb the force of the landing at the Touch frame. Body Vertical keys are set at the Lift and Touch frames accordingly.

You can adjust the timing of touch and lift dynamics by:

• Changing Body Vertical keys at the Touch and Lift frames.
• Setting, changing or deleting Body Vertical keys during a footstep.
• Changing the stiffness or springiness of the biped’s legs at Touch and Lift frames with the Ballistic Tension parameter.

Ballistic Tension

Ballistic tension refers to the stiffness or springiness of the biped’s landing at the end of a jump, or takeoff at the start of a jump. The Ballistic Tension parameter (page 2–954) changes the biped’s motion only when it is set for footsteps.
immediately preceding or following an airborne period.

You can edit the Ballistic Tension parameter only at Body Vertical keyframes where the body touches down (a Touch key) or lifts off (a Lift key). On the Motion panel Track Selection rollout (page 2–945), Body Vertical must be selected and a key must be present at the current frame. With footsteps, a Body Vertical key is always set automatically at the landing footstep’s Touch frame and the takeoff footstep’s Lift frame.

Ballistic Tension can range from 0 to 1, with 0.5 as the default value. Increasing Ballistic Tension to 1.0 makes the legs stiffer at takeoff or landing. Decreasing the tension to 0.0 makes the legs springier and less stiff.

With *biped dynamics* (page 3–916), the height and trajectory of the biped during airborne periods is determined by gravity calculations and other biped-specific information.

With *spline dynamics* (page 3–1015), the airborne height and trajectory are not set for you automatically; you must set them manually with keyframes.

When Dynamics Blend is set to 1, biped dynamics are used. At 0, spline dynamics are used. You can animate this value to switch between the two during your animation.

**Procedures**

**To locate vertical center of mass keys:**

1. Select any part of the biped and access the Motion panel.

2. On the Track Selection rollout, click Body Vertical.

3. Use the Next Key and Previous Key buttons on the Key Info rollout to jump to the next or previous center of mass Body Vertical keyframes.

Tip: If the selected vertical COM key is a touchdown key from an airborne period, you can change the Ballistic Tension parameter on the Key Info rollout to control knee bend. Turn on Trajectories on the Display rollout to view how changing parameters affects the trajectory.

**To set a Body Vertical key:**

1. On the Track Selection rollout, click Body Vertical.

2. Turn on Auto Key.

3. Click Select and Move on the main toolbar.
4. Click and drag the center of mass up or down in the viewports.

The biped is repositioned vertically, a key is created in the center of mass Body Vertical track.

**To set ballistic tension:**

1. On the Biped rollout, turn off Footstep Mode if necessary.

2. In the Track Selection rollout, select the biped's Body Vertical track.

3. Move to the Vertical track keyframe you want to adjust, either a Touch or Lift key.

   The Ballistic Tension parameter is available only on Touch and Lift keys.

4. In the Key Info rollout, expand the Body bar to access the Ballistic Tension parameter.

5. Adjust the Ballistic Tension value.

   Adjusting the ballistic tension changes the amount of crouch before a jump, and the amount of dampening that occurs after landing.

**To change Dynamics Blend for multiple Body Vertical keys:**

1. Choose Graphs Editors menu > Track View – Dope Sheet.

2. Select all the Body Vertical keys you want to change.

3. Right-click over one of the selected keys to display the TCB dialog.

4. Change the value of Dynamics Blend in the TCB dialog. This changes it for all selected keys.

   Note: This only affects the biped during airborne periods in a footstep animation. Changing Dynamics Blend keys in a walk motion does not affect the motion.

---

**Saving Footstep Animation**

After you have animated the biped with footsteps, there are two ways you can save the data.

- A BIP file saves both the footsteps and any animation on the upper body. You can save the entire footstep sequence, or just a portion of it.
- An .STP file saves just the footstep data. These files, in ASCII format, are sometimes used by game developers to save just the leg and foot motion data.

To save a either type of file, click Save File in the Biped rollout. Choose the desired file type from the Save as type pulldown.

For more detailed information on these file formats and how to work with them, see *Loading and Saving BIP Animation* (page 2–920) and *Loading and Saving STP Files* (page 2–924).

---

**Footsteps and Freeform Animation**

*character studio* provides two distinct modes of animation, *footstep* and *freeform*.

*Footstep animation* (page 3–943) was originally designed for bipedal characters, that is, characters that walk on two legs. It uses a structured system of dynamics and balance to create secondary motion in the upper body, including arm swinging and tail swaying that is automatically applied when footsteps are used. By using default footsteps, you are assured that the biped's foot doesn't slide or pass through the ground, and that the foot easily rolls from heel to the ball of the foot as is common in a typical walk.

*Freeform animation* (page 3–943) provides a more traditional method of animating to those familiar
with 3ds Max, or other character animation systems. Keys are set by using the **character studio** Set Key tools found in the **Key Info rollout** or by turning on Auto Key mode, moving the time slider and transforming the biped parts.

Freeform animation includes preset key types called planted, sliding, and free keys; these make it very quick to lock a biped’s foot or hand in space and get results similar to those of footstep animation.

You can add freeform animation to footstep animation during airborne periods, making it possible to use both footstep and freeform animation on the same biped.

Freeform animation is particularly useful for:

- Animating a character with more than two legs.
- Animating a biped switching between foot-based motion and freeform motion, such as a biped doing handstands, jumping into a swimming pool, or leaping up to begin flying through the air.

Freeform animation also provides animated pivot points on the feet and hands. This makes it possible for you to simulate the roll of a foot from heel to toe, or create detailed finger animation.

You can convert back and forth between footstep and freeform animation within some limitations. While it is easy to convert any footstep animation to freeform, there are limitations on the conversion from freeform animation to footstep.

Because of these limitations, a common workflow is to use footstep animation to rough out the animation, then convert to freeform to finalize the motions. The totally freeform animation is not bound by the rules of the footstep method, so it’s easy to do anything you want, such as add keys at the beginning or end of the clip.

*Freeform Animation (page 2–886)*

---

**Freeform Animation Between Footsteps**

For certain types of footstep animation, it is necessary to suspend calculations of gravitational effects on the biped.

For example, if you want the biped to run, dive into a pool then climb out of the pool, you would create footsteps for the running and climbing portions of the animation but not the swimming portion. When you activate footsteps, the biped will become airborne during the swimming period, jumping high in the air between the running and climbing footsteps.

If you don’t suspend gravity during the airborne period, you won’t be able to change the biped’s Body Vertical position to bring it down and place it in the pool. For more information on how the biped behaves during airborne periods between footsteps, see *Adjusting Vertical Motion (page 2–878)*.

To suspend gravity during an airborne period, you can create a freeform period in your animation. During a freeform period, you can animate the biped in freeform mode, which includes positioning the biped anywhere in the scene regardless of the length of the airborne period.

The Track View - Dope Sheet editor is used to insert a freeform period between footsteps. During a freeform period, vertical dynamics (gravitational effects) are suspended, and Body Vertical keys use *spline dynamics (page 3–1015)* instead.
Procedure

To convert an airborne period to freeform mode:

1. Create a footstep animation with at least one airborne period, and activate the footsteps. For the simplest method of creating a footstep pattern with an airborne period, see Creating Footsteps Automatically (page 2–862).

2. Access Track View by choosing Graph Editors menu > Track View - Dope Sheet from the 3ds Max menu.

3. Expand the footstep key display for the biped.

4. Right-click the footstep key display area. The Footstep Mode dialog appears.

5. In the Footstep Mode dialog, choose the Edit Free Form (no physics) option.

   In each airborne period in Track View, a hollow yellow box appears.

6. In the Track View footstep key display, click inside the yellow box for the airborne period for which you want to suspend gravity. This fills the yellow box, indicating that vertical dynamics are suspended for that period.

7. Play the animation. The biped uses vertical dynamics during all footstep motions except the freeform period.

Note: If you activate footsteps after a freeform period has been set between footsteps, the biped might skip footsteps at one end of the freeform period. For this reason, you should activate footsteps before setting up a freeform period.

8. During the freeform period, animate the biped and set keyframes as you like.

To edit footstep timing after creating a freeform period, you must choose the Edit Footsteps option in the Footstep Mode dialog.

Converting Between Footstep and Freeform Animations

There might be times when you want to convert a footstep animation to a freeform animation, or vice versa. This can occur when someone gives you an animation file that’s animated in one mode, while you prefer to work in the other.

Animators tend to develop a preference for either freeform or footstep animation. The ability to convert between the two means you can work in either format without concern for compatibility with other artists.

Using the Convert tool on the Motion panel > Biped rollout (page 2–936), you can convert between footstep and freeform animation.

There are no special considerations when converting from footsteps to freeform; this procedure works for all footstep sequences. However, to convert successfully from freeform to footstep animation, you must observe certain rules in order for footsteps to be generated.

Converting from Freeform to Footsteps

When converting from freeform to footsteps, footsteps are generated for a foot only during periods between two planted keys. In other words, the conversion process looks for times when a foot has two consecutive, identical keys with an IK Blend setting of 1 and Object space selected. In this case, a footprint icon is placed at the foot’s location, with the duration of the footprint set by the time between the two identical keys. This is the only condition under which footsteps are generated.

If your freeform motion hasn’t been prepared with planted keys for converting to footsteps, you can convert it to footsteps by loading it as a motion capture file and specifying footsteps as the extraction method. This technique uses a different method to determine footstep location and duration, and so can sometimes successfully convert to footsteps where the Convert command cannot. See Importing Motion-Capture Data (page 2–1061).

Procedure

To convert between footsteps and freeform animation:

1. On the Motion panel > Biped rollout, click Convert.

   Depending on which is the current animation method, either the Convert to Freeform dialog (page 2–999) or the Convert to Footsteps dialog (page 2–999) appears.

2. Change settings in the dialog as necessary, and click OK.

   If you’re converting to freeform animation, the footprint patterns are removed from the viewport, gravity and dynamics are removed, and footstep mode is disabled. You are now working with a purely freeform animation.

   If you’re converting to footsteps, and the operation is successful, footsteps appear in the viewport, biped dynamics (page 3–916) is turned on, and Footstep mode is enabled.
Freeform Animation

While *character studio* calculates vertical dynamics and gravity based on its footstep-driven technology, you don’t always want your character strictly under these controls. You might want the character to fly, swim, or to do something improbable in a physical world. For these situations, Biped supports a comprehensive set of freeform animation controls that allow you to take total creative control over your character’s pose, movement, and timing.

*character studio* gives you the option to animate characters using freeform mode exclusively, or to create freeform periods during a footstep animation. In freeform mode (without footsteps), you can pose every joint of your character exactly as you like using traditional keyframe methods. Hands and feet can be locked down in space by setting planted keys. You can also animate the pivot points for hands and feet to simulate rolling motion. You can blend dynamically between forward kinematics and inverse kinematics to introduce higher-level control.

To use freeform animation in Footstep mode, you create freeform periods between footsteps using Track View – Dope Sheet. You can convert an existing footstep animation into a freeform animation and back again. This lets you mix the use of footstep and freeform methods.

**Warning:** You can’t add a freeform period at the beginning or end of a footstep animation.

**Tip:** If you want to do this, stretch out the timing for the first or last set of footsteps, then convert the footstep animation to freeform.

### Freeform Method

A freeform animation contains no footsteps; instead it relies on the transforms of the biped body objects and center of mass. Use Freeform for motions like swimming or falling where footsteps are not necessary. If you are a familiar with creating all of your keyframes manually to animate a character, you may want to use the freeform method exclusively.

To start a freeform animation, turn on Auto Key and start positioning the biped. You can also leave Auto Key off and use the red set key buttons on the Key Info rollout (page 2–954) to create keyframes.

You can also create freeform animation by importing motion capture data and choosing freeform rather than footstep.

**Tip:** Take advantage of both methods by combining footsteps and freeform animation. You can create a freeform period for any airborne period between footsteps. A freeform period replaces the ballistic motion calculated using the GravAccel value with a user defined spline motion.

If you are using footstep extraction with motion capture data, you often need a freeform interval to accommodate falling or tumbling motion in the data. The Fit to Existing option on the Motion Capture Conversion Parameters dialog allows for a combination of both methods. Extracting footsteps from motion capture files eliminates sliding feet, a common problem with motion capture data.

Note that while you can add a freeform period to a footstep animation, you **cannot** add a footstep period into a freeform animation. If you want to...
add a footstep animation to an existing freeform, you can use the motion flow editor to create a script that sequences the footstep with the freeform.

**Inverse Kinematics**

Footstep and freeform animations use the same inverse kinematics (page 3–958) constraints and extensions. This means that in a footstep animation, you can now edit keys to change footstep duration. By definition, a footstep is the start and end of a sequence of IK constraints in World Space with an IK Blend value greater than 0. Deleting and inserting keys or changing IK space or IK blending alters footstep duration.

In cases involving edits that alter the length of ballistic intervals (when a biped is airborne), the software ensures that there is a vertical key occurring at the lift-off and touchdown frames. This calculates the correct ballistic motion, so vertical keys are automatically inserted if not present.

There are three types of IK keys you can create: planted, sliding and free keys.

- **Planted keys** have an IK Blend of 1. They are joined to the Previous IK Key and are in Object space, rather than Body space. Planted keys lock the foot or hand to the ground, or to any object.

- **Sliding keys** have moving IK constraints. Sliding footsteps are created if there is a moved IK constraint occurring in the footstep interval. In a footstep animation this means that the foot can be placed anywhere, even though there is a footstep icon. Footstep icons can be thought of as gizmos rather than the absolute location of a foot. Sliding keys have an IK blend of 1, and are in object space, but are not joined to the previous IK key.

- **Free keys** have an IK blend of 0, and are in body space. They are not joined to the previous IK key. Free keys have no IK constraint.

IK constraints are implemented with a pivot-based system. This allows you to pivot a hand or foot around a selected pivot. For example, in a walking motion you can select a pivot on the heel of a foot and rotate the foot around it. You can then shift the pivot to the ball of the foot.

**Procedures**

**To create a purely freeform animation:**

1. Create a biped.
2. Move the time slider to any given frame then do one of the following:
   - **Auto Key** Turn on Auto Key, then move or rotate any biped component. This sets a key for that component.
   - Pose any part of the biped, then in the Key Info rollout, click Set Key .
   - Pose the hands and feet and then in the Key Info rollout click Set Planted Key . This will create keys that cause the hands or feet to stick in space.

For more information on setting keys, see Setting Keys for Feet and Hands (page 2–904).

Note: character studio doesn’t behave the same as 3ds Max when creating keys. It doesn’t automatically create keys at frame 0 when you create your first set of keys at a later frame. For this reason, it’s often useful to select all the parts of the biped at frame 0, then click Set Key to creating holding keys for all.

**To create a freeform animation from a footstep animation:**

1. Select the biped whose footstep animation you want to convert to freeform.
2. On the Motion panel Biped rollout, click Convert.
Creating Freeform Animation

The topics in this section deal with the creation of freeform animation for bipeds. They are:

- Selecting Biped Tracks (page 2–888)
- Animating by Moving Links (page 2–890)
- Animating by Rotating Links (page 2–891)
- Rotating Multiple Biped Links (page 2–895)
- Using Controllers (page 2–896)
- Using Props (page 2–898)

Selecting Biped Tracks

To animate your character with freeform methods, you need to know how to select the body part you want to animate, as well as the type of movement you want to affect for that part of the body. 3ds Max and Biped provide a number of different methods for selecting and moving these animation tracks. Several involve using the 3ds Max Track View, a powerful environment for viewing and managing the geometry and motion data in your scene.

For each biped body part, motion data is viewable in Track View or on the track bar. Once you’ve selected the biped object, using one of the methods described below, you can see its associated motion data on the track bar or displayed in the Transform branch for that object in Track View.

Biped lets you expand and collapse certain animation tracks to give you more control over your character’s movement as you set keyframes. For example, tracks for body parts in the arms can be animated using five separate tracks for maximum control.

You can also collapse these tracks for simplicity, and use a single key to pose the entire arm. Tracks
can be expanded or collapsed in this way for the arms, legs, ponytails, neck, tail, and spine.

In 3ds Max, you have the ability to display the motion data as function curves. You can see and manipulate function curves either in the Track View – Curve Editor, or by using the Workbench (page 2–1012). The Workbench provides specialized tools for analyzing and fixing motion problems found in the curves.

For fast track selection, you can also use the Track Selection rollout. These buttons let you quickly select the motion tracks for the horizontal and vertical movement of the biped center of mass, as well as selection of opposite limbs, or symmetrical limbs. Biped is unique in the way it separates the tracks for the center of mass into three tracks (one each for vertical, horizontal, and rotation).

**See also**

Dynamics & Adaptation Rollout (page 2–980)

Track Selection Rollout (page 2–945)

Track View (Biped) (page 2–1002)

**Procedures**

**To access Track View, do one of the following:**

- On the 3ds Max toolbar click Curve Editor.
- Select any biped object in the viewport, then right-click and choose Curve Editor.

  The hierarchy list automatically displays the track of the selected biped object.

- Choose Graph Editors menu > Track View - Curve Editor.

**To select from the screen:**

1. Place the cursor over the biped link whose tracks you want to examine. Use zoom controls, as necessary.

2. Pause over a part of the biped, and a tool-tip appears, informing you which object is at the cursor position.

3. Click to select the biped link.

  **Tip:** Another feedback device is available once you’ve made your selection. The selected object’s name is displayed in the topmost field in the Modify, Hierarchy, Motion, and Display panels.

4. On the Track View, click Zoom Selected Object.

The Track View hierarchy window repositions to show the selected object at the top of the window display. Nested below the object’s name are the animation, or transform, tracks for that object, if any exist for the current motion.

**Note:** By default, all keys for arm objects are in the Clavicle track, and all keys for leg objects are in the Thigh track. If you select a biped foot and click Zoom Selected Object, you may need to scroll up the Track View hierarchy to view the Thigh track transform keys. These keys also store foot transforms.

**Tip:** Use controls in the Separate Tracks area of the Keyframing Tools rollout (page 2–962) if you prefer transform tracks for individual objects.

**To display footstep tracks:**

1. Select any biped with footstep animation.

2. In the Biped rollout of the Motion panel turn on Footstep Mode.

3. Right-click in the viewport and choose Curve Editor.

4. On the Track View menu bar, choose Modes > Dope Sheet.

5. Click any footstep in the viewport and the hierarchy list navigates to the Footstep track.
Chapter 14: Character Studio

Selecting Tracks from the Track Selection Rollout

The center of mass has three separate animation tracks, two for motion and one for rotation. These tracks can be selected on the Track Selection rollout (page 2–945):

- Body Horizontal
- Body Vertical
- Body Rotation (selects the Body Turning track)

Selecting Tracks with the Select By Name Tool

You can navigate to and select tracks for a given object using the text-entry field next to the Zoom Selected Object in Track View. Type the object name in the text field, using wildcards as necessary, and then press Enter.

Selecting Tracks from the Track View

You can navigate to a given object simply by traversing the Biped hierarchy in the Track View hierarchy window.

Note that child objects in the hierarchy are nested below parent objects. You may need to open several parent objects to get to the nested object you want. The biped tracks are grouped as follows:

- Center of Mass
- Footsteps
- Pelvis (branch1) Spine, Neck (branch), Head, Ponytail.
- Pelvis (branch2) Thigh, Calf, Foot, Toes.
- Pelvis (branch3) Tail.
- Neck (branch 1), Head
- Neck (branch 2), Clavicle, UpperArm, Forearm, Hand, Fingers.

Each of these tracks can be seen in Track View, expanded trackbar and Workbench.

Note that the hands and fingers are grouped with the arms, and the fingers and toes are grouped with the legs.

The body’s translation keys are separated into vertical and horizontal tracks.

Animating by Moving Links

Use the standard 3ds Max Move transform to move biped links.

As shown in the table below, there are two types of movements you can apply to a biped link:

- **General Move** – When you select and move the center of mass object, it and all of its children move; that is, the entire biped moves. When you move the center of mass and one or more legs are planted on the ground with IK constraints (IK Blend=1.0), the Biped tries to maintain the legs’ planted position while the body moves.

- **Inverse Kinematics** – Applies to all parts of the arms, legs, fingers, and toes, except the clavicles. If you attempt to move a hand or foot beyond the biped’s kinematic limit, the arm or leg straightens out and moves as far as possible in the direction you drag.

The pelvis, head, neck, non-base spine links, and non-base tail links cannot be moved. They can only be rotated, although they move when their parent moves.

When you select multiple biped parts and move them, the move applies only to selected biped parts that have no selected ancestors. For example, when the entire biped is selected, only its center of mass object is moved. When all of the finger joints are selected, the bases of all the fingers are moved.
Tip: You can select the children of a hierarchy by double-clicking the parent.

To quickly select and move a biped and its entire animation to a new location in space, use Move All mode (page 2–936).

Biped provides controls to help you give both arms or both legs the same pose. See Copy/Paste Rollout (page 2–966) for more information.

### Animating by Rotating Links

Use the standard 3ds Max Rotate transform to adjust a biped’s posture by rotating its links. Use the main toolbar button, or right-click and choose Rotate from the quad menu.

To make biped movement appear natural, certain biped joints are limited in how they can rotate, such as the elbows and knees. When a joint can rotate in all three axes, X, Y, and Z, it is said to have three degrees of freedom (DOF). A joint’s DOF can be modified by selecting it and then setting options on the Locks (page 2–500) rollout of the Hierarchy panel.

Note: Changing a joint’s DOF will not replace its default DOF, meaning a locked axis by default can not be unlocked manually.

The table below shows the degrees of freedom of each link. Biped allows a bit greater freedom than most human bodies are capable of. All rotations are performed in the local coordinate system.

Tip: First select the link to rotate, then click Rotate. While the Motion panel is active, Biped sets the transform managers to reflect the degrees of freedom of that link. For example, if you select the pelvis and then click Rotate, Biped changes the coordinate system to Local and turns on the Y axis constraint. (For joints that have more than one

### Tip:
You can select the children of a hierarchy by double-clicking the parent.

### To quickly select and move a biped and its entire animation to a new location in space, use Move All mode (page 2–936).

degree of freedom, you might later need to change the axis constraint setting.)

To rotate the biped pelvis in all three dimensions, refer to Pelvis as Ball Joint (page 2–892).

**Biped Motion Constraints**

Some biped parts have special-case conditions that govern how you can transform them, as described in the table and sections that follow.

---

### Pelvis as Ball Joint

The pelvis can be rotated in all three axes: X, Y, and Z. This ball joint provides three degrees of freedom, improving the flexibility of animating with a biped, because the pelvis gyrations are isolated from the center of mass (COM) rotation. This causes the COM to assume a smoother trajectory, which also influences the biped’s head and arms. As a result, they will look more natural moving in the body’s COM rotational space.

It’s important to be aware of the following behavioral changes resulting from this:

- The three-DOF pelvis motion is displayed as three separate Euler or quaternion (TCB) function curves in the Curve Editor and Workbench.
- Using key reduction on the biped’s spine produces improved results.
• Rotations on the new pelvic axes (X and Z) are keyable in layers and supported in MAXScript.

• The default parametric footstep animation is slightly adjusted to use the three-DOF pelvis.

• If a legacy biped asset such as a BIP file is loaded onto the 3ds Max biped, the pelvis-related data will be adapted to the new DOFs and the new coordinate space within which the pelvis rotates.

• Using the Motion Mixer or Motion Flow, assets containing new pelvic rotation tracks will be blended with old assets lacking these tracks.

Special Rotation: Elbows and Knees  
Elbows and Knees perform a special rotation when you rotate them about their X axis. They don’t actually rotate around their X axis; this does not make sense because they have one degree of freedom. Instead, the upper and lower arm/leg are rotated together about an invisible axis defined by the line stretching from the shoulder to the wrist, and the hip to the ankle. This special rotation can be very useful for positioning the arms and legs.

The special rotation can also be useful for creating characters with reverse knee bends. When the knees are rotated backward, at more than a 90-degree rotation from the front-facing human knee posture, Biped assumes the character has backward knees or bird legs, and uses this as a reference position for all .bip motions.

Balance: Spine  
Biped uses only the spine, in conjunction with the center of mass, to maintain the biped’s balance. Because of this, rotating all of the spine or any one of its links causes the horizontal position of the body to change relative to its center of mass. These adjustments are performed in the center of mass’s local reference coordinate system, ensuring that the figure will rotate naturally about its center of mass; for example, during flips in the air.

On the Motion panel Key Info rollout (page 2–954), you can turn this behavior off by setting Balance Factor to 0.0 for corresponding horizontal center of mass keys. The Balance Factor control is in the Body group on the rollout.

Independent Orientation: Arms, Head, Feet  
Changing the orientation of a clavicle (the root Arm object) changes the position, but not the orientation, of its corresponding upper arm. In effect, the clavicles are a support from which the arms are suspended.
Likewise, the orientation of the neck changes the position, but not the orientation, of the head. Although linked to the neck, the head typically rotates independently of the neck, and interpolation of these individually set orientations produces more natural-looking motion.

Similar to the head and arms, changing the orientation of the upper or lower leg changes the position, but not the orientation, of the corresponding foot. In this way, the foot orientation remains relative to the ground plane.

**Adjusting Keys with TCB Rotation**

Rather than creating extra keys to fine-tune the motion of the biped limbs, you can use the TCB controls to adjust ease in, ease out, and limb trajectory on keys that already exist.

**Visualizing Rotation Animations with Function Curves**

Another way to visualize your rotation animation is through the Curve Editor (page 2–507). Each key you add is displayed and connected to other keys, creating a curve that represents your animation. You can use either the TCB Rotation Controller (page 2–377) or the Euler XYZ Controller (page 2–318) (on the Quaternion/Euler rollout (page 2–948)) to display your rotation curve as Quaternion or Euler, respectively. Each controller affects the curve differently based on separate rotation calculations. To learn more about this, refer to Working with Euler Curves on Biped Animation (page 2–916).

**Procedures**

**To change TCB for a biped arm:**

1. On the Key Info rollout, turn on Trajectories.
2. Select a biped arm.
3. Use Next or Previous key to locate an arm key.
4. If the TCB group is not already displayed, click the TCB divider.
5. Change the Tension, Continuity, and Bias spinners.

The trajectory changes to reflect the new parameters. Play the animation to see the change.
Tip: You can also access TCB controls by right-clicking on keys in the trackbar, Track View – Curve Editor or the Workbench Curve View.

Rotating Multiple Biped Links

Selecting and Rotating Multiple Links

When you select and rotate multiple biped links, the rotation is individually applied to each selected link. This is a convenient way to get fingers to curl, for example, or to keyframe a biped’s arms, legs, multiple-jointed neck, or tail.

To select and rotate multiple links:
- Select and rotate any number of links.
  Typically, you select an object and all of its children; for example, the hand and all of its fingers.

Using Bend Links Mode and Twist Links Mode

You can use Bend Links Mode (page 2–952) to rotate multiple links for the biped’s spine, neck, or tail. Bend Links transfers the rotation of one link to the other links in a natural way. When applied to the spine, it is particularly useful for positioning the biped’s hips.

You can also use Twist Links Mode on the Bend Links rollout to twist multiple links along the X axis while preserving their relationship with the two other axes. Combining these two modes opens up a wider range of controls over your spine, neck or tail.

To rotate all links in the spine, neck, or tail:
1. On the Bend Links rollout, turn on Bend Links Mode.
2. Select and rotate a single spine, neck, or tail link. The other links in the spine, neck, or tail rotate to match the single link’s rotation.

3. On the Bend Links rollout, turn on Twist Links Mode.

4. Rotate the link in local X. The other links in the spine, neck, or tail twist properly to match the single link’s rotation in X.

Tip: You can use Bend Links mode either to pose the biped or to animate the spine, neck, or tail while in Keyframe mode (page 3–960).

Tip: You can also use the other Twist Links tools in the Bend Links rollout (page 2–952) to further control the links’ rotation.

Using Controllers

Character studio lets you add 3ds Max controllers to the biped object tracks. This allows you to mix the biped animation with standard 3ds Max animation techniques.

Why Add Controllers

Adding controllers to biped body parts lets you create animation that is difficult to do with character studio alone. For example, you can create “stretchy” cartoon arm or leg animation by adding a Scale controller to animate the bipeds arms and legs. You could make a character shaking by using a Noise controller for its limb rotations or for a Scale controller on the spine objects to make a character breathing. An Audio controller could be used to synchronize movement with sound.

Biped SubAnims

Different controllers can be added together, blended or sequenced in a list called a Biped SubAnim. These are the same as the weighted list controllers in 3ds Max. By animating the controller weights you can increase or decrease the effects of the different controllers. You can enable, disable or collapse the list controller animation tracks. If you collapse the track, you can then bring them into the Motion Mixer, Motion Flow, or Layer editor or export them to a game engine.

Note: Biped SubAnims exhibits different behaviors based on whether you assign a controller or a constraint as the SubAnim. A SubAnim with a controller assigned will layer the controller animation with the existing biped animation. If you use a constraint, however, this will replace the existing Biped Animation.

Tip: SubAnims are best used when combined with freeform animation. You can use them with footsteps animations but you may experience unexpected results. If this happens, simply convert the footstep animation to freeform before applying the SubAnims.

Assigning SubAnims

Biped SubAnims can be applied several different ways. You can assign controllers to the Biped SubAnim in the Assign Controller (page 2–934) rollout of the Motion panel.

Controllers can also be added in the Animation Workbench (page 2–1012) using the Controller button to display the controller list. Right-click and choose Assign Controller from the right-click menu. You can assign controllers to multiple objects by using the SubAnims filter.

Procedures

To add a controller to a biped object:

1. Select the biped object that you want to control, and set a key for that object.

2. In the Motion panel, expand the Assign Controller rollout.

The Biped SubAnim entry is displayed in the list window.
3. Expand the Biped SubAnim entry in the Controller window.
   List controller entries are displayed for BipScale, BipRotation, and BipPosition.

4. Expand the list controller you want to add to and highlight the first Available entry.
   The Assign controller button becomes active.

5. Click the Assign Controller button.
   An Assign Controller dialog appears.

6. Choose the controller to want to use, and click OK.

7. Play the animation and observe the effect.
   You can animate the parameters for the controllers using Track View or by right-clicking the list entry in the controller window and then choosing Properties.
   Controllers can also be assigned in the Animation Workbench by displaying the Controllers list, choosing an Available entry, right-clicking and choosing Assign Controller.

**To collapse a controller:**
You can collapse a controller to use the animation in the Motion Mixer, or with Layers, or to export to a games engine.

1. Select the biped object with the controller, for example an arm with an added noise rotation controller.

2. On the Motion panel, in the Assign Controller rollout, click the Biped SubAnim controller you want to collapse.

3. Right-click the Biped SubAnim and choose Properties.
   A dialog appears with the Collapse choices.
   If a different dialog appears, you don’t have the correct selection in the list window. Be sure you’ve selected the Biped SubAnim entry and not something else.

4. Turn on the tracks you want to collapse in the Enable group.

5. Turn on the options you want to use in the Collapse group.

6. To perform the collapse, click the Collapse button.
   The controller tracks are “baked” into the Biped tracks. The new keys will appear in the track bar, or in the Workbench Curve View if the Workbench is open.

**To add controllers to multiple biped parts at the same time:**

1. In the viewport select the biped parts to which you want to add list controllers.

2. Open the Workbench.
   The selection list in the Select panel has the biped parts highlighted.

3. Click the Controllers button on the Workbench toolbar.
   The controller list appears to the right of the select tab.

4. Select the tracks you want to affect.

5. On the Filter panel, locate the part to Filter group. Set it to Selected Parts if it isn't already.

6. Choose a SubAnims filter from the drop-down list.

7. Adjust any other options you need to in the Filters tab, then click Position, Rotation, or Scale to add the subanims.

8. Expand the controller list to observe the newly added controllers.

**To animate the weights of an added controller:**
You can animate the weights of an added controller to determine when the effect takes place. A weight of 0 will yield no effect, a weight of 100 will provide the full effect. See the tutorial “Using Controllers
with Biped” for an example of animating the weights.

1. Add a controller to a biped object, using either method outlined above.

2. Immediately after adding the controller select the appropriate BipScaleList, BipRotationList, or BipPositionList entry in the controller list, and expand it to see the Weights.

3. Expand the Weights and select Weight 0.

4. In the Keyframing Tools rollout on the Motion panel, click the Manipulate SubAnims button.

   Three new rollouts appear in the Motion panel: Position List, Scale List and Rotation List.

5. Navigate to the appropriate List rollout. In the Layer window highlight the Controller you wish to weight.

   The Weight field becomes available

6. Turn on Auto Key, move the time slider and enter values in that field, or use the spinner to set keys to animate the weights.

   Warning: Don’t even think about using the 3ds Max Set Key button to animate the weights. Avoid using this button with character studio as a rule. Use Auto Key or use the Key Info rollout set key buttons instead.

### Using Props

Props are objects that a biped could be holding or carrying, such as a gun, sword, or briefcase. They are represented as boxes that are additional links in the biped hierarchy, an extension of the biped structure you can access at creation time or in Figure mode. If you are loading motion-capture data that contains prop information, this will transfer to the biped prop.

Each biped can have up to three props. Prop data will work seamlessly with other advanced features of character studio: in the Mixer, Motion Flow, Unification, and Layered edits.

Props are defined in the Structure rollout.

Props appear as boxes in the biped hierarchy. They can be moved, stretched, and scaled in Figure mode as other biped parts can. Props are supported by Physique, and are animated using the biped Transform controller in the same way as other objects. Create your prop and position it in relation to the biped in Figure mode. Props can be made to follow the motion of either hand by keyframing the Position and Rotation coordinate space of the prop.

Bipeds with multiple props as swords

### Animating Prop Linkage

Props can change linked parents (similar to the 3ds Max Link controller) at any keyframe. This is done using the Position Space and Coordinate Space lists in the Prop section of the Key Info rollout (page 2–954). Once a key is set on the prop at a given frame, you can set or change the coordinate space in which it is transformed by choosing a new space from the drop-down list. You set rotation and position coordinate space independently.
Using Props

Importing Motion-Capture Prop Data

If your motion-capture file includes prop data, character studio can read that data and apply it to a prop object.

Upon loading a CSM file (page 3–925), the motion data will be applied to the prop. If the prop switches from one hand to another, the program will automatically determine the switch of the prop's coordinate spaces as the prop is exchanged between the hands. This can be easily changed once the data is in the scene: go to the desired frame, choose a new coordinate space (as described in the previous section), then set a key. When loading a BIP file for retargeting onto other characters, the props move with each of the hands. The software ensures that the hands come together at the precise position on the prop during transfers.

Props can be animated with 3ds Max controllers and that animation can then be collapsed onto the prop's transform controller for editing with motion flow or the mixer.

Procedures

Example: To animate a biped swinging a prop with one hand:

1. Create a biped with a single prop.
   The biped appears with a single prop displayed as a box positioned near the biped's right hand.
2. On the Motion panel, on the Biped rollout, turn on Figure Mode.
3. Scale the prop so it is the correct size and proportion to be a sword.
4. Rotate and move the prop so it is in the correct orientation in relation to the right hand.
5. Turn off Figure mode.
6. Set a key for the prop at frame 0. To do this, make sure the prop is selected, then use the Set Key button in the Key Info rollout.
7. Now animate the biped as you like, or open a BIP file of a character swinging a sword.
8. Turn on Auto Key, then select the prop.
9. Animate the prop using standard 3ds Max transforms.

Example: To animate the biped switching the prop to the other hand:

1. Follow the steps in the previous procedure to animate the biped swinging the prop.
2. Move to the frame where you want the biped to switch the prop the other hand.
3. Move the biped’s other hand so it is in contact with the prop, and set a key for the hand.
4. Select the prop and set a key for it.
5. Move the time slider ahead one frame and set another key for the prop.
6. On the Key Info rollout, expand the Prop section.

   The lists for Position and Rotation coordinate spaces should be available. Change the Position...
from the right hand to the left hand, and click Set Key again.

The prop will now follow the movement of the left hand in the frames that follow.

Note: By default, the prop’s rotation remains in Body space. Depending on your animation, you might also want to set keys so the Rotation space is Right Hand before the switch, and Left Hand after the switch.

**To collapse the transforms of a prop:**

1. Animate the prop however you like. You can add list controllers to the prop as you can to any other part of the biped.
2. When the animation is correct, select the prop.
3. In the Motion panel hierarchy list, select the prop transform list you want to collapse, and then right-click.
   
   A quad menu appears.
4. Choose Properties from the quad menu.
5. In the dialog that is displayed, make the appropriate choices, and then click Collapse.

   After a short delay, the track bar displays the keys that have been added.

   **Tip:** If you see a different Properties dialog that doesn’t offer you the Collapse button, you are too low in the hierarchy. Select the next level up in the hierarchy and try again.

---

**Freeform and IK**

**Using IK Keyframe Parameters**

Biped’s inverse kinematics solution has three parameters set at each key of the arm and leg keyframe tracks. As the limb moves through each key:

- **IK Blend** sets the motion interpolation to be a blend of forward and inverse kinematics. This allows you to blend swinging motions with hand-or-foot directed motions. Rotating an arm to move a hand is an example of forward kinematics. Using the position of the hand to move the arm is an example of inverse kinematics. The default blend is 0.0, or full forward kinematics. An IK Blend of 1.0 is full inverse kinematics.
- **Body or Object** determines the reference coordinate space of the IK path. This allows you to move the IK path with your character’s body or temporarily attach the hands or feet to follow other objects. The default is Body.
- **Join To Prev IK Key** determines if the key should be part of the previous key (and have the same reference position as the previous key).

Biped has three automatic ways to set these parameters. Setting planted, sliding, or free keys creates keys with different combinations of these three parameters.

- Setting a planted key creates a key with IK Blend set to 1.0, Object and Join To Prev IK Key turned on.
- Setting a sliding key creates a key with IK Blend set to 1.0, Object turned on, and Join To Prev IK Key turned off.
- Setting a free key creates a key with IK Blend set to 0, and Body turned on. Join To Prev IK Key is turned off.

**IK Blend**

The IK Blend control is in the Key Info rollout (page 2–954); visible when you expand the IK divider bar. You set IK Blend while in Keyframe mode.
IK group parameters

IK Blend can be set per key for any arm or leg track. The IK Blend setting determines whether, at a particular key, an arm or leg is moving through it using inverse kinematics, forward kinematics, or a blending of the two kinematic solutions.

An IK Blend value of 0.0 means full forward kinematics. The arm (or leg) is moved by interpolating the rotations of the joints at the keys. The hand (or foot) tends to move along sweeping circular arcs in this case, and the motion appears to be motivated by the apparent swinging at the joints.

An IK Blend value of 1.0 means full inverse kinematics with the hand (or foot) being used as an end-effector. A spline path is computed through the keys of the hand, and the hand moves along that spline. Joint angles for the rest of the arm are computed to allow the hand to follow the spline. The motion, in this case, appears to be directed by the hand (or foot).

An IK Blend value between 0.0 and 1.0 means a combination of inverse and forward kinematics; when IK Blend is closer to 0.0, forward kinematics are more heavily weighted in the solution, and when IK Blend is closer to 1.0, inverse kinematics are more heavily weighted.

It is best to use forward kinematics when you want the arms to swing, such as when a biped is walking. In the case of a boxer, however, since the hand should follow a directed path when punching, inverse kinematics should be used.

To set the IK Blend value of a key:

1. Select a single arm or leg track by selecting one or more parts of a biped’s arm or leg.

   The IK Blend spinner and the other controls in the IK area are enabled only when a single arm or leg track is selected.

2. Set a key if one doesn’t already exist.

3. Set the desired value of IK Blend.

Body and Object Options

By default, Biped calculates the kinematics solution using the coordinate system of the biped figure’s center-of-mass, or the Body coordinate system. This means that the IK path of the hand (or foot) translates and rotates with your character as it moves. For example, the boxer’s hand trajectory always moves relative to the weaving, bobbing, and turning of the boxer’s body.

The Object option is used for animating dynamic links between the limbs and other objects in the scene.

The IK Blend control activates when a biped arm or leg (hand and foot) key is current.

- 0 with Body turned on is forward kinematics (page 3–944), or normal biped space.
- 1 with Body turned on is inverse kinematics (page 3–958), creates more straight-line motion between biped keys.
- 1 with Object turned on, but no IK object specified, puts the limb fully into world space.
Use this to control foot sliding in a freeform animation.

- 1 with Object turned on and an IK object specified puts the biped limb into the coordinate space of the selected object; the biped limb follows the specified object.

**Join To Prev IK Key**

This IK constraint is used to specify if a footstep is sliding or planted. If Join To Prev IK Key is on, then the biped foot maintains a reference position to the previous key, keeping the foot planted. If Join To Prev IK Key is off during a footstep, then the foot can be moved to a new position creating a sliding footstep.

Join To Prev IK Key also functions to lock the biped hands in space. Use Set Planted Key on the biped hand to lock their position in space.

Tip: If you are having trouble with a foot or hand popping back to a previous ‘keyed’ position, check to make sure that the Join To Prev IK Key is off, especially when you’re using pivot points.

See also

*Key Info Rollout (page 2–954)*

**Understanding Walk Cycle Constraints**

Walking motions in both freeform and footstep animations should follow the rules of certain IK constraints. In both freeform and footstep animation, a footstep interval is the start and end of a sequence of IK constraints in world space, with IK Blend set to be greater than 0.0. A biped foot in the Move state should have body space turned on with an IK Blend of 0.0. By using these IK constraints, you can convert between the two animation methods seamlessly.

In a freeform walking animation, typically you need two key types for the legs:

- If the foot is planted on the ground, the key must have IK Blend=1.0 with Object Space and Join To Prev Key turned on.
- If the foot is in the air between footsteps, then IK Blend=0.0 with Body Space turned on, and Join To Prev Key turned off.

In the course of creating a walk or run cycle, you need to alternate these IK constraints for the feet. If the foot is sliding on the ground, then the IK constraints are IK Blend=1.0 in Object Space with Join To Prev Key tuned off. All of these IK parameters can be found on the Key Info rollout.

To speed up the process of applying these IK constraints, the Key Info rollout has three additional set key buttons: Set Planted Key, Set Sliding Key, and Set Free Key. By clicking one of these buttons, all the necessary IK constraints are applied automatically. For example, by clicking Set Planted Key, all of the IK constraints necessary are applied at once; IK Blend=1.0 with object space and Join To Prev Key turned on.

See also

*Key Info Rollout (page 2–954)*

**Walking Keys**

Let’s examine the IK constraints for one footstep. The footstep rolls on the heel of the foot, then rotates down flat on the ground, then raises up on the ball of the foot, rotates at the end of the toes, and finally lifts off of the ground.
The foot is touching the ground at the heel. In the Key Info rollout, Set Planted Key is clicked to set IK Blend=1.0 with object space and Join To Prev Key turned on. A pivot is selected on the heel of the foot.

Pivot point shifts to ball of foot at frame 16.

The next keyframe is also a planted key, as the foot is flat on the ground. In the Key Info rollout, Set Planted Key is clicked. The pivot on the ball of the foot is selected.

This key has the pivot on the ball of the foot as well. Click Set Planted Key. Two consecutive keys with the pivot at the ball of the foot are necessary to rotate the foot about the ball of the foot.

After rotating the foot about the pivot at the ball of the foot, you set another planted key with the pivot on the toe.
Foot rotates off pivot at end of toe at frame 19.

Here is another planted key with a pivot at the end of the toe; the foot rotates about the tip of the toe.

Free Key allows foot to travel off the ground at frame 20.

If you adhere to these rules in creating footsteps in a freeform animation, then you can use Convert in the Biped rollout to easily change from a freeform animation to a footstep animation. Note that IK constraints in a footstep animation are applied exactly the same way as in a freeform animation. If you examine a footstep animation, you will notice that the foot IK constraints follow the same rules as for a freeform animation. Footsteps are simply gizmos that define a foot’s coordinate system. A foot can slide and move relative to the footstep. Also, if you delete or add a key in a footstep animation, the footstep duration is changed.

**Setting Keys for Feet and Hands**

You can animate biped’s body parts as you do other 3ds Max objects: by setting keys for postures at keyframes.

**character studio** provides three different ways to set keys at the current frame:

- Pose the biped body part, and then click one of the set key buttons in the Key Info rollout.
- Turn on the Auto Key button, and then pose the biped part. You can transform the parts using transform tools, or you can copy and paste poses and postures to keyframe the biped.
- Right-click the time slider and use the Create Key dialog to create keys for selected biped parts.
Warning: Do not use the large Set Key button, found below the viewports, when animating a biped. Doing so will cause unpredictable results. Instead, always use the Set Key buttons found on the Key Info rollout.

If you are animating a walk cycle or an intricate hand animation, then you should make use of the three different types of set key buttons in the Key Info rollout. Each set key button applies different IK constraints, depending on whether a foot or finger is in a planted state, a move state, or a sliding state. For more information on the three set key buttons, see Key Info Rollout (page 2–954).

You can also set keys to make hands and feet follow a stationary or animated object. See Animating IK Attachments (page 2–908).

If a Bones system using the IK controller or a particle emitter is linked to the biped, the Auto Key button must be on in order to position the biped’s limbs. This is also true for biped objects if you turn on 3ds Max Trajectories at the top of the Motion panel, or if you choose Views > Show Ghosting.

The Set Key options on the Key Info rollout have the advantage that you can easily experiment with different poses for your character without unintentionally setting keys as a side-effect. Use the Set Key buttons to commit the changes you make to the pose. The Auto Key mode approach is especially useful when you make adjustments to keyframes that have already been set, or if you are used to working with Auto Key in 3ds Max and tend to forget to click the Set Key buttons.

Tip: Use Set Key to insert a key on a frame where a key doesn’t exist. You’ll often want to refine the motion using controls in the Key Info rollout, without selecting and moving an object in the viewport.

Keyboard shortcut: Pressing 0 (zero) is equivalent to clicking Set Key on the Key Info rollout.

To use character studio-specific shortcuts, make sure that the Keyboard Shortcut Override Toggle (page 3–872) is active.

Ground Plane Collision Detection for the Pelvis and Feet

When one or two feet are planted, and the pelvis or a planted foot is rotated, character studio detects collisions of the foot and its toes with the ground plane defined by the planted foot’s footstep or pivot point. As the pelvis or foot is rotated, character studio uses inverse kinematics to alter the rotations of the leg joints so that the foot and its toes do not go below the plane defined by the footstep or pivot point.

Note: A biped foot on a sliding footstep is a special case. The biped foot can be moved to any position and orientation for the duration of the footstep.

Note: Changing rotation values for the legs and toes also maintains collision detection, but the position adjustment is not made until you set a key.

Animating Pivots

In both freeform and footstep animation, pivots allow you to rotate the biped’s hands and feet around various points. For example, by activating a pivot on the ball of a foot, you can rotate the foot around the ball of the foot. The biped’s hands and feet have the same number of pivots, and pivot location is similar. Pivots are active only if the biped hand or foot is in world or object coordinate space. In a walking motion, you can pivot on the heel first, then on the ball of the foot, and finally...
on the toes. Pivots are essentially extensions of the IK chain.

By setting a planted key for the hand, the hand is anchored in world space; you can move the biped or the collarbone and the hand remains planted. Pivots on the hands make it easy to animate hands and fingers.

While pivots are used in both freeform and footstep animation, the pivots are only visible and accessible when in Freeform mode.

**Biped IK**

To understand interactive IK limb manipulation using **character studio**, it is useful to distinguish two types of limb joints: primary and secondary.

The primary joints are the shoulder, elbow, hip, and knees. Animals use primary joints to coordinate the positioning of hands and feet, as these joints have the most influence and flexibility in positioning tasks. Even the placement of fingers and toes over specific spots is the task of the primary joints.

The secondary joints are the wrists, ankles, toes, and fingers. These joints are typically used for grasping and support rather than positioning, so they most frequently exercise independent joint angle control suited to a particular task, such as rotating the foot to raise the heels during walking, or curling the fingers around an object. Because these joints have little influence on end effector position, they are rarely engaged for positioning tasks. For example, if you want to place your finger on your nose, you will most naturally rotate only your shoulder and elbow, keeping your wrist stationary.

**character studio** mimics the IK behavior of "natural" systems. The primary joints are used for IK positioning, while the secondary joints are independently and precisely controlled by the animator. The secondary joints will not rotate unless the animator explicitly selects and rotates them. Therefore, if an IK pivot is set, and the limb is interactively manipulated, (say, the finger is moved onto the nose), only the primary joints adjust to satisfy the IK constraint. The secondary joints remain in place and will never "drift" in an IK solution; they simply obey the values set by the animator. Because there is no drift for the secondary joints, the animator does not have to tediously assign "tension" values to hold them in place.

If an IK pivot point constraint has been set, some by-products of **character studio** "natural IK" are that:

- Interactively rotating a secondary joint will always adjust the primary joints to hold the IK pivot in place.
- **character studio" special rotations," the forearm/calf X-axis rotations, rotate the elbow about the axis from the shoulder to the wrist and rotate the knee about the axis from the hip to the ankle. These rotations give the animator a direct way to interactively rotate the primary joints while holding the IK pivot in place.
- Interactively translating a limb part to move the IK pivot will alter only the primary joints.
- Interactively rotating a primary joint will move the IK pivot with it.

After an IK pivot has been placed, applying 1) and 2) gives the animator exact control over all possible IK solutions. The IK pivots can be easily moved by applying 3) and 4). In general, you don't need to remember these "rules," because the system works in an intuitive way. You merely need to position the pivots as desired, set the IK constraint, and then fine-tune the posture of the limb, if desired, by rotating the secondary joints and using the special rotation to adjust the primary joints.

**Note:** During animation playback, the Ankle Tension parameter is used to set the relative
importance of the interpolated ankle joint over the interpolated knee joint for intervals in between keyframes. This is relevant only to interpolation on bipeds.

Using IK constraints and pivots on the biped hands and feet allows you to animate quadrupeds.

You can also select an object if you like at this point, by selecting a non-biped object in the viewport.

3. Turn on Select Pivot.
4. Select a pivot in the viewports.
   Pivots are shown as red dots on the hands and feet. Use wireframe viewport shading if you have problems seeing the choices.
5. Turn off Select Pivot.
6. Rotate the hand or foot around the selected pivot.
   Tip: If you find that you are not rotating around the selected pivot, set two consecutive keys at adjacent keys with the same pivot.

See also
Key Info Rollout (page 2–954)

Procedure
To use pivots:
1. Select a biped hand or foot.
2. On the Key Info rollout, click Set key, and then choose Object.

Animatint a Quadruped

While character studio was initially designed as an specialized program for animating two-legged, or bipedal characters, it works quite well for creatures that walk on four or more legs.

Here are some general rules to follow when animating characters that don’t walk upright on two legs:

• Use Freeform animation, not Footstep animation, if your character walks on four legs all the time.
• Pose the biped to match the mesh in Figure mode, scaling and rotating body parts so the spine is horizontal, and the arms stretch to reach the ground.
• If appropriate for your mesh, set Leg Links to 4 and rotate the legs so the knees point backwards. You can set this value at creation time in the Create Biped rollout on the Create panel, or later using the Structure rollout (page 2–984) on the Motion panel.
• Animate pivot points with planted keys to mimic the rolling of the feet from heel to toe.
Chapter 14: character studio

Treat the hands the same as the feet. Set planted keys on the hands and feet, then move the center of mass object to bend the knees and elbows. See Key Info Rollout (page 2–954) for more information on the three set key buttons.

- You can save 3ds Max objects as part of the BIP file. If you need additional legs (for a centipede) or extra arms or wings you can use standard bone objects with IK chains, and save all of it with the BIP file.
- The Balance Factor in the Key Info rollout Body group, is designed to synchronize upper body and lower body movement. Set Balance Factor to 0 if you find the movement of spine links is affecting the biped’s hip movements in an undesirable way.

### Animating IK Attachments

A biped can interact with other objects in the 3ds Max scene. Links between objects are usually static, unless you’re using the Link controller. In character studio, such attachments are "animatable" as well; during the course of an animation, the links between the hands, feet, and objects in the scene can change as your character interacts with them.

This capability is useful for:

- Creating freeform motions (without footsteps and gravity) that require that feet or hands be planted with IK, and then released. Examples are climbing a ladder, riding a bike, or rowing a boat.
- Motions that involve the temporary manipulation of objects, such as bouncing or kicking a ball, opening a door, or touching another biped.

An object to which a hand or foot can be attached is called an **IK object**. See the tutorial “Interacting with Objects” for lessons that show you how to make a biped iron clothing, ride a skateboard, bounce a basketball, climb a ladder, and pick up a briefcase.

### Procedures

**To make a hand or foot follow an object:**

1. Create the object for the hand or foot to follow.
2. Select the biped’s hand or foot.
   - Tip: You can select any part of the biped’s arm to set keys for the hand, or any part of the leg to set keys for the foot.
3. In the Key Info rollout (page 2–954), expand the IK divider to see the IK section of the rollout.
4. Click Set Key.
   - Once a key is set, the IK Blend value and other IK parameters become available.
5. Click Select IK Object, and choose the object for the hand or foot to follow. The object name appears in the field below the Body and Object radio buttons.
6. On frames where you want the hand or foot to start following the object, set a key, set IK Blend to **1.0** and choose the Object option on the Key Info rollout. You can also click Set Sliding Key to set these parameters all at once.
   - Note: If Object space is turned on with no IK object specified, the IK constraints will be in World space. In effect, the hand or foot will be attached to the world, and will not move during the time such a key is set.

Set one key when you want the attachment to begin, and a second key when you want the attachment to stop. This defines an Object space interval, the duration of a temporary attachment.

7. On the frame that defines the end of an attachment interval, set IK Blend to **1.0**, choose
the Object option, and turn on Join to Prev IK Key. You can also click Set Planted Key to set these parameters all at once.

8. On frames where you don’t want the hand or foot to follow the object, set a key, set IK Blend to 0.0 and choose the Body option. You can also click Set Free Key to set these parameters all at once.

To anchor a hand or foot:
You can use anchoring to temporarily lock a hand or foot to a specific point in space while you are animating IK attachments.

1. Move and rotate the hand or foot into the desired posture.

2. On the Keyframing Tools rollout, click the button for the limb you want to anchor: Anchor Right Arm, Anchor Left Arm, Anchor Right Leg, or Anchor Left Leg.

   Note: The arm or leg you select beforehand does not actually have to be the same as the arm or leg you are anchoring.

3. Set keys for the arm or leg as described in the previous procedure.

   Note: You can also use anchors to hold a foot or hand in position while you render the animation. However, be aware that anchors are turned off when you close the MAX file. If you want to use anchors from one session to the next, you must turn them on again the next time you open the file.

---

**Editing Freeform Animation**

The topics in this section deal with the editing of freeform animation for bipeds. They are:

- **Editing Biped Keys** (page 2–909)
- **Copying and Pasting Postures and Poses** (page 2–910)
- **Mirroring Motion** (page 2–913)
- **Using Layers** (page 2–913)
- **Editing Trajectory Keys** (page 2–914)

---

**Editing Biped Keys**

- You can move back and forth between keys by clicking the Previous Key and Next Key buttons on the Key Info rollout. The fields to the right of these buttons indicate the key number and frame number.

- As with other 3ds Max objects, you can also move back and forth between keys by turning on the 3ds Max Key Mode Toggle, selecting an element associated with a given track, and then using the 3ds Max buttons Next Frame and Previous Frame. For example, you can view keys, move between them, and set keys for a right arm track if any of the right arm's objects (clavicle, upper arm, lower arm, hand, fingers) are selected. Or use the < and > keys on the keyboard to move back and forth between keys in Key Mode.

- You can delete a key by clicking Delete Key in the Key Info rollout. The biped part that has the key must be selected, and the current frame must be the keyframe you want to delete. Keys that are locked (appearing in red in Track View) cannot be deleted.
Tip: When you’ve selected the biped part you want to transform, click Lock Selection Set on the 3ds Max prompt line. Now you can transform the part without accidentally selecting a different part of the biped. The default keyboard shortcut for Lock Selection Set is the spacebar.

**Copying and Pasting Postures and Poses**

The Copy/Paste rollout on the Motion panel provides controls to help you copy and paste biped postures, poses, and tracks. A posture (page 3–996) is the rotation and position of any selection of biped objects. A pose (page 3–996) is the rotation and position of all the objects in a particular biped. A track (page 3–1023) is the animation for any selection of biped parts. For information on working with tracks, see **Copying and Pasting Tracks** (page 2–926).

You can create and store postures, poses, and tracks in multiple buffers accessed by a drop-down list. You can choose from that list and see a thumbnail image associated with the selection, then paste that selection onto the same biped or any other biped in the scene. You can choose between posture, pose, or track for these operations.

Using these tools lets you work in a traditional pose-to-pose method of animating. You can create a variety of poses and postures, store them in the list, then in Auto Key mode, copy them to any biped at any frame to create animation.
Use the Copy Tracks function to copy the animation of biped parts onto other parts and other bipeds. You can further manipulate these tracks with the Curve Editor and Dope Sheet Editor, using all the standard tools found there. Copy Tracks works with both footstep and freeform animation.

Tip: The copy collections (page 2–966) feature acts as an additional layer of organization, allowing your copied postures, poses, and tracks to be grouped together so you can transfer them between files within a single session. After saving a collection, you can load it into another scene either by replacing the current collection or by appending yours to it. If you choose to append, the collection maintains the copy buffer structure.

Note: You must create a copy collection before you can copy a biped’s posture, pose or track.

**Using Paste Posture**

The Paste Posture command is useful for copying a posture in one frame of an animation to another frame of the animation. Copy the posture, then turn on Auto Key and move to another frame, then paste the posture.

The Paste Posture and Paste Pose commands are also useful for copying a pose from one biped to another. Copy the pose or posture, select the other biped, and then paste.

Copying a posture then using Paste Posture Opposite is particularly useful for copying the posture of an arm or leg or a part of an arm or leg onto the opposite arm or leg of the same biped.

Both Paste Posture and Paste Posture Opposite work differently in and out of Figure mode. Out of Figure mode, only the orientation of the copied links is pasted. In Figure mode, both the orientation and the scale of the copied links are pasted. Also, when you paste the finger base, toe base, spine base, tail base, or clavicles in Figure mode, the position of that link relative to the biped’s body is pasted.

**Copying the Entire Biped Pose**

The Copy Pose functionality allows you to copy the rotation and position of all the parts of the entire biped at once. It doesn’t contain the animation track data, only the individual keys at that frame, and the buttons to copy tracks are unavailable when Copy Pose is in use.

You can create animation using Copy Pose by simply copying different poses to the same biped at different frames, and setting keys for those poses. Copy Pose works with the character studio Set Key buttons found on the Key Info rollout (page 2–954), and with Auto Key mode.

**Warning:** Don’t use the Set Key Mode toggle or the large Set Keys button next to Auto Key. These will not produce the correct results.
Procedures

To copy a posture:
1. Select the set of biped parts that defines the part of the biped’s posture you want to copy.

2. On the Copy/Paste rollout, click Create Collection and rename the new collection Biped Posture.

3. Click Posture to toggle Posture mode and then click Copy Posture. The thumbnail image appears in the image window below the Copied Postures drop-down list.

4. Rename the posture by editing the name in the Copied Postures name field. The posture of the set of selected objects in the biped is copied to the list. You can retrieve this posture and use it to paste (or paste opposite) to any biped at any frame.

For hands-on experience using the Copy/Paste rollout functions, see the lesson called “Creating a Simple Freeform Animation” found in the Animating with Freeform tutorial.

To paste the posture:
Note: Turning on the Auto Key button before pasting posture automatically sets a key for all objects whose posture has changed.

1. Choose the Posture you want from the copied postures drop-down list.

2. Select the biped you want to paste to, or move to another frame for the same biped.

3. Click Paste Posture.

   The copied posture is pasted onto the selected biped. It doesn’t matter which part of the biped is selected; all biped parts whose posture was saved by the most recent Copy are pasted.

   **Warning:** If you paste a posture while the Auto Key button is off, no key is set. If you want the pasted posture to set a key, you must click the **character studio** Set Key button in the Key Info rollout while objects are still selected.

To paste a limb posture on the opposite limb:

1. On the Copy/Paste rollout, click Posture.

2. Select all of the limb, arm, or leg whose posture you want to copy.

3. Click Copy Posture.

   The posture thumbnail image is displayed in the image window, and the new posture name appears in the named posture field.

4. Rename the posture.

   The default names combine the chosen body track with the selected bodyparts. It’s a good idea to replace this with a descriptive name you can easily identify with the action it represents.

5. Click Paste Posture Opposite.

   The opposite limb now has the posture of the limb you copied.

To copy the entire pose of a biped:

1. Select any part of the biped whose pose you want to copy.

2. On the Copy/Paste rollout, click Create Collection and rename the new collection Biped Pose.

3. Click Copy Pose.

4. Advance to a new frame or select another biped.

5. Turn on Auto Key.

6. Click Paste Pose or Paste Pose Opposite.
Tip: You can use Paste Pose Opposite to create symmetrical runs and walk cycles.

**Keyboard Shortcuts**

The following are Biped keyboard shortcuts to the copy and paste posture commands. Make sure the **Keyboard Shortcut Override Toggle** (page 3–872) is active.

<table>
<thead>
<tr>
<th>Shortcut</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alt+C</td>
<td>Copy Posture</td>
</tr>
<tr>
<td>Alt+V</td>
<td>Paste Posture</td>
</tr>
<tr>
<td>Alt+B</td>
<td>Paste Posture Opposite</td>
</tr>
</tbody>
</table>

**Mirroring Motion**

Mirror, on the **Keyframing Tools rollout** (page 2–962), mirrors the motion of the biped through both the X and Y axes of the World coordinate system. The entire biped animation, including all footsteps and keys, is mirrored symmetrically through an axis that joins the center for the biped to the world origin. For example, if a biped is walking from the center of the world grid toward the user, the mirror will change the motion so the biped is now walking away from the user.

Use Mirror if you want to create the opposite of a motion you’ve already created. For example, if a biped walks to the left and swings its right arm, mirroring the motion results in a motion where the biped walks to the right and swings its left arm.

The mirrored motion replaces the existing motion for the biped. If you want to keep the existing motion and add the mirrored motion, use Paste Opposite in the **Copy/Paste rollout**.

Note: This feature mirrors only those biped tracks that have at least one key. The position of a keyless object is not mirrored.

**Using Layers**

Layers allow you to add successive layers of animation above the original biped animation. This is a powerful way of making global changes to your character animation. For example, simply add a layer, and rotate the spine forward at any frame, and a run cycle becomes a crouched run.

The original biped motion is kept intact, and can be viewed by switching back to the original layer. Layers can be viewed individually, or as a composite of all the animation in all the Layers. Layers behave like a freeform animation (page 3–945): the biped can adopt any position.
Layers allow you to easily adjust raw motion capture data containing keys at every frame. Simply add a layer, and keyframe the biped. You can also use layers to change the global position of the biped in a freeform or footsteps animation by adding a layer and moving the center of mass.

**Procedures**

**To increment all keys using layers (global offset):**
1. On the Motion panel Layers rollout, click Create Layer to create a new layer. Enter a name for the layer in the Layer name field.
2. Create an offset (or “increment”) by setting one key. You can either use Auto Key mode, or click Set key on the Key Info rollout (page 2–954) (this can be done at any frame.)
3. Click Collapse to collapse the layer.

**To increment an interval of keys with an envelope (blended offset):**
1. Create a new named layer.
2. Create an offset by setting one key. You can use either Auto Key mode, or click Set Key on the Key Info rollout at the frame where the increment is to occur.
3. To create the envelope, use Snap Set Key to create keys before and after the incremented range.
4. Click Collapse to collapse the layer.

**To increment an interval of keys without an envelope (nonblended offset):**
1. Create a new named layer.
2. Create an offset by setting two keys. You can use either Auto Key mode, or click Set Key on the Key Info rollout. Set one key before the frame where the increment starts, and another after the frame where the increment ends.
3. Use Snap Set Key to create keys before and after the incremented range to clamp the motion to the offset only occurs in the range between the two keys.
4. Click Collapse to collapse the layer.

*Layers (page 3–961)*

*Layers Rollout (page 2–974)*

**Editing Trajectory Keys**

By turning on biped trajectories, selecting the center-of-mass track, and turning on Sub-Object: Trajectories, you can select a key on the trajectory. Then either use Bend Horizontal in the Keyframing Tools rollout (page 2–962) to bend the trajectory about the selected key, or simply move the key. You can move center of mass trajectory keys either horizontally or vertically. This allows you to view the entire trajectory of the center of mass and bend or edit the trajectory.

Tip: You can select the center of mass’s horizontal or vertical tracks by clicking the appropriate button in the Track Selection rollout (page 2–945).
Editing Trajectory Keys

Above: Bending the trajectory
Below: Moving a key on the trajectory

Warning: Do not use 3ds Max trajectories (Motion panel > Trajectories text button) to edit biped trajectories.

Procedures

To bend a biped trajectory:
1. Select an animated biped.
2. On the Biped rollout of the Motion panel, expand the horizontal bar (click the plus sign at the left) to display the Modes and Display groups.
3. In the Display group, turn on Trajectories.
   The trajectory is displayed in the viewport for whatever biped part is selected.
4. In the Track Selection rollout, click Body Horizontal.
   The center of mass object trajectory is displayed.
5. At the top of the panel, below Selection Level, turn on Sub-Object, and choose Trajectories on the drop-down list if it isn't already displayed.
6. In a viewport, select as many keys as you want on the trajectory.
   The selected keys turn red in the viewport.
7. If you want to bend the trajectory open the Keyframing Tools rollout and locate the Bend Horizontal spinner. Then adjust the Bend Horizontal values as desired.

To edit keys on the Center of Mass trajectory:
1. Load a Freeform animation.
2. On the Key Info rollout turn on Trajectories.
3. On the Track Selection rollout click Body Horizontal or Body Vertical.
4. Turn on Sub Object Trajectories at the top of the Motion panel.
5. In the viewports select and move keys on the Center of Mass trajectory.
Working with Biped Animation

Working with Euler Curves on Biped Animation

You can control a biped’s position and orientation using Euler curves in addition to quaternion curves in the Workbench and Curve Editor. Using the Euler XYZ controller is an efficient way to animate your biped because you can use Bezier tangents to change the interpolation of your XYZ curves (quaternion curves do not have tangents). To learn more about how the Euler XYZ and TCB Rotation controllers differ from each other, refer to Euler XYZ Rotation Controller (page 2–318).

You can switch between Euler XYZ and TCB Rotation controllers via the Quaternion/Euler rollout (page 2–948). The Curve Editor (page 2–1012) displays the animation curves based on the chosen controller. Each curve is labeled starting with one of the following:

- “Quaternion Rotation of the ...”
- “Tangent Euler Rotation of the ...”
- “TCB Euler Rotation of the ...”

You can animate most biped parts (center of mass, pelvis, spine, head, neck, arms, legs, and tail) in Euler. However, fingers and toes are considered differently, as all first base links are controlled as quaternion and any subsequent links as TCB/Euler. Fingers and toes do not have tangents.

Biped limbs with only one degree of freedom (DOF), such as forearms and lower legs, are controlled with a single TCB/Euler curve.

Note: Props are not supported with the Euler controller.

Rotation curves on a biped (including its center of mass) are always set in local parent space, whether they are controlled in Euler or quaternion.

The XYZ function curves of an Euler rotation track are locked together. This means that creating a new key on one axis automatically does so for all axes. Also, moving a key in time drags all three axes with it.

Displaying Position Curves

Bezier position curves are available only for the biped’s hands, feet, and center of mass (COM). Hands and feet’s positions are set in world space while the COM position is set local to the world.

FK/IK key blending is illustrated as follows:

- Full lines represent IK periods.
- Gaps between lines represent FK periods.
- Vertical dotted lines represent a change in pivot points.
Note: Keys set to Join to Prev IK Key (page 2–900) are locked in value until the next un-joined key.

Tip: The Workbench and Curve Editor are synchronized so changing the curve display from the Workbench toolbar (page 2–1012) also updates the display from the Curve Editor, as well as activate the corresponding tool from the Biped Toolbar (page 2–535).

Curve Conversion Between Quaternion and Euler

When an animation converts from one controller to the other, its integrity is maintained as much as possible. This means that despite variations in key interpolation results, the keyframed poses are preserved.

If you convert a quaternion rotation curve to Euler, the resulting tangent keys are set to Smooth. If, on the other hand, you switch an Euler rotation curve to quaternion, the bezier interpolation from the tangents is maintained as much as possible. However, if that interpolation is too extreme and can not be matched by TCB values, it is then reduced to fit under quaternion limits.

Using Euler animations with Layers, Motion Mixer, and Motion Flow

Both Euler tangents and quaternion TCB data are stored in each keyframe. Therefore, even if you are using the Euler XYZ controller, you can still change the profile of your curves using quaternion/TCB control values (on the Key Info rollout (page 2–954)).

If you add a new layer to an Euler controlled biped part, that layer is converted into quaternion until it is collapsed back with the original layer. On collapse, the curve changes back into Euler following the same conversion rules stated earlier.

When clips containing Euler animations are brought into the Motion Mixer, Euler tangents are preserved in the blending process. However, once they are mixed together in a mixdown (page 3–973), the resulting animation becomes quaternion.

Tip: When creating a mixdown, you can preserve your Euler tangents by turning on A Keyframe Per Frame in the Mixer Preferences dialog (page 2–624).

Motion Flow follows the same rules as the Motion Mixer. If clips brought into Motion Flow contain Euler animations, their tangents are preserved. However, creating an unified motion results in a quaternion animation.

Tip: Euler tangents can be preserved when creating a unified motion by turning on A Keyframe Per Frame in the Unify Options dialog (by clicking Create Unified Motion in the Motion Flow Scripts Group (page 2–1048)).
Copy-Pasting Data between Euler and Quaternion Curves

When you copy a track and paste it onto another, its type (Euler or quaternion) is pasted as well. This sometimes results in animations switching from quaternion to Euler and vice-versa.

Euler tangents of copied poses or postures are never copied. If you copy an Euler track and paste it onto any type of track with Auto Key turned on, the current TCB or tangent values (depending on the type of track onto which you pasting) are ignored and instead set to Default.

Following the same rule, pasting a pose or posture on a Euler track with Auto Key turned on doesn’t transfer the TCB values of the copied track. If a new key is created before pasting the track, the resulting tangent is set to Default.

Loading and Saving Biped Assets with Euler Curves

When you load an external biped asset file (BIP) onto a biped, they each might contain different animation controllers (for example, a Euler asset loaded onto a quaternion biped). When this happens, the biped animations are converted to match the controller from the biped asset file.

When you save a biped asset file, it stores both Euler tangents and quaternion TCB control values.

Note: While this doesn’t affect overall performance, it may slightly impact the biped asset file size.

Working with XRef Bipeds

Using the XRef Objects dialog (page 3–397), you can externally reference bipeds in your scene. This lets you work efficiently in a collaborative environment because the changes that the artist applies to his source XRef biped updates your master scene content. See XRef Objects (page 3–394) for more information.

Externally Referencing a Biped

When you create an XRef biped, certain modes on the Motion Panel’s Biped rollout (page 2–936) become unavailable as XRef data is read-only:

- Figure Mode (page 2–982)
- Footstep Mode (page 2–988)
- Motion Flow Mode (page 2–1043)
- Mixer Mode (page 2–652)

As a result, you need to go back to the source scene in order to make desired changes to your biped.

Example: Changing the Structure of an Xref Biped

An integrator externally references a biped into his master scene. He discovers that the biped does not have the right number of spine and neck links, and
that the arm links are too short to reach a specific goal target. Because Figure Mode is unavailable in the master scene, the artist currently in the source scene inputs the changes to the biped’s structure, and then saves his file. This update now reflects in the master scene.

Example: Modifying the Footsteps of an Xref Biped
An integrator externally references a biped into his master scene. He sees the footstep animation but cannot edit it because Footstep Mode is unavailable. The artist currently in the source scene goes into Footstep Mode and alters the animation. This update now reflects in the master scene.

Externally referencing a biped automatically creates a new “XREF LAYER” in the Layers rollout (page 2–974), whether or not the source biped contains any animation. As a result, the original layer becomes a level one “Local Layer” which you can use to add animation on top of it.

Note: If the XRef biped contains multiple animation layers in the source scene, 3ds Max collapses them into one layer before creating the XRef.

Note: Saving animation (page 2–920) from your XRef biped breaks the XRef link.

Loading, Saving, and Displaying Biped Motion

Working with Biped Motion Files
character studio uses a variety of file formats to save, load, and edit motion.

- BIP file (.bip)

The native character studio file format for saving biped motion. A BIP file saves all information about biped motion: footsteps, keyframe settings including limb rotation, the scale of the biped, the active gravity (GravAccel) value, and prop animation. IK Blend values for the keys and Object Space settings are also saved.

See Loading and Saving BIP Animation (page 2–920).

- BVH file (.bvh)

The BioVision motion capture format. Typically, BVH files are obtained from motion capture hardware that records the movements of a human performer. Data saved in a BVH file includes both skeletal data, and information about limb and joint rotations.

Note: For the BVH file specification, see the BVH.rtf document on the program disc.

- CSM file (.csm)

The Character Studio Marker format. This is an alternative format for recording motion capture data. It stores positional data for various markers on a biped figure.

See Motion Capture Rollout (page 2–1065).

Note: For the CSM file specification, see the CSM.rtf document on the program disc.

- MIX file (.mix)

A MIX file contains data from the Motion Mixer, such as trackgroups, tracks, and transitions.

See Using the Motion Mixer (page 2–604).

- MFE file (.mfe)

The Motion Flow Editor format saves scripts you create in the Motion Flow Editor, including clip references and transitions.

See Motion Flow Mode (page 2–1043).

- MNM file (.mnm)
The Marker Name File format matches custom marker names in a CSM or BVH file with the standard, preset marker names used by a biped. Note: For BVH and CSM file specifications, see the BVH.rtf and CSM.rtf documents on the program disc.

- **STP file (.stp)**

  The Step file format saves footstep data. Unlike a BIP file, it does not save keys for the feet or upper body. STP files are ASCII files. The main purpose for this format is to enable developers to write programs that generate step files. Biped can later be used to create keys for the software-generated footsteps. See Loading and Saving STP Files (page 2–924).

**Motion File History Lists**

The file dialogs for Biped motion files include a history list that lets you quickly choose directories where you have recently saved or opened files. 3ds Max maintains a separate history list for each type of motion file.

Note: When you load or save motion flow snippets, or mixer clips through the reservoir, if a file is already specified for that snippet or clip, its directory will appear at the top of the history list, even if that directory was not originally in the history list. If you cancel the load or save of the snippet or clip, that directory will not be added to the history. If you go ahead and load or save the snippet or clip, the directory will be added to the history.

**Loading and Saving BIP Animation**

Biped motion (BIP) files have a .bip file name extension. They save all information about biped motion: footsteps, keyframe settings including limb rotation, the scale of the biped, and the active gravity (GravAccel) value. IK Blend values for the keys and Object Space settings are also saved. IK objects, props and other objects in the scene can also be saved with the .bip file.

There are several ways to create or acquire .bip files:

- By loading one of the sample animation files that come with 3ds Max. Refer to the installation and support guide for more details.

- By creating your own animation with footsteps or freeform methods, and saving the animation with the Save button in the Biped rollout. See the procedures that follow.

- By loading and filtering a motion capture file, then saving the animation with the Save button in the Biped rollout. See Filtering Motion-Capture and Marker Data (page 2–1061).

When you save a Motion Mixer (page 2–604) (MIX) file or a Motion Flow Editor (page 2–1026) (MFE) file, the paths to the referenced BIP files are also saved. If these paths are broken (for example, if the BIP files have been moved or renamed), a Missing Motion Mixer Files dialog or Missing Motion Flow Files dialog, respectively, opens listing the missing files. To rectify this, open the Asset Tracking dialog (page 3–487) and set a new path for the files.

**Procedures**

**To load biped motion from an existing BIP file:**

1. ![Select the biped you want to animate, and go to the Motion panel.](image)

2. ![On the Biped rollout, make sure you are not in Figure mode, and click Load File.](image)

   Note: When Figure mode (page 2–982) is active, the Load File option loads figure (FIG) files.
Anything done in Figure mode changes the basic shape and structure of the biped. When Figure mode is turned off, the Load File tool loads BIP files, which animate the figure.

3. In the file dialog, choose the BIP motion file to load, and then click OK.

4. The biped repositions itself in the scene, as it assumes the initial position of the animation file. You might need to use Zoom Extents to see the biped after it is repositioned.

Tip: The Biped keyboard shortcut \[ \text{Alt}+\text{R} \] sets the animation range to that of the currently selected biped. Since the length of the animation can change after loading a BIP file, this keystroke can be useful. To use it, make sure that the Keyboard Shortcut Override Toggle is active.

To save animation you have created or imported to a BIP file:

1. Animate the biped with footsteps and/or freeform animation.

2. ![ ] Select the biped that has the animation you want to save, and go to the Motion panel.

3. ![ ] On the Biped rollout, make sure you are not in Figure mode, and click Save File.

4. In the file dialog, enter a name for the motion file, and then click OK.

Click the Help button on the FBX dialog to view the latest 3ds Max FBX Plug-in Guide.

---

**Motion Mapping: Retargeting Biped Motion**

One of the more powerful features of Biped is the ability to retarget or map the motion of any biped onto any other biped. If you map the motion of a biped without a tail onto a biped with a tail, default tail motion for the biped with a tail will be computed. Default motion will also be computed when mapping the motion of a biped with fewer links in the legs, spine, or neck onto a biped with more links in the legs, spine, or neck. There are a few ways to perform motion mapping. You can:

- Go into Figure mode and change the structure of your biped. When you exit Figure mode, the new structure of the biped will adapt to the existing animation.
- Save a BIP or STP file from one biped, and load it onto another biped of a different structure and size.
- Copy footsteps from one biped, and paste them onto the footsteps of a differently structured and scaled biped.

**Scale Stride Mode**

Scale Stride mode gives you control over whether or not certain aspects of motion mapping occur.

If Scale Stride mode is active (the default):

- When you exit Figure mode after loading a FIG file or changing the biped's leg length, pelvis width, or height, the locations of the footsteps will be scaled to match the leg length and pelvis width, and gravity will be changed to match the new height of the biped.
- When you load a BIP or STP file, the locations of the footsteps in the file will be scaled to match the leg length and pelvis width of the
Chapter 14: character studio

existing biped. Gravity will be adjusted to be proportional to the gravity stored in the file. (A motion stored in a BIP or STP file has a gravity value associated with it.)

- When you paste footsteps copied from one biped onto another biped, the locations of the footsteps in the buffer will be scaled to match the leg length and pelvis width of the existing biped. Gravity will be adjusted to be proportional to the gravity stored in the file. (A motion stored in a BIP or STP file has a gravity value associated with it.)

If Scale Stride mode is not active, no computations will be performed in any of the above cases. Then you might see your biped moving over footsteps that are spaced inappropriately far apart or close together for the size of your biped. Typically, you should leave Scale Stride mode active, unless you want to maintain the spatial relationship between the biped and other objects in your scene.

Procedure

To turn off Scale Stride mode:

1. Select the biped, and go to the Motion panel.
2. On the Biped rollout, click the bar at the bottom to expand the rollout. (If the rollout is already expanded, the bar shows a minus sign at the left, instead of a plus.)
3. In the Modes group, click Scale Stride Mode to turn it off.
   The button changes to indicate stride scaling has been turned off.
4. Use Figure mode to edit the figure.
   When you return to Keyframe mode or Footstep mode, the biped’s stride length is unchanged, regardless of the biped figure’s new proportions.

Merging and Cloning a Character

At some point you might need to use the File > Merge command to merge a character into your scene. Also, you can use Merge to clone a biped that has a mesh with the Physique modifier applied, as described in this topic.

Cloning a Character

To clone a character (that is, a biped with a Physique mesh), save a scene that contains the character, change the original biped’s name, and then use File > Merge to merge the copy from the saved file. You can merge from a saved version of the scene that is currently open. See the procedures for details.

Procedures

To merge a skinned biped:

1. Before you merge, make sure the root name of the biped you want to import is different from that of bipeds already in your scene. If there is a name conflict, select the conflicting biped, go to the Motion panel, and use the Structure rollout’s Root Name field to change the biped’s root name.
   If you skip this step, you will get a Duplicate Name dialog for every object in the merged biped’s hierarchy!
2. Choose File > Merge, then choose the MAX file that contains the biped to import.
   The Merge dialog displays.
3. Click to turn on Select Subtree in the Merge dialog.
4. Locate and click the biped’s center of mass name in the Merge dialog list.
The default name for the biped center of mass is \textit{Bip01}. If the biped was renamed on the Structure rollout, find the renamed center of mass in the list.

\textbf{Note:} The center of mass is the root object in the biped hierarchy, if this is selected with Select Subtree turned on, then all the child links are selected, including extra bones and the mesh skin (the mesh skin is linked when Attach To Node is used in Physique).

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure}
\caption{Selecting a biped while merging a MAX scene}
\end{figure}

In the illustration, the center of mass object is named \textit{Hero}. With Select Subtree active, all the children are also selected when you click \textit{Hero}, including the Physique mesh.

5. Click OK.

Probably a Duplicate Name dialog is displayed. If it isn't, the merge is done; if it is, see the following step.

6. On the Duplicate Name dialog, turn on \textit{Apply To All Duplicates}, and then click Merge.

\textbf{Note:} Even when the bipeds in your scene have different root names than the biped you are merging, the biped finger/toe/head dummies in the file to be merged can have the same names as other biped dummies in your scene. This step merges these dummy objects. Dummies with duplicate names can appear in the Select Objects dialog, so the duplicate names are not a problem.

The biped and its animation is merged with the scene.

\textbf{To hide the finger, toe, and head dummy objects:}

The dummy objects for fingers, toes, and the head are visible on the newly merged biped. Usually these dummies are hidden from sight. They are used by Physique to create envelopes for all the finger tips, toe tips, and head; these dummies display when a character is merged. The quickest way to hide them again is simply to toggle the Objects button in the Biped rollout's Display group, as described in these steps.

1. With the merged biped still selected, go to the Motion panel.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure}
\caption{Fingertip dummies displayed as blue cubes}
\end{figure}

The number of biped dummies varies according to how many fingers and toes the character has.

2. At the bottom of the Biped rollout, click the bar by the plus sign to expand the rollout.
3. In the Display group, turn Objects off and then back on again to hide the biped finger/toe/head dummy objects.

To clone a skinned biped:
1. Save a copy of the scene that contains the biped you want to clone.
2. On the Structure rollout, change the original biped’s root name, as described above.
3. Merge the saved biped, as described in the previous procedure, “To merge a skinned biped.”
   The original biped, with its Physique modifier, is cloned. It appears in the same location as the original biped.
4. On the Motion panel, on the Biped rollout, turn on Move All Mode.
5. Use Select And Move to move the clone to a new location in the scene.

**Combining BIP Motions**

*character studio* provides two main ways of combining BIP files to build more complex character animations.

- **Motion flow** (page 2–1026) uses BIP files as *clips* in a *script*. The motion-flow script joins clips together using *transitions*. Transitions can be unconditional, they can be chosen at random, or they can be governed by rules such as collision detection. You can control when a transition begins and ends. You can use motion flow to animate a single biped, or a crowd of bipeds.

Motion flow scripts are saved as Motion Flow Editor (MFE) files.
- The **Motion Mixer** (page 2–604) also uses BIP files and MFE files as clips. In addition to creating transitions from one BIP animation to another, over time, Mixer scripts can combine the upper-body movement of one biped with the lower-body movement of another, adjust the timing of movements, and provide a number of other effects. The Mixer is especially useful when you work with *motion-capture files* (page 2–1059).

   Mixer scripts are saved as BIP files or MIX files.

---

**Loading and Saving STP Files**

Step (STP) files save footsteps, but don’t save body keyframes.

The STP file format is an ASCII format that enables developers to write programs that generate step files for biped motion. The online document stp.rtf, provided with *character studio* in the ..\cstudio\docs directory, describes the STP format.

**Procedures**

---

**To load footstep data:**

1. Select the biped to animate via saved footsteps, go to the Motion panel.
2. On the Biped rollout, make sure you are not in Figure mode, then click Load File.
3. In the file dialog, choose Step Files (.STP) as the file type to load.
4. Choose the footstep file to load, and then click OK.

The footsteps are loaded onto the biped, and new default keys are generated to match the footsteps.
To save footstep data:

1. Select the biped whose footsteps you want to save, and go to the Motion panel.
2. On the Biped rollout, make sure you are not in Figure mode, then, click Save File.
3. In the file dialog, choose Step Files (.STP) as the file type to save.
4. Enter a name for the footstep file, and then click OK.

Using Motion-Capture Data

Besides animating a biped with footsteps or with keyframing (freeform animation), you can import a motion-capture file. The overall workflow for motion capture is straightforward:

- Import the motion-capture data
  
  See Importing Motion-Capture Data (page 2–1061).
- Filter the data
  
  Motion-capture files are typically dense, with keys on every frame. Filtering the data reduces the number of keys, resulting in an animation with better performance. You filter the data with the Motion Capture Conversion Parameters dialog (page 2–1070). This dialog can reduce large numbers of keys at once. It is displayed when you use the Motion Capture rollout to load a BIP, BVH, or CSM file. Once you have loaded a motion-capture file, you can filter the data further by clicking Convert From Buffer (also on the Motion Capture rollout), which also displays this dialog.
  
  See Filtering Motion-Capture and Marker Data (page 2–1061).
- (Optional) Edit the data
  
  Once you are happy with the converted animation, you can use the freeform animation tools to make specific changes.

  Tip: The Motion Mixer (page 2–604) provides another way to edit motion-capture data.

Motion-capture files can be one of three file types: the native character studio BIP format, the BioVision (BVH) format, or the Character Studio Marker (CSM) format.

For an introduction to using motion capture, see the tutorial “Working with Motion-Capture Data.”

Correcting Posture

A particular motion file might position a biped body part inappropriately. For example, the collarbones might be rotated down too far, affecting your mesh deformation. All you need to do is go into Figure mode, rotate the biped collarbones up, and then exit Figure mode: this corrects the collarbone position for the entire animation. The motion references the Figure mode position, if the biped is adjusted, and this adjustment is reflected in your animation when you exit Figure mode.

Tip: Save a FIG file for the biped pose you used when you applied Physique. Then you can use the FIG file to reload this position if you need to reapply the Physique modifier or reinitialize the Physique settings.

How Biped Uses Figure Mode

When you animate the biped, the Biped plug-in maintains the at-rest pose you have created for these elements of the biped body:

- Spine
- Neck
- Clavicles
- Tail
Chapter 14: character studio

- Ponytails
- Center of mass position, relative to the body.

When Biped adapts the keyframed motions stored in BIP files to different characters, the keyframes of the above elements are recreated as an offset from the at-rest posture associated with each character’s figure. The at-rest posture associated with the arms and legs is always assumed to be a standing posture, with straight legs.

**Restructuring a Biped to Match a BIP File**

When you load a BIP file, there is an option to restructure the biped to match the file. If you turn this on when you load the file, the biped’s structure will change to match the figure of the biped in the BIP file.

**Talent Figure Mode and Adjust Talent Pose**

*Talent Figure Mode* and *Adjust Talent Pose* on the Motion Capture rollout have a purpose similar to that of Figure mode. They are used to size and position biped body parts to better fit raw motion capture data. After importing motion capture data, you might discover that certain biped limbs or the biped scale need a global adjustment in order to provide a closer match to the figure of the talent who performed the motion.

See also

*Motion Capture Rollout (page 2–1065)*

**Copying and Pasting Tracks**

Biped’s Copy/Paste rollout on the Motion panel provides controls for copying and pasting biped tracks from one part of the biped to another, or from one biped to a different biped. At the top of this rollout are three buttons: Posture, Pose, and Track.

This section covers the copying and pasting of tracks. For information on the other options on this rollout, see *Copying and Pasting Postures and Poses (page 2–910)*.

To copy and paste biped tracks, turn on Tracks. The remaining controls in the rollout change to reflect that you are working with tracks:

- The copy button changes to a Copy Tracks button.
- The two Paste buttons become Paste Tracks and Paste Tracks Opposite, respectively.
The Paste Horizontal, Paste Vertical, and Paste Rotation buttons in the Paste Options group (page 2–973) become active.

For hands-on experience in using Copy and Paste Tracks, see the lesson called Creating a Simple Freeform Animation in the tutorial Animating with Freeform.

**Procedure**

**To copy a track from one biped to another:**

1. Select any part of the biped and access the Motion panel.
2. On the Copy/Paste rollout, click Create Collection and rename the new collection Biped Track.
3. Click Track to use Track mode. Then, select the biped parts whose tracks you want to copy.
4. Click Copy Track.
   Biped creates a new track buffer, and adds it to the list as the active buffer. The buffer’s name indicates which biped parts you selected.
5. Select any part of the other biped.
6. In the Paste Options group, enable all three Paste buttons.
7. Click Paste Track or Paste Track Opposite.
   The tracks for all biped parts are applied to the other biped regardless of which parts are selected on the biped.

**Repositioning the Biped**

The method you should use to reposition a biped depends on which tools were used to animate the biped:

- If the biped uses freeform or footstep animation, use Move All mode. This is also the easiest way to move a biped that is not animated.
- If the biped uses freeform animation and IK attachment (that is, there are keys where IK Blend is greater than zero), then you need to use a dummy object.
- If the biped is animated with motion flow, use the Start Position spinners.

**Procedures**

Note: The procedures in this topic assume that you have already selected the biped and gone to the Motion panel.

**To reposition a freeform animation (with no IK attachment) or a footstep animation:**

1. On the Biped rollout, turn on Move All Mode.
   The biped’s center of mass is selected and displayed in a larger-than-usual size. On the main toolbar, Select And Move is turned on. Move All mode is a convenient way to select the biped’s center of mass, and to reposition the biped. Use it when the biped is not yet animated, when the biped has freeform animation with no IK attachment, or when it has footstep animation.
   Note: The alternative way to move a biped with footstep animation is to select all of its footsteps, rather than its center of mass.
2. Move the biped.
   The Collapse button on the Move All dialog box allows you to reset the position and rotation values in the Move All dialog to zero, but does not change the position of the biped.
3. Turn off Move All Mode.

To reposition a biped with limbs attached to an Object Space object (IK attachment):

1. Create a dummy object and position it near the biped’s center of mass.

2. On the main toolbar, use Select And Link to link both the Object Space object and the biped’s center of mass to the dummy object.
   
   Important: Make sure you link both at the same frame.

3. Move the dummy object to reposition the biped.

To reposition a biped with limbs attached to world space (IK attachment):

A biped with limbs in world space has an IK Blend setting of 1.0 for each limb, with no Object Space object specified. For example, when you plant the feet of a biped so its knees will bend when you lower its center of mass, or you plant the hands of a biped doing pushups, typically you do not specify an Object Space object.

1. Create a dummy object near the biped’s center of mass.

2. On the main toolbar, use Select And Link to link both the biped’s center of mass and the biped part with planted keys to the dummy object.

   Tip: To be on the safe side, you can double-click the upper limb and link all of the limb to the dummy.

   Important: Make sure you create all links at the same frame.

3. Move the dummy object to reposition the biped.

Note: Depending on the animation, at some of attached object’s keys you might need to set IK Blend back to 0.0. Otherwise, the limb can get “stuck” in a posture.

To reposition a biped animated with a motion flow script:

By default, the biped’s position at the beginning of a motion flow script is the position specified by the first BIP or STP file in the script.

1. Turn on Motion Flow mode.

3. Turn off Motion Flow mode.

To use layers to reposition a biped with freeform animation:

Using layers and Auto Key when you reposition a freeform biped gives you some editing choices, as described below.

1. On the Layers rollout, click Create Layer.

   Note: If the biped uses footstep animation, the Move All Mode button will become unavailable.

2. Turn on Auto Key.

3. Reposition the biped as described in the previous procedure, “To reposition a freeform animation (with no IK attachment) or a footstep animation.”

4. Turn off Auto Key.

   You now have these aids to animation editing:

   - Lower layers show the biped’s original position, as does the red stick figure.

   - Clicking Snap Set Key on the Layers rollout snaps the biped to its position on the previous layer, and sets a position key. The
Previewing Biped Motion

There are two types of animation playback available within Character Studio:

- You can use the Play Animation button in the viewport playback controls to play biped animation, the same as you can any other 3ds Max animation.
- Use the Biped Playback button (page 3–916) on the Biped rollout to play back the animation with the biped displayed as a stick figure, while hiding everything else in the scene.

Note: It is possible to turn on both buttons at once. This is not recommended. Depending on your system configuration, turning on Play Animation and Biped Playback at the same time can considerably slow down performance.

Biped Playback

Biped playback previews the motion of all existing, visible bipeds. If you hide a part or all of biped, the hidden biped or biped part does not appear in the Biped playback. Objects in the animation that are not bipeds do not appear in Biped playback. If the 3ds Max home grid is visible, a grid appears at Z=0 in the Biped playback viewport.

While Biped controls are visible in the Motion panel, you can also press [V] to start or stop Biped Playback. For this keyboard shortcut to work, the Keyboard Shortcut Override Toggle must be turned on.

Biped always previews the existing animation range. Biped Playback responds to the parameters in the 3ds Max Time Configuration dialog. If Real Time playback is chosen in this dialog, Biped plays back at the current frame rate, sometimes skipping frames if necessary. If Real Time is turned off, Biped plays back as fast as it can, depending on the capacity of the graphics card installed on your system.

Note: Hardware acceleration has no effect on Biped playback. If you are using a hardware-accelerated display card, you might find 3ds Max playback to be faster under certain circumstances.

Procedures

To preview biped motion using biped playback stick figure:

1. Activate the viewport with the view you want to see.
2. Hide or show the bipeds you want to appear in the playback.
3. Select one of the visible bipeds, and go to the Motion panel.
4. On the Biped rollout, click Biped Playback.

Stick-figure biped animation plays back in the active viewport. Animation plays back for all visible bipeds.

To preview biped motion using the full biped model:

1. Drag the time slider.
2. Click Play Animation.

Biped animation plays back in the active viewport. Depending on your system, biped animation might not play back in real time using 3ds Max viewport playback.

Warning: You might miss critical frames of your animation if Real Time is selected in the Time Configuration dialog.
In Place Mode

Create or select a biped. > Motion panel > Biped rollout > Expand rollout > Modes group > In Place button on In Place flyout

In Place mode (page 3–956) allows you to display biped motion as if it were occurring on a treadmill. Regardless of the distance the biped covers under control of the current motion file, the biped stays within the active viewport when you’ve turned on In Place Mode.

In Place playback prevents lateral (XY) movement of the biped center of mass during animation playback; vertical motion along the Z-axis is preserved. Biped limbs, footsteps, and center of mass keys can be adjusted in this mode. When the center of mass is moved on the XY axes in this mode, the footsteps move.

Use this feature to view biped playback without requiring a follow camera. In this viewing mode, visible footsteps appear to slide under the biped.

For export to games, this feature is valuable, as many game engines intelligently move the character’s center of mass laterally according to game play. In Place mode makes it easy to view, tune, and export animation in a manner that is complementary to game engine playback.

Note: Trajectories do not display using In Place mode.

In Place Mode Options

The In Place Mode button is the default button on a three-button flyout. There are two further options:

- **In Place X Mode**—Locks center of mass X-axis motion. Use this for game export where the character stays in place but the swinging motion of the hips and upper body along the Y-axis is preserved.

- **In Place Y Mode**—Locks center of mass Y-axis motion. Use this for game export where the character stays in place but the swinging motion of the hips and upper body along the X-axis is preserved.

Using In Place Mode to Adjust Keyframes

In Place Mode is a good way to adjust keys on a biped that already has animation applied to it. Rather than scrolling the view at different frames to keep a running biped visible, turn on In Place Mode. Now when you scrub the time slider, or use the Next Key and Previous Key buttons, the biped remains visible. A key that needs adjustment can be quickly spotted and corrected.

Tip: Judging lateral center-of-mass motion using In Place mode is difficult. In Place mode limits center-of-mass motion on the XY axes; all sense of body momentum on these axes is suspended during playback. You might want to turn off In Place playback to gain a sense of lateral momentum when setting or adjusting horizontal keys (Body Horizontal Track) for the center of mass.

Procedure

To use In Place mode to adjust keyframes:

1. Select a biped that has animation, and go to the Motion panel.
2. On the Biped rollout, click the bar at the bottom to expand the rollout. (If the rollout is already expanded, the bar shows a minus sign at the left, instead of a plus.)
3. In the Modes group, click In Place Mode to turn it on.
4. At the bottom of the 3ds Max window, turn on Auto Key.
5. Find a frame where the biped needs adjustment, and modify or add keys.

Trajectory Display

When a biped is animated, you can view its motion not only using Biped Playback, but you can also see the path, or trajectory, the biped (or selected biped links) follows throughout the motion.

You turn on trajectory display by clicking Trajectories in either of these user-interface locations:

- Motion panel > Biped rollout > Expand Biped rollout > Display group > Trajectories button
- Motion panel > Key Info rollout > Trajectories button

Tip: Do not use 3ds Max trajectory controls to display or edit biped trajectories. These include the options accessed with Object Properties > Display Properties > Trajectory on the quad menu, and those under Motion panel > Trajectories text button.

Trajectories provide useful visual feedback as you edit keys, showing the effects on the motion path for the parameters you’re adjusting. You also can use trajectory display to compare filtered and unfiltered motion capture data.

Changes to Tension, Continuity, Bias, Dynamics Blend, Ballistic Tension, and the overall gravity setting GravAccel are reflected in the trajectories.

Note: Trajectories do not display while you play an animation using In Place mode.

You can customize the trajectory information for the selected biped link by using the Display Preferences dialog (page 2–944). You can choose between Bone Base and Bone Tip, show an entire trajectory, or a moving range of frames.

See also

Biped Color-coded Keys and Trajectories (page 2–1005)

Procedure

To edit biped trajectory keys in a viewport:

1. Select an animated biped and go to the Motion panel.
2. On the Track Selection rollout, turn on Body Horizontal or Body Vertical.
3. At the bottom of the Biped rollout, expand the Modes And Display sub-rollout if necessary by clicking its name.
4. In the Display group, turn on Trajectories.
5. Turn on Sub-Object selection level.
6. On the main toolbar, turn on Select And Move.
7. Use the Transform gizmo to move the keys on the trajectory.

Display Preferences

The Display Preferences dialog (page 2–944) lets you customize how bipeds are displayed while you work with them. This topic introduces some of the commonly used options.
Use controls on this dialog to change footstep, trajectory, and playback display.

In the Trajectories group, you can choose between the Bone Base or Bone tip for trajectory display. You can show the entire trajectory, or define a range of frames for partial trajectory display.

In the Footsteps group, you can choose colors for the left and right footsteps, and generate various colors or standard colors in the viewport or Track View. You can also Show or Hide All Footsteps or Footstep Numbers.

In the Playback group, you can define which bipeds will appear in Biped Playback. (This can be useful for speeding performance if your scene contains a number of bipeds.)

**See also**

Display group (page 2–939)

**Biped User Interface**

The Biped user interface is split up into “modes” of operation. You activate these modes by selecting the appropriate button in the Biped rollout on the Motion panel, which is visible when a biped is selected.

There are four modes available:

- **Figure mode** is used to change the biped skeletal structure and to align the biped to a mesh.
- **Footstep mode** is used to create and edit footstep animation.
- **Motion Flow mode** is used to create scripts that combine motion files into longer animations.
- **Mixer mode** is used to view, save, and load animation created with the Motion Mixer.

As with other parts of 3ds Max, the rollouts change depending on the mode the software is in. When no modes are active, the following rollouts are displayed:

- **Assign Controller Rollout (character studio)** (page 2–934)
- **Biped Apps Rollout** (page 2–935)
- **Biped Rollout** (page 2–936)
- **Track Selection Rollout** (page 2–945)
- **Quaternion/Euler Rollout** (page 2–948)
- **Twist Poses Rollout** (page 2–950)
- **Bend Links Rollout** (page 2–952)
- **Key Info Rollout** (page 2–954)
- **Keyframing Tools Rollout** (page 2–962)
- **Copy/Paste Rollout** (page 2–966)
- **Layers Rollout** (page 2–974)
- **Motion Capture Rollout** (page 2–1065)
- **Dynamics & Adaptation Rollout** (page 2–980)

The Assign Controller, Biped Apps, and Biped rollouts are displayed during all modes. The remaining rollouts depend on the mode.
In Figure mode, *Structure* (page 2–984) is the only additional rollout.

In Footstep Mode, the rollouts displayed are: *Footstep Creation* (page 2–988), *Footstep Operations* (page 2–990), and *Dynamics & Adaptation*.

In Motion Flow mode, *Motion Flow* (page 2–1045) is the only additional rollout displayed.

In Mixer mode, *Mixer* (page 2–652) is the only rollout displayed.

When no modes are active, you can edit tracks and keys, set IK constraints, work with layers, and work with motion capture data. You can also create freeform animation without any of the modes active simply by turning on the Auto Key button and moving or rotating any part of the biped.

---

**Motion Panel (Biped)**

Once you have created a biped, use the Biped controls on the Motion panel to animate the biped, load and save Biped files, and fit the biped to a mesh representing your character.

Create a biped if one does not exist, and select any part of the biped to see the controls on the Motion panel.

Depending on the active mode, the Motion panel contains the following rollouts:

- *Assign Controller Rollout (character studio)* (page 2–934)
- *Biped Apps Rollout* (page 2–935)
- *Biped Rollout* (page 2–936)
- *Track Selection Rollout* (page 2–945)
- *Copy/Paste Rollout* (page 2–966)
- *Footstep Creation Rollout* (page 2–988)
- *Footstep Operations Rollout* (page 2–990)
- *Motion Flow Rollout* (page 2–1045)
- *Mixer Rollout* (page 2–652)
- *Key Info Rollout* (page 2–954)
- *Keyframing Tools Rollout* (page 2–962)
- *Display group* (page 2–939)
- *Layers Rollout* (page 2–974)
- *Motion Capture Rollout* (page 2–1065)
- *Dynamics & Adaptation Rollout* (page 2–980)
- *Structure Rollout* (page 2–984)

---

**Center of Mass**

The parent object of the biped is its center of mass, which appears as a blue octahedron near the center of the biped’s pelvis. The name of this object is the root name of the biped (*Bip01* by default).

The center of mass is sometimes referred to as the COM.

**Center of Mass Animation Tracks**

Unlike other objects and biped body parts, the center of mass has three separate animation tracks:

- Body Horizontal
• **Body Vertical**

• **Body Turning (selected with the Body Rotation button)**

You can use these buttons, available on the *Track Selection rollout* (page 2–945), to select each track as well as the COM itself.

**Linking the Center of Mass Object**

Using the *Select And Link tool* (page 2–422) you can link the center of mass object to another object if you need to reposition an animation sequence. An example of this might be a surfer. You could create an animation of a biped running up and down the surfboard, hanging its toes off the end of the surfboard, and so on, and then link the center of mass object to the board. When you animate the surfboard, the biped animation would travel with it.

![The biped moves with the surfboard because the center of mass is linked to the surfboard.](image)

The biped moves with the surfboard because the center of mass is linked to the surfboard.

Because the COM is the root object in the biped hierarchy, it is the only object in the biped that can be linked directly to other objects in the scene with Select And Link. A different technique is used to make other body parts, such as feet and hands, follow other objects in the scene. See *Animating IK Attachments* (page 2–908).

**Center of Mass Shadow**

The center of mass shadow object, the circle between the biped’s feet on the world plane, provides a sense of where the character’s center of mass is positioned relative to the feet. Another use of the center of mass shadow is to link objects to it. For example, a camera and camera target could be linked to the shadow object to follow the character.

![The center of mass shadow between the biped’s feet.](image)

The center of mass shadow between the biped's feet.

**Motion Panel Rollouts (Biped)**

**Assign Controller Rollout (character studio)**

Select a biped’s COM. > Motion panel > Assign Controller rollout

The Assign Controller rollout assigns and appends different transform controllers to individual objects. You can also assign controllers in Track View. Animation controllers are plug-ins that handle all of the animation tasks in the software. For a complete list of available Animation controllers, see *Assign Controller* (page 2–546).
### Interface

**Assign Controller**—Displays a selectable list of controllers for a selected track.

Once controllers have been added, right-click the Biped SubAnim entry in the list and choose Properties to display the SubAnims dialog.

**Sub Anims Property**

- Enable: Position List, Rotation List, Scale List
- Collapse: Position, Rotation, Don’t Delete, Per Frame

#### Enable section

**Enable**—Selectively activates or disables the three list controllers. Choose any combination of Position, Rotation, and Scale.

**Position List**—When turned on, selects the Position controller to be collapsed into the Biped SubAnim track.

**Rotation List**—When turned on, selects the Rotation controller to be collapsed into the Biped SubAnim track.

**Scale List**—When turned on, selects the Scale controller to be collapsed into the Biped SubAnim track.

#### Collapse section

**Position**—Collapses the Position controller when you click Collapse.

**Rotation**—Collapses the Rotation controller when you click Collapse.

**Don’t Delete**—Prevents the removal of the list controller after collapsing and hides the controller instead.

**Per Frame**—Creates a key per frame during the collapse, preventing the controller from collapsing onto the key times of the biped and SubAnim controller.

**Collapse**—Performs the collapse.

---

### Biped Apps Rollout

Select a biped. > Motion panel > Biped Apps rollout

The Biped Apps rollout allows you to choose either of two tools for working with the biped motion.

#### Interface

- **Mixer**—Opens the Motion Mixer, where you can layer animation files to customize biped motion.
  
  See *Using the Motion Mixer (page 2–604).*

- **Workbench**—Opens the Workbench, where you can analyze and adjust biped motion curves.
See Working with the Workbench (page 2–1008).

**Biped Rollout**

Select the biped > Motion panel > Biped rollout

Use controls on the Biped rollout to put the biped into Figure, Footstep, Motion Flow, or Mixer modes, and to load and save .bip, .stp, .mfe, and .fig files. You'll find other controls on the Biped rollout, as well.

The Modes group on the Biped rollout lets you turn on the Buffer, Bend Links, Rubber Band, Scale Stride, and In Place mode.

The Display group on the Biped rollout lets you adjust how the biped is displayed, providing controls to show or hide Objects, Bones, Footsteps, and Trajectories.

In addition, the Biped rollout provides controls for converting footsteps into a freeform animation, or a freeform into a footstep animation.

Note: The Modes group, Display group, and Name field are hidden by default. Click on the Modes and Display expansion bar to display them.

Note: In previous versions of character studio, the Biped rollout was called the General rollout.

---

**Interface**

The **Figure Mode**—Use Figure mode (page 2–982) to fit a biped to the mesh or mesh objects representing your character. Leave Figure mode on when you attach the mesh to the biped with Physique. Figure mode is also used to scale a biped with a mesh attached, to make biped "fit" adjustments after Physique is applied, and to correct posture in motion files that need a global posture change.

The **Structure Rollout** (page 2–984) appears when Figure mode is active.

Note: When Figure mode is turned on, the biped jumps from its animated position to its Figure mode pose. Animation is preserved when you exit Figure mode.

The **Footstep Mode**—Create and edit footsteps; generate a walk, run, or jump footstep pattern; edit selected footsteps in space; and append footsteps using parameters available in Footstep mode.

Two additional rollouts display on the Motion panel when Footstep mode (page 2–988) is active:

- Footstep Creation rollout (page 2–988)
- Footstep Operations rollout (page 2–990)
Motion Flow Mode—Create scripts and use editable transitions to combine .bip files together to create character animation in Motion Flow mode (page 2–1043). After creating a script and editing transitions, use Save Segment on the Biped rollout to save a script as one long .bip file. Save a .mfe file; this enables you to continue Motion Flow work in progress.

Tip: Use Motion Flow mode to cut motion capture files together.

Note: The Motion Flow rollout (page 2–1045) appears when Motion Flow mode is active.

Mixer Mode—Activates any current Mixer (page 2–604) animation on the Biped and displays the Mixer rollout (page 2–652).

Biped Playback—Plays the animation for all bipeds unless they are excluded on the Display Preferences dialog (page 2–944). This playback mode usually gives real-time playback, which you may not get if you use Play on the 3ds Max toolbar.

Note: In Biped Playback mode, the biped is displayed as bones only, with no other scene objects visible.

Load File—The Open dialog (page 2–942) lets you load .bip, .fig or .stp files.

Save File—Opens the Save As dialog, where you can save Biped files (.bip), figure files (.fig), and step files (.stp) files.

Convert—Convert a footstep animation to a freeform animation. This works in both directions. Displays the Convert to Freeform dialog (page 2–999) or Convert to Footsteps dialog (page 2–999) depending on the direction.

• Convert uses biped foot IK Blend values to extract footstep.

• Use Convert to extract footstep from an animation saved using Save Segment in Motion Flow mode.

• Convert the animation in either direction depending on how you like to work. Convert to freeform for unrestricted key editing. Convert to footstep to take advantage of footsteps.

Move All Mode—Allows the biped to be moved and rotated with its relative animation intact. You can transform the biped interactively in the viewport or with the dialog box that opens when the button is active.

When this button is active, the biped’s center of mass enlarges to be more easily selected for translation.

The Collapse button on the Move All dialog box allows you to reset the position and rotation values in the Move All dialog to zero, but does not change the position of the biped.

Modes group

Note: The Modes group is hidden by default. To display it, click on the Modes & Display expander in the Biped rollout.

Buffer Mode—Edit segments of an animation in Buffer mode. Copy footsteps and associated biped keys into the buffer using Copy Footsteps on the Footstep Operation rollout first, then turn on Buffer mode to view and edit the copied segment of your animation.

Tip: Paste buffered motion back to the original animation repeatedly to create looping motions.

Edit footstep and biped animation that have been copied into the buffer using Copy Footsteps on the
Footsteps Operation rollout. The changes can be pasted back by turning off Buffer Mode, turning on Paste Footsteps on the Footstep Operation rollout, and overlapping the buffered footsteps with the original footsteps. The buffered motion is spliced into the original animation.

**Rubber Band Mode**—Use this to reposition the biped elbows and knees without moving the biped hands or feet in Figure mode. Reposition the biped center of mass to simulate the physics of wind or weight pushing against the biped. Figure mode must be turned on to enable Rubber Band Mode.

To reposition biped knees and elbows, turn on Figure mode and turn on Rubber Band mode. Select the Move transform tool, then select and drag a biped upperarm or thigh in the viewports. Use this as an aid to fitting a biped to a mesh.

To reposition the biped center of mass relative to the rest of the biped skeleton, turn on Figure mode and turn on Rubber Band mode. Select the Move transform tool, then select and drag the center of mass in the viewports. Use this to account for wind force or pushing against a heavy object. See *Shifting the Biped's Balance* (page 2–876).

Note: Rubber Band mode behaves differently than Non-Uniform Scale. For example, if you "Rubber-Band" the biped thigh, the thigh and biped calf objects scale proportionally to keep the biped foot stationary. Using Non-Uniform Scale, the calf retains its scale and the foot moves.

Moving the biped center of mass (blue diamond) behind the character, turns this default walk cycle into a struggle against a high wind.

**Scale Stride Mode**—Footstep stride length and width are scaled to match the stride length and width of the biped figure. Scale Stride mode is on by default.

Displays when Scale Stride mode is off.

Scale Stride mode is on by default, so scaling occurs automatically when you load a .bip, .stp, or .fig file. Scaling occurs when you paste footsteps and when you scale the biped’s legs or pelvis.

For example, if you load a .bip file that was saved from a larger biped, the footsteps come into your current scene scaled to match the selected smaller biped. If Scale Stride mode is off, the footsteps come into the current scene without being scaled down.

If you turn off Scale Stride mode and then go into Figure mode and scale the biped up or down, the footstep stride width and length remains the same when you exit Figure mode.
In Place Mode—Use In Place mode to keep the biped visible in the viewports while the animation plays. Use this for biped key editing or adjusting envelopes with Physique. It prevents XY movement of the biped center of mass during animation playback; however, motion along the Z axis is preserved. This is a three-button fly-out. In Place mode is stored with the 3ds Max file.

In Place X Mode—Lock center of mass X-axis motion. Use this for game export where the character stays in place but the swinging motion of the hips and upper body along the Y-axis is preserved.

In Place Y Mode—Locks center of mass Y-axis motion. Use this for game export where the character stays in place but the swinging motion of the hips and upper body along the X-axis is preserved.

Biped keys for limbs, footsteps, and center of mass can be adjusted using In Place mode. When the center of mass is moved on the XY-axes in this mode, the footsteps move. View biped playback without requiring a follow camera. In this viewing mode, visible footsteps “slide” under the biped.

For export to games, this feature is valuable since many game engines intelligently move the character’s center of mass laterally according to game play. In Place mode makes it easy to view, tune, and export animation in a manner that is complimentary to game engine playback.

Tip: Another way of following a moving character is to link a camera and camera target to the center of mass shadow, which is the disc between the biped’s feet.

Note: Trajectories do not display when In Place mode is active.

Display Objects flyout—This flyout lets you display bones and objects, together or independently:

- Objects—Displays biped body objects; these will render if you do not turn them off before rendering. Hide the biped objects before scene rendering. You can also hide individual body objects by using the standard 3ds Max Hide controls found in the Display panel and Display Floater.

- Bones—Displays biped bones. Bones, which do not render, are represented as the color of the corresponding links. Displaying Bones is useful for seeing exactly where the joints fall in relation to the biped objects.

Note: The Display group is hidden by default. To display it, click on the Modes and Display expander in the Biped rollout.
Chapter 14: character studio

Objects and Bones—Displays bones and objects simultaneously.

Display Footsteps flyout—This flyout lets you display or hide footsteps and their numbers:

- **Show Footsteps and Numbers**—Displays biped footsteps and footstep numbers.
  Footstep numbers specify the order in which the biped will move along the path created by the footsteps. Footstep numbers are displayed in white and do not render, but do appear in preview renderings.

  - **Show Footsteps**—Displays biped footsteps in the viewport, but no footstep numbers. Footsteps are represented as green and blue foot-shaped outlines by default; these are also visible in preview renderings.

  - **Hide Footsteps**—Turns off footsteps and footstep numbers in the viewport.

- **Twist Links**—Toggles the display of twist links used in biped. Default=on.

- **Leg States**—When this button is on, the viewport displays Move, Slide, and Plant at each foot at the appropriate frame.

- **Trajectories**—Displays trajectories for selected biped limbs.

  Tip: You can edit keys on the biped’s horizontal and vertical track by turning on Trajectories, turning on Sub-Object, selecting the horizontal or vertical center of mass track and transforming keys in the viewports. Use Trajectories when editing keyframe parameters to visualize their influence, and to compare raw and filtered motion capture data.

- **Display Preferences**—Displays the Display Preferences dialog (page 2–944) which is used to change footstep colors, trajectory parameters, and to set the number of bipeds to be played back when you use Biped Playback on the Biped rollout. Footstep color preference is a good way to distinguish between the footsteps of two or more bipeds in a scene.

Name Rollout

The Name rollout lets you change the name of the biped. When you change the name in the Biped rollout, the center of mass is renamed and the entire biped hierarchy inherits the new name.
Save As Dialog (Biped)

Select a Biped. > Motion panel > Biped rollout > Save File

The Save As dialog lets you save biped (BIP), figure (FIG), and step (STP) files.

When saving FIG files (in Figure mode), the Save As dialog is a standard Windows Save File dialog. However, when you save BIP or STP files, you can save objects and animation controllers with the file.

Interface

History—This drop-down list lets you choose directories where you have recently saved Biped motion files. See Motion File History Lists (page 2–920).

File Name—The name of your FIG, BIP, or STP file.

Save as type—Sets the file type for your saved file.

- Saves an incremented version of the segment without overwriting an existing file.
- Figure file (.FIG)—Saves the structure and position of a biped in Figure mode. After fitting the biped to a mesh in Figure mode, save a figure file. If the biped is accidentally moved in Figure mode, reload this file.
- Biped file (.BIP)—Saves a biped motion file. A BIP file includes footsteps and keyframe data. Biped files store the complete movement and allow you to create libraries of motion. Create your own BIP library by animating the biped and saving a BIP file.
- Step file (.STP)—Save footstep timing and location data in an ASCII format. Step files contain no body keys (spine, arms, etc.).

Save Segment—Lets you select segments of your animation for your BIP or STP file.

- From: Starts saving at this frame of the named animation.
- To: Stops saving at this frame of the named animation.
- Active Time Segment: When on, animation in the active time segment is saved.
- Biped Animation Period: When selected, only time containing biped animation is saved.
- Edited Transition Interval: Saves frames in a transition only. Select a clip on the Motion Flow Script rollout, open the Transition Editor, and then select Save Segment to activate this control.

Tip: Game developers can save only the motion in the transition.

A Keyframe per Frame—Saves a key at every frame. Turn this on if you plan to extract footsteps using
Load Motion Capture on the Motion Capture rollout.

**Save MAX Objects group**

**Save MAX Objects**—When on, any IK, Head Target, or linked object in the scene is saved with the BIP file.

**Object list**—Each object associated with the biped in the scene is displayed here along with its object type.

- **All**—When on, all associated objects are saved with the BIP file.
- **Selected**—When on, only the highlighted objects are saved with the BIP file.

**Save List Controllers group**

**Save List Controllers**—When on, any animation controllers assigned to the biped are saved with the BIP file.

**Controller List**—Each animation controller used with the biped in the scene is displayed here along with the object that it controls.

- **All**—When on, all associated animation controllers are saved with the BIP file.
- **Selected**—When on, only the highlighted animation controllers are saved with the BIP file.

---

**Open Dialog (Biped)**

*Select a biped. > Motion panel > Biped rollout > Load File*

The Open dialog lets you load biped (BIP), figure (FIG), and step (STP) files.

When you load a FIG file (in Figure mode), the Open dialog is a standard Windows Open File dialog. However, when you load a BIP or STP file, you can preview the animation and control how much information is loaded into your biped.

---

**Note:** This option is unavailable when you load a BIP file into a clip or onto a biped that is in Edit Clip mode, because all the clips in the motion flow would have to be adapted.

**Interface**

**Open dialog for BIP or STP files**

**History**—This drop-down list lets you choose directories where you have recently opened Biped motion files. See *Motion File History Lists (page 2–920).*

**File Name**—The name of your FIG, BIP, or STP file.

**Files of Type**—Sets the type of file to load.

- **Figure file (.FIG)**—Load a Figure file. Figure mode must be active to load a Figure file.
Figure files allow you to apply the structure of one biped to another. Reload a Figure file if you accidentally lose your biped Figure mode pose; this pose is the biped fitted to a mesh.

Note: When you load a FIG file, the Open dialog is a standard Windows Open File dialog.

- **Biped file (.BIP)**—Load a biped motion file (clip). Motion files include footsteps, keyframe settings, the biped scale, and the active gravity value (GravAccel). IK Blend values for keys and IK objects and their animation are also loaded.

If you select a BIP file saved with a previous version of character studio, the preview will not be visible. After selecting the file for loading, you will be notified that the file is obsolete and should be resaved, unless you have indicated that you no longer want to see this message.

- **Step file (.STP)**—Load footsteps without body keyframes. Using this ASCII file format enables developers to write programs that generate step files for biped motion. Biped will generate body keys for the loaded steps. See stp.rtf in the cstudio\docs directory for more details on the step file format.

Note: In Figure mode, you can only load FIG files. In other modes, you can load BIP or STP files.

**Motion Preview**—Lets you manually scrub through the animation in a BIP or STP file before opening it.

**Restructure biped to match file**—When on, the structure of the current biped is changed to match the structure in the BIP file.

**Set lowest starting foot height to Z=0 (.bip files only)**—Sets the lowest starting foot height to Z=0. This is an option in the Load File dialog. Default=On.

In character studio, the height of a motion clip can be retained. This is important if you want to retain the height of a motion clip for motions adapted to characters of different sizes. If, for example, the character is jumping off a rock and you want to retain the Z position of the character, you would turn this option off. Leave this option off if Motion Flow motions must be blended that begin and end at different heights, such as three clips that have the character mounting a bicycle, riding the bicycle, and dismounting the bicycle.

Turning off this option can, however, cause a jump in the motion during motion flow transitions. Turn this on for smooth transitions in Motion Flow mode. If adaptation takes place, the height is set so that the lowest foot at frame 0 starts at the Z=0 height. This lines up clips along the Z axis and creates smooth transitions.

Tip: Use Load Motion Capture File on the Motion Capture rollout (page 2–1065) to load the raw version of the motion capture .bip files that come bundled with character studio. These files have no footsteps and keys at every frame. Loading files using Load Motion Capture File allows you to filter the data and extract footsteps.

**Load MAX Objects group**

**Load MAX Objects**—When on, character studio will import any IK, Head Target, or linked object saved with the BIP data.

**Object list**—Each object saved with the BIP file is displayed in this list along with its object type. The only way to eliminate an object from the animation is to resave the BIP file without it and reload.

Note: The settings for loading 3ds Max objects are only active if Load MAX Objects is checked and there are objects in the data.

**Prompt for Duplicates**—Opens a Merge dialog for each object in the BIP file that has a duplicate in the scene.

In this dialog, you can Merge, Skip, or Delete Old.
If Prompt for Duplicates is off, the objects in your scene will be automatically overwritten.

Retarget—When on, the position of the objects in the BIP file adapt to the size of the target biped, based on either height or limb sizes.

Scale IK Object’s Size—When on, the imported objects are scaled in size to match the target biped.

Load List Controllers group

Load List Controllers—When on, and sub-animation controllers saved with the BIP file are loaded onto your target biped.

Controller list—Displays the sub-animation controllers in the BIP file.

Note: The only way to eliminate a controller from the animation is to resave the BIP file without it and reload.

Display Preferences Dialog

Select a biped > Motion panel > Biped rollout > Display group > Display Preferences

Use the controls in the Display Preferences dialog to change footstep colors and trajectory parameters, and to set the number of bipeds to play back when you use Biped Playback on the Biped rollout.

You access the Display Preferences dialog by clicking the Display Preferences button on the Display group in the Biped rollout.

Interface

Trajectories group

Note: Trajectories do not display using In Place mode.

Bone base—Displays bone base trajectories.

Bone Tip—Displays bone tip trajectories (default).

Show Entire Trajectory—Displays trajectories for all animated frames.

Before Trajectory—Sets the number of frames to display trajectories before the current frame.

After Trajectory—Sets the number of frames to display trajectories after the current frame. Using Before and After Trajectory will result in a “traveling” trajectory display that will move with the biped through space.

Footsteps group

Left—Selects the color for left footsteps. Double-click the color swatch next to this selection to display the Color Selector and set the color for left footsteps.

Right—Selects the color for right footsteps. Double-click the color swatch next to this selection to display the Color Selector and set the color for right footsteps.
**Generate Various Colors**—Asks whether you want different colors for left and right footsteps. Based on your response, generates various colors for footsteps in the viewports. This works with multiple bipeds.

**Generate Normal Colors**—Changes right footsteps to blue and left footsteps to green, the default. Applies to all bipeds in the viewports.

**Viewport Colors in Track View**—Displays viewport footnote colors in Track View.

**Normal Colors in Track View**—Displays normal footnote colors in Track View.

**Show All**—Shows all footsteps.

**Hide All**—Hides all footsteps.

**Show All Numbers**—Shows all footstep numbers.

**Hide All Numbers**—Hides all footstep numbers. Show and hide are useful when there are multiple bipeds in the viewports.

**Playback group**

Controls in this group limit the number of bipeds to play back when you use Biped Playback on the Biped rollout on the Motion panel.

**Show Time**—Displays frame numbers in the viewport during playback.

**All Bipeds**—Lists all bipeds in the scene. Select a biped name in the window and click the right arrow to move it into the list of bipeds that will be visible during playback with Biped Playback.

**Bipeds Visible in Playback**—Lists bipeds visible during playback with Biped Playback. Select a biped name and click the left arrow to exclude it from this list.

---

**Track Selection Rollout**

The Track Selection rollout give you specialized tools for manipulating the biped center of mass (COM) (page 2–933). The center of mass object is the root of the biped hierarchy, and controls the entire biped structure. Changing its position and orientation affects the biped as a whole, which is an important part of posing and animating the biped. Also available on this rollout are tools for selecting symmetrical and opposite biped body parts.

The COM can be selected in different ways:

- If the viewport rendering method (page 3–853) is set to Wireframe, you can select the COM in your viewport, located near the center of the biped’s pelvis.
- You can turn on Move All Mode on the Biped rollout (page 2–936), which enlarges the COM in your viewport. This is useful if the viewport rendering method is set to Smooth, and the biped’s pelvis covers the center of mass.
- You can open the Select Objects dialog (page 1–78), which displays all visible objects in your scene. The first listed biped item (Bip01, for example) usually refers to the root; you can select it from there.
- You have access to three tools on the Track Selection rollout (on the Motion panel) to edit the COM’s position and orientation: Body Horizontal, Body Vertical, and Body Rotation. Choosing one automatically selects the center of mass.

Once the biped’s center of mass is selected, you can move or rotate it using the Transform gizmo
(page 3–1025). Controlling the COM using the Track Selection rollout tools is sometimes quicker because selecting the center of mass in your viewports can be difficult if your biped resides inside a bigger rigged model. As long as you select your biped by any limb, activating the COM tools from the Track Selection rollout automatically selects the center of mass with the proper Transform gizmo:

- Body Horizontal and Body Vertical enable the Move gizmo.
- Body Rotation enables the Rotate gizmo.

When you key the COM’s position or orientation using Set Key (page 3–718) or Auto Key (page 3–717), the animation data is stored within the respective biped transform tracks.

The biped Transform tracks contain the COM keyed data.

**Procedures**

To Edit the COM's position and orientation:

1. Create a biped.

2. On the Motion panel, expand the Track Selection rollout and turn on Body Horizontal. The Move Transform gizmo appears at the COM’s location, highlighting the X and Y axes because they are referring to the biped Horizontal Transform track.

3. Select the Move gizmo's Z axis. This turns off Body Horizontal and turns on Body Vertical.

4. Turn on Body Rotation on the Track Selection rollout. The Move Transform gizmo is replaced by the Rotate Transform gizmo. You can now change the biped’s orientation.

To Lock all Biped COM Tools:

This procedure follows the concept from the previous procedure, and centers on selecting multiple COM tracks at the same time, as well as locking them.

1. On the Track Selection rollout, turn on Body Horizontal.
2. Turn on Lock COM Keying.
Lock COM Keying allows you to activate all center of mass tracks at the same time.

3. Turn on both Body Horizontal and Body Rotation.

4. Select any other part of your biped.
The COM track controls become inactive. Note that Lock COM Keying is storing the selected controls.

5. Reselect the biped COM either by selecting the blue octahedron near the center of the biped’s pelvis, or by clicking one of the three COM track controls.
Lock COM Keying restores the selected controls.

Interface

Body Track Tools (Center of Mass Tracks)
Body Horizontal and Body Vertical refer to the center of mass’s translation axes while Body Rotation focuses on its rotate axes. Once you turn them on, you can move or rotate the COM by either using the Transform gizmo, by entering values in the Coordinate Display area (page 3–708).
Tip: You can also set COM positions using the Tension, Continuity and Bias values on the Key Info rollout (page 2–954) (in the TCB group).

When you activate Body Horizontal or Body Vertical, you have access to advanced Biped Dynamics parameters (page 3–916), such as Balance Factor (page 3–914) and Ballistic Tension (page 3–914), which you can control from the Key Info rollout (page 2–954) and Dynamics & Adaptation rollout (page 2–980).

Note: Tension, Continuity, and Bias affect the COM Body Vertical keys only when the value of Dynamics Blend (page 3–932) is less than 1.0. To turn gravity off at a vertical center of mass key, set the value of Dynamics Blend to 0.0.
Tip: To view the way a parameter change affects the animation, Turn on Trajectories (page 3–1025).

Keyed keys for COM tracks are color coded as follows:
- Keys containing Body Horizontal tracks are red.
- Keys containing Body Vertical are yellow.
- Keys containing Body Rotation are green.
Note: If a frame contains multiple keyed COM tracks, the key’s color code is divided accordingly.

A key’s color reflects its keyed COM tracks.

Body Horizontal—Selects the center of mass to edit horizontal biped motion.

The Body Horizontal track has a Balance Factor (page 2–877) parameter that automatically orients the biped to maintain balance. This saves the animator from having to reposition the pelvis when the biped leans forward, backwards, or sideways.

Note: Biped Dynamics (page 3–916) parameters can be animated from no effect to full effect at each keyframe.
Body Vertical—Selects the center of mass to edit vertical biped motion.

The Body Vertical track uses the Dynamics Blend parameter to control gravity in a footstep animation. A Dynamics Blend value of 1.0 uses the value of GravAccel (page 3–950) (global gravity value) to calculate an airborne trajectory for the biped. No keyframes are required to position the biped in the air, a trajectory is calculated automatically. A value of 0.0 uses Spline Dynamics for the vertical position of the biped; you must create keyframes to position the biped vertically.

The Body Vertical track also has a Ballistic Tension (page 3–914) parameter that controls how much the biped knees bend when the biped lands from an airborne period. This means that keys do not need to be created at the lowest position of the biped after landing; a trajectory is calculated automatically.

Note: You can create keys manually to override the calculated trajectory during the landing period. However, vertical keys must have Dynamics Blend=0.0 in order to fully override the trajectory during the airborne period.

Body Rotation—Selects the center of mass to edit biped rotational motion.

Lock COM Keying—When on, allows you to select multiple COM tracks at the same time. Once locked, the tracks are stored in memory, and are remembered every time the COM is selected.

Note: Locked COM tracks are also honored after a scene reset or a session change.

Symmetrical—Selects the matching object on the other side of the biped. For example, if the right arm is selected, clicking Symmetrical Tracks selects the left arm too. You can then make changes to both sides of the body at once. Symmetrical works for single and multiple biped parts.

Opposite—Selects the matching object on the other side of the biped, and deselects the current object. For example, if the right arm is selected, clicking Opposite Tracks selects the left arm and deselects the right arm. Opposite Tracks can be used for single or multiple objects.

Biped Color-coded Keys and Trajectories (page 2–1005)

Quaternion/Euler Rollout
Select the biped > Motion panel > Quaternion/Euler rollout

This rollout contains options to switch between Euler or quaternion controllers on biped animations. These choices offer alternative ways to control an animation in the Curve Editor. For more details, refer to Working with Euler Curves on Biped Animation (page 2–916).

Procedures
To switch between quaternion and Euler rotation controllers:

1. Create a biped.
2. Turn on Auto Key.
3. Select the biped’s upper arm and rotate it so it extends forward.
4. Go to frame 20 and rotate the upper arm so it extends sideways.
5. Go to frame 40 and rotate the upper arm back to its original orientation.
In the Motion Panel, on the Quaternion/Euler rollout, notice that the Quaternion option is active by default.

Note: If you change options for that biped limb, your choice is preserved in the 3dsmax.ini (page 1–18) file, from which it is restored after a scene reset or session change.

6. On the Biped Apps rollout, click Workbench to open it.

7. On the Quaternion/Euler rollout, choose the Euler option.

The curves have been converted to display Euler controlled rotations. You now have access to the curve’s tangent handles to change the curve’s interpolation.

8. Choose a different axis ordering from the Axis Order drop-down list (under the Euler option).

The curve display changes to reflect the new ordering while preserving the biped posture.

9. Choose the Quaternion option to convert the curves back to a TCB interpolation.

Note: Converting a curve from Euler to quaternion can affect its interpolation. See Working with Euler Curves on Biped Animation (page 2–916) for details.

Interface

The following options set the rotation controller for biped animations.

**Quaternion** — Converts the selected biped animation to quaternion rotation. If the biped selection has not been animated yet, this starts as the default option.

If you change options for any biped limb, your choice is preserved in the 3dsmax.ini file, from
which it is restored after a scene reset or session change.

**Euler** — Converts the selected biped animation to Euler rotation.

**Axis Order** — Lets you choose the order in which the Euler rotation curves are calculated. Available only when Euler is active. Default=YZX.

Changing the ordering reflects on the curves, which are modified accordingly. However, this change does not affect the animation itself.

Note: This setting is independent of the Workbench Axis Order setting.

---

**Twist Poses Rollout**

Select a biped. > Motion panel > Twist Poses rollout

The toolset of this rollout lets you create and edit twist poses for a biped’s limbs. You can either use the rollout’s preset poses (which you can modify and rename), or create your own. When you add a new pose, you establish a reference between the selected limb’s relative orientation and the rollout’s Twist value of 0 (which means no twist). When more than one reference pose are set for a rotated limb, the limb’s twisting is calculated based on the nearest pose.

Tip: It is suggested that you add twist poses for all major limb rotated poses. This ensures that rotating your biped’s limb produces well-calibrated twisting.

Note: You don’t technically have to enable *twist links* (page 2–987) to use the Twist Poses rollout toolset. However, if your biped does not contain twist links, the Twist and Bias settings are not used.

The Twist Poses rollout tools only affect limbs with three degrees of freedom (DOF), such as upper arms and thighs, because you can control their twist links by rotating them. Two-DOF limbs (forearms and calves, for instance) differ due to the fact that you can only control their twist links if you rotate their child limb.

**Procedures**

**Example: To Add and Edit Twist Poses:**

This procedure takes into account the concept of adding *twist links* (page 2–987) to biped limbs and concentrates on using the tools from the Twist Poses rollout to set up basic poses.

1. Prepare a biped with five twist links on each upper arm.

Tip: You can use See-Through (page 1–55) on the biped’s limbs to better distinguish the twist links inside.
2. Exit Figure Mode, and then expand the Twist Poses rollout.

3. Select the right upper arm.
   The rollout controls are enabled because you selected a three-DOF limb.

4. Use Previous Key and Next Key to cycle through the different pose presets.
   Tip: You can often use these presets as a starting point for posing your limbs.

5. Choose pose1 from the drop-down list.
   The biped’s arm extends upwards and shows some twisting.

6. Click Set.
   This assigns the Twist value of 0 to the upper arm’s twist links.
   Note: A twist change is always reflected on both sides (in this case, both upper arms).

7. Rotate the upper arm locally around its Y axis so it extends on the side.

8. Click Add to create a new pose. Rename it Arm At Side.
This new pose resets the current Twist value of the twist links.

9. Rotate the upper arm locally around its X axis. The twisting in the upper arm is calculated based on the limb’s proximity to the saved poses.

Note: Changing the Twist value automatically resets the current limb’s orientation to the active twist pose.

Bias—Sets the distribution of rotation along the twist links. A setting of 1.0 concentrates the twist towards the top link while a setting of 0.0 instead concentrates it towards the bottom link. The default setting is 0.5, distributing the rotation evenly throughout the links. The twist links from the opposite side are so affected.

Note: Changing the Bias value automatically resets the current limb’s orientation to the active twist pose.

Note: You can also set a Bias value for Two-DOF limbs.

Add—Creates a new twist pose based on the selected limb’s orientation and resets Twist and Bias to their default values.

Note: Adding a new pose for one limb automatically makes it available for the limb on the opposite side.

Set—Updates the active twist pose with the current Twist and Bias values.

Delete—Removes the current twist pose.

Default—Replaces all twist poses of all three-DOF limbs with five default preset poses.

---

**Bend Links Rollout**

Select the biped > Motion panel > Bend Links rollout
This toolset combines the Bend Links Mode, previously located on the Biped rollout, with other tools to allow an easier control over a chain link, such as a biped spine, neck or tail.

Note: Activating one of the Bend Links rollout modes deactivates any of the others. However, clicking Zero Twist or Zero All maintain any mode currently active.

Note: The Bend Links rollout is displayed in Mixer Mode, Motion Flow Mode or Footstep Modes.

Procedures

To bend a spine naturally using Bend Links Mode:

1. Select any link in the biped’s spine.
2. Rotate the spine link. Notice that all chain links rotate the same way.
3. On the Bend Links rollout, click Bend Links Mode to activate it.
4. Rotate the spine link. The other links in the chain rotates to match the single link’s rotation, creating a natural bend along the spine.

To twist a spine naturally using Twist Links Mode:

1. Select any link in the biped’s spine.
2. On the Bend Links rollout, click Bend Links Mode to activate it.
3. Rotate the spine link until you reach a pronounced bend.
4. Rotate the spine link in local X. Notice that all chain links rotates in a weird way due to the fact that they do not maintain their relationship with the two other axis. Undo the rotation.
5. On the Bend Links rollout, click Twist Links Mode to activate it.
6. Rotate the spine link in local X. The rotation averages up the spine for all links while the spine maintains its existing profile.

To twist a spine link without affecting the chain using Twist Individual Mode:

1. Select the bottom link in the biped’s spine, just above the pelvis.
2. On the Bend Links rollout, click Bend Links Mode to activate it.
3. Rotate the link so the spine’s shape follows a noticeable curvature.
4. On the Bend Links rollout, click Twist Individual Mode to activate it.
5. Select a link in the middle of the spine and rotate it in local X. The rotation only affects the selected link.

To smooth out a spine using Smooth Twist Mode:

1. Select the bottom link in the biped’s spine.
2. On the Bends Links rollout, click Twist Individual Mode to activate it.
3. Rotate the link 45 degrees in local X.
4. Select and rotate the spine’s top link –45 degrees in local X.
5. On the Bends Links rollout, click Twist Individual Mode to activate it.
6. Rotate either the bottom or top spine link. The chain links rotates to smooth out the orientation difference between the two link
extremities. Adjust the Smoothing Bias control to distribute the chain’s rotation towards the base or top link.

**Interface**

**Bend Links Mode**—This mode can be used to rotate multiple links of a chain without having to select all of them beforehand. Bend Links Mode transfers the rotation of one link to the other links, following a natural curvature.

Note: Using Bend Links Mode in Auto Key mode or setting a key after twisting results in keys on all the links of the selected chain. See *Separate Tracks* (page 2–962) for further details.

**Twist Links Mode**—Similar to Bend Links Mode, this mode takes the rotation in local X applied to the selected link and increment it equally throughout the rest of the chain while maintaining the relationships between the links in the other two axes.

Note: Using Twist Links Mode in Auto Key mode or setting a key after twisting results in keys on all the links of the selected chain. See *Separate Tracks* (page 2–962) for further details.

**Twist Individual Mode**—Similar to Bend Links Mode, this mode allows a selected chain link to be rotated in local X without affecting its parent or child. The chain therefore maintains its shape while the individual link is adjusted.

Note: Using Twist Individual Mode in Auto Key mode or setting a key after twisting results in keys on all the links of the selected chain. See *Separate Tracks* (page 2–962) for further details.

**Smooth Twist Mode**—This mode takes into account the orientation in local X of the chain’s first and last links in order to distribute the rotation of the other links. This results in a smooth rotation between every chain link. The rotation distribution can be set by adjusting the Smoothing Bias control or by rotating either the first or last link of the chain.

**Smoothing Bias**—Sets the rotation distribution based on a value between 0.0 and 1.0. 0.0 biases towards the first link and 1.0 towards the last link of the chain. The chain’s smoothness can be interactively set by dragging the bias setting between those 2 values.

**Zero Twist**—Resets every chain link’s rotation to 0 in local X based on the current orientation of the chain’s parent. This does not change the current shape of the chain.

**Zero All**— Resets every chain link’s rotation to 0 in all axes based on the current orientation of the chain’s parent. This adjusts the current shape of the chain so it becomes parallel to the biped.

**Key Info Rollout**

Select the biped. > Motion panel > Key Info rollout

Tools in the Key Info rollout allow you to do the following:

- Find the next or previous key for the selected biped body part.
- Use the Time spinner to slide a key back and forth in time.
- Change Tension, Continuity, and Bias for a key and display trajectories.
- Adjust biped dynamics.
- Set planted, sliding, or free keys.
- Set IK constraints and pivots for the biped hands and feet.

When the Body Vertical COM (center of mass) track is active, you can change the vertical dynamics of the motion, on a key-by-key basis. When the Body Horizontal COM track is active you can change the balance factor for shifts in weight distribution.

Note: On the time slider or in Track View, you can move one Biped key past another. See Moving Keys (page 2–1004).

Activating Parameters

Groups of the Key Info rollout are unavailable depending on what part of the biped is selected and if a key is current. Body Vertical, Body Horizontal, and Body Rotation refer to the three tracks used to animate the biped center of mass. Select one of the three center of mass tracks on the Track Selection rollout, then use Next Key or Previous Key to find a key to edit.

- If Body Vertical is active and a key is current, then parameters for Dynamics Blend, Ballistic Tension, Z Position, Time, and TCB parameters (Tension, Continuity and Bias) are active. Ballistic Tension is available only at keys just before or just after an airborne state, as between footsteps in a run or jump.

  Note: TCB controls are not effective at Body Vertical keys just before and just after an airborne period, between footsteps, if Dynamics Blend=1. Biped Dynamics calculates the airborne trajectory; in this case, lower the value of Dynamics Blend to use the TCB controls. In a walk sequence where footsteps overlap, Dynamics Blend has no effect and TCB controls can be used.

- If Body Horizontal is selected and a key is current, the Balance Factor parameter, XY Position, Time, and TCB parameters are active.

- If Body Rotation is selected and a key is current, Z Position, Dynamics Blend, Ballistic Tension are grayed.

- If a biped leg is selected and a key is current, then Time and TCB parameters are active. XYZ Position and Body Dynamics parameters are made unavailable. In a footstep animation, Time is made unavailable at a Touch and Lift key.

- If a biped arm is selected and a key is current, then Time and TCB parameters are active. XYZ Position and Body Dynamics parameters are made unavailable.

Interface

The Key Info rollout is divided up into several groups: TCB, IK, Head, Body, and Prop. You can expand and hide each of these groups by clicking on the line next to its name.

The field displays the key number.
**Time**—Enter a value to specify when in time the key occurs.

Use this to fine-tune keyframe timing on a character by moving a key backwards and forwards in time.

**Set Key**—Creates keys at the current frame when you are moving biped objects. This is identical to Set Key on the 3ds Max toolbar.

You can experiment with different biped poses without updating the motion until you find the desired pose. You can also quickly fine-tune your motion by setting a key and adjusting the key parameters on the Key Info rollout without having to transform the biped in the viewports.

Note: If a biped key is current, then TCB, XYZ position spinners, and IK Blend parameters can be updated without using Set Key or having the Auto Key button turned on.

Note: If 3ds Max bones using the IK Controller or 3ds Max Particle Emitters are linked to the biped, or if you are displaying 3ds Max trajectories or ghosting, the Auto Key button must be on while the biped is positioned. These objects update their parameters in real time as they are positioned.

**Delete Key**—Deletes the key of the selected object at the current frame.

By default, biped arm, hand, and finger keys are stored in the clavicle track. If you delete keys for any one of these objects, you lose positions for the rest of the arm objects at that frame. If you plan on extensive hand animation, turn on Arms in the Separate Tracks group of the Keyframing Tools rollout. This creates separate tracks for each biped arm object. Deleting an upper arm key will preserve hand and finger keys.

**Set Planted Key**—Sets a biped key with IK Blend=1, Join To Previous IK Key turned on, and Object selected in the IK group.

In a Footstep or Freeform animation, all footsteps that do not slide should have Join To Previous IK Key turned on.

Tip: Right-click to open the *Planted Key Defaults dialog*, which lets you set new default values for subsequent TCB keys.

**Set Sliding Key**—Sets a biped key with IK Blend=1, Join To Previous IK Key turned off, and Object selected in the IK group. This creates a sliding footstep. Sliding footsteps display in the viewports with a line running through the middle of the footstep. Sliding footsteps are understood as footsteps with moving IK constraints.

In a Footstep or Freeform animation, if the foot slides rather than being planted, use Set Sliding Key.

Tip: Right-click to open the *Sliding Key Defaults dialog*, which lets you set new default values for subsequent TCB keys.

**Set Free Key**—Sets a biped key with IK Blend=0, Join To Previous IK Key turned off, and Body selected in the IK group.

In a Footstep or Freeform animation, a biped leg in a move state should have a “free” key.

Tip: Right-click to open the *Free Key Defaults dialog*, which lets you set new default values for subsequent TCB keys.

To change the default values for TCB keys, right-click either Set Planted Key, Set Sliding Key, or Set Free Key to open the respective dialog.
Use—When on, subsequent keys set with either Set Planted Key, Set Sliding Key, or Set Free Key use the TCB values from the respective dialog. Otherwise, the system uses the default values.

Tension—Controls the amount of curvature in the animation curve. Default=25.

Continuity—Controls the tangential property of the curve at the key. Default=25.

Bias—Controls where the animation curve occurs with respect to the key. Default=25.

Trajectories—Shows and hides trajectories for the selected biped object. You can edit keys on the biped’s horizontal and vertical track by turning on Trajectories, turning on Sub-Object, selecting the horizontal or vertical center of mass track, and transforming keys in the viewports.

• You can bend the horizontal center of mass trajectory around selected horizontal keys by using the Bend Horizontal spinner in the Keyframing Tools rollout.

• Display trajectories to view how parameter changes in the Key Info rollout affects the biped motion. Changing Tension, Continuity, and Bias in the Tcb group affects the trajectory around the current key. Changing the value of IK Blend for a hand or foot will affect the trajectory between keys.

• Leave Trajectories on and turn on Show Buffer Trajectories on the Motion Capture rollout to compare a raw motion capture trajectory with the filtered trajectory on the biped. This assumes a motion capture file has been loaded.

• Changing Dynamics Blend for a center of mass vertical key or changing the value of GravAccel will change gravity in a foostep animation and will therefore affect the trajectory.

Simple—Collapses the lower part of the Key Info rollout, for simplified viewing.
TCB group

You can use the TCB controls to adjust easing and trajectories on keys that already exist.

**XYZ Position**—Reposition the selected biped part using these spinners.

A hand or foot can be repositioned in world coordinate XYZ. The biped center of mass can also be positioned using these spinners.

**TCB Graph**—Charts the effect that changing the controller properties will have on the animation. The red mark at the top of the curve represents the key. The marks to the left and right of the curve represent an even division of time to either side of the key.

The TCB graph is a stylized representation of the animation around a single key.

**Ease To**—Slows the velocity of the animation curve as it approaches the key. Default=0.

High Ease To causes the animation to decelerate as it approaches the key.

The default setting causes no extra deceleration.

**Ease From**—Slows the velocity of the animation curve as it leaves the key. Default=0.

High Ease From causes the animation to start slow and accelerate as it leaves the key.

The default setting causes no change of the animation curve.

**Tension**—Controls the amount of curvature in the animation curve.

High Tension produces a linear curve. It also has a slight Ease To and Ease From effect.

Low Tension produces a very wide, rounded curve. It also has a slight negative Ease To and Ease From effect.

The default value of 25 produces an even amount of curvature through the key.

**Continuity**—Controls the tangential property of the curve at the key. The default setting is the only value that produces a smooth animation curve through the key. All other values produce a discontinuity in the animation curve causing an abrupt change in the animation. Default=25.

High Continuity values create curved overshoot on both sides of the key.

Low Continuity values create a linear animation curve. Low continuity creates a linear curve similar to high tension except without the Ease To and Ease From side effect.

The default setting creates a smooth continuous curve at the key.

**Bias**—Controls where the animation curve occurs with respect to the key. Default=25.

High Bias pushes the curve beyond the key. This produces a linear curve coming into the key and an exaggerated curve leaving the key.

Low Bias pulls the curve before the key. This produces an exaggerated curve coming into the key and a linear curve leaving the key.
The default setting distributes the curve evenly to both sides of the key.

**IK group**

This group lets you set IK keys and adjust parameters for IK keys.

**Note:** You can now make and adjust settings for multiple selected IK-capable biped parts. For example, say at the same frame one foot has a planted key and the other has a sliding key. This means they both have (by default) IK Blend values of 1.0 and Ankle Tension values of 0.0. If you select both feet, all of the Key buttons near the top of the Key Info rollout are available, and you can change IK Blend and Ankle Tension values for both.

**IK Blend**—Determines how the software mixes forward kinematics and inverse kinematics to interpolate an intermediate position. An example of forward kinematics is moving the arm to control the hand. An example of inverse kinematics is moving the hand to control the arm.

Activates when a biped arm or leg (hand and foot) key is current.

* 0 with *Body* chosen is normal biped space (forward kinematics).
* 1 with *Body* chosen is inverse kinematics, which creates more straight-line motion between biped keys.
* 1 with *Object* chosen, but no *IK Object specified*, puts the limb fully into world space.

* 1 with *Object* chosen and an *IK Object specified* puts the biped limb into the coordinate space of the selected object; the biped limb follows the specified object.

**Ankle Tension**—Adjusts the precedence of the ankle joint over the knee joint. When set to 0, the knee takes precedence. When set to 1, the ankle takes precedence.

This effect is only visible between keyframes.

**Select Pivot**—Activate to designate pivots around which the biped hands and feet should rotate. After clicking a pivot in the viewports, turn off Select Pivot and then rotate the hand or foot.

Select Pivot is available only if the biped hand or foot is in World or Object coordinate space (page 1–443).

**Pivot Selection Dialog**—Opens a small dialog that shows the current pivot for the selected limb on the limb’s respective hand or foot, and lets you change it. When the chart is green (or blue) and red, indicating that you’re on an IK key, the red dot indicates the current location of the pivot. To designate a different pivot, click another dot on the chart. This provides an alternative method to using Select Pivot (see preceding).

The dialog is named according to the displayed hand or foot, depicts the actual number of digits and joints in use, and resizes itself accordingly.

The displayed chart uses three different schemes, depending on the context:

* green/blue and red dots for the right/left hand or foot when on an IK key (pivot is editable)
* gray and white dots when in an IK period but not on a key (pivot is visible but not editable)
* no dots if you’re in an FK (forward kinematics) period, or no limb or multiple limbs are selected (dialog disabled; no relevant data exists)

These are shown in the following illustration:
Note: When on an IK key, the left hand and foot charts use a blue/red color scheme:

**Join to Previous IK Key**—When on, places the biped foot in the coordinate space of the previous key. Turn off to put the biped foot into a new reference position.

Turn off and move the biped foot to create a sliding footstep, for example.

**Body**—The biped limb is in biped coordinate space.

**Object**—Object Space: the biped limb is either in World coordinate space or the coordinate space of the selected IK object. Coordinate space can be blended between keys.

**Select IK Object**—Chooses an object for the biped’s hand or foot to follow when IK Blend is 1 and Object is selected. The selected object’s name is displayed next to the button.

This selection cannot be animated; only one IK object can be active for each hand and foot throughout the animation.

**Tip:** If you want to change the object the hand or foot follows at different times in the animation, select a dummy object as the IK object, and assign a Link Constraint to the dummy object to make it link to different objects at different times.

---

**Head group**

![Head](image)

The Head group lets you define a target object for the target to look at.

**Target Blend**—Determines the extent to which the target blends with the head’s existing animation.

A setting of 1.0 causes the head to look directly at the target, 0.5 causes the head to blend half of its existing animation with looking at the target, and a setting of 0.0 causes the head to ignore the target, maintaining its existing animation.

**Select Look At Target**—Click to select an object for the head to look at.

Note: When an object is selected, its name is displayed next to the button.

---

**Body group**

![Body](image)

These parameters apply to the biped center of mass and are used by **character studio** to calculate the biped’s airborne trajectory based on gravity (GravAccel) and time between footsteps, the amount of knee bend on landing (Ballistic Tension) and how the biped objects adapt to maintain balance (Balance Factor).

**Balance Factor**—Position the biped’s weight anywhere along a line that extends from the center of mass to the biped’s head. This center of mass (Body Horizontal track) parameter can be keyframed. To activate Balance Factor select the Horizontal Track (in the Track Selection rollout),
set a key and enter a value in the Balance Factor field.

For example, to create a *sit then walk* sequence, you could shift the biped’s weight (balance) between 0 (the character is supported by the chair) for the sit key and 1 for the stand key (the character’s pelvis shifts to maintain balance).

If a character is seated, and reaches across the table, leave Balance Factor at 0; however the character leans, he will pivot from the center of mass. The pelvis will not move back to maintain balance.

In a walking motion, a value of 2 will swing the hips and keep the biped head steady; a value of 0 will keep the hips steady and swing the upper body.

The Balance Factor determines how far the biped’s hips will shift forward or backward to compensate for forward or backward bending of the spine. When the biped has a normal weight distribution between the upper and lower body, the default value of 1 causes the hips to swing backward as the biped bends over to compensate for the forward weight.

At times, when the biped leans, you will want the biped’s hips to refrain from shifting to compensate for the forward weight. This would be when the biped is sitting or falling down. A Balance Factor of 0 (the minimum value) causes the hips to stay still when the biped leans forward or backward.

A value of 0 places the biped’s weight at the center of mass. A value of 1 places the biped’s weight above the center of mass. A value of 2 places the biped’s weight in the head. Click the spinner up arrow to move the biped’s weight distribution toward the head. Range=0.0 to 2.0; Default=1.

Note: You can also shift the center of mass by turning on Figure mode, selecting the center of mass object, and using Rubber Band mode (page 2–936) to move the center of mass to a new position. This method cannot be keyframed, but it allows you to move the center of mass outside the biped body. For example, you can simulate pushing a heavy object by moving the center of mass behind the biped.

**Dynamics Blend**—Select the Body Vertical track (center of mass vertical track) and control the amount of gravity in an airborne period, as in a running or jumping motion. This parameter has no effect on a walking motion where footsteps overlap.
A value of 1 uses the GravAccel (page 2–980) value to calculate gravity. A value of 0 removes the effects of gravity calculation and flattens a jumping or airborne motion.

Ballistic Tension—Select the Body Vertical track (COM) and control the amount of spring or tension when the biped lands or takes off from a jump or run step. The change is subtle.

A walk cycle will not activate this value. The biped has to be airborne, then the Lift and Touch vertical keys will display a Ballistic Tension value.

If there are more than three vertical keys during a support period, you can also edit Ballistic Tension for the lift-off key; otherwise Biped uses the same value for touchdown and lift-off, since it is assumed that there is only one vertical dip in the motion. Low values are high tension (less dip in the trajectory). Default=0.5; Range=0 to 1;

Hand coordinate space for position and rotation at the current frame.

Position Space—Lets you set the prop position space to World, Body, Right Hand, or Left Hand.

Rotation Space—Lets you set the prop rotation space to World, Body, Right Hand, or Left Hand.

Keyframing Tools Rollout

Select the biped. > Motion panel > Keyframing Tools rollout

Use controls on the Keyframing Tools rollout to clear animation on a biped or selected parts, mirror biped animation, and cause the Neck to rotate in body space rather than parent space. You can also bend the horizontal center of mass track around a selected horizontal key.

Separate Tracks

By default, 3ds Max uses an optimized method for key storage. For example, keys for the fingers, hand, forearm, and upper arm are stored in the Clavicle transform track. If you prefer instead to have a transform track available for each arm object, use the Separate Tracks group to make these transform tracks available; transform tracks are displayed in Track View.

Prop group

The Coordinate Space pulldowns will set the Prop to refer to the World, Body, Right Hand or Left
When the Separate FK Tracks options are on for the Arms and Fingers, only these tracks receive keys.

Tip: Separate Tracks are designed to be used with forward-kinematic (FK) rotations. Using the Move tool to change the position of a biped limb with Separate Tracks requires that you turn on Set Parents Mode. If Set Parents Mode is off, then the limb you move is stored relative to its parent objects, and the new parent positions are not stored. The parent objects will snap back to their originally stored location. Turning on Set Parents Mode ensures that the position of the entire biped limb is stored.

Note: Separate Tracks are intended to be used as a preference. It is better to turn them on once for the tracks you plan to edit by hand. Turning off Separate Tracks that are currently on causes a key to be stored for every biped object in the limb for the frames where any biped keys previously existed.

Procedure

**Example: Use separate finger tracks to create a clenching fist:**

1. Create a biped with five fingers that have three joints apiece.
2. Turn on Set Parents Mode.
3. Turn on Separate FK Tracks for Arms.
4. Select the right hand and set a free key at frame 0.
5. Go to frame 30, move the hand up and forward, and then set a planted key.
6. Go to frame 40, set a free key (this will have IK on by default), select the pivot at the base of the hand (only hand pivots are present, not finger pivots), and reset the key.
7. The hand should now move up and then rotate at its base.
8. Select a finger. So far, it has no keys.
9. Animate each finger individually, so they curl up one at a time.

When the Separate FK Tracks options are off, all limb tracks receive keys.
Interface

Enable Subanims—Enables Biped subanims. For more information about Biped subanims, see Using Controllers (page 2–896)

Manipulate Subanims—Modifies Biped subanims. For more information about Biped subanims, see Using Controllers (page 2–896)

Clear Selected Tracks—Removes all keys and constraints from the selected objects and tracks.

Clear All Animation—Removes all keys and constraints from the biped.

Mirror—Mirrors the entire biped animation.

Set Multiple Keys—Select keys using filters or apply a rotational increment to selected keys. Use this to change periodic motion keys in Track View. Displays the Set Multiple Keys dialog (page 2–965)

Set Parents Mode—When a limb key is created, keys are created for the parent objects also, provided Set Parents Mode is turned on. Use Set Parents Mode when you turn on Separate FK Tracks.

Set Parents Mode stores the position of the entire limb when a biped limb is moved using inverse kinematics instead of rotated using forward kinematics. For example, if Set Parents Mode is off and Separate Tracks are turned on for the biped arms, then the arm will snap back to its original position if you transform the biped hand.

If Separate Tracks are turned on for a biped body part, then turn on Set Parents Mode. This lets you use the Move transform to position the biped limbs.

Note: Separate Tracks adds biped object transform tracks.

Anchor Right Arm, Left Arm, Right Leg, Left Leg—Let you temporarily fix the location and orientation of hands and feet. Use anchors when you are setting up animation with inverse kinematics object space, in which the arm or leg follows an object in the scene. Anchors ensure that the arm or leg keeps its alignment until you set the second key that establishes the object-space sequence.

Tip: An alternative to anchors is to use Set Planted Key on the Key Info rollout (page 2–954). When you use Set Planted Key, the limb is positioned to the previous IK key (Join To Previous IK Key).

Show All in Track View—Shows all the curves for the options in the Keyframing rollout in the track view.

Separate FK Tracks group

By default, character studio stores a finger, hand, forearm, and upper-arm key in the Clavicle track. The toe, foot, and calf keys are stored in the thigh track. This optimized approach to key storage works well in most cases. If you need extra tracks, turn them on for a specific biped body part.
For example, turn on Arms if you plan to create extensive finger-hand animation; if an arm key is deleted, it will not affect the finger-hand keys.

You must turn on Set Parents Mode for these toggles to take effect.

**Arms**—Turn on to create separate transform tracks for the finger, hand, forearm, and upper arm.

By default, there is one finger track per hand. All finger keys are stored in the Finger0 transform track, the first link of the biped thumb.

**Neck**—Turn on to create separate transform tracks for the neck links.

**Legs**—Turn on to create separate toe, foot, and calf transform tracks.

**Tail**—Turn on to create separate transform tracks for each tail link.

**Fingers**—Turn on to create separate transform tracks for fingers.

**Spine**—Turn on to create separate spine transform tracks.

**Toes**—Turn on to create separate transform tracks for toes.

**Ponytail 1**—Turn on to create separate ponytail 1 transform tracks.

**Ponytail 2**—Turn on to create separate ponytail 2 transform tracks.

---

**Set Multiple Keys Dialog**

Keys can be selected manually in Track View or the Track Bar and an increment applied to the selected keys. State Filters in this dialog select certain biped keys for you, based on foot states (Touch, Plant, Lift, and Move). Select Left Leg and the Move state filter, then click Select to select all the left leg keys in a Move state for example (Move is the leg state between footsteps).

**Interface**

**Change Multiple Keys group**

These controls allow you to apply to a set of keys the rotation or IK translation of a limb at the current frame. First select the keys in Track View, then rotate or move the limb, then click Apply Increment.

**Apply Increment**—Adjusts the rotation and/or position of a limb at the selected keys. Use this feature when you need to set the position of a limb over multiple keys.

**Scale Tail Keys**—Exaggerates or tones down the default motion applied to the biped’s tail for three types of rotation. To activate all three spinners, select tail keys in the biped Tail track in Track View.

**Forward**—Sets the amount of forward and backward swing in the tail.
Sideways—Sets the amount of side-to-side swing of the tail.

Twist—Sets the amount of local X axis rotation of each tail object.

Select Multiple Keys group
These controls allow you to select keys according to the foot state at that frame. This is very helpful when you want to apply an increment to all keys of a particular type in a particular track.

- First, select the tracks you want: Left Leg, Right Leg, Body Horizontal, Body Vertical.
- Then select the foot states: Touch, Plant, Lift, Move
- Then click Select to select all the matching keys. Selected keys are highlighted in white in Track View.

Copy/Paste Rollout
Controls on the Copy/Paste rollout let you copy and then paste posture, pose, or track information from one part of a biped to another, or from one biped to a different one. These are the three categories of information you can copy and paste:

- Posture—The positioning of selected biped objects.
- Pose—The positioning of the entire biped.
- Track—The animation track from the selected biped objects.

Note: Your copied information will be stored in the current copy collection.

Copy Collections
Copy collections are designed to make it easier to manage copied posture, pose, and track information by grouping it together. This improves the way copied animation data is organized when it is transferred between files within a session:

- You can display smaller sets of poses, postures, and tracks in the list.
- You can load more than one CPY (page 3–925) file into a single scene.
- You can either append a loaded set to an existing one or replace it entirely.

Note: You must create a copy collection before you can copy a biped's posture, pose or track.

Copy/Paste Buffers
In character studio, you can save multiple copy/paste buffers for each of the three modes: Posture, Pose, and Track. These are available from the Copied Postures/Poses/Tracks drop-down list; the active buffer that the Paste buttons use is the one whose name is visible in the field at the top of the list. A thumbnail view gives a preview of what the active buffer has saved.

Buffers are saved with your MAX scene file, and also remain available in your 3ds Max session, even if you reset.

The default name of a buffer depends on which mode you are in. In the Posture and Pose modes, the name of the buffer consists of abbreviated names of the body parts you selected, followed by a sequence number. For example, RArmRFing1 is the first buffer for the posture or tracks of the biped’s right arm and finger. In Pose mode, the name of the buffer is always “Pose,” followed by a sequence number. For example, Pose03.

To give a buffer a custom name, make it active, highlight its name in the field at the top of the buffer list, and then enter a new name.

For hands-on experience using the Copy/Paste rollout, see the lesson called "Creating a Simple
Freeform Animation” found in the tutorial entitled *Animating with Freeform*.

Tip: When copying poses or postures containing COM data, the Paste Options (page 2–973) are activated.

**Paste and Paste Opposite**

For each mode, there are two paste options: Paste, and Paste Opposite. These are useful in different situations:

- **Paste**—In the Posture and Pose modes, Paste is useful for copying positioning from one biped to a different biped, or for restoring a biped’s positioning at a different frame of an animation. In Track mode, Paste is useful mainly for copying movement from one biped to a different biped.

- **Paste Opposite**—In Posture mode, Paste Opposite is useful for making one limb assume the posture of the other, either at the same frame or different frames. In Pose mode, Paste Opposite reverses the biped’s pose, or applies that reverse pose to a different biped. In Track mode, Paste Opposite can make a biped’s limbs move symmetrically, or apply the opposite of the copied movement to a different biped.

Tip: After pasting a pose or tracks to a different biped, often you have to reposition it. This is easily done with Move All mode.

Note: If a copied pose, posture or track contains sub-animations, they can be pasted to another pose, posture or track as long as the same sub-animations already exist. Otherwise, they are ignored.

**Procedures**

**Example: To load multiple collections between files within a single session:**

1. Create a biped and load some animation onto it.

2. On the Copy/Paste rollout, click Create Collection and rename it **Upper**.

3. Select all of the biped’s links from the spine up and, after making sure you’re in Posture mode (page 2–972), click Copy Posture. Repeat this step for every 10 frames of your animation.

4. Create a new collection and rename it **Lower**.

5. Go to frame 0. Select all of the biped’s links from the pelvis down and copy a posture at every 10 frames.

6. Choose the Upper collection from the Copy Collections drop-down list and save it. Then, select the Lower collection and save it as well.
7. Save your scene and reset it (File > Reset).

8. Create a new biped and load the Upper collection.

9. For every 10 frames, select the biped’s upper body and paste the corresponding posture from the Copied Postures drop-down list. Set a key for each pasted posture.

10. Load the Lower collection and repeat last step with the biped’s lower body selected, setting a key for each posture.

11. Delete the Lower collection.

12. Click Max Load Preferences and make sure both options are checked. Close the dialog and load the saved 3ds Max file.

   Notice that the Copy Collections drop-down list now contains three collections: two Upper collections (one from the current file and one from the incoming) and one Lower collection from the incoming file.

To capture different snapshots:

1. Under the thumbnail snapshot of the Copied Postures group, click Capture Snapshot from Viewport.

2. Rotate your current viewport to different user views and copy a biped posture.

   Notice that your snapshot matches the viewport angle.

3. Click Capture Snapshot Automatically and copy a posture again.

   Notice that your snapshot is displayed from a frontal view.

4. Click No Snapshot and copy another posture.

   The capture has been replaced by a gray canvas.

Example: To maintain copied COM data when pasting poses:

1. Create a biped and then create a new collection. Rename it Poses.

2. Make sure you’re in Pose mode and click Copy Pose at frame 0. Then, go to frame 30.

3. Using tools from the Track Selection rollout (page 2–945), move your biped away from its current position and rotate it in all three axes.
The biped with offset position and orientation

4. In the Paste Options group (page 2–973), enable all three Paste buttons.

5. Click Paste Pose. The biped resets back to its original position and orientation since its copied COM data is maintained. Undo the step.

6. Disable Paste Rotation but keep the other two buttons enabled.

7. Click Paste Pose. The biped resets back to its original position but remains rotated. This is due to the fact that the copied COM orientation is not maintained on paste. Undo the step.

8. Disabled both Paste Horizontal and Paste Vertical but enable Paste Rotation once again. Click Paste Pose.

Example: To maintain COM offsets using By Velocity:

1. Create a biped. Then, on the Track Selection rollout (page 2–945), turn on Body Horizontal.

2. Set a key at frame 0. Then, make sure Pose mode is selected and copy your biped’s pose.

3. Go to frame 10 and move the Body COM 50 units in the Y axis. Set a new key.

4. In the Paste Options group (page 2–973), enable Paste Horizontal but leave By Velocity unchecked.

5. Go to frame 30 and paste your biped’s pose. The biped jumps to the center of your scene. Undo the step.

6. Go back in the Paste Options group and turn on By Velocity. Then, try pasting your pose again. Notice how the biped’s COM position is now offset by another 50 units in Y.

Example: To set TCB/IK Values when pasting postures:

1. Create a biped and then create a new collection. Rename it Hands.

2. Select the biped’s right hand and, on the Key Info rollout (page 2–954), set a key.

3. In the TCB group, set Ease To to 10, Ease From to 50, and all three TCB values to 5.

4. In the IK group, set IK Blend to 0.5 and choose the Object Space option. Then, set another key.
5. Make sure you're in Posture mode and click Copy Posture.

6. Create a new biped next to the original one. Create a box next to its right hand.

7. In the IK group, constrain the biped’s hand to the box by clicking Select IK Object and then selecting the box in your viewport. Keep the Body Space option selected.

8. **Auto Key** On the Keyframing Tools rollout (page 2–962), turn Separate Tracks off for the arms. Then turn Auto Key on.

9. In the Paste Options group (page 2–973), set the Auto-Key TCB/IK Values to Default.

10. Click Paste Posture.

   The hand assumes the copied posture and the key’s TCB and IK values are set to default. Keys are also set for the whole arm.

11. Go to frame 30 and turn Separate Tracks on.
12. Set Auto-Key TCB/IK Values to Copied and paste the posture.

The copied value information is transferred to this new key. The key values are now 10 and 50 for the Ease To/Ease From, 5 for the TCB, and 0.5 for the IK Blend. The box is still the IK Object and Object Space remains selected. Also notice that the hand is the only keyed limb.

13. Go to frame 15, set the Auto-Key TCB/IK Values to Interpolated and paste the posture again.

This new key averages up the values based on the previous and next keys, setting Ease To/Ease From to 5 and 25, TCB to 15 and IK Blend to 0.25. Also, Body Space is selected from the previous key.

**Interface**

- **Create Collections**—Clears the current collection name and the poses, postures and tracks associated with it.
- **Load Collections**—Loads a CPY file and displays its collection name at the top of the Copy Collections drop-down list, making it active.
- **Save Collections**—Saves all the postures, poses and tracks stored within the active collection of the current session in a CPY file.
Delete Collection—Removes the current collection from the scene.

Delete All Collection—Removes all collections from the scene.

Max Load Preferences—Displays a dialog with options for actions to take upon Max file open.

Keep Existing Collections—When on, sets biped to overwrite the existing Copy/Paste Buffer upon load. Default=Off.

Load Collections—When on, sets biped to load the Copy/Paste buffer from the incoming file, appending the current buffer. Default=On.

Posture, Pose, and Track—Choose one of these buttons to choose which kind of information you are copying and pasting. The copy/paste buttons change to indicate the current mode. Default=Pose.

Copy/Paste buttons—These buttons change according to the current mode, as described below in Posture (page 2–972), Pose (page 2–972) and Track (page 2–972).

Delete Selected—Deletes the selected posture, pose, or track buffer. The selected buffer is the active one; that is, the buffer whose name is currently displayed in the Copied Postures/Poses/Tracks list.

Delete All—Deletes all the buffers in the Copied Postures/Poses/Tracks list.

Posture mode

Copy Posture—Copies the posture of the selected biped objects and saves it in a new posture buffer.

Paste Posture—Pastes the posture of the active buffer onto the biped.

Paste Posture Opposite—Pastes the posture of the active buffer onto the opposite side of the biped.

Pose mode

Copy Pose—Copies the current pose of the entire biped and saves it in a new pose buffer.

Paste Pose—Pastes the pose of the active buffer onto the biped.

Paste Pose Opposite—Pastes the opposite of the pose of the active buffer onto the biped.

Track mode

Copy Track—Copies the tracks for the selected biped objects and creates a new track buffer.

Paste Track—Pastes the track or tracks in the active buffer onto the biped.

Paste Track Opposite—Pastes the track or tracks in the active buffer onto the opposite side of the biped.
Copied Postures group

Copied Postures/Poses/Tracks list—For each of the modes, lists the buffers you have copied. The active buffer is the one that will be pasted by the paste buttons. To make a buffer active, choose it from the drop-down list. To change the name of a buffer, make it active, highlight its name, and enter a new name.

Thumbnail buffer view—For Posture and Track mode, displays a schematic view of the parts of the biped in the active copy buffer. For Pose mode, displays a schematic view of the entire biped. This can help you preview the effect of pasting the active buffer.

No Snapshot—When chosen, replaces the snapshot with a gray canvas.

Show/Hide Snapshot—Toggles maximize/minimize of the snapshot view.

Paste Options group

The Horizontal, Vertical and Rotation copy options found in previous versions of character studio have been replaced by the Paste Options. By default, copying poses or postures with the COM selected copies all three COM tracks.

Paste Horizontal/Vertical/Rotation buttons—When turned on, the COM’s Body Horizontal, Vertical or Rotation data are set to be pasted next time you perform a paste operation. Choosing to paste COM data maintains the world space positions and orientation of the copied COM onto the current data tracks. Otherwise, the COM’s current positions and orientation are maintained when the copied data tracks are pasted. See Example: To maintain copied COM data when pasting poses: (page 2–968)

Tip: This choice can be seen as pasting absolute or relative COM animation. The former will overwrite the current data with the copied one while the latter will maintain the current data, ignoring all copied information.

By Velocity—When on, determines the values of the active COM tracks based on the previous trajectory of the COM through the scene. This option is only enabled when the Paste Horizontal/Vertical/Rotation buttons are active. See Example: To maintain COM offsets using By Velocity: (page 2–969)

Note: If there is no previous trajectory from which to gather the velocity data, the COM result is considered as absolute.

Auto-Key TCB/IK Values—Active only in Auto Key mode (page 3–717).
Note: If part of the copied biped is linked to an IK object, that object is not transferable using the copy/paste process. However, the Join to Prev IK Key option is maintained, as well as they Body or Object options. If a copied pose or posture contains an IK Object, the data becomes baked into the biped’s link while keeping the key in Object space.

Note: If part of the pasted biped is linked to an IK object, that object is maintained even while the new pose or posture is honored. In other words, if an incoming pose requires a change in an existing link between a biped limb and an IK object, the link is maintained and adjusted accordingly.

- **Default**—Sets (on the Key Info rollout (page 2–954)) the TCB Ease To and Ease From to 0, and Tension, Continuity and Bias to 25. These settings are unrelated to what was copied or where it is pasted. Any IK key values already set are maintained. Otherwise, values will be obtained from the position in time between the previous and next keys.

- **Copied**—Sets the TCB/IK values to match those from the copied data. If a copied pose or posture is not on a key, the TCB/IK values are based on interpolation from the previous and next keys.

- **Interpolated**—Sets the TCB values to an interpolation from the animation on which you are pasting. If an existing key is being pasted, its TCB values are maintained. Along the same lines, existing IK values are also maintained when pasted. If no key is present, the IK values are set from the position in time between the previous and next keys.

---

**Layers Rollout**

Select the Biped > Motion panel > Layers rollout

Controls on the Layers rollout allow you to add layers of animation above the original biped animation. This is a powerful way of making global changes to your character animation. For example, add a layer to a run cycle and rotate the spine forward at any frame, and it becomes a crouched run. The original biped motion is kept intact and can be viewed by switching back to the original layer. You can view layers individually or as a composite of all the animation in all the layers. Layers behave like freeform animation; the biped can adopt any position.

Tip: You can globally translate both footstep and freeform animation by doing a layered edit on the center of mass (page 2–933). For example, by adding a layer and moving the center of mass you can move a freeform or footstep animation.

With layers, you can easily adjust raw motion-capture data, which contains keys at every frame. Simply add a layer and keyframe the biped. The original layer is displayed as red bones.
Honoring IK Constraints Across Layers

You can maintain a biped's IK constraints across layers by retargeting its hands and feet to the original layer. This assures that the biped’s constrained body parts are honored and locked in place while you make animation changes on the upper layers.

You can also choose to retarget a biped using another one as reference. This is useful when you need to precisely match hands and feet positioning between two animated bipeds with different body proportions.

You can save an animation containing honored constraints across layers in a BIP (page 3–916) file. However, if the layered animation links to another biped as reference, that link is not saved with the animation.

Procedures

Example: To Maintain IK Constraints Across Layers:

This procedure takes into account the fundamentals of animating across layers and expands on the concept of honoring IK constraints.

1. Prepare a biped with IK keys on its feet, and its left hand constrained to an IK object.

2. Select your biped and expand the Layers rollout on the Motion panel.

3. Create a new layer and rename it Low center of mass.

The Retarget Left Arm button in the Retargeting group becomes active, which indicates that the current layer honors the IK constraint of the base layer for this body part.
4. Turn on Auto Key mode (page 3–717).

5. On the Track Selection rollout, turn on Body Vertical.
This selects the biped’s center of mass.

6. Lower the center of mass on the Z axis until the biped’s head is under the base layer’s head display (represented as a red box).

Tip: To avoid deselecting the center of mass, you can lock it by clicking the Selection Lock Toggle (page 3–707) (or press the spacebar).

The entire biped is lowered except its left hand, which remains locked to the object because the current layer retargets it to match the respective IK constraint of the base layer.

7. In the Retargeting group, turn on both Retarget Left Leg and Retarget Right Leg. Then, click Update.

The biped’s IK feet are adjusted to match those of the base layer. The animation keys are updated to reflect the current layer’s retargeted feet.

Tip: If some body parts assume odd positions, simply drag the time slider (page 3–701) a few frames past your current frame, and then drag it back home.
You can continue animating the biped to your liking. Collapse your layers when you are satisfied.

**Example: To Maintain IK Constraints From a Reference Biped:**

This procedure centers on using an animated biped as a retarget reference for another biped with disproportionate body parts. This method is often used when a motion is imported from raw data and adapted to bipeds with different proportions.

1. Prepare an animated biped or load a BIP file onto one.
2. Create a second biped alongside and rename it *Disproportionate Biped*.
3. Select *Disproportionate Biped* and enter Figure Mode.

You can now change the biped's structure.

4. Scale its upper arms and thighs to make them disproportionate from the rest of its body.

Tip: You can quickly select body parts on both sides of a biped if you first select the body part, then click Symmetrical on the Track Selection rollout.
5. ![Exit Figure Mode](image)

6. Keep Disproportionate Biped selected and expand the Layers rollout.

7. ![Click Select Reference Biped](image) Click Select Reference Biped and select your original biped in the viewport. Disproportionate Biped adopts the animation from the reference biped, whose name is now displayed next to the Select Reference Biped button.

8. ![Add a new layer](image) Add a new layer and rename it Retargeted Biped.

9. ![Turn on both Retarget](image) Turn on both Retarget Left Arm and Retarget Right Arm, and then click Update. Both hands precisely match those from the reference biped. The animation keys are updated to reflect the current layer’s retargeted hands.

10. ![Turn on both Retarget](image) Turn on both Retarget Left Leg and Retarget Right Leg. Then, click Update. The feet are correctly retargeted to the reference biped, updating the respective animation keys.
11. Use Previous layer and Next Layer to switch between the original and Retargeted Biped layers. The base layer displays the non-targeted motion while Retargeted Biped shows an adjusted motion that matches both hands and feet from Disproportionate Biped with the original biped.

12. You can continue animating the biped to your liking. Collapse your layers when you are satisfied.

**Interface**

- **Previous-Next Layer**—Navigate through the layers using the up and down arrows.
- **Level**—This field displays the current layer (Level).
- **Active**—Toggles the displayed layer on and off.
- **Name Field**—Type a name to easily identify a layer.
- **Create Layer**—Creates a layer, and the Level field increments. Position the biped to create keys in a layer.
- **Delete Layer**—Deletes the current layer. All layer numbers 'above' the one deleted are decremented by one.
- **Collapse Layers**—Collapses all the layers into layer 0. Legs that stray from the original footsteps in higher layers are "pulled in" to the original footsteps.
- **Snap Set Key**—Snaps the selected biped part to its original position in layer 0 and creates a key. Use this in higher layers to return the selected biped part to the original motion. If a layer has a posture key that bends the character forward at frame 2 and you want to return the biped to its original posture motion at frame 50, use Snap Set Key at frame 50 with a spine object selected. The character will interpolate from its forward posture position to its original posture position between frame 2 and 50.
- **Activate Only Me**—View the animation in the selected layer. Choose Play after turning on Activate Only Me to view a layer’s keys in motion.
- **Activate All**—Activates all the layers. Playing the animation shows a composite of all the layers.
- **Visible Before**—Sets the number of preceding layers to display as stick figures.
- **Visible After**—Sets the number of succeeding layers to display as stick figures.
Key Highlight—Displays keys by highlighting the stick figures.

Retargeting Group

The tools in this group let you animate a biped across layers while maintaining the IK constraints of the base layer. You can also choose to use a different biped in your scene to use as reference for your biped’s retargeted hands and feet.

Biped’s Base Layer—Choose this method to use the IK constraints from the selected biped’s original layer as retarget reference. Default=active.

Reference Biped—Choose this method to use the biped whose name is displayed next to the Select Reference Biped button as retarget reference.

Select Reference Biped—Lets you choose a biped to use as retarget reference for the selected biped. The chosen biped’s name is displayed next to the button.

Retarget Left Arm—When on, the IK constraints of the base layer are honored for the biped’s left arm.

Retarget Right Arm—When on, the IK constraints of the base layer are honored for the biped’s right arm.

Retarget Left Leg—When on, the IK constraints of the base layer are honored for the biped’s left leg.

Retarget Right Leg—When on, the IK constraints of the base layer are honored for the biped’s right leg.

Update—Calculates the selected biped’s hands and feet positions for every set key based on the retarget method (Base Layer or Reference Biped), the active retarget body parts buttons, and the IK Only option.

IK Only—When on, the biped’s constrained hands and feet are retargeted only during the frames on which they are IK controlled. When off, the hands and feet are retargeted during both IK and FK keys. Default=off.

Dynamics & Adaptation Rollout

Select the biped. > Motion panel > Dynamics & Adaptation rollout

The controls on the Dynamics & Adaptation rollout let you specify the way you want to create biped animation. The parameters let you modify gravity strength, dynamic properties for keys generated by newly created footsteps, the number of transform tracks available on the biped, and prevent key adaptation.

Biped Dynamics and Spline Dynamics

These parameters specify how new biped center of mass keys are created and therefore how you want to work with the biped. Turning on Spline Dynamics will create center of mass keys, without gravity and balance calculation, for newly created footsteps. This may feel more familiar to new users who are already familiar with spline interpolation.

Biped Dynamics calculates biped airborne trajectory, knee bend on landing and positions the biped to maintain balance when the spine is rotated. When parameters change, the biped adapts. Turn on Biped Dynamics and use this adaptation to your advantage.

You can always change from one method to the other on a per-key basis or for the entire animation at any time.
GravAccel—Sets the strength of the gravitational acceleration used to calculate the biped’s motion.

By default, this parameter is set to accurately simulate Newtonian gravity as found on the Earth’s surface.

At a value of 0, the biped still runs but the feet hardly get off the ground.

Biped Dynamics—Creates new center-of-mass keys using Biped Dynamics.

Keys for the center of mass (COM) Balance Factor and Dynamics Blend parameters are set to a value of 1. Biped calculates airborne trajectories and biped balance.

Note: Use Dynamics Blend on the Key Info rollout > Body group to set a vertical COM key that is a blend between Dynamics and Spline Interpolation; a value of 1 is full Dynamics, a value of 0 is full Spline interpolation.

Spline Dynamics—Creates new center-of-mass keys using full spline interpolation. All new vertical COM keys are created with Dynamics Blend=0, and all new horizontal COM keys are created with Balance Factor=0.

Footstep Adapt Locks group

Lock specified tracks to prevent automatic adjustments being made to those tracks when footsteps are moved in space or edited in time. All the locks except for Time work for footstep editing in space. Time locks upper body keys when footsteps are edited in time (Track View). Adapt Locks only applies to a Footstep animation, not a freeform animation.

When you move a footstep in space or adjust footstep timing, Biped automatically adapts existing keyframes to match the new footsteps. Adapt locks allows you to preserve the exact position of already created keys for a selected track.

Adapt Locks does not need to be on all the time. For example, if you want to raise all the footsteps along the world Z-axis, without changing the upper body position, turn on Footstep Adapt Locks group > Body Vertical Keys, turn on Footstep mode, select all the footsteps and move them up along the world Z-axis. The footsteps are repositioned, the legs are adapted, but the upper body retains the same motion rather than being raised with the footsteps. Now turn off Body Vertical Keys, and the upper body still retains its original motion.

Use Footstep Adapt Locks > Time to retain upper body motion while editing footstep duration in Track View. When the duration of a footstep is changed, the biped leg will adapt by re-timing the touch, plant, and lift keys. The biped upper body keys will retain their exact motion.

Body Horizontal Keys—Turn on to prevent adaptation of body horizontal keys when footsteps are edited in space.

Body Vertical Keys—Turn on to prevent adaptation of body vertical keys when footsteps are edited in space.
Body Turning Keys—Turn on to prevent adaptation of body turning keys when footsteps are edited in space.

Right Leg Move Keys—Turn on to prevent adaptation of right leg move keys (a leg move key, is a leg key between footsteps) when footsteps are edited in space.

Left Leg Move Keys—Turn on to prevent adaptation of left leg move keys (a leg move key, is a leg key between footsteps) when footsteps are edited in space.

Freeform Keys—Turn on to prevent adaptation of a freeform period in a footstep animation. The biped’s position during a freeform period will not move if footsteps after the freeform period are moved further away.

Time—Turn on to prevent adaptation of upper body keys when footstep duration is changed in Track View.

Note: Leg and foot keys for frames in which the foot is in contact with the ground are always automatically adapted.

Adjusting Vertical Motion (page 2–878)

Figure Mode

Select the Biped > Motion Panel > Biped rollout > Figure mode

While Figure mode is active, you can change biped structure and fit that structure to a character mesh. It can be used for a variety of other procedures as well.

• **Figure mode is a reference position to fit a biped to a mesh.** Use Figure mode to fit a biped to the mesh representing your character. This "reference" or Figure mode position, in which the biped is aligned to the mesh, is necessary when a mesh is linked or attached to the biped with Physique. After the biped is positioned to fit within a mesh, leave Figure mode on during the process of attaching a mesh to the biped with Physique, or when using Select And Link on the 3ds Max toolbar to link the mesh objects of a character to the biped.

  The relationship or "fit" position between the biped and the mesh can always be restored by turning on Figure mode, regardless of which motion file happens to be loaded. After fitting a biped to a mesh in Figure mode, use Save on the Biped rollout to save a figure file (.fig). If you accidentally reposition the biped in Figure mode, load the figure file.
• **Figure mode is used for biped adjustment after a mesh is attached to correct biped joint location.** After using Physique to attach a mesh character to the biped, you may want to reposition a biped limb relative to the mesh. For example, if the biped shoulder joint is too far out relative to the mesh shoulder, then the Physique modifier must be inactivated, the biped limbs adjusted, and then a Reinitialize in Physique must be performed before reactivating the Physique modifier.

• **Figure mode is used for biped adjustment after a mesh is attached to correct posture in a motion file.** Figure mode is also used to make adjustments after a character is attached or linked to the biped. After loading a *.bip* motion file, for example, you may find that the character is hunched too far forward during the entire animation. Rotating the biped’s spine objects in Figure mode will correct the character’s posture for the entire animation. This is a basic procedure where you simply rotate the biped limbs in Figure mode and then exit Figure mode; the posture will be corrected for the entire animation.

• **Figure mode is used to define biped structure.** The Structure rollout (page 2–984) is displayed when you work in Figure mode, allowing you to tailor the biped to your mesh character. After creating a biped, make all of your biped structure changes on the Structure rollout. For example, you may want to use one toe with one toe link if your character is wearing shoes or if animating individual toes do not need to be keyframed individually. Set the biped structure before “fitting” the biped to the your mesh character.

• **Reverse-Knee Characters.** If your character mesh has reverse knees, rotate the biped calves or thighs along the local X axis 180 degrees in Figure mode; the biped local X axis is along the length of the limb. *character studio* assumes you want a reverse knees character if the calves or thighs are rotated past 90 degrees in the local X axis. When Figure mode is turned off, the biped walks, runs, and jumps with reverse knees.

### Notes on Fitting the Biped to a Mesh in Figure Mode

These are quick notes designed to give you a general sense of the issues involved when a biped is fitted to a mesh.

• Use the Structure rollout to set the number of toes and fingers; specify the number of links per finger and toe. One toe with one toe link is often sufficient if your character wears shoes, or if animating individual toes will not be necessary.

• Put the lowest biped spine object at the character’s belt-line.

• Scale the biped fingers to slightly protrude from the character’s hand.
• Rubber Band mode and scale are used to size the biped limbs to fit the biped to a mesh.
• Use the options from the Twist Links group (page 2–987) to transfer twisting animation in the biped’s associated mesh.
• Use Props to represent weapons or tools attached to your character.
• Use Select And Link on the 3ds Max toolbar to link non-deformable (mechanical) objects to the biped. Do this after Physique is applied to prevent Physique from generating extra links (Envelopes). Superfluous envelopes (links) can be turned off in Physique however, so this is not critical.
  Note: Objects like eyeballs and weapons should be linked to the biped after Physique is applied; otherwise links (Envelopes) will extend to these objects when Physique is applied.
• Reposition and use Ponytails on the Structure rollout to animate a character’s jaw, ears, hat, hair and ponytails.
• A saved .fig file can be reloaded if the biped is repositioned in Figure mode by mistake.

Move the first link on each finger to position the fingers relative to the mesh; use local and world coordinate systems for this. Scale the finger links to position the joints. After positioning the thumb, rotate the first thumb link around the local X-axis until the local Z-axis creates a natural rotation for the thumb (refer to the image). A User view and toggling back and forth between a shaded and wireframe display is helpful when fingers are positioned.

---

**Structure Rollout**

Select the biped. > Motion panel > Biped rollout > Turn on Figure mode > Structure rollout

Turn Figure mode on to enable parameters on the Structure rollout. The Structure rollout provides parameters for changing the biped’s skeletal structure to match your character mesh (dinosaur, robot, human and so on). You can also add up to three props to your biped, to represent tools or weapons.

After setting parameters to suit your character, use the Height parameter to scale the biped to the size of the mesh representing your character. This is the first step in fitting a biped to a mesh in Figure mode.

**Procedures**

**To Scale a Biped and a Physique Mesh:**

1. Position a biped within the mesh.
2. Select the biped, turn on Figure mode, and then change the biped height on the Structure rollout.
   The biped and mesh scale together.

**To Skin a Biped with Twist Links:**

This procedure takes into account the process of skinning a character and expands on the concept of using twist links to better deform a skinned mesh.

1. Position a biped within the mesh.
2. Select the biped and turn on Figure Mode.
3. On the Structure rollout, turn on the Twists option.
   This enables the input fields for all biped limbs.
Note: Horse Link is only available if your biped has four leg links.

4. Set Forearm to 5.

Both forearms have five twist links.
Tip: To get a better view of your twist links, you can select the forearms and turn on See-Through in the Display Properties rollout (page 1-55) on the Display panel (or press \texttt{Alt+x}).

See-Through is turned on for the right forearm only.

5. Add a Skin modifier (page 1-791) to the mesh.

6. Unfreeze all the biped twist bones.

7. On the Skin Parameters rollout of the Motion panel, add all the biped bones to the skin except the forearms.

8. Select and freeze the twist bones again.

9. Turn on Edit Envelopes on the Parameters rollout.

10. Select and adjust the Envelopes of the twist bones until the desired behavior is achieved, moving and rotating the hand to test.

</table>

**Arms**—Sets whether or not arms will be generated for the current biped.

**Neck Links**—Sets the number of links in the biped neck. Default=1. Range=1 to 25.

**Spine Links**—Sets the number of links in the biped spine. Default=4. Range=1 to 10.

**Leg Links**—Sets the number of links in the biped legs. Default=3. Range=3 to 4.
Tail Links—Sets the number of links in the biped tail. A value of 0 specifies no tail. Default=0. Range=0 to 25.

Ponytail1/2 Links—Sets the number of Ponytail Links. Default=0. Range=0 to 25.

You can animate hair with ponytail links. Ponytails are linked to a character’s head and can be used to animate other appendages. Reposition ponytails in Figure mode and use them to animate a character’s jaw, ears, nose, or anything that should move with the head.

Unlike the process of selecting the biped hand and dragging to reposition the entire arm, ponytails must be keyed using rotational transformations.

Fingers—Sets the number of biped fingers. Default=1. Range=0 to 5.

Finger Links—Sets the number of links per finger. Default=1. Range=1 to 3.

Toes—Sets the number of biped toes. Default=1. Range=1 to 5.

Toe Links—Sets the number of links per toe. Default=3. Range=1 to 3.

Tip: Characters wearing shoes might need only one toe with one link.

Props 1/2/3—Turns on up to three props, which can be used to represent tools or weapons attached to the biped. By default, prop 1 appears next to the right hand, prop 2 appears next to the left hand, and prop 3 appears centered between in front of the torso.

You can animate props throughout the scene, like any object. You can use 3ds Max controllers to animate props and can then collapse animation onto the prop’s transform controller for use in Mixer, Motion Flow, and Layer editing.

Ankle Attach—Specifies the ankles’ point of attachment along the corresponding foot block. The ankles can be placed anywhere along the centerline of the foot block, from the heel to the toe.

Ankle Attach=0.25 and Ankle Attach=0.5

A value of 0 places the ankle attachment point at the heel. A value of 1 places the ankle attachment point at the toes. Click the spinner up arrow to move the ankle attach point toward the toes. Range=0 to 1.

Height—Sets the height of the current biped.

Use to size the biped to your mesh character before Physique is attached. This parameter is also used in a procedure to scale your character after Physique is attached.

Triangle Pelvis—Turn on to create links from the upper legs to the lowest biped spine object when Physique is attached. Normally the legs are linked to the biped pelvis object.

The pelvis area can be a problem when the mesh is deformed with Physique. Triangle Pelvis creates a more natural spline for mesh deformation.
Triangle Pelvis creates two links that extend from the legs to the lowest biped spine object. A link from the biped pelvis to the lowest spine object is also created. This provides natural deformation to this area after Physique is applied and the character is moving. If you are working on a new character, turn this on before applying Physique. If Bones is turned on in the Display rollout, links from the legs to the lower spine object are visible.

Twist Links group

The bone twist option, previously limited to the biped’s forearm, has been expanded to include all limbs. These settings allow better mesh deformation on skinned models (using Physique (page 2–834) or Skin (page 1–791)) when twisting occurs on animated limbs. Use the Twist Poses rollout (page 2–950) for better control over your twist links.

Note: If a limb has twists, the twist links will control the skin deformation while the base link (the biped’s forearm, for example) drives the animation. Twist links can not be animated.

Twists—Enables twist links for biped limbs. When enabled, twist links become visible but remain frozen. You can unfreeze them using Unfreeze By Name or Unfreeze By Hit on the Freeze rollout (page 1–54).

Upper Arm—Sets the number of twist links in the upper arms. Default=0. Range=0 to 10.

Forearm—Sets the number of twist links in the forearms. Default=0. Range=0 to 10.

Thigh—Sets the number of twist links in the thighs. Default=0. Range=0 to 10.

Calf—Sets the number of twist links in the calves. Default=0. Range=0 to 10.

Horse Link—Sets the number of twist links in the horse link. Default=0. Range=0 to 10.

Note: You must set Leg Links to 4 to enable Horse Link.

Body Type group

The Body Type group lets you select the biped’s body type:

- **Skeleton**—The skeleton body type provides a realistic skeleton which fits naturally into mesh skins.
- **Male**—The male body type provides a silhouette mold based on basic male proportions.
- **Female**—The female body type provides a silhouette mold based on basic female proportions.
- **Classic**—The classic body type is the same as the biped object from older versions of character studio.
Footstep Mode Rollouts

Footstep Mode

Select a Biped. > Motion panel > Biped rollout > Footstep Mode

When Footstep mode is active, you can create or edit footsteps to generate a walk, run, and jump footstep pattern. You also edit selected footsteps in space and append footsteps using parameters available in Footstep mode.

If footsteps are extracted during motion capture import, turn on Footstep mode to edit footsteps in the viewports.

A powerful feature in Biped is the ability to adapt keyframes when footsteps are edited in space or time. The following tracks are influenced in the vicinity when a footstep is edited in space:

- Body Horizontal keys change to step or hop within range of new footstep locations.
- Body Vertical keys change to match possible changes in stride length, since the body must be lower in order to step longer distances.
- Body Rotation keys change to bank into turns created by changes in path curvature or body speed.
- Right or left leg keys in a move state must be adapted to step between new locations.

Note: If for some reason you do not want the adaptation to occur, use the Footstep Adapt Locks settings on the Dynamics & Adaptation rollout (page 2–980) to keep the biped from correcting the body position.

Two additional rollouts display when Footstep mode is active: Footstep Creation rollout (page 2–988) and Footstep Operations rollout (page 2–990).

Footstep Creation Rollout

Select a Biped with footsteps > Motion panel > Biped rollout > Footstep Mode > Footstep Creation rollout

The Footstep Creation rollout, available on the Motion panel when Footstep mode is on, provides controls for creating and editing footsteps. Create a walk, run, or jump footstep pattern using these controls.

Tip: All footsteps created here are inactive; you activate them using Create Keys for Multiple Footsteps on the Footstep Operations rollout (page 2–990).

The timing parameters at the bottom of the rollout work with Create Footsteps (append) and Create Footsteps (at current frame) to change timing for newly created footsteps. These change depending on whether you select Walk, Run, or Jump mode.

Procedures

To create multiple footsteps:

1. On the Biped rollout, click Footstep Mode.
   You are now in Footstep mode, and can create, activate, or edit footsteps.
2. On the Footstep Creation rollout, choose the gait you want to create — Walk, Run, or Jump.
3. Click Create Multiple Footsteps.
   The Create Multiple Footsteps dialog displays for the selected gait.
4. Set multiple footstep parameters, and then click OK.
5. On the Footstep Operations rollout, click Create Keys for Inactive Footsteps to activate the footsteps.
To create footsteps manually, beginning at the current frame:

1. On the Footstep Creation rollout, click Walk, Run, or Jump and set timing parameters for that gait.
2. Click Create Footsteps (at current frame).
3. Click in a viewport to create a footstep. Continue clicking to create more footsteps.
5. Play the animation.

To append footsteps onto the existing footsteps:

1. On the Footstep Creation rollout, click Create Footsteps (append).
2. Click in a viewport to create a footstep. Continue clicking to create more footsteps.
   By default, footsteps alternate from foot to foot. The first click creates a right footstep, the next click creates a left footstep, and so on. Look at the prompt line and the cursor to see which type of footstep will be created next.

Interface

- Footstep Creation

  - Create Footsteps (append)—Turn on Create Footstep mode. Manually place footsteps by clicking in any viewport. Hold the mouse button down after clicking to move a footstep. Release the mouse button to place the footstep.

Each new footstep is appended to the end of the biped’s footstep sequence. Create Footsteps alternates right and left footsteps as you create new ones. Press [Q] to toggle between a left and right footstep.

Newly created footsteps are bright green for right footstep and bright blue for left footstep. Once the footsteps have been activated, the footsteps change color to pastel green and pastel blue.
Each new footstep will start at the same time as the most recent footstep on the opposite side. Alternately, it may start after the end of the previous footstep.

**Timing parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run Footstep</td>
<td>6</td>
</tr>
<tr>
<td>Airborne</td>
<td>9</td>
</tr>
</tbody>
</table>

Use these parameters with Create Footsteps (append) or Create Footsteps (at current frame) to apply timing to newly created footsteps. These parameters are different for each gait and change as you select a different gait.

**Walk Footstep**—(Walk only): Specifies the number of frames a new footstep will be on the ground during a walk.

**Double Support**—(Walk only): Specifies the number of frames when both feet will be on the ground at the same time during a walk.

**Run Footstep**—(Run only): Specifies the number of frames a new footstep will be on the ground during a run.

**Airborne**—(Run and jump only): Specifies the number of frames when the body will be in the air during a run or a jump.

**2 Feet Down**—(Jump only): Specifies the number of frames when two sequential footsteps, on opposite sides, will be on the ground during a jump.

**Footstep Operations Rollout**

Select the Biped > Motion Panel > Biped rollout > Footstep Mode > Footstep Operations rollout

Once footsteps are created on the Footstep Creation rollout, use parameters on the Footstep Operations rollout to activate and deactivate footsteps, and to adjust the footstep path.

**Create Keys for Inactive Footsteps**—Activates all inactive footsteps. Activation creates default keys for any footsteps that do not have them. If a footstep does not have keys, it is displayed as bright green (right foot) or bright blue (left foot). After keys are created for the footsteps, the footsteps change color to pastel green and pastel blue.

**Deactivate Footsteps**—Removes the body keys assigned to the selected footsteps, making those footsteps inactive. The footsteps themselves remain in the scene.

**Delete Footsteps**—Deletes the selected footsteps.

**Copy Footsteps**—Copies the selected footsteps and biped keys to the footstep buffer. Biped will only copy a continuous sequence of footsteps (2,3,4,5...). You can’t copy discontinuous footsteps (3,4,7,8...).
If any footsteps exist that have not been activated, the Copy button is grayed. Activate the footsteps first, then try again.

Tip: Turn on Buffer mode on the Biped rollout to view and edit only the buffered footsteps and biped motion.

A pasted footstep is inactive until it overlaps a like foot and turns red. Mouse up to activate the new footsteps.

Paste Footsteps—Pastes footsteps from the footstep buffer into a scene. The footsteps appear inactive in the scene. Move them so they overlap the active footsteps. When a footstep turns red, mouse up and the pasted footsteps will activate.

Warning: If any footstep in the buffer overlaps in time with a footstep previous to the one onto which you are pasting, a message appears and the paste is not performed. This can occur if the first footstep you are pasting and the original footstep you are pasting onto both have double support periods during the same duration of the footstep. The second pasted footstep and the footstep prior to the one you are pasting onto may overlap in time.

To correct the problem, you may want to move the right edge of the preceding footstep from the original scene to the left, or move the left edge of the second pasted footstep to the right while in buffer mode. Which option you choose depends on what footstep timing and support relations you want to end up with.

Tip: To create a cycle of a motion with alternating footsteps, you must copy and paste at least three footsteps. All body keys between the start of the first step and end of the last step are also copied and pasted.

Bend—Bends the path for the selected footsteps. The path is bent to the left or right as you move the spinner. Other footsteps after the selected footsteps will be moved to maintain their positions relative to the repositioned footsteps.

The Bend spinner is grayed if inactive footsteps are present.

Scale—Changes the width or length for the selected footsteps. The selected footsteps are scaled around the first footstep in the selection.

First select the width or length box (or both), then use the spinner to set the amount of scaling.

If any footsteps exist that have not been activated, the Scale spinner is grayed out. Activate the footsteps first, then try again.

Length—When Length is selected, the Scale spinner changes the stride length of the selected footsteps. Length and Width may both be active at the same time.
Width—When Width is selected, Scale changes the stride width of the selected footsteps. Length and Width may both be active at the same time.

To make the biped walk in place:
• In the First Step group, Set Parametric Stride Length to zero.

To make the biped walk backward:
• In the First Step group, set Parametric Stride Length to a value less than zero.
The absolute value of the Parametric Stride Length is still the length of the stride.

To make the biped speed up as it walks:
1. In the Timing group, click Interpolate.
The controls in the Last Step group are enabled.
2. In the Last Step group, set Time To Next Footstep to be a value less than Time To Next Footstep in the First Step group.
You can adjust the values in either group, or both. The important thing is to make the Last Step a shorter time than the First Step.

Create Multiple Footsteps Dialog: Walk

Select the Biped. > Motion Panel > Biped rollout > Footstep Mode > Footstep Creation rollout > Walk > Create Multiple Footsteps > Create Multiple Footsteps Walk dialog

The Create Multiple Footsteps dialog for the walk gait creates a sequence of walking footsteps using a series of parameters.

Warning: This dialog displays when you select the Walk gait on the Motion panel’s Footstep Creation rollout, then click Create Multiple Footsteps.
Note: The Create Multiple Footsteps dialog appears differently depending on the gait chosen. For other gaits, see Create Multiple Footsteps Dialog: Run (page 2–995) and Create Multiple Footsteps Dialog: Jump (page 2–997).

Procedures
To make the biped walk up or down stairs:
• In the First Step group, set Actual Stride Height to a value other than 0. A value higher than 0 will cause the biped to step up, while a value below 0 will make it step down.

Start Left—Starts the footstep sequence with a left step.
Start Right—Starts the footstep sequence with a right step.
Alternate—Footsteps will alternate between right and left. Alternate is always selected when the
Walk gait is selected. You can only clear Alternate when Run or Jump gaits are selected.

**Number of Footsteps**—Determines the number of new footsteps to be created.

**Parametric Stride Width**—Sets the stride width as a percentage of the pelvis width. A value of 1.0 produces a stride width equal to the pelvis width. A value of 3.0 produces a wide, waddling stride. Changes to this setting automatically change the Actual Stride Width.

Parametric describes the parameter in terms of biped anatomy, and Actual describes the value in 3ds Max units.

![Stride Width=1 and Stride Width=3](image)

**Actual Stride Width**—Sets the stride width in modeling units. Changes to this setting automatically change the Parametric Stride Width.

**Total Distance**—Displays the total distance the footsteps will travel with the current settings. This value cannot be changed directly.

**OK**—Creates footsteps with the current settings.

**Cancel**—Cancels footsteps creation.

**Default**—Resets the values on the dialog to default values.

**Timing group**

**Auto Timing**—Sets timing parameters automatically. Auto Timing affects the following timing parameters for the Walk gait:

- Walk footstep, Double Support

When Auto Timing is selected, these parameters are automatically adjusted to reasonable values. Control the footstep sequence by adjusting the Stride Length and Time To Next Footstep parameters.

When Auto Timing is off, you can control the footstep sequence by adjusting the gait timing parameters, but you can’t change the Time To Next Footstep parameter.

**Interpolate**—Control acceleration or deceleration of the series of footsteps. When this box is selected, a second set of step parameters under Last Step is enabled.

Biped creates footsteps starting with the values of the parameters under First Step and ending with the values of the parameters under Last Step.

By interpolating between the two, Biped produces a footstep series that changes over time.

When Interpolate is cleared, the Last Step parameters are grayed out. Biped creates all the footsteps using only the parameters under First Step.

**Start After Last Footstep**—Appends the newly created footsteps to the end of the existing footstep sequence.

**Start at Current Frame**—Inserts the newly created footsteps at the current frame after the existing footstep sequence, allowing you to make a gap in time before the footsteps start again.

**First Step and Last Step groups**

**Parametric Stride Length**—Sets the stride length for the new footsteps as a percentage of the length of the biped’s leg. The default value of 0.75 gives an average stride of normal proportions.

A value of 1.0 will produce a stride length equal to the leg length, which makes the biped stretch slightly to reach the next step. A value of 0.0 will
make the biped walk in place. A negative stride length will make the biped walk backwards.

When a biped walks backwards, it does not simply reverse the forward movement but maintains the correct foot-state sequence with the toe touching the ground first, followed by the heel.

Adjusting Parametric Stride Length automatically changes the value for Actual Stride Length.

Stride Length=0.75 and Stride Length=1

**Actual Stride Length**—Sets the stride length for new footsteps in 3ds Max units.

The same rules apply as for Parametric Stride Length (described above).

Adjusting Actual Stride Length automatically changes the value for Parametric Stride Length.

**Actual Stride Height**—Sets the rise or fall between footsteps. You can use this parameter to create a set of footsteps going up or down a slope or a stairway.

The value for Actual Stride Height is the difference in height in units between each of the new footsteps. Positive values step up and negative values step down.

**Time to Next Footstep**—Specifies the number of frames in each foot movement cycle. A cycle starts with the frame that a foot touches the ground, continues as the foot lifts and moves, and ends with the frame before the foot touches the ground again. This parameter is only enabled if Auto Timing is on.

**Speed**—Displays the number of units the biped will move per frame. It changes in response to changes in the other parameters but cannot be adjusted directly.

The following two parameters are only enabled when Auto Timing is off.

You can use these parameters instead of Auto Timing to control the speed of the forward motion over the series of footsteps. However, because these parameters both affect the footsteps’ time in contact with the ground, using them to slow down a walk gives the walk a hesitant, ‘stop-go’ quality.

**Walk Footstep**—Specifies the number of frames each footprint will be on the ground during a walk.

The higher the number, the longer each biped foot remains in contact with the ground and, consequently, the slower the speed of the walking motion.

**Double Support**— Specifies the number of frames both feet will be on the ground at the same time during a walk.

The higher the number, the longer the period during which both feet remain in contact with the ground during each walk cycle and, consequently, the slower the speed of the walking motion.
The dotted line surrounds the double-support period (6 frames)

Create Multiple Footsteps Dialog: Run

Select the Biped > Motion Panel > Biped rollout > Footstep Mode > Footstep Creation rollout > Run > Create Multiple Footsteps > Create Multiple Footsteps Run dialog

The Create Multiple Footsteps dialog for the run gait allows you to create a sequence of running footsteps by setting a series of parameters. This dialog will display when Run is selected on the Footstep Creation rollout first, and then Create Multiple Footsteps is clicked.

Interface

Start Left—Starts the footstep sequence with a left step.

Start Right—Starts the footstep sequence with a right step.

Alternate—Turn on to alternate between right and left footsteps. When this box is cleared, all of the footsteps will be either right or left, producing the effect of a hopping run on one foot.

Number of Footsteps—Determines the number of new footsteps to be created.

Parametric Stride Width—Sets the stride width as a percentage of the pelvis width.

A value of 1.0 produces a stride width equal to the pelvis width. A value of 3.0 produces a wide, waddling stride. Changes to this setting automatically change the Actual Stride Width.

Parametric describes the parameter in terms of biped anatomy, and Actual describes the value in 3ds Max units.

Stride Width=1 and Stride Width=3

Actual Stride Width—Sets the stride width in modeling units. Changes to this setting automatically change the Parametric Stride Width.

Timing

Auto Timing—Sets timing parameters automatically.

Auto Timing affects the following timing parameters for the Run gait:

- Run footstep, Airborne

  When Auto Timing is selected, these parameters are automatically adjusted to reasonable values. You control the footstep sequence by adjusting the Stride Length and Time to Next Footstep parameters.

  When Auto Timing is off, you can control the footstep sequence by adjusting the gait timing parameters, but you can’t change the Time to Next Footstep parameter.

Interpolate—Control acceleration or deceleration of the series of footsteps. When this box is selected, a second set of step parameters under Last Step is enabled.

Biped creates the footsteps starting with the values of the parameters under First Step and ending with the values of the parameters under Last Step.
By interpolating between the two, Biped produces a footstep series that changes over time.

When Interpolate is cleared, the Last Step parameters are grayed out. Biped creates all the footsteps using only the parameters under First Step.

**Start After Last Footstep**—Appends the newly created footsteps to the end of the existing footstep sequence.

**Start at Current Frame**—Inserts the newly created footsteps at the current frame after the existing footstep sequence allowing you to make a gap in time before the footsteps start again.

**First Step and Last Step**

**Parametric Stride Length**—Sets the stride length for the new footsteps as a percentage of the length of the biped’s leg. The default value of 0.75 gives an average stride of normal proportions.

A value of 1.0 will produce a stride length equal to the leg length, which makes the biped stretch slightly to reach the next step. A value of 0.0 will make the biped run in place. A negative stride length will make the biped run backwards.

When a biped runs backwards, it does not simply reverse the forward movement but maintains the correct foot-state sequence with the toe touching the ground first, followed by the heel.

Adjusting Parametric Stride Length automatically changes the value for Actual Stride Length.

**Actual Stride Length**—Sets the stride length for the new footsteps in 3ds Max units.

The same rules apply as for Parametric Stride Length (described above).

Adjusting Actual Stride Length automatically changes the value for Parametric Stride Length.

**Stride Height**—Sets the rise or fall between footsteps. You can use this parameter to create a set of footsteps going up or down a slope or a stairway.

The value for Actual Stride Height is the difference in height in units between each of the new footsteps. Positive values step up and negative values step down.

**Time to Next Footstep**—Specifies the number of frames in each foot movement cycle. A cycle starts with the frame in which a biped foot touches the ground, continues as the foot lifts and moves, and ends with the frame before the foot touches the ground again. This parameter is only enabled if Auto Timing is on.

**Speed**—Displays the number of units the biped will move per frame. It changes in response to changes in the other parameters but cannot be adjusted directly.

The following two parameters are only enabled when Auto Timing is off. You can use these parameters instead of Auto Timing to control the speed of the forward motion over the series of footsteps.
Run Footstep—Specifies the number of frames each footstep will be on the ground during the run. The higher the number, the longer the biped foot remains in contact with the ground and, consequently, the slower the speed of the running motion.

![Footsteps 2 and 3 are on the ground for 5 frames each](image)

Airborne—Specifies the number of frames the body will be in the air between footsteps. The higher the number, the longer the biped hangs in the air for each step and, consequently, the slower the speed of the running motion.

The Create Multiple Footsteps dialog for the jump gait allows you to create a sequence of jumps by setting a series of parameters. It displays when you’ve selected Jump on the Footstep Creation rollout on the Motion panel, and then click Create Multiple Footsteps.

### Create Multiple Footsteps Dialog: Jump

Select the biped. > Motion Panel > Biped rollout > Footstep Mode > Footstep Creation rollout > Jump > Create Multiple Footsteps > Create Multiple Footsteps Jump dialog

The Create Multiple Footsteps dialog for the jump gait allows you to create a sequence of jumps by setting a series of parameters. It displays when you’ve selected Jump on the Footstep Creation rollout on the Motion panel, and then click Create Multiple Footsteps.

### Interface

- **Start Left**—Starts the footstep sequence with a left step.
- **Start Right**—Starts the footstep sequence with a right step.
- **Alternate**—When this box is selected, the footsteps will alternate between right and left. When this box is cleared, the footsteps will be either right or left steps, causing the biped to hop on one foot.

### Number of Footsteps—Determines the number of new footsteps to be created.

### Parametric Stride Width—Sets the stride width as a percentage of the pelvis width. A value of 1.0 produces a stride width equal to the pelvis width. A value of 3.0 produces a wide, waddling stride. Changes to this setting automatically change the Actual Stride Width.

### Timing

- **Auto Timing**—Sets timing parameters automatically. Auto Timing affects the following timing parameters for the Jump gait:
  - 2 Feet Down, Airborne

When Auto Timing is selected, these parameters are automatically adjusted to reasonable values. You control the footstep sequence by adjusting the Stride Length and Time To Next Footstep parameters.

When Auto Timing is off, you can control the footstep sequence by adjusting the gait timing...
parameters, but you can’t change the Time To Next Footstep parameter.

**Interpolate**—Allows you to control acceleration or deceleration of the series of footsteps. When this box is selected, a second set of step parameters under Last Step is enabled.

Biped creates the footsteps starting with the values of the parameters under First Step and ending with the values of the parameters under Last Step.

By interpolating between the two, Biped produces a footstep series that changes over time.

When Interpolate is cleared, the Last Step parameters are grayed out. Biped creates all the footsteps using only the parameters under First Step.

**Start After Last Footstep**—Appends the newly created footsteps to the end of the existing footstep sequence.

**Start at Current Frame**—Inserts the newly created footsteps at the current frame after the existing footstep sequence, allowing you to make a gap in time before the footsteps start again.

**First Step and Last Step**

**Parametric Stride Length**—Sets the stride length for the new footsteps as a percentage of the length of the biped’s leg. The default value of 0.75 gives an average stride of normal proportions.

A value of 1.0 will produce a jump length equal to the leg length, which makes the biped stretch slightly to reach the next step. A value of 0.0 will make the biped jump in place. A negative stride length will make the biped jump backwards.

When a biped jumps backwards, it does not simply reverse the forward movement but maintains the correct foot-state sequence with the toe touching the ground first, followed by the heel.

Adjusting Parametric Stride Length automatically changes the value for Actual Stride Length.

**Actual Stride Length**—Sets the stride length for the new footsteps in 3ds Max units.

The same rules apply as for Parametric Stride Length (described above).

Adjusting Actual Stride Length automatically changes the value for Parametric Stride Length.

**Actual Stride Height**—Sets the rise or fall between footsteps. You can use this parameter to create a set of footsteps going up or down a slope or a stairway.

The value for Actual Stride Height is the difference in height in units between each of the new footsteps. Positive values step up and negative values step down.

**Time to Next Footstep**— Specifies the number of frames in each foot movement cycle. A cycle starts with the frame a particular foot touches the ground, continues as the foot lifts, moves, and ends with the frame before the foot touches the ground again. This parameter is only enabled if Auto Timing is on.
The following two parameters are only enabled when Auto Timing is off. You can use these parameters instead of Auto Timing to control the speed of the forward motion over the series of footsteps.

2 Feet Down—Specifies the number of frames that the left and right footsteps will be on the ground during the jump. The higher the number, the longer the pause between each jump and, consequently, the slower the speed of the jumping motion.

Airborne—Specifies the number of frames the body will be in the air during the jump. The higher the number, the longer the biped hangs in the air for each jump and, consequently, the slower the speed of the jumping motion.

Convert to Freeform or Footsteps Dialogs

Select the Biped. > Motion panel > Biped rollout > Convert

When you click Convert on the Biped rollout of the Motion panel, a Convert To dialog displays:

Speed—Displays the number of units the biped will move per frame. This changes in response to changes in the other parameters but cannot be adjusted directly.

The following two parameters are only enabled when Auto Timing is off. You can use these parameters instead of Auto Timing to control the speed of the forward motion over the series of footsteps.

2 Feet Down—Specifies the number of frames that the left and right footsteps will be on the ground during the jump. The higher the number, the longer the pause between each jump and, consequently, the slower the speed of the jumping motion.

Airborne—Specifies the number of frames the body will be in the air during the jump. The higher the number, the longer the biped hangs in the air for each jump and, consequently, the slower the speed of the jumping motion.

convert to Freeform or Convert to Footsteps, depending on the animation method of the currently loaded motion. Use Convert to Freeform for unrestricted key editing or Convert to Footsteps to take advantage of footsteps.

Note: By default, jumping or airborne periods between footsteps are calculated by character studio based on gravity strength (GravAccel) and time between footsteps. Biped elevation during these jumping and airborne periods will be lost when converting to freeform from footsteps (unless you create a vertical COM key in the airborne period in the footstep animation), a freeform animation uses spline interpolation for the center of mass position and does not account for gravity. Elevation in airborne periods is restored if you convert back to footsteps.

When to Use Convert

- Use Convert after using Save Segment in Motion Flow mode to save a script as a .bip file. Exit Motion Flow mode, load the .bip file and click Convert to extract footsteps. Save Segment applies IK Blend values of 1 to the biped foot keys for the keys at footsteps. If a freeform animation is part of the script in Motion Flow mode, and you want to convert the entire script motion to footsteps, then use the Save Keys at every Frame option in Save Segment and use Load Motion Capture File on the Motion Capture rollout. This will allow you to extract footsteps using the proximity method.

- Use Convert if you are working on a footstep animation and want to switch to a freeform animation.

- Use Convert if you have started a freeform animation and want to convert to a footstep animation. In order to convert a freeform animation to a footstep animation, the file must be properly set up by locking the feet to world space using IK Blend before converting to
footsteps. When creating freeform animations, you should set your leg keys to IK Blend=1.0 during the periods you want the feet to be planted, and set the move keys to IK Blend=0.0. This will insure that the feet are locked and rid of unnecessary foot sliding as the body is moved. When converting, if the leg keys have been set up this way, Biped will extract footsteps during any duration where IK Blend=1.0.

**Interface**

**Convert to Freeform dialog**

*Generate a keyframe per frame*—Creates keys at every frame.

Note: Converting footsteps to freeform creates foot IK Blend values of 1 for the biped feet for the original footstep keys. This simplifies keyframing by putting the feet into world coordinate space, which prevents them from sliding when the biped is moved. These foot IK Blend values are also used when you click Convert (on the Biped rollout) to convert back to footsteps.

**Convert to Footsteps dialog**

*Generate a key per frame*—Creates a key at every frame, and extracts footsteps based on foot IK Blend values equal to 1. Save Segment in Motion Flow mode stores the active script as a .bip file without footsteps. The biped foot keys are assigned IK Blend values of 1 for the original footstep keys. After loading a .bip file saved using Save Segment in Motion Flow mode, use Convert (on the Biped rollout) to extract footstep.

Convert is also useful if you have already converted from footsteps to freeform in which case the feet are assigned an IK Blend value of 1 for the keys that represented footsteps.

**Flatten Footsteps to Z=0**—The entire biped is repositioned to place the footsteps at Z=0.

Note: An IK Blend value of 1 for the feet puts them into world coordinate space and prevents them from slipping while setting biped keys in a freeform animation.

**Footstep Mode Dialog**

Graph Editors menu > Track View – Dope Sheet > Right-click on a footstep track.

Right-click anywhere in the Footstep track in Track View (Dope Sheet) to display the Footstep Mode dialog. This is a modeless dialog and can remain visible while you continue to work in Track View.

This dialog allows you to:

- Control the duration information displayed with the footsteps.
- Create a freeform period between footsteps.
- Select the right or left edges of footstep blocks or the whole block.
Footstep Mode Dialog

Interface

Edit Footsteps—In this mode (which is the default), you can edit the biped’s footsteps to change their duration; start and end frames; airborne duration; and so on.

Edit Free Form (no physics)—In this mode, you can edit the biped’s body keys for the frames at which the biped is airborne.

Free Form suspends the physically based dynamics that normally control biped motion. This is essential when you want to make the biped fly, or sit down, or fall over. Note that the freeform period must be between footsteps.

Footstep Number Display group

The footstep blocks can have any one of four time settings displayed for them. You can only show one of these at a time.

The footstep step number is always displayed on the footstep blocks (in boldface).

Start and End Frame—Displays the start and end frames of the footstep (from Touch to Lift). Biped displays just the start frame if the footstep block is too small to show both. Zoom in to see both start and end numbers.

Both footsteps 0 and 1 begin at frame 0 and end at frame 19.

Start Frame—Displays just the start frame number (Touch).

Both footsteps 0 and 1 begin at frame 0.

Duration—Displays the number of frames that the foot is in contact with the ground (from Touch to Lift).

Both footsteps 0 and 1 are in contact with the ground for 20 frames.

Double Support—Displays the number of overlapping frames in which both feet are in contact with the ground.

You can also turn on the following two numbers for the intervals between the footsteps.
display both numbers at the same time by selecting both boxes.

Footsteps 0 and 1 share a double-support period of 20 frames.

No Support—Displays the number of frames that the whole biped is airborne; that is, the frames in which neither of the feet have any contact with the ground.

The no-support period between frames 3 and 4 and 4 and 5 is 12 frames.

Foot Air Duration—Displays the number of frames that each foot has no contact with the ground.

The foot air duration for the left footstep track between frames 3 and 5 is 31 frames.

Footstep Edge Selection group

Select Start of Footstep—Selects the leftmost key for the current footstep selection.

Select End of Footstep—Selects rightmost key for the current footstep selection.

Track View (Biped)

Graph Editors menu > Track View - Dope Sheet or Track View - Curve Editor

In this Track View - Dope Sheet view of a walking motion, footsteps are represented by colored squares, footstep numbers appear in boldface inside the squares, in between the start and end frames of the footstep. The numbers between the colored boxes represent foot-air duration.

Biped and Track View

The Dope Sheet can be used to create and adjust biped keyframes, edit biped footsteps, and specify freeform periods. Biped keys display as dots on the tracks. Footsteps display as squares that can be moved in time. Biped dynamics and footsteps work together; if footsteps are moved in time, Biped adapts leg keys and vertical positions to account for the editing. There are a couple of restrictions: you can’t overlap footsteps on the same track, or move footsteps into negative time.

The Curve Editor can be used to make adjustments to biped keyframe animation. The Curve Editor is a Track View mode that allows you to work with motion expressed as function curves on a graph. It lets you visualize the interpolation of the motion, the object transformations that the software creates between the keyframes. You can see and control the motion and animation of the objects in the scene using the keys found on the curves. You can even draw curves directly on the graph.
Footsteps in Track View - Dope Sheet

By default, left leg footsteps are blue and right leg footsteps are green. Inactive footsteps are more saturated values of blue and green, active footsteps are pale blue and green. The left edge of each footstep block indicates when a foot touches a footstep (Touch State). The right edge of each footstep block indicates the last frame the foot is on a footstep (Lift State). The space between two footsteps indicates an airborne state for the foot (Move State). The period between the Touch and Lift States is the Plant State.

Editing Biped Keys in Track View

Track View is often used to change multiple keys simultaneously. For example, to change Dynamics Blend for all the vertical centers of mass keys, select all the vertical keys, display the TCB (Tension, Continuity, and Bias) dialog by right-clicking over the selected keys and change the Dynamics Blend parameter.

Right-click a key in Track View to display the TCB dialog.

Separate Tracks

By default, Biped stores all of the toe, foot, and calf keys in the thigh track. The finger, hand, forearms, and upper-arm keys are stored in the clavicle track. All the spine keys are stored in the spine 01 track. Although you can see all of these objects in the Track View hierarchy, they have no transform track, unless you enable them in the Separate Tracks group of the Keyframing Tools rollout (page 2–962).

For example, if you rotate a biped foot, a key is created in the biped thigh track. This optimized approach works well in many cases. If your animation requires extensive hand and finger keyframing, turn on Arms on the Keyframing Tools rollout; all of the arm transform tracks are now enabled, down to the first finger link on each finger. Now if you delete an upper arm key, your finger-hand animation is preserved.

How Dynamics and Footsteps Relate

When footsteps are created, a footstep track displays in Track View – Dope Sheet. Footsteps appear as blue and green blocks, laid out to show their exact placement in time. If you compare the center of mass tracks to the footsteps, you will notice that frames where leading and trailing edges of the footsteps occur also have keys for the center of mass Body Vertical and Horizontal tracks. These keys contain dynamics information used by character studio to calculate airborne body position relative to gravity, and leg bend on landing and balance. Biped Dynamics is the reason you do not need a vertical center of mass key at the top of a jumping motion or at the bottom of dip when the biped lands from an airborne period.

Click and drag the middle of a footstep to move it in time. Click and drag one edge of a footstep to stretch the footstep in time.

Note: Changing the duration of footsteps or moving them relative to one another may change the “support relationships” of the footsteps. Whenever the support relationships change, Biped generates new keys and deletes any existing leg keys in the airborne period between the edited footsteps.
Because of Biped Dynamics, no keys are necessary for the highest part of this jumping motion or for the dip when the biped lands; character studio calculates the trajectory of the Body. This image shows the center of mass trajectory. Keyframes are white squares on the trajectory.

Simply change gravity (GravAccel on the Dynamics & Adaptation rollout), and the jumping motion is flattened. The biped looks like it’s hopping on the moon.

By selecting half the footsteps in Track View - Dope Sheet and moving them to the right in time, the biped has to jump higher to account for the added time to the next footstep. Notice that the yellow dots, representing frames, are tightly bunched together; there are more frames in this airborne period.

Here, the center of mass is moved in the Z plane. Now the biped heel never hits the ground; the biped appears to do a jump using just its toes. Here, character studio understands that you want to override the calculated trajectory and position the keyframe yourself.

Moving Keys
You can use the time slider to move one Biped key past another. The result is as if the original key were deleted from its original frame and copied to the new frame. Simply drag the key to the new frame, then release the mouse to complete the move. The key’s various Biped properties (ease values, TCB values, IK blend, and so on) are not changed.

You can move a key past either the following key or the previous one. You can also move it past multiple keys. If you move a key onto a frame where a key is already present, it replaces the original key.

In Track View, you can move a key past another using the transform track. You can also scale keys forward in time such that some keys are now past the keys that weren’t scaled. If keys move into negative time, a warning reminds you that keys in negative frames can’t be used for footstep animation: a workaround is to set new keys in the negative frames, instead of moving existing ones.

If you change the key to Euler control (on the Quaternion/Euler rollout) and then drag it past another, the key’s tangent type is maintained.

If you add a layer (on the Layers rollout), set two keys, and then move the first one past the second one, this also works.

Freeform Animation
It is left to you to create all the keys in a freeform animation; Biped Dynamics is not active and does not recalculate body position. Balance Factor is active in a freeform animation. A completely freeform animation contains no footsteps.

To start an entirely freeform animation, simply create a biped and begin keyframing.

Note: Once you initiate a freeform animation, you cannot add footsteps to it in Footstep mode. You can, however, convert your freeform animation to a footstep animation using Convert on the Biped rollout.

You will often want a freeform period in a footstep sequence; for a walk then fall type of motion for
example. In cases like this, a freeform period is specified between footstepis in Track View using the Footstep Mode dialog (page 2–1000). A combination of footsteps and freeform is often required when motion capture data is imported. A freeform period is created using controls in the Footstep Mode dialog and display as a yellow boxes between footsteps in Track View.

Right-click the footstep track to display the Footstep Mode dialog; here you specify a freeform period, select multiple footstep edges, and select footstep numbering display options.

Biped Color-coded Keys and Trajectories

Biped uses color coding for IK keys in three places: Track View, Track Bar, and when trajectories are displayed in the viewports. Also, depending on the types of keys, trajectories themselves can be color coded. The color coding helps you visualize when IK and FK are in use, and transitions between them.

This topic describes color coding of non-COM (page 3–920) tracks. For information about COM key color coding, check here.

Note: Most of the information presented in this topic describes new functionality in 3ds Max 9 Extension 1. The only legacy functionality discussed here concerns color coding of IK keys in Track View.

Color-coded Keys in Track View and on the Track Bar

Biped IK keys as displayed in Track View and on the track bar use the following color scheme:

- orange for planted keys
- yellow for sliding keys
- blue for body-space IK keys with a non-zero value for IK Blend
- All other keys use the default color: gray.

Color-coded biped keys in Track View and on the track bar

Visualizing Pivot Trajectories and Keys

To view trajectories for Biped parts in the viewports, go to the Motion panel and on the Biped rollout > Modes And Display sub-rollout, or on the Key Info rollout, turn on Trajectories.

To make Biped pivots easier to interpret and manipulate, Pivot trajectories and their keys are represented in the viewport during IK periods and display in the color of the associated key type:

- orange for planted keys
- yellow for sliding keys
- blue for body-space IK keys

Tip: One way to create a body-space IK key is to set a regular IK planted or sliding key, and then, at that frame, on the Key Info rollout > IK section, choose Body. Or you can convert an FK key that’s already set to Body by increasing its IK Blend value above 0.0.

During FK periods the node trajectory and its keys display in purple (the same keys are gray on the track bar).

During FK/IK blend periods the trajectory of the resulting blend is displayed and its color is determined by the amount of the blend; for example, a blend of 0.5 to a sliding key results in a trajectory that is a 50:50 blend of yellow and purple.
Because pivots are located in all extremes of the hands and feet, their trajectories discontinuous when both FK and IK periods are employed. The following figure shows a simple example of this. During the planted IK periods, the pivot trajectories show just the keys on the heel and toe (because the keys are planted, each pivot stays in place), and during the FK periods the trajectories are derived from the foot's node pivot location. This gives you more-detailed information about the animation that is driving the foot.

In the following illustration, while the biped walks, the right hand reaches up to touch something in IK, as shown by the yellow trajectory, made by two sliding IK keys. Later, the biped touches its own face, using body space IK, as shown by the bright blue keys. The color transition in the trajectory from purple to blue indicates a changing blend from FK to body-space IK, showing the interpolated value of the IK Blend parameter.

Following is a chart showing the result of going from one key type to another. The last three rows of the chart show transitions between object and body space that produce pure FK. In the past, it was hard to know what type of trajectory these combinations produced. The new trajectory colors clarify the result.

In the chart, the letters have the following meanings:
- O: object space
- B: body space
- IK: a key where IK Blend > 0. It is always accompanied by the space: O or B.
- FK: a key where IK Blend = 0, no matter what space it’s in

Note: When separate tracks exist for either a limb or its digits, the FK trajectory of the bone base is always drawn, regardless of whether the trajectory display is set to Bone Base or Bone Tip on the Display Preferences dialog (page 2–944).

### Biped Shortcuts

The table in this topic shows the default keyboard shortcuts for **character studio**. To customize your shortcuts, use the path specified above.
Use the Keyboard Shortcut Override toggle (page 3–872) on the main toolbar to enable the character studio keyboard shortcuts.

All character studio keyboard shortcuts activate when the Motion panel is active and the Keyboard Shortcut Override button is active.

* Not available for customization in the Customize User Interface dialog.

Using the Workbench

The Workbench is a customized version of Track View that you use for correcting and improving biped animation. It extends the functionality of existing curve editors by giving you different options for visualizing and manipulating curves, and provides filters to perform general rotation, position and other biped-specific operations. Curves can be analyzed for error conditions and filters applied to the identified keyframes, or selected biped tracks can be filtered to generally improve the motion of a track without errors.

See also

Navigating the Workbench (page 2–1010)
Workbench Workflow

Here are the overall steps you would follow to use the Workbench to analyze and fix a biped for problems

1. Create your animation and play it. Visually note anything that jumps out at you as being wrong or incorrect.
2. With the biped selected in the viewport, open the Workbench by clicking the Workbench button in the Biped Apps rollout on the Motion panel.
3. Select the biped body part that seems to have the problem. You can select it in the viewport, or from the list in the Select panel. Be aware that some biped objects share tracks. For example, all the objects in a leg or an arm share a single track.
4. On the Analyze panel, choose an analyzer from the drop-down list. Set the analysis conditions, then click Analyze. Any errors the analyzer encounters will be displayed in a list at the bottom of the Analyze panel. The Curve view also indicates the problem area by displaying a vertical bar.
5. On the Fix panel, select the errors you want to fix. Select the filter for the fix, adjust its parameters, and then click Fix Selected. You can select the errors one at a time, or in any combination. You can sort the errors by time or body part, depending on what kind of fix is needed.

If the results aren't satisfactory, try changing the parameters and fixing again. Repeat the process until you find the combination of parameters that correct the movement. Or try a different fixer or filter (these are described later in this topic).

Animation Workbench Tools

The Animation Workbench provides three types of tools to use with biped animation: analyzers, fixers, and filters.

Analyzers

These are used to find out-of-the ordinary properties in your animation. Certain analyzers parse the waveform of your motion tracks and detect variation from the curves. There are two detectors available that do this; Noise and Spike. There are also analyzers for finding and fixing knee conditions, specifically knee wobble and extension.

For more information, see Analyze Panel (page 2–1017).

Fixers

Fixers address problems found by the analyzer. The fixers work by running a specified operation over just the analyzer result. They don’t change the complete animation, just areas around the problem.

For more information, see Fix Panel (page 2–1020).

Filters

Filters are operations that are performed on the specified animation tracks. Unlike fixers, they affect the complete specified time interval, not just the analyzer result.

The Rot Smoothing, Rot Blurring, Rot Boosting, Adv Rot Smoothing, Pos Smoothing, Pos Blurring and Pos Boosting filters are all variants of one
type of filter. They all share the same parameters: Width and Damping.

For more information on these filter types, see Filters Panel (page 2–1023).

Navigating the Workbench

The Animation Workbench, a customized version of Track View, uses some of the standard Track View controls, and adds new ones of its own. The areas of the Workbench interface include:

- The Tab panels: Select, Analyze, Fix, and Filter
- The Curve view, with Track View toolbars for key selection, manipulation, and view navigation.
- The Workbench toolbar, with tools for choosing Coordinate space, display of sub-animations, and tools to hide the Tab area and controller list.

Each section of the Workbench User has specific navigation techniques.

See also
Selecting Workbench Tracks (page 2–1011)

Navigating the Tab Panel

Simply click the tabs to move from one panel to another. The tools displayed change with each panel. The overall workflow is left to right for the tabs, and top to bottom within each panel. Selections are displayed in lists: clicking a name in a list selects that entry. Operations are usually performed by clicking a button at the bottom of the panel.

Tip: The Tab panels can be hidden once the operations are performed and you don’t need to see the panels any more. Click the Tab button in the Workbench toolbar to hide the panel display.

Displaying the Controller List

Click the Controllers button in the Workbench toolbar to display the Controller List. When the controller list is displayed you can select multiple tracks as you like, right-click them and assign controllers using the pop-up menu. You can also get to properties for controllers such as Noise that don’t have keyframes.

See also
Selecting Workbench Tracks (page 2–1011)

Navigating the Curve View

Use the standard 3ds Max Track View navigation tools to adjust the view of curves in the Curve view window. Zoom, Zoom Extents Horizontal and Vertical, and Pan are often used to get a better view of an entire curve, or a portion of a curve. As a default, the curve view automatically displays the curve of whatever biped object is selected in the viewport.

The Workbench window can be resized to make it easier to work with curves. You can float or hide
toolbars to give you even more room. You can dock toolbars left and right as well.

**Docking the Workbench**

You can dock the Workbench in a viewport. With the Workbench open, right-click the viewport’s label and choose Views > Extended, then choose Biped Animation Workbench. The open workbench docks in the viewport.

Tip: This works best if you change your layout so there is at least one horizontal viewport.

**Selecting Workbench Tracks**

As a default behavior, whatever biped part is selected in the viewport will have its curves displayed in the Curve view. You can also use the Select panel (page 2-1016) to select biped parts by name. The functionality of the Select panel is derived from the 3ds Max Select Objects dialog; you can invert selection sets or enter names into the Selection field to find a track.

You can also use the controller window as a selection mechanism. With the Controllers list visible you can click on track entries there to work on the curves.

Note: Sometimes a curve will not appear in the display at first. Click Zoom Extents Horizontal and Zoom Extents Vertical to make sure the curve can be seen.

The Workbench toolbar lets you choose the type of curve to display and the coordinate space in which it is displayed. For example, if you know you are dealing with rotational errors, choose an Rot or Quat type curve. If it is an error of positional data, choose Pos.

If you open the Track View – Curve Editor or expand the track bar while you have the Workbench open, you will see a simultaneous display. The views are all synchronized, so selecting a track in one graph editor selects it in all.

When using footstep animation, you can see the footstep keys by opening a Track View – Dope Sheet window.

**Show Layered Edit**

You can affect a layered range of keys by turning on Show Layered Edit. This is a special Workbench mode that extends the edit to affect keys surrounding the one you are editing. It works like soft selection in 3ds Max but gives you greater control over the displacement. It can help you blend your edits into existing motion.

**Analyzing Curves**

Once you have selected curves, you can analyze them to discover error conditions. You choose between four kinds of detectors; Noise, Spike, Knee Wobble or Knee Extension. You can also
select only a the portion of a curve to analyze. Perform the analysis by clicking the Analyze button. The errors are found based on the detector’s parameter settings. If no errors are found, try adjusting the parameters and clicking Analyze again. Lowering the Standard Deviation value will yield more errors.

When an error has been detected, the biped part name appears in the Analyze Results list. If multiple errors are detected, the entry displays a number that tells how many errors were found. Errors are also displayed in the Curve View as vertical brown lines.

Once errors have been located, you can use the tools on the Fix panel to correct those keys and the keys around them. Or you can use the error location merely to identify the keys, then manually make changes using standard interpolation techniques. Right-clicking a key in the Curve view will display the properties dialog that allows for such adjustments.

The basic fixing techniques involve smoothing, blurring, boosting, or key deletion. This is similar to audio-editing software, where you view music as a waveform, and then edit the waves in various ways to alter the sound. Similarly, the motion of the biped body parts, as defined by position and rotation tracks, can be evaluated for error conditions regarding speed, angle, acceleration, or change of direction.

Of course, you can also fix curves manually. You can select the key on the curve and move it, using the standard Track View key buttons duplicated in the Workbench, such as Move, Slide, Scale or Delete Keys.

You can achieve a layered range of keys by turning on Show Layered Edit. This is a special Workbench mode that extends the edit to affect keys surrounding the one you are editing. It works like soft selection in 3ds Max but gives you greater control over the displacement. It can help you blend your edits into existing motion.

Fixing Curves

After you have selected curves and analyzed them for error, you can use the tools found on the Fix panel to process the curves and reduce the errors. The fixes are determined by which type of fixer you choose, and the parameters you set for that fixer. Clicking Fix Selected or Fix All at the bottom of the panel performs the Fix operation.

In general, fixes are made either by changing the position or value of a key, or by removing the key.

Workbench User Interface

The Animation Workbench is a tool for working with biped function curves. It is a customized version of Track View, with many of the same toolbars and buttons, plus some new ones.

In addition to the standard Track View features, the workbench has tools to help you select curves, analyze them for errors, and automatically fix those errors based on various settings. This is especially useful when working with motion-capture data, or other animation that has many keys.
Of course, you can also display and manipulate function curves for bipeds in the standard 3ds Max Track View and expanded track bar, as well. However, you have access to the automatic error-analysis tools only in the Workbench.

Note: On the time slider or in Track View, you can move one Biped key past another. See Moving Keys (page 2–1004).

The Animation Workbench displays rotation curves in local biped space for both quaternion and euler rotations. This improves the speed of curve manipulation since the whole biped doesn’t need to be calculated in order to draw a single curve.

Note: This does not affect position curves, which are still evaluated in world space.

Note: Curve display will only change for certain objects in COM space: base of spine, neck, clavicles, upper arms, upper thighs, and feet.

Procedures
To display the local rotation curve of an animated spine link:
1. Create a biped and select its upper spine link.
2. Set a key at frame 0.
3. Go to frame 10 and rotate the spine link 30 degrees in the local Z axis.
4. Open the animation workbench.

Only one curve is displayed because the upper spine rotates in local space by default.

5. Select the biped’s head.

Notice how there are no curves in the workbench because the head doesn’t inherit the spine link’s rotation and doesn’t have an internal rotation of its own.
Chapter 14: character studio

Interface

1. Tab panels (Select, Analyze, Fix, and Filter).
2. Display Tab panels
3. Display Controllers list
4. Workbench toolbar
5. Curve View
6. Curve View toolbars (same as Track View toolbars).

Animation Workbench Tab Panel

The Animation Workbench Tab panel consists of four panels:

- **Select panel**—Provides tools to select curves for biped body parts. For more information on the Select panel user interface, see Select Panel (page 2–1016).

- **Analyze panel**—Evaluates the curves for error conditions. For more information on the Analyze panel user interface, see Analyze Panel (page 2–1017).

- **Fix panel**—Provides a variety of methods to be applied to the errors located by the analysis. For more information on the Fix tab user interface, see Fix Panel (page 2–1020).

- **Filters panel**—These are a special type of fixer that perform an operation over each key that is selected. When no keys are selected it performs the operation over the whole curve rather than using the results of the last error analysis. Use this when you have errors visible in the motion, but the fixer refuses to find them. For more information on the Filter panel user interface, see Filters Panel (page 2–1023).

Use the Tab button on the Workbench toolbar to display and hide the Tab panel.

Curve View

To the right of the Tab area is the Curve View, where keys and curves for the selected biped parts are displayed. This is the same as the Track View Key window.

Curve View Toolbars

Directly above and below the Curve View are some of the standard 3ds Max Track View toolbars. They give access to tools used to navigate the view and manipulate the keys. The toolbars below the Curve View are used for selection and navigation; toolbars above the Curve View are used to move, slide, and scale keys; to scale values; and to add new keys.

Animation Workbench Toolbar

The Workbench toolbar extends the toolset found in the 3ds Max Track View. The Workbench toolbar includes:

- **Tab**—Hides or displays the Workbench Tab panel, which contains the tools for automated error analysis and correction fixers and filters.

- **Controllers**—Hides or displays a controller-window hierarchy list. This is the same list you see in standard Track View with the same right-click menus used to assign controllers.

- **Curve Type**—Determines which curves are displayed for the selected object.

  Rot Curve, Rot Speed, Rot Accel, and Rot Jerk curves represent rotation.

  Pos Curve, Pos Speed, Pos Accel and Pos Jerk curves represent position.

  Note: Choosing Rot Curve or Pos Curve turns on Show Biped Rotation Curves or Show Biped,
Position Curves, respectively, in the Biped toolbar of the Curve Editor (page 2–535).

Noise curves represent random position and rotation.

Each biped part can show any of these curves, except for the Horizontal and Vertical tracks, which show only positional curves, and the Turning track, which shows only angular curves.

The Axis order drop-down lets you choose the order in which the rotation curves are calculated. Curves in previous version of Character Studio were always drawn in XYZ. This ordering follows the same rules as the Euler Axis Order on the Quaternion/Euler rollout (page 2–948).

When manipulating position curves, the Workbench allows the curves to be displayed relative to the World, the Biped Root, or any object in the scene as picked via the arrow button.

**World**—Displays curves relative to the World.

**Biped Root**—Displays curves relative to the biped root object (COM).

**Scene Root**—Displays the curves relative to a selected object. Turn on the arrow button, then click the object in a viewport. The name of the object will be displayed on the button.

The **X, Y, and Z buttons**—Choose which curves of the selected object are displayed in the Workbench.

**Note:** Toggling X, Y, or Z also toggles the corresponding Biped toolbar button of the Curve Editor (page 2–535).

The **180 limit**—Sets the Quat Curve to display as “clamped” between 180 and −180 degrees, instead of accumulated. Default=off.

**Draw While Moving**—Sets the Workbench to update the curves as you move keys. When off, curves display as optimized lines until you release the mouse after moving or changing a key. Default=on.

**Show Layered Edit**—When on, displays a graphic tool for adjusting sets of keys along a curve within a range.

To set the range, click to highlight one of the square handles, and then drag it. As you drag, the handle follows the curve.

**Enable Sub Anims**—When on, sets the Workbench to display the curves of the selected part’s subanim in combination with the position or rotation curves. Subanims are list controllers which can be added to provide additional animation controls to biped body parts. Default=off.

**Biped Key Manipulation**

Interactive key manipulation behaves in the Workbench much as it does in Track View. The difference is that you can’t move keys beyond other keys. This has always been a restriction of biped animation.
See also

*Working with the Workbench (page 2–1008)*

---

**Select Panel**

Select a biped body part. > Motion panel > Biped Apps > Workbench > Select panel

The Select panel of the Animation Workbench provides tools for selecting bipeds or biped components. The selected biped part’s animation tracks can be manipulated using curves displayed in the Workbench, or by using the Analyze, Fix, and Filter panels to automatically identify errors and fix them.

The objects whose curves might be displayed are set using the selection drop-down list. To change the curves that are displayed go into the Controller window and select the curves you want to see.

Once the selection has been made, you can hide the entire Tab area by clicking the Tab button on the Workbench toolbar. This will give you more room to work on the curves in Curve View.

The functionality of the Select tab is similar to the standard 3ds Max Select Objects dialog (page 1–78).

See also

*Analyze Panel (page 2–1017)*

---

**Procedures**

To display a biped body part curve in the Workbench, do one of the following:

- On the Select panel of the Animation workbench, click to highlight the name of the body part in the scrollable Selection list.
- On the Workbench toolbar, turn on Controllers. In the hierarchy list, highlight the body part track whose curve you want to see.

**To hide or unhide the Tab panel:**

1. Click the Tab button on the Workbench toolbar.
   - The Tab panel disappears from view.
2. Click the Tab button again.
   - The Tab panel returns to view.

---

**Interface**

---
Selection field—Enter the name of the biped part you want to locate. That name (if found) will be highlighted in the Selection list. This is useful when you can’t find an entry by scanning the list.

You can use the question mark and asterisk characters as wildcards, in order to select multiple objects at once.

Selection list—The Selection list displays all the body parts of all the bipeds in the scene.

You can use the Shift, Ctrl, and Alt keys to build selection sets, as in the rest of 3ds Max.

All—Selects every entry in the list.

None—Clears the selection so nothing is highlighted.

Invert—Selects everything not highlighted in the list.

Subtree group

Display—Indents the list to show the biped hierarchy. Default=off.

Select—When on, selecting one biped part selects both it and all of its children. Default=off.

Named selection list—When you create a named selection in the scene, the named selection becomes available.

Select From Viewport—When Select From Viewport is on, you can click the biped body parts directly in the viewport, rather than from the list. The curves are immediately displayed in the Workbench Curve View. This is handy if you don’t know the name of the part you need to select.

Analyze Panel

Select a biped body part. > Motion panel > Biped Apps > Workbench > Analyze panel

The Analyze panel provides tools to evaluate the curves for the selected biped parts, and review them for certain error conditions. It can spot spikes and noise in the curves, and locate specific keyframes that are responsible for discontinuous motion. The errors are displayed as brown lines over the curves, and are also listed at the bottom of the Analyze panel. You can then use the Fix panel to automatically fix errors, or you can fix errors by manually adjusting keys and curves in Curve view.

Brown lines on the curve show the errors.

Procedure

To analyze a curve:

1. On the Select panel, choose the biped object whose curve you want to correct.

   You can select the object from the Select list, in a viewport, or from the Controllers hierarchy.

2. Click the Analyze tab, then on the Analyze panel, choose the analyzer you want to use from the drop-down list.
By default, there are two choices: Noise Detector and Spike Detector.

3. If you chose Noise Detector, choose the appropriate Property from the Property drop-down list.

4. Click Analyze.

Any errors found are displayed in the error result list at the bottom of the panel. The errors also appear in Curve View as brown lines.

5. If no errors are found, try lowering the standard deviation value or make sure you have used the appropriate property when using the noise detector. For example, if you have a problem with the rotation of a leg, but you choose a Pos property, that error will not be detected.

### Interface

![Interface](image)

#### Parts to Analyze—These options choose which parts to analyze:

- **Display Curve Part**—When this is turned on, the curve displayed is analyzed.

- **Selected Parts**—When this is turned on, the parts selected in the list or viewport are analyzed. Use this when you want to analyze an entire biped without displaying all of the curves in Curve View.

#### Time to Analyze—Sets the range to be analyzed.

You can choose either:

- **Entire Animation**—Analyzes the entire animation.
Note: This is independent of the active 3ds Max time segment.

- **Active Time Segment**—Choose this to use the active time segment, as set by the 3ds Max Time Configuration dialog.
- **From / To**—These values let you specify a range with a particular start and end frame.

**Analyzers group**

**Analyzers drop-down list**—Lets you choose which analyzer will be used to evaluate the curves. Each analyzer can present its own individual settings. The default choices are Noise Detector and Spike Detector.

- **Noise Detector**—Finds any large change in the animation, either rotational or positional as determined by the standard deviation value. Can operate on specific curves as determined by the selection in the Property drop-down list, regardless of what’s currently visible in the Workbench.

  Note: It’s important to understand that noise isn’t always bad. For example, in an animation of a person waving his hand, then suddenly punching: the movement from the wave to the punch, plus the pullback from the punch might be analyzed as noise, but it is noise that you want. The Workbench will identify the magnitude of these changes by showing you the acceleration and the jerk curves. By being selective with the fixers, you can smooth out only what you want to improve, and maintain the rest.

- **Spike Detector**—Finds any large change in the animation that also contains a change in direction (in quaternion space or position space). Can operate on all curves in the animation, regardless of what’s currently visible in the Workbench. The analysis can be adjusted for Standard Deviation, which is the degree to which the animation departs from its overall pattern.

- **Knee Wobble**—Finds knees that wobble or shake when a foot is planted. Uses Frame and Fluctuation parameters to determine what is a wobble error.

- **Knee Extension**—Finds knees that overextend when a foot is planted. Uses a Knee Angle parameter to determine extension errors.

**Property drop-down list**—Lets you choose the criterion that the Noise detector uses to evaluate the curves errors. Use Rotational (Rot) properties to analyze rotational errors; use Position (Pos) properties to analyze move transform errors.

Note: This control is not available when using the Spike detector.

Options in this drop-down list include:

- **Rot Speed**—Looks for noise in the speed of the rotational angle.
- **Rot Accel**—Looks for noise in the acceleration of the rotational angle.
- **Rot Jerk**—Looks for noise in the jerk of the rotational angle.
- **Pos Speed**—Looks for noise in the speed of the position.
- **Pos Accel**—Looks for noise in the acceleration of the position.
- **Pos Jerk**—Looks for noise in the jerk of the position.

**Standard Deviation**— Lets you set the degree to which the animation can depart from its overall pattern. For example, in data that is somewhat noisy by design, the Noise detector can look for instances that are noisier. Lower deviation numbers mean higher sensitivity, and thus more errors found.
Error results list—Displays all errors that the analyzer finds. Each entry lists the name of the body part, and the number of errors found.

Errors are also graphically highlighted with a vertical brown line in Curve View. Clicking an error entry in the list highlights that error in Curve View.

Analyze—Click to perform the analysis.

Clear Results—Deletes the results of the latest analysis.

Load Analysis File—Loads the results of a previous analysis.

Save Analysis—Saves the results of the latest analysis.

See also
Fix Panel (page 2–1020)

Fix Panel

Select a biped body part. > Motion panel > Biped Apps > Workbench > Fix panel

The Fix panel provides access to the tools that can be used to automatically fix the errors found by the Analyze panel (page 2–1017). There are a variety of methods available to automatically correct errors found in the curves. Smoothing, blurring, and removing keys are all options. Or, if you prefer, you can correct the error manually by adjusting the interpolation per key, using standard 3ds Max methods. You can move the key on the curve, or right-click the key to access interpolation controls.

A fix is performed as a specific operation on a particular biped body part or set of parts, at a particular time. In general, fixes either change the value of a key or remove keys to produce corrected motion.

The results of last analysis are displayed in the Analyze Results list. Clicking an error in the list once displays the error as a yellow line over the curve; clicking the error twice updates the viewport scene, making the error the current frame. Errors can be sorted by Part or by Time.

Fixes can be applied to individual errors, selected errors, or to all errors at once.

See also
Filters Panel (page 2–1023)

Procedures

To fix an individual error:
1. Click to highlight the error in the Analyze Results list.
2. Choose the Fixer type you want to use to automatically correct the problem.
3. Click Fix Selected.
4. Observe the change in the Curve View.
5. Play the animation in the viewport to see if the error has been corrected.
6. If the error is still visible, try changing the parameters for the fixer, or choosing a different fixer. The Rot and Pos fixers attempt to solve the problem by changing the values of the keys; if they don’t give good results, it might be more useful to use the Remove Keys fixer.

To fix multiple errors:
1. Highlight all the errors in the Analyze Results list.
2. Choose the Fixer type you want to use to automatically correct the problem.

You can use the [Ctrl] and [Shift] keys to add to your selection.
3. Click Fix All.

4. Check your results as you would if you were fixing a single error (see the previous procedure).

To remove keys from curves automatically:

1. On the Select panel, highlight the biped part in the list.
   Tip: If you don’t know the name of the part, you can click it in a viewport.

2. On the Analyze panel, choose the appropriate Analyzer type and properties.

3. Click Analyze.
   The errors are listed in the error result list at the bottom of the panel.

4. On the Fix panel, choose the errors you want to fix.

5. In the Fixers drop-down list, choose Remove Keys.

6. Click Fix Selected.
   The removed keys will disappear from the list and the curves.
   Tip: You can use the Delete Keys option and Interval Width to create a threshold for deleting keys. If you turn on Delete Keys, the Interval Width will disallow the deletion of keys based on that value. Use this if too many keys are being deleted when you use Remove Keys.

### Interface

![Image of interface](image)

**Analyze Results error list**—Displays all the errors the analyzer found for the selected body parts. The name of the Biped object is preceded by the frame number of the error. Clicking the error once displays a yellow line at that frame in the Curve View. Clicking it twice moves the current frame to match the error frame number: the viewports display that frame as well.

**Sort by:**—Lets you change the display of the error analysis results.

- **Part**—Displays all the errors for each part listed together.
- **Time**—Displays all the errors sequentially, by frame.
Fixers—Determines the method used to attempt to correct the errors found by the analyzer. In general, try to match the fixer to the analyzer property. For example, if you have selected a Noise detector with Rot Speed, then choose a Fixer with Rot in the name as well. The exception to this would be when it is obvious that you’d prefer to remove the keys rather than modify them. In that case, choose a Remove Keys fixer.

Fixer options include:

- **Rot Smoothing**—Corrects rotational errors by smoothing the curve. Can be repeated on the same track for greater effect. Slower than blurring, but keeps more detail of the curve.

- **Rot Blurring**—Corrects rotational errors by blurring the curve. Good if you just want to keep the general shape of the animation, but don’t want to keep the details. May remove too much detail in the animation.

- **Adv Rot Smoothing**—Works even better than the normal smoothing filter when it comes to only modifying large changes. Can be repeated on the same track for greater effect. It is the slowest filter, great at keeping minute details, which can be very important, especially with motion-capture data when you want to keep nuances.

- **Pos Smoothing**—Corrects move transform problems by smoothing the curve. Can be repeated on the same track for greater effect. Slower than blurring, but keeps more detail of the curve.

- **Pos Blurring**—Corrects positional problems by blurring the curve. Good if you just want to keep the general shape of the animation, but don’t want to keep the details. May remove too much detail in the animation.

- **Remove Keys**—Fixes errors by deleting keys based on an interval setting.

- **Knee Wobble**—Fixes knees that wobble or shake when a foot is planted. Uses a Knee Angle value as criteria for error status.

- **Knee Extension**—Fixes knees that overextend when a foot is planted. Uses a Fluctuation value as criteria for error status.

Fixer parameters

Individual fixers display different parameters. These include:

- **Width**—Determines how much of the curve is affected around the keyframe.

All the Fixers except for Remove Keys display this parameter.

- **Damping**—Determines how the fix is blended into the existing curve. Changes how effective the fixer should be. A higher value, the more dramatic the change. A damping value of 1.0 is normal behavior.

All the Fixers except for Remove Keys display this parameter.

- **Delete Keys**—Allows for selective key removal based on Interval Width. When Delete Keys is used, keys are removed only within the Interval Width. When Delete Keys is not turned on, Remove Keys will remove the selected keys without considering the Interval Width.

This parameter is available only when Remove Keys is the fixer.

- **Interval Width**—Determines the number of frames around the error to consider when deleting keys.

This parameter is available only when Remove Keys is the fixer.

- **Knee Angle**—Sets the rotation angle to determine what constitutes knee extension errors.

If the knee is planted and its angle is less than or equal to the knee limit angle, then the
center-of-mass object is adjusted so that the knee angle doesn’t exceed the limit. This parameter is available only when Knee Extension is the fixer.

- **Frames**— Determines the interval to consider for fluctuation evaluation. This parameter is available only when Knee Wobble is the fixer.

- **Fluctuation**— Establishes the amount of change allowed before knee wobble is identified. This parameter is available only when Knee Wobble is the fixer.

If the knee angle fluctuates greater than the fluctuation threshold for 2 knee angles within the frame interval threshold, then the knee’s angle is changed, so that the wobble is eliminated.

**Fix Selected**— Applies the Fixer operation to the selection in the Analyze Results error list.

**Fix All**— Applies the Fixer operation to all the errors, whether they are selected in the Analyze Results error list, or not.

### Procedure

**To filter a track:**

1. Choose the parts you want to filter: either just a particular curve, or an entire selection.
2. Choose the time range you want to filter: either the entire biped animation, the active time segment, or a custom range.
3. Choose the filter you want to apply. Adjust its individual parameter as required.
4. Click Filter at the bottom of the panel.
5. Observe the effect on the graph in the Curve view.
6. Play the animation in the viewport and observe the difference, if any. Click Undo if the results are unexpected or incorrect.

Filters are simply operations that can be performed to different biped body parts. They are similar to fixers, but they operate over an interval of time rather than the results of the last analysis. Thus you can use a filter without analyzing. Certain filters share parameter types and functionality as fixers, though the values are not shared and are distinct for each filter. Use a filter whenever you want to perform a general operation over a body parts motion, like smooth out or boost up some noise."
Parts to Filter—Sets the filter to act on either the display object or the entire selection of objects.

- **Display Curve Part** —Sets the filter to act on the displayed object curves.
- **Selected Parts** —Sets the filter to act on the active selection. Especially useful when working on the whole biped.

Time to Filter—Sets the range to be filtered to either the entire biped animation, the active time segment, or a custom range of frames.

- **Entire Animation** —Sets the time to filter to be the complete biped animation (disregarding the active time segment).
- **Active Time Segment** —Sets the time to filter to be the scene active time segment. You set the active time segment in the 3ds Max Time Configuration dialog.
- **From / To** —Sets the time to filter to a custom range of frames.

Filters group

**Filters list**—Choose the filter to use from this drop-down list.

The available filter types include smoothing, blurring, boosting, key reduction, and subanims.

- **Rot filters** work in quaternion rotation space, and modify the quaternions of the specified animation tracks.
- **Pos filters** work in the specified positional coordinate system, and modify the positions of the animation tracks.
- **Blurring** —Uses basic Gaussian filters that take a weighted average over the width. Blurring filters are good for smoothing out noise, but can also over-smooth areas that aren’t noisy. See Blurring, Smoothing, and Boosting parameters (page 2–1025), below.
- **Smoothing** filters, on the other hand, are much better than blurring filters for keeping the general shape of the track or curve. They affect only areas that have big changes. The drawback of the smoothing filters is that they don’t change the curve as dramatically as the blurring filters do, so sometimes you’ll need to run the smoothing filter multiple times to smooth out a particularly noisy area.
- **Adv Rot Smoothing** works even better than the normal angular smoothing filter when it comes to modifying only large changes and not small ones. See Blurring, Smoothing, and Boosting parameters (page 2–1025).
Filters Panel

(There is no comparable “advanced position” fixer or filter.)

- **Boosting**—Boosting filters are the opposite of blurring filters. They increase, rather than decrease, changes in the track. Boosting filters are helpful if you want to make a track have more exaggeration or a little more jerkiness.

  See *Blurring, Smoothing, and Boosting parameters* (page 2–1025).

- **Sub Anims**—The Sub Anims filter manages sub-animation of biped objects. Clicking a button that corresponds to a transform (Position, Rotation, or Scale) displays a dialog that lets you assign a controller to that transform. Assigning a controller in this way assigns it only to the selected biped parts. This is very handy for adding controllers to multiple biped parts all at once. Also includes the ability to enable or disable the three list controllers selectively, and avoids creating SubAnims, where they already exist.

  See *Sub Anim parameters* (page 2–1025).

- **Key Reducer**—Creates tracks with fewer keys, by removing certain keys based on tolerance and key spacing parameters. This works similarly to how key reduction works during motion-capture import.

  See *Key Reducer parameters* (page 2–1026).

- **Knee Wobble**—Corrects knees that wobble or shake when a foot is planted. If the knee is determined to wobble by the filter, the center of mass object is adjusted to eliminate the wobble.

- **Knee Extension**—Corrects knees that overextend when a foot is planted. If the knee extension is identified by the filter, the center of mass object is adjusted to eliminate the extension.

**Blurring, Smoothing, and Boosting parameters**

- **Width**—Width is the size of the filter kernel width in frames. It tells you how much of the animation is taken into effect when filtering a specified keyframe.

- **Damping**—The Damping value changes how effective the filter should be. A higher value, the more dramatic the change. A damping value of 1.0 is normal filter behavior.

**Sub Anim parameters**

<table>
<thead>
<tr>
<th>Filters:</th>
<th>Sub Anims</th>
<th>Position</th>
<th>Rotation</th>
<th>Scale</th>
</tr>
</thead>
</table>

- **Enable**—Turns Position, Rotation, and Scale subanims on and off for the selected biped parts.

- **Collapse**—Adds the subanim animation of the selected biped part to that part’s Transform controller.

  Note: When you choose the Sub Anims filter, the Filter button at the bottom of the panel disappears. That’s because the operations of this filter are immediate.

- **Don’t Delete**—Maintains the subanim in the list as it’s collapsed onto the biped.

- **Per Frame**—Sets keys at every frame of the collapsed controller.

The Sub Anims filter tools are also available from the Motion panel. You can assign controllers...
to a biped subanim, and then collapse it by right-clicking and choosing Properties. The difference between using this in the Motion panel and in the Workbench is that you can apply subanims to multiple biped objects in one step when using the Workbench filter.

**Key Reducer parameters**

*Create Key Per Frame*—When on, the filter creates a key per frame for every selected track. Default=off.

*Tolerance*—Sets the maximum angular or positional deviation for a track (other than a COM track). Default=3.0.

Values are in units of translation for position tracks, and in degrees for rotation tracks.

*Key Spacing*—Sets the minimum number of frames between keys (other than COM keys).

Tolerance is computed first, then Minimum Key Spacing computes further key reduction.

*COM Parameters*—These Tolerance and Key Spacing settings affect key reduction only on specified center-of-mass (COM) tracks (horizontal, vertical, or rotational).

*Filter*—Click to apply the active filter to the selected tracks.

---

**Using Motion Flow**

Select a biped > Motion panel > Biped rollout > Motion Flow Mode

Motion flow mode provides an area to graphically arrange clips into a network and tools to create and edit transitions between clips. Motion flow mode is used to organize clips into a network to animate one or more bipeds. The network of clips are joined together by transitions. A motion flow script is used to associate the network of clips with the biped. To animate one biped, you create a single motion flow script that uses a list of clips to animate the biped. To animate multiple bipeds or a crowd of bipeds, you can either use the random method of clip selection or a delegate-driven approach.

The random method simply picks clips at random and creates random scripts for each biped. This approach works well if the bipeds are standing still or are far apart and don’t require collision detection: a crowd of cheering fans at a ball game, for example. Clip and transition percentages are set with the *Create Random Motion* command during motion synthesis.

When dealing with a crowd, or multiple bipeds that are close together, the delegate driven approach is the best solution. This approach uses
many parameters to simulate moving crowds and incorporates collision detection, surface follow and other parameters. The delegate–driven method uses a network of clips, but instead of random selection, it bases clip selection on a delegate’s speed and heading. In a delegate–driven crowd simulation, clips are arranged to follow a logical sequence. For example, the first clip could be a start walk clip, then a walk loop, then a branch to a turn right and turn left clip, then a slow to stop clip and so on. During motion synthesis, this arrangement is used to pick clips. If the software senses a collision ahead, the slow to stop clip is selected, or a veer to avoid clip is chosen. For a detailed breakdown of delegate driven crowd behavior, see Crowd Animation (page 2–1154).

The first step in Motion Flow mode is to add clips in the Motion Flow Graph for use in scripts. Clips represent all or part of a .bip file. Transitions represent different paths through the clips in the Motion Flow Graph. A transition looping back to the same clip represents a cycle or loop.

If a biped is using a shared motion flow, then the title of the graph dialog says “Shared Motion Flow Graph”, followed by the name of the shared motion flow. Shared Motion Flows are used to control multiple bipeds with one shared motion flow.

There are two ways to create clips in the Motion Flow Graph (page 2–1045). The first method lets you create a blank clip to which you later assign a .bip file. The second method lets you create multiple clips at once by choosing a several .bip files at once.

**Procedures**

**To create clips in the Motion Flow Graph:**

1. Select a biped
2. Open the Motion panel.
3. Click Motion Flow Mode on the Biped rollout.
4. On the Motion Flow rollout, click the Show Graph button to open the Motion Flow Graph.
5. On the Motion Flow Graph toolbar, click Create Clip
6. Click a few times inside the Motion Flow Graph dialog.
   
   Clip icons will appear in the Motion Flow Graph (page 2–1045) that are named clip1, clip2 and so on.
7. On the Motion Flow Graph toolbar, click Select Clip/Transition.
8. Right-click over a clip in the window.
A clip dialog is displayed.

9. Click Browse in the clip dialog and choose a .bip file.

10. Optionally, set the start and end frame and then click OK.
The selected icon displays the clip name in the Motion Flow Graph (page 2–1045); this clip can now be used for script creation.

11. Click Select Clip/Transition again and load .bip files for the other clips you created.

Creating Transitions

Transitions, shown as arrows, link motion files (clips) together to create longer character animation and crowd simulations. Transitions can be created manually with the Transition Editor (page 2–1051) or automatically by the software.

To create optimized transitions, use the Optimize Selected Transition on the Motion Flow Graph toolbar or Optimize Transition in the Transition Editor. By default, minimum motion loss is used to compute transitions. Optimized transitions use an
Creating Transitions

algorithm that minimizes foot sliding. Optimized transitions take longer to compute but yield very fluid results.

Crowd simulations can use dozens of motion clips so automatic creation of optimized transitions can be a big time saver. Whether you plan on animating one or many bipeds using Motion Flow mode you’ll need transitions between the clips in the Motion Flow Graph.

Procedures

To create transitions using From > To or To < From method:

1. On the Motion Flow rollout, click the Show Graph button to open the Motion Flow Graph.

2. On the Motion Flow Graph toolbar, click Create Multiple Clips.
   
   The Open dialog appears. Use it to choose the location of your .bip files.

3. While holding down the [Ctrl] key, choose multiple clips in the Open dialog.
   
   Once processed, multiple clips appear in Motion Flow Graph (page 2–1045).

4. Turn on either Create Transition From -> To or Create Transition To <- From on the Motion Flow Graph toolbar and then drag from one clip to another clip.

To create transitions using Create All Transitions:

1. On the Motion Flow rollout, click the Show Graph button to open the Motion Flow Graph.

2. On the Motion Flow Graph toolbar, click Create Multiple Clips.
   
   The Open dialog appears. Use it to choose the location of your .bip files.

3. While holding down the [Ctrl] key, choose multiple clips in the Open dialog.
   
   Once processed, multiple clips appear in the Motion Flow Graph dialog.

4. Click Select Clip/Transition and select all the clips you added.

5. To create transitions between all the clips, turn on Create All Transitions on the Motion Flow Graph toolbar.

6. At the Biped dialog, click Yes to create transitions from each selected clip to itself.
Possible transitions from one clip to the next are automatically generated.

To optimize transitions in the Motion Flow Graph:

1. After adding several clips and transitions, click Select Clip/Transition and select one or more transitions.

2. On the Motion Flow toolbar, click Optimize Selected Transitions. The Transition Optimization dialog is displayed.

3. Click OK. A processing bar scrolls across the top of the Motion Flow Graph (page 2–1045).

Creating a Motion Flow Script

A script is a list of clips (.bip files) that controls the character you are animating. To create a script, add clips to the Motion Flow Graph (page 2–1045), then click Define Script in the Scripts section of the Motion Flow rollout (page 2–1045), and click a sequence of clips in the Motion Flow Graph. Default transitions are assigned if no transitions exist between the clips. The clip names and starting frame numbers display in the list on the Motion Flow Script list.
Creating a Motion Flow Script

A sample script as it appears in the Scripts group on the Motion Flow rollout

Random scripts vary the order of the clips found in the Motion Flow Graph. Scripts are run in a top-down order to animate the character. Click Play to view scripted motions on the biped.

Tip: As the length of a script varies, use Alt+R to set the Active Time in 3ds Max to the length of the script.

Once a script is put together, you have additional controls that let you adjust the starting frame, the starting X, Y, or Z locations and the starting rotation of the animation.

Procedure

To create a Motion Flow script:

1. Create a motion flow graph with three or more motion files.

For information on how to set up the graph, see To create multiple clips in the Motion Flow Graph (page 2–1028).

2. In the Scripts section of the Motion Flow rollout, click Define Script, and then select a sequence of clips from the Motion Flow Graph dialog (page 2–1045).

As you select the clips in the Motion Flow Graph dialog, they are added to the script list.

3. Give the script a new, descriptive name.

Adding a descriptive name is less confusing if you ever append Motion Flow Editor files together.

Note: Transitions are automatically made in the Motion Flow Graph as you add clips to the script.
Chapter 14: character studio

4. Click the Play Animation button to see the biped move to the scripted clips.

5. Click Stop Animation. Change the Start Frame setting to 25 and move the frame slider. Now the biped will hold its start position until frame 25, then start moving.

6. Change the Start Position X:, Y:, or Z: setting. These settings let you control the position of the footsteps that the character follows.

7. Change the Start Rotation setting to 90. Often, the footsteps in a .bip file are not oriented in the direction you want. This setting lets you adjust which direction the character faces.

Note: Each Start setting affects the entire animation. You cannot select a single entry in the script and make a change to affect only that clip.

Saving, Loading, and Appending Motion Flow Graphs

To save Motion Flow Editor files:
1. Create a Motion Flow Graph with three or more motion files.

   For information on how to set up the graph, see To create multiple clips in the Motion Flow Graph (page 2–1028).

2. Create a script using the clips in the Motion Flow Graph.

   For information on how to create a script, see To create Motion Flow Scripts (page 2–1031).

Scripts, transitions, and clip references are saved in a Motion Flow Editor .mfe file, for later editing. A .mfe file allows you to save a Motion Flow and script from one biped and load it onto another biped.
Saving, Loading, and Appending Motion Flow Graphs

3. Click the Save File button to save a Motion Flow Editor .mfe file. The Save As dialog is displayed.

4. Specify a folder on your hard drive where you plan to store your Motion Flow Editor files.

To load Motion Flow Editor files:
1. Select a biped.

2. Open the Motion panel.

3. On the Biped rollout, click Motion Flow mode.

4. On the Motion Flow rollout, click Load File. The Open dialog is displayed.

5. Navigate to the folder where your .mfe files are stored.

6. Choose the file to load.

7. Click the Play Animation button to see the biped move to the scripted clips.

To append Motion Flow Editor files:
1. Select a biped.

2. Open the Motion panel.

3. On the Biped rollout, click Motion Flow mode.

4. On the Motion Flow rollout, click Load File. The Open dialog is displayed.
5. Select a *.mfe* file from the folder where your Motion Flow Editor files are stored.

6. Click Append File.
The Open dialog is displayed again.

7. Choose a different *.mfe* file.
A new script appears in the script drop-down list and the appended sequence of clips appears directly below the original sequence of clips in the Motion Flow Graph dialog, so you may have to scroll down to see it.

---

**Customizing Transitions**

Select a biped. > Motion panel > Biped rollout > Motion Flow Mode > Motion Flow rollout

A good transition links two clips together seamlessly, the motion through the transition should appear natural, as though the motion was captured as one long motion sequence. If clips do not transition smoothly, you may find it necessary to edit or customize your transitions. There are two ways to manually edit transitions:

- In the Motion Flow Graph, you can right click a transition arrow.
- If you have defined a script, highlight a clip and click the Edit Transition button.

Transitions can be edited automatically by using the Optimize Transition features. When you create a script, default transitions are set between the clips. Default transitions use minimum motion loss and are quick to compute. However, the best quality transitions are the optimized transitions. Optimized transitions use a minimum foot sliding algorithm to compute the transition and yield very good results.

**Procedures**

To manually customize transitions between two clips:

1. On the Biped rollout, select a biped and turn on Motion Flow mode.
2. Create or load a script with at least two clips.
   For information on how to create a script, see *To create Motion Flow Scripts* (page 2–1031)
3. Choose the first clip in the clip list in the Scripts section on the Motion Flow rollout.
4. Click Edit Transition to display the Transition Editor for the selected clip and the clip following it in the list.
5. Scrub the Frame spinners in the Ghost areas of the Source Clip and Destination Clip, to find a place in both clips to start the transition.
   Two stick figures appear to help you find an appropriate start frame. The yellow figure represents the Source Clip and the red figure represents the Destination Clip.
The stick figures can be positioned far apart during this process. Look for body motions in the two clips that will transition well.

6. Click Set Start Frame in both the Ghost areas when a good Start Frame is located. Character studio repositions the destination clip for a best body fit between the two clips.

7. Set the transition duration in the Length field. A transition duration of 10 to 25 frames is normal.

8. Click OK.

9. Click Play Animation or scrub the time slider to view the transition.

To automatically customize transitions between two clips:

1. On the Biped rollout, select a biped and turn on Motion Flow mode.

2. Create or load a script with at least two clips.
   For information on how to create a script, see “To create Motion Flow Scripts” (page 2–1031)

3. Choose the first clip in the clip list in the Scripts section on the Motion Flow rollout.

4. Click Edit Transition to display the Transition Editor for the selected clip and the clip following it in the list.

5. At the upper-left corner of the Transition Editor, click Next Transition in Script.

6. Click Optimize Transition.
   The Transition Optimization dialog is displayed.

7. Choose either Search Entire Clip or Search Near Existing Transition, and click OK.

8. Click OK on the Transition Editor dialog.

9. Click Play Animation or scrub the time slider to view the transition.

Creating Random Motion

You can randomly traverse clips in a motion flow graph to animate one or more bipeds using controls in the Create Random Motion dialog. You set parameters for random motion in the Motion Flow Graph, in the clip and transition dialogs, as well as in the Create Random Motion dialog.

You create random motion by first adding clips to the Motion Flow Graph and adding transitions between the clips. Clips and transitions are then given percentages, which are used to create random motion for one or more bipeds. You can manually control the “weighting” for a possible start clip, transitions, and frame range. This allows you to animate multiple bipeds in a crowd scene for example. A different script is created for each biped.
Note: If you want to create random motion for multiple bipeds, they must be sharing a motion flow.

**Procedure**

To create a random script for one biped:

1. On the Biped rollout, select a biped and turn on Motion Flow mode.

2. On the Motion Flow rollout, click Show Graph
   This displays the Motion Flow Graph.

3. On the Motion Flow Graph toolbar, click Create Multiple Clips.
   The Open dialog appears where you can choose the location of your .bip files.

4. After adding several clips and transitions, click Select Clip/Transition and select all the clips.

5. On the Motion Flow Graph, click Synthesize Motion Flow Graph and click Yes when asked if you want to create transitions from each selected clip to itself.

6. On the Motion Flow Graph toolbar, click Select Random Start Clips.
   All the transitions linking clips are weighted at 100, meaning all the transitions have a even chance of starting first.

7. Region select all the clips in the Motion Flow Graph.
   The clips all turn purple and are assigned a weighting of 100. All the clips have an even chance of starting first.

8. In the Scripts section on the Motion Flow rollout, click Create Random Motion.

   This should be long enough to include the clips you want in the animation.

10. Click Create.
A random script is created based on clips in the Motion Flow Graph. You can vary clip and transition percentages in the clip dialog or Transition Editor to favor a clip or transition if you like.

11. Click Play Animation or scrub the time slider to view the transition.

**Details of Random Motions**

When choreographing a random motion for your biped, the default “weighting” for all clips and transitions is set to 100. This ensures that all clips and transitions have an equal chance of being randomly chosen. You can adjust the weighting of transitions in the Motion Flow Graph or Transition Editor to give transitions a higher probability of being selected. You can also set a specific start clip for your biped to use while the remainder of the clips in the script are randomly chosen from the Motion Flow Graph.

**To customize transition “weighting” and setting a start clip:**

1. On the Biped rollout, select a biped and turn on Motion Flow Mode.

2. On the Motion Flow rollout, click Show Graph.
   
   This displays the Motion Flow Graph.

3. On the Motion Flow rollout, click Load File
   
   The Open dialog is displayed.

4. Choose a .mfe file from the folder where your Motion Flow Editor files are stored.

   The clips and transitions appear in the Motion Flow Graph. Each transition displays its “weighting” value, 100 by default.

5. Click Select Clip/Transition and right-click a transition that you want to adjust.
   
   The Transition Editor dialog is displayed.

6. Adjust the Probability setting to give the transition a higher or lower probability of being randomly chosen for the motion flow script.

   **Note:** The Probability range is 0 to 100.

7. On the Motion Flow Graph toolbar, click Select Random Start Clips.

8. Select the clip you want used as the start clip.
   
   The clip turns purple and is assigned a weighting of 100. The selected clip will be used first by any biped using the random motion script.

9. In the Scripts section on the Motion Flow rollout, click Create Random Motion.

10. On the Create Random Motion dialog, set a value for Minimum Animation Length.

   This should be long enough to include the clips you want in the animation.

11. Click Create.
A random script is created based on clips in the Motion Flow Graph and the Minimum Animation Length.

12. Click Play Animation or scrub the time slider to view the transition.

**Unifying Motion**
The Create Unified Motion command allows you to create one motion from a script. The entire unified motion is then available when you exit Motion Flow mode. Create Unified Motion converts a script into a freeform unified motion. The created motion replaces animation present when the Motion Flow Mode button is turned off. This is useful if you want to make changes to the biped like raising its arms or turning its head.

**Procedure**
**Example: To create a unified motion:**
1. Create a biped.
2. On the Biped rollout, turn on Motion Flow Mode.
3. On the Motion Flow rollout, click Show Graph.
   This displays the Motion Flow Graph.
4. On the Motion Flow rollout, click Load File and choose *flobees.mfe* from the Open dialog.
5. Click Create Unified Motion.
6. On the Biped rollout, turn off Motion Flow mode.
7. Open the Layers rollout and click Create Layer.
8. Activate the Front viewport and turn on Auto Key.
9. At frame 0, select and rotate the biped’s upper left arm about the Y axis.
10. Turn off Auto Key and click Play Animation.

Sharing Motion Flow

*Shared Motion Flow (page 2–1056)* allows you to assign one motion flow to multiple bipeds or crowds. Rather than building a motion flow network of clips for each biped, you can create a motion flow with all the clips and transitions to animate multiple bipeds. Random motion creation will use each biped’s own motion flow. If a biped’s motion flow happens to be a shared motion flow, then the shared motion flow will be used to compute random motion.

A biped that shares a motion flow shares only the clips you have added to the Motion Flow Graph. Scripts are unique to each biped, although the scripts point to the clips of the shared motion flow. You can manipulate each biped’s motion flow and scripts in the usual ways. You can create random motion on a biped that shares a motion flow, or create a motion flow script using the crowd system.

There are a few indicators in the user interface that show if a biped is using a shared motion flow. If it is, a white circle surrounds the Shared Motion Flow button when you edit that biped. If you edit that biped’s motion flow graph, the title of the graph dialog will say "Shared Motion Flow Graph", followed by the name of the shared motion flow.

Note: All bipeds in a shared motion flow should have the same leg scale and structure. Adaptation for differently sized bipeds does not occur in a shared motion flow. If you want differently sized bipeds in a crowd, then create a shared motion flow for each size.

Tip: The only way to save a shared motion flow, along with the bipeds sharing it, and keep everything hooked up correctly is to save it all in a .max file.

**Procedure**

Example: To share a random motion flow among multiple bipeds:

1. Create three bipeds.
2. On the Biped rollout, turn on Motion Flow Mode.
3. On the Motion Flow rollout, click Show Graph.
   This displays the Motion Flow Graph.
4. Click Create Multiple Clips and add at least four clips to the Motion Flow Graph. The Open dialog appears where you can choose the location of your .bip files.
5. After adding the clips, click Move Clips and arrange the clips so they are not so close to one another. This will make it easier to see the transitions later.
6. Click Select Clip/Transition and region select all the clips.
7. On the Motion Flow Graph, click Synthesize Motion Flow Graph and click Yes when asked if you want to create transitions from each selected clip to itself.
8. On the Motion Flow Graph toolbar, click Select Random Start Clips.

All the transitions linking clips are weighted at 100, meaning all the transitions have an even chance of being randomly used.

9. Region select all the clips in the Motion Flow Graph dialog.

The clips all turn purple and are assigned a weighting of 100. All the clips have an even chance of starting first.

10. On the Motion Flow rollout, click Shared Motion Flow.

The Shared Motion Flow dialog is displayed.

A new shared motion flow is created.

13. On the Select dialog, choose all the bipeds.

The bipeds are added to the list. If you add clips to the motion flow graph they will be shared by the bipeds.

14. Click OK to close the Shared Motion Flow dialog.

15. In the Scripts section of the Motion Flow rollout, click Create Random Motion.

The Create Random Motion dialog is displayed.

16. On the Create Random Motion dialog, turn on Create Motion for all bipeds sharing this motion flow.

Failure to do this will result in the motion flow being added only to the selected biped.

17. Click Create.

A random script is created for each of the bipeds that shared the motion flow.
18. Click Play Animation or scrub the time slider to view the transition.

**To apply a shared motion flow to a different group of bipeds:**

New in character studio is the ability to save and load shared motion flow setups. With this facility, you can create and refine a crowd simulation using bipeds that don’t have meshes attached, thus avoiding the computational overhead that Physique requires. Once the simulation is ready, you can save the shared motion flow setup, apply it to a similar set of bipeds with Physique applied, and then render the final animation with no further crowd setup required.

For best results, the two sets of bipeds should have the same number of members and be of comparable structure and size, and the biped structures should have the same root names.

1. Create a biped/crowd simulation using a shared motion flow.
   
   For details, see Using bipeds in a crowd simulation (page 2–1175).

2. On the Shared Motion Flow dialog, click Save and save the shared motion flow in .smf format.

3. Set up a new scene containing the same number of bipeds, each with a character mesh with Physique applied. The easiest way to do this is to set up one such character and then clone it.

   Make sure the bipeds have the same root names (e.g., Bip01, Bip02) as those in the original setup.

4. Select one of the bipeds, and on the Motion panel, turn on Motion Flow mode, and then click Shared Motion Flow.

5. On the Shared Motion Flow dialog, click New, and then click Load and load the shared motion flow from step 2.

The shared motion flow is loaded and applied to the new set of bipeds. The biped names appear in the dialog list. If “(wrong scale)” appears after any biped names, use the Reset Wrong Scales buttons to correct the scales.

6. Click the Put Multiple Bipeds In Motion Flow button to place all of the bipeds in the list in Motion Flow mode, and then click OK to exit the dialog.

7. Play the animation to ensure that it’s correct, and then render.

Refer to Working with Crowd Animation (page 2–1154) for information regarding crowd animation.

### Setting Up Paths for Motion Flow Files

On a Motion Flow Graph, the location of the referenced .bip files is saved in the .mfe file. If a .bip file cannot be found, the program looks to the motion flow directory specified in \plugcfg\biped.ini. By default, this directory is MoFlowDir=<maxdir>\cstudio\moflow.

If a .bip file is not found in the motion flow directory specified in the biped.ini file, then 3ds Max looks for the file in the same location as the currently loaded .max file. If it is still not found, the program appends the local path of the referenced file to the path to the current .max file. The file is saved back to the same location in which it is found.

If a referenced .bip file cannot be found in its current location, there are two ways to resolve this.

- From the Reset Unfound Motion Flow Files dialog, direct 3ds Max to the folder where the missing .bip file resides.
• Find and move the missing .bip file to the specified Motion Flow folder.

Note: When you find the .bip file, you can turn on the Add Directory To .INI File option and the directory is automatically added to your biped.ini file. Since the biped.ini file accepts multiple search paths, the new directory is added as another MoFloDir= line.

The program will search the directories in the order they appear and will use the first instance of the file that it finds. When network rendering, the file names need to be UNC-compatible.

Procedure

To load a Motion Flow scene from another system:

1. Open a Motion Flow scene that was created on a different system.

   If referenced .bip files cannot be found, the Reset Unfound Motion Flow File dialog is displayed.

2. If any of the referenced .bip files are on your local drive, navigate to the folder where they reside and select the .bip file.

3. Turn on the Add Directory To .ini File option, and click Open.

   Turning on the Add Directory To .ini File option automatically adds another MoFloDir= line to your biped.ini file.

   Note: Turn on Add Directory To Search if you want to search for referenced .bip files during your current session, but do not want to add the directories to the biped.ini file.

4. Click Play Animation after paths for all the referenced .bip files are properly set.
Motion Flow User Interface

Select a biped. > Motion panel > Biped rollout > Motion Flow Mode

The Transition Editor uses **ghosts** to represent the source (yellow) and destination (red) clips. Use these stick-figure ghosts to judge body position and set a likely start frame in both clips for the transition.

In Motion Flow mode, you combine BIP files, using either velocity-interpolated transitions or optimized transitions that compute minimum foot sliding, to create longer character animations. First, clips are added and referenced to BIP files in the Motion Flow Graph. These are then selected to create a script in the Motion Flow Script list. The Transition Editor is used to adjust transitions between BIP files. Scripts, transitions, and clip references are saved in a Motion Flow Editor file (MFE) for later editing.

**Random Motion and Crowds**

Random motions can be created for one or more bipeds using the Create Random Motion command. You can animate a crowd of bipeds for example. For a crowd, you must share one motion flow script among many bipeds.

If you are driving a crowd using delegates and behaviors, then rather than a completely random motion, the software picks appropriate clips based on the delegate's speed and direction. If the delegate slows to a stop, the software will find and use a clip that slows to a stop, if one exists.

In all crowd simulations you must load clips and create transitions before synthesizing the crowd motion. Often, many clips are used to synthesize crowds. Automatic transitions relieve you of having to create transitions between clips manually.

One additional rollout displays in Motion Flow mode:

- **Motion Flow (page 2–1045):** Display the Motion Flow Graph; load and save motion flow files (MFE). The Motion Flow rollout also contains a Scripts section where you can create scripts, edit transitions, create a unified motion, and create random motions for the bipeds.

**Note:** In Motion Flow mode, some **character studio** controls are disabled.

**Workflow: Getting Started with Clips and Transitions in Motion Flow Mode**

Create your own library of BIP files from imported, and converted, motion capture data, and from your own character animation. With a biped selected, turn on Motion Flow mode. Select Show Graph on the Motion Flow rollout to open the Motion Flow Graph. On the Motion Flow Graph, click Create Clip, and add clips in the Motion Flow dialog. Associate the clips to BIP files by first turning on Select Clips-Transitions on the Motion Flow Graph toolbar and then right-clicking a clip icon; a clip dialog appears, allowing you to browse for a clip.

Click Define Script on the Motion Flow rollout, then select a series of clips on the Motion Flow Graph. By left-clicking on a clip it will appear in...
the Scripts list. The clips are connected visually in
the Motion Flow Graph with red arrows (active script) representing default transitions (Minimum Motion Loss). The default duration for a transition is 25 frames, which provides good results in many cases. Transitions, by default, use velocity interpolation between clips.

Use Edit Transition in the Scripts section to
fine-tune the transitions between clips. Select
a clip in the Scripts list, then from the Scripts commands, click Edit Transition; the Transition Editor displays, and the source and destination clip names are displayed at the top of the Transition Editor.

In the Source Clip area, Start Frame represents
the frame in the source file where the transition starts. For example, if Source Clip Start Frame is 60, the transition from the source clip starts at frame 60. The duration of the transition is set in the Length field at the upper left; Length values are in frames. In this example, if Length is set to 10, the transition to the destination clip takes 10 frames. In the Destination Clip area, Start Frame represents the frame in the destination clip that the transition starts; a value of 80, for example, starts the transition at frame 80 of the destination clip.

In this example, the source clip plays from 0 to 60, there is a 10 frame transition from frame 60 of the source clip to frame 90 of the destination clip (frames 80 to 90 cover the destination clip transition period), then the rest of the destination clip plays.

When the Transition Editor displays, the first things to try, before manually editing the transition, are the Optimized Transitions. Optimized transitions use a minimum foot sliding algorithm. The top right-hand corner of the Transition Editor dialog is the icon for optimized transitions. If the optimized transition is not satisfactory, try editing the transition manually.

Manual transition editing offers the most control;
the Frame spinners in the Ghost areas of the
Transition Editor allow you to scrub the source and destination clips while viewing two stick figures. Find a good start frame in both clips using the Frame spinners. Things to look for in both clips are similar supporting feet, body momentum that will appear natural, and arm motion similarities. If velocity changes between the clips are too abrupt, use the Length field to adjust the duration of the transition.

On the Motion Flow rollout, click Save File to save
your work as an MFE file; transitions and scripts are saved. These BIP files contain no footsteps. Biped foot keys are saved with an IK Blend value of 1 for footsteps. To extract footsteps, exit Motion Flow mode, use Load File on the Biped rollout, and then click Convert. Convert looks at foot IK Blend values of 1 to extract footsteps.

Tip: The location of any referenced BIP file is saved in the MFE file. If the BIP file cannot be found, a Missing Motion Flow Files dialog opens up respectively, in which the missing files are listed. To rectify this, open the Asset Tracking dialog and set a new path of the missing files.

The additional topics that discuss Motion Flow mode in this section are:

Motion Flow Rollout (page 2–1045)

Motion Flow Graph Dialog (page 2–1045)

Motion Flow Scripts Group (page 2–1048)

Transition Editor (page 2–1051)

Create Random Motion Dialog (page 2–1055)

Shared Motion Flow Dialog (page 2–1056)

Transition Optimization Dialog (page 2–1058)

Clip Properties Dialog (page 2–1059)
**Motion Flow Rollout**

Select a biped. > Motion panel > Biped rollout > Motion Flow Mode > Motion Flow rollout

The Motion Flow rollout displays when Motion Flow mode is turned on in the Biped rollout. Load, append, and save motion flow editor files (.mfe), display the Motion Flow Graph (page 2–1045) and display the Shared Motion Flow dialog using controls on this rollout.

To load, append, or save a Motion Flow Editor, .mfe, file refer to the following procedures:

- **To load Motion Flow Editor files (page 2–1033)**
- **To append Motion Flow Editor files (page 2–1033)**
- **To save Motion Flow Editor files (page 2–1032)**

**Interface**

- **Load File**—Load a Motion Flow Editor file (.mfe). Motion Flow Editor files include:
  - **Clips**—References to biped animation files.
  - **Transitions**—Names, attributes, and connections between clips.
  - **Scripts**—Different paths through a set of connected clips and transitions.

  **Tip:** The location of the referenced .hip files is saved in the .mfe file. If the .hip file cannot be found, the program looks to the Motion Flow directory specified in plugcfg\biped.ini. By default, this setting is:

  MoFlowDir=<maxdir>\cstudio\moflow

If you load an .mfe file onto a biped using a shared motion flow, you will get a warning and the biped will be removed from the shared motion flow. The biped will get the newly loaded motion flow and all its scripts.

- **Append File**—Append a Motion Flow Editor (.mfe) file to the .mfe that is already loaded. Displays a load file dialog.

  The appended graph will appear directly below the bottom of the existing graph in the graph window, so you may have to scroll down to see it.

- **Save File**—Save a Motion Flow Editor (.mfe) file.

  Saving a .mfe file from a biped having a shared motion flow will save the motion flow and its scripts as if it were not shared. It will be a normal .mfe file.

  **Note:** To save a script as a .bip file, use Unified motion to have the scripted motion available when you exit Motion Flow mode.

- **Show Graph**—Opens the Motion Flow Graph (page 2–1045). The first step in script creation is to add clips to the Motion Flow Graph.

- **Shared Motion Flow**—Displays the Shared Motion Flows dialog (page 2–1056). Allows you to create, delete, and modify shared motion flows. Shared motion flows are used to animate one or more bipeds to simulate a crowd. If the selected biped is using a shared motion flow, then the icon has a white circle around it.

**Motion Flow Graph Dialog**

Select a biped. > Motion panel > Biped rollout > Motion Flow Mode > Motion Flow rollout > Motion Flow Graph > Motion Flow Graph dialog

Use tools in the Motion Flow Graph to add clips to the graph, calculate optimized transitions, set
random script transition values, move and delete clips, and display clip dependencies. Clips and transitions display as icons in the Motion Flow Graph dialog. The Motion Flow Graph displays when you click Show Graph on the Motion Flow rollout (page 2–1045) on the Motion panel.

The first step in Motion Flow mode is to add clips in the Motion Flow Graph for use in scripts. Clips represent all or part of a .bip file. Scripts represent different paths through the clips in the Motion Flow Graph. The first clip in the current script is red. Transitions are shown as arrows between clips; red arrows represent the path through the active script. Black transition arrows indicate unloaded scripts. A transition looping back to the same clip represents a cycle or loop.

If the biped is using a shared motion flow, then the title of the graph window will say "*SHARED* Motion Flow Graph", followed by the name of the shared motion flow. Shared Motion Flows are used to control multiple bipeds with one shared motion flow.

By default, minimum motion loss is used to compute transitions. Optimized transitions use an algorithm that uses minimum foot sliding. Optimized transitions take longer to compute but yield very high quality results.

**Random Scripts for One or More Bipeds**

You can create random scripts by using the Create Random Motion command in the Script group on the Motion Flow rollout. Random scripts are created by randomly traversing clips in a motion flow graph. To use Create Random Motion, each biped must be in the same shared motion flow.

To use a shared motion flow to create random scripts for multiple bipeds, the first step is to click Shared Motion Flow on the Motion Flow rollout, and then add bipeds that will share one shared motion flow. On the Motion Flow Graph, clips are added and transitions are created between all the clips. Then Create Random Motion is used to compute a random motion for all the bipeds.

Clips and transitions are given percentages that are used by the software to generate random scripts. Percentages for clips and transitions are set in the clip dialogs and in the Transition Editor dialog.

You can load many clips and use Create All Transitions to create all possible transitions between the clips. You can then use Optimize Selected Transitions to create optimized transitions. Once the transitions are created, you can quickly create scripts with optimized transitions or generate random motions for a crowd of bipeds.

A .mfe file stores pointers to the clips, transition parameters, and scripts.

See **Placing Motions on the Motion Flow Graph** (page 2–1027) to add clips to the graph, or Creating Random Motion (page 2–1035) to create a random script and transitions.

### Interface

Create Clip—Select and click in the dialog window to create clips.

The clips are empty. Right-click a clip using the Select Clip tool to display the Clip Properties dialog (page 2–1059); then select a .bip file and...
set its duration in the Clip Properties dialog. You can also set the Random Start Probability here. Random Start Probability is used when multiple clips are selected as possible start clips when you generate a random motion flow.

Note: Setting clip duration is not critical for transitions; the Transition Editor (page 2–1051) allows you to start and end a transition on any frame of a clip.

Create Multiple Clips—Load multiple motion files.

Displays an open file dialog. Select multiple files and click OK; multiple files are loaded into the Motion Flow Graph window.

Set lowest starting foot height to Z=0 (.bip files only)—Sets the lowest starting foot height to Z=0. This is an option in the Load File dialog. Default=On.

In Biped, the height of a motion clip can be retained. This is important if you want to retain the height of a motion clip for motions adapted to characters of different sizes. If, for example, the character is jumping off a rock and you want to retain the Z position of the character, you would turn this option off. Leave this option off if Motion Flow motions must be blended that begin and end at different heights, such as three clips that have the character mounting a bicycle, riding the bicycle, and dismounting the bicycle.

Turning off this option can, however, cause a jump in the motion during motion flow transitions. Turn this on for smooth transitions in Motion Flow mode. If adaptation takes place, the height is set so that the lowest foot at frame 0 starts at the Z=0 height. This lines up clips along the Z axis and creates smooth transitions.

Create Transition From → To—Create a transition between two clips.

Click+drag from one clip to another in the Motion Flow Graph dialog. Click on a single clip and then mouse up to create a loop transition. It is necessary to have this capability in order to create random scripts. You can create transitions which are not included in a script.

Create Transition To → From—Create a transition between two clips.

Click+drag to one clip from another in the Motion Flow Graph dialog. Click on a single clip and then mouse up to create a loop transition. It is necessary to have this capability in order to create random scripts. You can create transitions which are not included in a script.

Create All Transitions—Creates transitions between every clip, including loop transitions. Select all the clips that require transitions, then click Create All Transitions. The transitions are not optimized. Use Optimize Selected Transitions to optimize the transitions. Optimized transitions take time to compute but are high quality.

Delete Clip/Transition—Deletes a clip or transition.

If a script is dependent on the clip, a dialog displays a warning; clicking OK on the dialog deletes the clip and the script that is dependent on it.

If you delete the selected clips and transitions from a shared motion flow, it will delete all the scripts from all the bipeds sharing that motion flow which are dependent on those clips and transitions.

Select Clip/Transition—Selects a motion clip or transition.

Right-click a clip to display the Clip Properties dialog (page 2–1059). Right-click a transition to display the Transition Editor dialog (page 2–1051).
Move Clip—Moves clips within the Motion Flow Graph. This does not affect the animation.

Pan—Pans the layout of the clips.

Zoom—Adjusts the view magnification of the Motion Flow window. Drag up to increase magnification. Drag down to decrease magnification.

Zoom Region—Click Zoom Region mode to drag a rectangular region and magnify that region to fill the Motion Flow Graph window.

Fit to Window—Resizes the contents to fit the size of the Motion Flow Graph window.

Save Clip Files—Lets you set a path where selected clip files can be stored.

Clip Mode—Edit biped footsteps and limbs for the selected clip. Use Set Key on the Keyframing rollout to set biped limb keys. Clips turn green in the Motion Flow Graph window in Clip Mode.

Show Script Dependencies—Displays the scripts that use the selected clip. If you push the Show Script Dependencies button on a shared motion flow graph, it will check all the bipeds sharing that motion flow for scripts dependent on the selected clips and transitions.

Select Random Start Clips—Turn on and select clips in the Motion Flow Graph window. Press [Ctrl]+click to add clips. Selected clips are used by Create Random Motion in the Scripts group to start on one of the selected clips based on percentage. If three clips are selected using the default weighting of 100, then each clip has an equal chance of being the start clip.

Show Random Percentages—Displays clip and transition percentages in the Motion Flow Graph window. Random start clips display in purple and display their probability of starting a random script. This also shows the probability (0 - 100) that each transition will be chosen. Create Random Motion in the Scripts group uses clip and transition percentages to generate random scripts.

Optimize Selected Transitions—Select one or more transitions and then click Optimize Selected Transition to optimize them. Displays the Transition Optimization dialog (page 2–1058) to set the location of the transition.

Optimized transitions take time to compute. A progress bar is displayed when you use this feature. Minimum foot sliding is the method used to compute an optimized transition.

Show Optimal Transition Costs—Displays costs in the Motion Flow Graph window. The lower the number the better the transition.

Check All Transitions—Checks the graph for overlapping transitions and transitions whose length is too long for the clip. It informs you of any problems, or tells you that none have been found.

Auto Clip Names—Names the clip based on the name of the motion file. Turn off to name a clip yourself.

Motion Flow Scripts Group

Select a biped. > Motion panel > Biped rollout > Motion Flow Mode > Motion Flow rollout > Scripts group

Create and delete scripts, name scripts, edit transitions, edit clips, and position the entire
animation using tools in the Scripts group. Create random motion for one or more bipeds using controls in this rollout. The Scripts group on the Motion Flow rollout is only available when Motion Flow mode (page 2–1043) is active.

**Scripts**

A Script is a list of clips (.bip files) that you constructed and are executed as you designed to animate a character. To create a script, add clips to the Motion Flow Graph, then select Define Script in the Scripts group and click a sequence of clips from the Motion Flow Graph window. Default transitions are assigned if no transitions exist between the clips. The clip names and starting frame numbers display in the list in the Scripts group.

Different scripts vary the order of the clips found in the Motion Flow Graph. Scripts are run in a top-down order to animate the character. Click Play to view script motion on the biped.

Tip: As the length of a script varies, use [Alt+R] to set the Active Time in 3ds Max to the length of the script. Turn on the Plug-in Keyboard Shortcut Toggle near the 3ds Max status line to enable character studio shortcuts.

**Transitions Between Clips**

By default, when a script is created, Minimum Motion Loss is used to find likely start frames for the source and destination clips.

Editing transitions using the **Transition Editor (page 2–1051)** allows you to determine where a transition occurs in the source and destination clip. Transition duration and the orientation of the destination clip can also be adjusted in the Transition Editor.

**Random Motion**

The Create Random Motion command traverses clips in the Motion Flow Graph based on transition percentages. Transitions are given percentages, and the software creates random scripts based on the transition percentages. This is a quick way to create crowd scenes or to try out different scripts on a single biped. For example, if five clips are present in the Motion Flow Graph and transitions exist between all the clips and each clip has a percentage or probability of being used, you can use Create Random Motion to create a script that is comprised of the five clips that are selected at random.

**Position the Entire Animation**

Use the Position, Rotation, and Start Frame controls to position the entire animation. If you are editing the script for a character in a scene with other objects or characters, use these controls to position the animation relative to the rest of the scene.

For more information regarding scripts, refer to **Creating a Motion Flow Script (page 2–1030)**.
Define Script—Displays the Biped Motion Flow Script dialog (no dialog displays if there are no scripts; in this case, simply select clips in the Motion Flow Graph).

The Biped Motion Flow Script dialog has the following options:

- **Create New Script**—Names a new script. Select clips in Motion Flow Graph to create the clip list for the new script.
- **Redefine Script**—Keeps the script name and removes clips in the list. Select clips in Motion Flow Graph to create a new clip list.
- **Insert Above Selected Clip item**—Inserts a clip above the selected clip in the list.
  First select a clip in the list, choose Insert Above Selected Clip item, and then click a clip in the Motion Flow Graph.
- **Insert Below Selected Clip item**—Inserts a clip below the selected clip in the list.
- **Append to End of Script**—Appends a clip to the end of the clip list.
- **Create Random Motion**—Displays the Create Random Motion (page 2–1055) dialog.
  Controls in the Create Random Motion dialog allow you to create random scripts to animate one or more bipeds. Random motion on multiple bipeds can be used to create a crowd scene.
- **Delete Script**—Deletes the current script; displays the previous script if one is present.
- **Create Unified Motion**—Converts a script into a Freeform unified motion. The created motion replaces animation present when Motion Flow Mode is turned off.
- **Go to Frame**—Make the first frame of the selected clip the current frame.
- **Cut**—Removes the selected clip from the script list and creates a default transition to the next clip on the list.
- **Copy**—Copy the selected clip to the clipboard.
- **Paste**—Paste a clip from the clipboard.
- **Clip Mode**—Edit biped footsteps and limbs for the selected clip. Use Set Key on the Keyframing rollout to set biped limb keys.
- **Edit Clip**—Displays the Clip Properties dialog (page 2–1059). Change the start and end frame for the current clip, or replace the current clip with another one. You can also set the Random Start Probability here. Random Start Probability is used when multiple clips are selected as possible start clips when you generate a random motion flow.
The clip name in the script list and the icon in the graph window are updated if the clip is replaced.

**Edit Transition**—Displays the *Transition Editor* (page 2-1051) for the selected clip.

Edit the transition for the selected clip and the clip following it. By default, when a script is created, Minimum Motion Loss is used to find start frames for the source and destination clips. Use Edit Transition to select your own start frames or to try out optimized transitions.

*Note:* Right-clicking a transition “arrow” in the Motion Flow Graph also displays the Transition Editor, but it will only give you the basic transition editing tools. To edit the transition’s Source Clip-Frame Start and the Destination Clip, use the Edit Transition button.

**Move the Entire Animation**

**Start Frame**—Set the start frame for the first clip in the script.

**Start Position X**—Move the entire script along a world X-axis.

**Start Position Y**—Move the entire script along a world Y-axis.

**Start Position Z**—Move the entire script along a world Z-axis.

**Start Rotation**—Rotate the entire script around the world Z-axis.

All transformation and rotation is based on the original position and affect the entire script.

---

**Transition Editor**

Select a biped. > Motion panel > Biped rollout > Motion Flow Mode > Scripts group > Select a clip in the script list. > Transition Editor

Display the Transition Editor by selecting a clip in the list of the Scripts group and clicking Edit Transition in the same group or right-clicking a transition arrow in the Motion Flow Graph.

**Transitions**

A good transition links two clips together seamlessly; the motion through the transition should appear natural, as though the motion was captured as one long motion sequence. Like an AB roll transition in video editing, an appropriate section in both clips is selected for the transition (dissolve) from the source clip to the destination clip. Velocity differences between the source and destination clips are matched during the period of transition producing a seamless result. By default, Minimum Motion Loss is used to find likely start frames in the source and destination clips when clips are appended to a script. Optimized transitions can be computed by using Optimize Transition in the upper right-hand corner of the Transition Editor dialog. Optimized transitions use a minimum foot sliding method to compute transitions. Optimized transitions take longer to compute, but produces very smooth motions.

Although only one arrow is used to represent a transition between two clips in the Motion Flow Graph, any number of transitions can be named and stored in the Transition Editor representing that transition. If, for example, you create 5 different transitions between two clips for one script, all of these transitions are available in a new script that uses the same two clips. Think of Motion Flow Graph as a data storage area; if all of the scripts are deleted, the transitions are preserved and can be stored in a .mfe file.
Automatic Transitions

When you create a script, default transitions are used between the clips. Default transitions use minimum motion loss and are quick to compute. However, the best quality transitions are the optimized transitions. Once the Transition Editor is open, the first thing to try, before manual editing, are the optimized transitions (upper-right corner of the dialog).

Length (Transition Duration)

Set the duration of a transition in the Length field. A value of 10, for example, creates a transition of 10 frames between the source and destination clips. During the period of transition, the velocity of the source clip is interpolated to the velocity of the destination clip. If the transition takes place at the last frame of the source clip and the first frame of the destination clip, and Length is set to 10, then the last frame of the source clip is interpolated with the first 10 frames of the destination clip.

Editing Transitions Manually (Ghosts)

Manually setting the Start Frame for the source and destination clips offers the most control. Unwanted motion in either clip can be avoided and judging the best Start Frames for both clips is left to you.

The Ghost area Frame spinners allow you to view and scrub the source and destination clips by displaying stick figures (ghosts); yellow and red stick figures represent the source and destination clips. When a suitable Start Frame is located for both clips, use Set Start Frame in the Ghost area to copy the Frame values to the Start Frame fields in the Source and Destination Clip areas.

Scrubbing the time slider over the transition period enables you to view the biped's transition from the yellow stick figure (source) to the red stick figure (destination).

Other Transition Editor Features

Rolling and Fixed specify whether a clip is rolling (in motion) or fixed (single frame) during the transition. Change the direction of the destination clip using the Angle field.

Other parameters in the Transition Editor allow you to create and name new transitions, scroll through the saved transitions, jump to the transition-starting frame, set automatic transition parameters, and go to the next transition in the script.

All transitions and their attributes are saved with a .mfe file.

See Customizing Transitions (page 2–1034) to manually and automatically customize transitions.

Interface

Probability—Set a probability value for random transitions. This is used by Create Random Motion when a random script is generated.

Length—Sets the number of frames for the duration of the transition.

Transitions are calculated by matching velocities in both clips. Smooth out abrupt velocity changes using longer transitions.
Ease In—Ease in value for the source clip.

Ease Out—Ease out value for the destination clip.

Transition Focus—Lets you specify a focus point on the biped where the transition takes place. Default = Center of Mass.

- Center Of Mass—The transition focus is based on the center of mass position of the biped as it transitions from one clip to the next.
- Left Foot—The transition focus is based on the left foot position of the biped as it transitions from one clip to the next.
- Right Foot—The transition focus is based on the right foot position of the biped as it transitions from one clip to the next.
- Both Feet—The transition focus is based on an averaged foot position of both of the biped’s feet as it transitions from one clip to the next.

Note: The best way to see the differences between the transition foci is by watching the yellow and red ghosts.

Angle—Sets the direction of the destination clip.

The angle of the destination clip is automatically set for best body fit between the two clips when the Start Frame values change. Use Angle to change the direction of the destination clip.

Displays the next transition in the Transition Editor, moves the time slider to the start frame of the next transition, and highlights the next clip in the Scripts list.

Optimize Transition—Displays the Transition Optimization (page 2-1058) dialog.

Options in the Transition Optimization dialog allow you to search for a location for the transition.

Go To Start Frame—Moves the time slider to the first frame of the transition.

The number field shows the start frame number.

Start Frame—Set the transition start frame for the source and destination clips in their respective fields. Duration for the source and destination clips display above the Start Frame fields.

Rolling—Keep the clip in motion during the transition.

Fixed—Freeze the biped at the Start Frame position during the transition.

Previous Transition—Go to the previous transition in the script.

Displays the previous transition in the Transition Editor, moves the time slider to the start frame of the previous transition, and highlights the previous clip in the Scripts list.

Next Transition—Go to the next transition in the script.
Ghost group

The Ghost group Frame spinners allow you to view and scrub the source and destination clips by displaying stick figures (ghosts); yellow and red stick figures represent the source and destination clips. The source and destination bipeds might not be near each other during this scrubbing process; the destination clip will be repositioned when you click Set Start Frame is clicked. When you locate a suitable start frame, click Set Start Frame to copy the values in the Frame field to the Start Frame field. Monitor foot position status in the field provided.

Frame—Use the Frame spinner to scrub a stick figure back and forth, which allows you to determine a start frame for the source and destination clips. Visual feedback of the stick figures is a good way to judge which start frames are needed for the source and destination clips.

Set Start Frame—Copy the value in the Frame field of the Ghost area to the Start Frame field in the Clip area. The position of the destination clip changes to match the biped body in the destination clip to the biped body in the source clip.

Locate an appropriate start frame for the source and destination clips by using the Frame spinner and viewing the positions of both stick figures, then click Set Start Frame.

The destination clip is rotated and positioned to match both bipeds. Use the Angle spinner to reorient the destination clip.

Playback group

These controls let you play back the transition from the Transition Editor dialog.

- **Play Transition Icon**—Toggles the playback of transition.
- **Speed**—Changes the playback speed.
- **Frames Before/Frames After**—Sets the number of frames to play before and after the transition period.
- **Selected Only**—When checked, plays only the selected biped in the scene.
- **Play Ghosts**—When checked, shows transition ghosts during playback.

Create Transition—Click to create a new transition. The transition number field increments. Edit and name the new transition. Any number of transitions can be stored.

Note: Clicking OK saves the displayed transition. Create Transition is used only if you want to work on a new transition.
Create Random Motion Dialog

You can randomly traverse clips in a motion flow graph to animate one or more bipeds using controls in the Create Random Motion dialog. Parameters for random motion are set in the Motion Flow Graph, in the clip and transition dialogs, as well as in the Create Random Motion dialog.

Random motion is created by first adding clips to the Motion Flow Graph window and adding transitions between the clips. Clips and transitions are then given percentages, which are used to create random motion for one or more bipeds. You can manually control the “weighting” for possible start clip, transitions, and frame range. This allows you to animate multiple bipeds in a crowd scene, for example. A different script is created for each biped.

Create Random Motion Dialog

Select a biped. > Motion panel > Motion Flow Mode > Motion Flow rollout > Scripts group > Create Random Motion > Create Random Motion dialog

You can randomly traverse clips in a motion flow graph to animate one or more bipeds using controls in the Create Random Motion dialog. Parameters for random motion are set in the Motion Flow Graph, in the clip and transition dialogs, as well as in the Create Random Motion dialog.

Random motion is created by first adding clips to the Motion Flow Graph window and adding transitions between the clips. Clips and transitions are then given percentages, which are used to create random motion for one or more bipeds. You can manually control the “weighting” for possible start clip, transitions, and frame range. This allows you to animate multiple bipeds in a crowd scene, for example. A different script is created for each biped.

If you want to create random motion for multiple bipeds, they must be sharing a motion flow. For more information about using random motions and transitions, refer to Creating Random Motion (page 2–1035).

Delete Transition—Click to delete a transition.

Previous Transition—Go to the previous stored transition. This button is grayed if no previous transition exists.

Next Transition—Go to the next stored transition. This button is grayed if no next transition exists.

OK—Store transitions and exit the dialog.

Interface

You can randomly traverse clips in a motion flow graph to animate one or more bipeds using controls in the Create Random Motion dialog. Parameters for random motion are set in the Motion Flow Graph, in the clip and transition dialogs, as well as in the Create Random Motion dialog.

Random motion is created by first adding clips to the Motion Flow Graph window and adding transitions between the clips. Clips and transitions are then given percentages, which are used to create random motion for one or more bipeds. You can manually control the “weighting” for possible start clip, transitions, and frame range. This allows you to animate multiple bipeds in a crowd scene, for example. A different script is created for each biped.

If you want to create random motion for multiple bipeds, they must be sharing a motion flow. For more information about using random motions and transitions, refer to Creating Random Motion (page 2–1035).

Script Name—Type a name for the script to be generated.

Random Start Range—Set the start and end frame range over which the new script(s) will start.

Minimum Animation Length—Set the minimum animation length.

When a random motion is created, it is done by making a motion flow script which traverses the clips in the Motion Flow Graph, adding clips based on random calculations. It will add clips until the length of the script is greater than or equal to the minimum animation length, specified here.

first clip in script—Gets the start position and rotation from the first clip.

biped’s current position/rotation—Uses the biped’s current position to start the script.

Create motion flow script—Creates a script after computing the motion.

If this is on, a motion flow script will be created. If not, a script will still be created internally in
order to generate the random motion, but it will be deleted after the random motion is generated.

**Append to existing script**—Appends random motion to the existing script.

**Create unified motion**—Creates a unified motion. The generated motion will be available when you exit Motion Flow mode.

If multiple bipeds are in the random calculation, then the motion is unified for each biped.

**Store as .bip file**—Stores the random motion as a .bip file.

If multiple bipeds are in the random calculation, they are saved separately with incrementing numbers.

**File Name**—Type a name for the .bip file.

A .bip extension will be added automatically.

**Directory**—Type a directory path or browse for the path.

**Browse**—Browse to a directory.

**Create motion for all bipeds sharing this motion flow**—Turn on to create a random script for each biped sharing the current biped’s motion flow.

You can create a shared motion flow by using the Shared Motion Flow command on the Motion Flow rollout and adding bipeds in the Shared Motion Flow dialog.

**Create**—Creates random motion for the selected biped or all the bipeds in the shared motion flow.

**Cancel**—Cancel and close the dialog.

---

### Shared Motion Flow Dialog

Select a biped. > Motion panel > Biped rollout > Motion Flow Mode > Motion Flow rollout > Shared Motion Flow > Shared Motion Flow Dialog

Controls in the Shared Motion Flow dialog allow you to assign one motion flow to multiple bipeds. Instead of choreographing a motion flow script for individual bipeds, you can create a motion flow with all the clips and transitions to create a script to animate multiple bipeds. Random motion creation will use each bipeds’ own motion flow. If a biped’s motion flow happens to be a shared motion flow, then the shared motion flow will be used to compute random motion.

A biped that shares a motion flow shares only the graph. Its scripts are unique to that biped, although the scripts point to the clips of the shared motion flow. You can manipulate that biped’s motion flow and scripts. You can create random motion on a biped that shares a motion flow, or create a motion flow script via the crowd system.

A white circle around the Shared Motion Flow icon indicates that a biped is using a shared motion flow. If you edit that biped’s motion flow graph, the title of the graph dialog will say "Shared Motion Flow Graph", followed by the name of the shared motion flow.

Bipeds in a shared motion flow should have the same lower body scale and structure. Adaptation for differently sized bipeds does not occur in a shared motion flow. If you want differently sized bipeds in a crowd, then create a shared motion flow for each size.

See *Sharing Motion Flow* (page 2–1039) for more details about setting up a shared motion flow.
Interface

**Shared Motion Flows list**—Lists shared motion flows.

**New**—Creates a new shared motion flow.

**Delete**—Deletes the current shared motion flow.

The scripts of the bipeds sharing the deleted motion flow will be deleted. Those bipeds will have an empty motion flow graph and no scripts.

**Load**—Loads a shared motion flow (.smf) file.

This file is created with the Save command (see following). The file contains the shared motion flow graph as well as the scripts for all bipeds sharing the motion flow.

**Save**—Saves a shared motion flow (.smf) file.

The file contains the shared motion flow graph as well as the scripts for all bipeds sharing the motion flow.

Use this facility to speed biped/crowd-simulation setup. Create and refine the crowd simulation with bipeds that don’t use Physique, save the shared motion flow, load or create your final crowd members that use Physique, and then load the shared motion flow. For a procedure, see *To apply a shared motion flow to a different group of bipeds: (page 2–1041).*

**Load .mfe**—Displays a load file dialog. Load an .mfe file into the shared motion flow.

Note: If you load a .mfe file, via the Motion Flow rollout, into a biped using a shared motion flow, you will get a warning and the biped will be removed from the shared motion flow. The biped will get the newly loaded motion flow and all its scripts. The shared motion flow will remain the same.

**Bipeds Sharing this Motion Flow list**—Lists the bipeds that share this motion flow.

**Add**—Displays a dialog where you can choose bipeds to add to the motion flow list.

Add bipeds to the list of bipeds that share a motion flow. When you add a biped, its current motion flow graph and motion flow scripts will be deleted. It will now have the shared motion flow graph. A biped can only share one motion flow graph. You must remove a biped from its shared motion flow in order to add it to a different shared motion flow.

**Remove**—Removes the selected bipeds in the list from the current shared motion flow.

These bipeds’ scripts will be deleted. They will have an empty motion flow graph.

**Put Multiple Bipeds in Motion Flow**—Put the bipeds in the list into Motion Flow mode.
Chapter 14: character studio

The crowd system needs Motion Flow mode to be turned on to perform calculations for motion. This is a convenient way of turning on Motion Flow mode for multiple bipeds.

- Take Multiple Bipeds out of Motion Flow—Take the bipeds in the list out of Motion Flow mode.

- Set Shared Moflow Leg Scale—Adapts the shared motion flow to the scale of the biped currently selected in the list. After this operation, the selected biped will have the correct leg scale, although other bipeds may not.

- Reset Wrong Scales—Just Legs: Reset the leg scale only of the bipeds that have the wrong scale, so that they adapt appropriately to the shared motion flow.

- Reset Wrong Scales—Entire Figure: Resets the entire figure structure of the bipeds that have the wrong scale, to match the figure structure of the correctly scaled biped.

When you add the first biped to the shared motion flow, the system adapts to the size of that biped. If the leg scale of a biped you add subsequently doesn’t match that of the first biped, it will be marked in the list with “wrong scale” after it.

All the bipeds you plan on using in a shared motion flow must have the same lower body structure and scale.

It can search either the whole clip, or it can search near the existing transition. You must specify the preferred length of the optimized transition. The software will try to get as close to that length as possible, still opting to give you the best length.

If it searches about the existing transition, you must specify the number of frames about which it will search before and after the existing transition.

Optimized transitions compute for minimum foot sliding over the range of the transition. This method yields very high quality results.

### Interface

<tr>
<td>Before: 20</td>
<td>After: 20</td>
</tr>
</tbody>
</table>
```

- Preferred Transition Length—Specify the length of the optimized transition.

- Search Entire Clip—Search the entire clip for an optimized transition start frame.

- Search Near Existing Transition—Create an optimized transition near the existing transition. You may search the range about the existing transitions by setting before and after frame values.

Options in the Transition Optimization dialog allow you to select the range over which the optimize algorithm will search for the transition.
Clip Properties Dialog

Parameters in the Clip Properties dialog allow you to browse for a clip, set a start and end frame for the clip and set a random start probability for the clip. Random start probability is used when you use Create Random Motion to generate a random script for a biped.

Using Motion Capture

Motion capture is the practice of getting motion data from live actors performing various actions. The motion data is captured (retrieved) via sensors placed at the actors’ joints and extremities. 3ds Max does not perform motion capture, but it accepts motion-capture data in the most commonly used formats. This data can be imported to the biped and used as is, or combined with other motions with Motion Flow (page 2–1026) or the Motion Mixer (page 2–604).
Motion-capture data typically needs some adjustment before it fits your biped or animation perfectly. When motion-capture data is imported to 3ds Max, it can be filtered to:

- Use fewer keyframes
- Create footstep motion
- Use props in the scene

In addition, some motion-capture files come with a separate marker file, which can be used to match the biped posture to the motion-capture actor.

**How Motion-Capture Data is Acquired**

Motion-capture data is typically acquired by one of several means:

- **Optical sensing technology**
  Optical systems have become quite popular over the last couple of years. These systems can offer the performer the most freedom of movement since they do not require any cabling. Optical systems incorporate directionally reflective balls, referred to as markers (page 3–969), that attach to the performer. Optical systems require at least three video cameras, each of which is equipped with a light source that is aligned to illuminate the field of view for that camera. Each camera is in turn connected to a synchronized frame buffer. The computer is presented with each camera view in order to calculate a 3D position of each marker; the resulting data stream therefore consists of 3D position data for each marker. This data is typically applied to an inverse kinematics system, to animate a skeleton.

- **Electro-magnetic sensing technology**
  This is a popular method used for performance capture. Magnetic capture involves the use of a centrally located transmitter, and a set of receivers that are strapped on to various parts of the performer’s body. These receivers are capable of measuring their spatial relationship to the transmitter. Each receiver is connected to an interface that can be synchronized to prevent data skew. The resulting data stream consists of 3D positions and orientations for each receiver. This data is typically applied to an inverse kinematics system to drive an animated skeleton. This magnetic approach shares the same lack of occlusion problems with the audio method, but it also shares the same negative factors, such as the hindrance of cables, lack of sufficient receivers, and the limited capture area. In addition, being magnetic, the system is affected by any sizable areas of metal in the vicinity of the capture area, such as girders, posts, and so on.

- **Prosthetic sensing technology**
  This is one of the early methods for capturing the motion from various parts of human anatomy. These methods include simple "on/off" type of motion-detection systems as well as complex motion-tracking systems. The latter type of prosthetic motion capture would be an ideal approach if it weren’t for the complex mechanical requirements and the performance-inhibiting qualities generally associated with such designs. However, the type of data provided can be clean, rotational data collected in real time without any occlusion problems. This method is based on a set of armatures that must be attached all over the performer’s body. The armatures are then connected to each other by using a series of rotational and linear encoders. These encoders are then connected to an interface that can simultaneously read all the encoders in order to prevent data skewing. Finally, through a set of trigonometry functions, the performer’s motion can be analyzed. These design restrictions seem to be quite difficult to overcome, and will probably limit the use of this type of device for character animation.

- **Acoustic sensing technology**
Acoustic capture is another method currently used for performance capture. This method involves the use of a triad of audio receivers. An array of audio transmitters are strapped to various parts of the performer’s body. The transmitters are sequentially triggered to output a "click" and each receiver measures the time it takes for the sound to travel from each transmitter. The calculated distance of the three receivers is triangulated to provide a point in 3D space. An inherent issue with this approach is the sequential nature of the position data it creates. In general, one would like to see a "snap shot" of the performer’s skeletal position rather than a time-skewed data stream. This position data is typically applied to an inverse kinematics system, which in turn drives an animated skeleton.

Importing Motion-Capture Data (page 2–1061)
Filtering Motion-Capture and Marker Data (page 2–1061)
Sliding Footsteps (page 2–1064)
Prop Bone (page 2–1065)

Importing Motion-Capture Data
In character studio, you can import both rotation and position type motion-capture files.

- BioVision (.bvh) files contain limb and joint rotation data.
- character studio marker files (.csm) contain raw marker position data generated by a motion-capture device: markers are attached to an actor during a motion-capture performance. Marker files typically require some calibration. If necessary, the biped is sized to fit the markers first, then the biped limbs are oriented to align them to the markers. Marker files should be loaded with keys at every frame and no footstep extraction; this is required for calibration, and also enables the calibration controls. Calibration controls are the second row of buttons on the Motion Capture rollout.

In character studio, the .csm marker file format supports a prop bone in either or both hands. See Prop Bone (page 2–1065).

Key reduction, track selection, footstep extraction, and clip looping are some of the options available using the Motion Capture import filter. Key reduction makes it easy to manipulate the biped and personalize the imported motion-capture data. Extracting footstep data from motion-capture data prevents inappropriate sliding feet, which are a common problem with motion-capture data. Typically you do not use an entire motion-capture clip as is, unless you capture motions at a studio for your own production. You should become familiar with the body motion in the files you have, then use Motion Flow mode to cut portions of these files together to create animation. For example, take a stretch motion in one clip, and combine it with the walking motion in another clip. The edited script can then be saved as a .bip file using the Save Segment command on the Biped rollout. Load this .bip file for standard motion editing. This provides a good starting place for you to edit the result to your liking.

All motion-capture controls are on the Motion Capture rollout (page 2–1065).

Filtering Motion-Capture and Marker Data
Motion-capture and marker data typically have keys at every frame. Filtering motion-capture data reduces keys, simplifying the job of altering or personalizing the motion data. Biped lets you filter the data of each track with its own filtering settings, so you have control over which nuances
of motion you want to pick up without filling the rest of the tracks with unwanted keys. Filtering is done using the Motion Capture Conversion Parameters rollout.

Other filtering options include footstep filtering and extraction, looping the data, and importing a portion of the motion-capture file.

3ds Max ships with a variety of raw (unfiltered) motion-capture data files, in .bip, .csm, and .bvh formats. Some of the same data is available in filtered versions, either with footsteps or freeform. Try your own filtering adjustments on the raw versions of this data. Importing the raw data displays the original motion very accurately when you select Show Buffer on the Motion Capture rollout. Use the Motion Capture buffer as a guide when adjusting and refining the filtered data. Several tools are available in the Motion Capture rollout to aid you in this process.

Create your own library of imported and optimized motion capture data by saving .bip files for use with other characters, or as part of a longer script in Motion Flow mode. Use a biped that has no mesh attached with Physique.

Tip: Overall, you import the data, adjust it to your liking, and save it as a .bip file. You can also run standard .bip files through this filtering process to create loops or to extract footsteps from a freeform animation.

Note: Marker files, such as .csm, contain position data. Hierarchical motion-capture files, such as .bvh, contain joint rotation data.

Character Studio Marker Files

The .csm format (page 3–925) is an ASCII file used to import positional marker data from motion-capture systems onto a biped.

Procedures

To import a motion capture file:

1. Select a biped in the viewports.
2. On the Motion Capture rollout, click Load Motion Capture File.
3. Choose the file type: .bvh, .bip, or .csm. Search for files in the cstudio\motions\mocap directories.

Tip: .csm marker files, loaded for the first time, should be imported with no key reduction and no footstep extraction. This enables the calibration buttons. Marker files typically need some calibration.
4. Select a file and click Open.
   The Motion Capture Conversion Parameters dialog displays (see Motion Capture Conversion Parameters Dialog (page 2–1070)).

5. Select the filter options you want and click OK.
   The biped adapts itself to the motion data. If Footstep Extraction is turned on, footsteps appear.
   Tip: Use a biped that does not have a mesh attached with Physique. Import motion-capture data with the idea of then saving a .bip file that can be used for any character. If skeletal scale information is loaded from a motion-capture file, a mesh with a Physique modifier might deform unnaturally.

To import a marker file:

Typically, when a marker file is loaded for the first time, it requires scale and position calibration. A raw marker file must be loaded, with no key reduction or footstep extraction, to enable the calibration functions. After calibration is performed, use Convert From Buffer to extract footsteps and reduce keys.

1. Select a biped.

2. On the Motion Capture rollout, click Load Marker Name File to load a marker name file (.mnm).
   This step is not required if the marker names in the marker file adhere to the character studio marker naming convention.

3. On the Marker Name File dialog, click Load CSM Marker File, and choose the .mnm file from the file open dialog that appears.

4. On the Motion Capture rollout, click Load Motion Capture File and choose a .csm marker file.

   The Motion Capture Conversion Parameters dialog displays (see Motion Capture Conversion Parameters Dialog (page 2–1070)).

5. Adjust the filter parameters and click OK.
   Note: Load raw marker data (No Key Reduction, Freeform) to enable the marker calibration buttons.
   The biped adapts itself to the marker data.

6. On the Motion Capture rollout, click Show Markers. On the Marker Display dialog, turn on Show Recognized Markers and the option for On All Objects.

7. Now, on the Motion Capture rollout, click Talent Figure Mode. Use Non-Uniform Scale or Rubber Band Mode (on the Biped rollout) to size the biped to the displayed markers.
   Note: This step is optional and should be used if you need to correct for slight differences in limb scale between the original talent who performed the motion and the scale of the biped after the data is imported. For example, if the leg is too short, scale the length of the leg in Talent Figure mode to adjust the knee position.

8. Click Talent Figure Mode again to exit the mode.

9. Key adaptation takes place when you exit Talent Figure mode. Now biped limb positions relative to the markers can be adjusted.

10. Align the biped limbs to the markers if necessary, then click Adjust Talent Pose to compute the offset for the entire animation.

11. Use Save Talent Figure Structure and Save Talent Pose Adjustment as a .fig and .cal file.

12. Load these files in the Motion Capture Conversion Parameters dialog when similar marker files are imported in the future.
At this point, you can use Convert From Buffer to extract footsteps and reduce keyframes. Both scale and position adjustments will be incorporated. Save the motion as an optimized .bip file.

### Sliding Footsteps

Motion-capture and marker data typically have keys at every frame. Filtering motion-capture data reduces keys, making the job of altering or personalizing the motion data much simpler. You can create your own library of imported and optimized motion-capture data by saving .bip files for use with other characters or as part of a longer script in Motion Flow mode. Use a biped that has no mesh attached to it with Physique. You import the data, adjust it to your liking, and save it as a .bip file. You can also run standard .bip files through this filtering process to create loops or to extract footsteps from a freeform animation.

### Motion Capture Import

Footstep motion capture is enabled automatically when importing motion capture data using the Sliding Tolerance and Sliding Angle controls in the Motion Capture Conversion Parameters dialog (page 2–1070).

#### Footstep Extraction group

The following options are active when Footstep Extraction is on during motion capture conversion.

- **Extraction Tolerance**—Sets the sensitivity of footstep extraction. character studio determines if the footstep is there by checking that the foot does not move beyond the distance determined by the Extraction Tolerance value. Smaller numbers are more sensitive and extract more footstep. The value is a percentage of foot length.

- **Sliding Distance**—Creates a sliding footstep (page 2–1064) when positional tolerance is reached. This value is a percentage of foot length. By default the foot must slide its own distance (100), before a sliding footstep is created.

- **Sliding Angle**—Creates a sliding footstep (page 2–1064) when rotational tolerance is reached. This value is in degrees. The default is set high (360 degrees), the foot must make a complete turn before a sliding footstep is created.

- **Only Extract Footsteps Within Tolerance**—Turns on Z-axis Tolerance. These controls filter out footsteps that do not fall within a given range of the ground plane. Use this when filtering motions, such as hopping or pitching a baseball, in which a foot might come off the ground and remain stationary, but its position is not intended as a footstep.

- **Flatten Footsteps to Z=0**—Moves extracted footsteps to Z=0. Use this to flatten out minor differences in the height of the extracted footsteps.
In 3ds Max, the CSM marker file format supports a prop bone in either or both hands (left, right, or middle). There are nine additional markers for the top, bottom, and middle of the three prop types. If the software detects these tracks, it creates a dummy helper (page 2–16) object.

The length of the prop is the average distance between the top and bottom prop marker during animation. The prop will be oriented in the plane of the three prop markers, and its origin will be at the bottom prop marker.

The dummies are named bip01prop, bip02prop, and so on. If a prop of that name already exists, its animation and size is reset upon loading the CSM file. The Marker Display dialog contains a check box for toggling display of the prop markers. The prop track names are LPRPB, LPRPM, LPRPT, MPRPB, MPRPM, MPRPT, RPRPB, RPRPM, and RPRPT. These stand, respectively, for left prop bottom, left prop middle, left prop top, middle prop bottom, middle prop middle, middle prop top, right prop bottom, right prop middle, and right prop top. You can change the track names by editing the MNM file.

The props don’t necessarily have a relation to the left and right hands. For example, a prop could be a hat.
independent of the biped motion in your scene, and can be used in various ways:

- Use **Convert From Buffer** to try alternate filter settings quickly; this saves you from having to browse for the same file.
- After importing a BVH or BIP file using footstep extraction and key reduction, you can use **Paste From Buffer** on selected biped limbs (and COM) to paste keys from the raw motion-capture data to the filtered data; do this if critical motion has been lost in the filtering process.
- If you specify **Load Buffer Only** in the Motion Capture Conversion Parameters dialog (page 2–1070), the motion file is loaded into the motion-capture buffer without altering the biped animation. Use this to paste posture and limb keys from any file onto the biped animation in your scene.

When you load a motion-capture file, the motion-capture buffer is loaded with motion-capture data from that file. This buffer is altered during calibration. It is also used to show the motion-capture markers and trajectories.

Internally, there is only one motion-capture buffer. It is often large, so its contents are not saved before a file load or a calibration. Therefore, if you undo a motion-capture file load, the contents of the motion-capture buffer do not change. That’s why you’ll still see old markers and trajectories. It is not possible to undo calibration.

**Marker Files**

Unlike a BIP or BVH file that contains limb rotation data, a CSM marker file (page 3–969) contains only marker position data. When a raw marker file is imported, only marker position data is buffered in the motion-capture buffer. 3ds Max uses the marker data to extract limb rotation data to position the biped. After using the calibration controls on the Motion Capture rollout to correct biped scale and posture relative to the markers, use **Convert From Buffer** to filter the raw marker data to key reduce and extract footsteps.

Note: A CSM marker file is an ASCII file.

**See also**

*Importing Motion-Capture Data (page 2–1061)*

**Procedures**

**To use Convert From Buffer:**

A motion-capture file should already be in memory. Use **Load Motion Capture File** on the Motion Capture rollout to import a motion-capture file if one is not already be in memory.

1. Select a biped.
2. On the Motion Capture rollout, click **Convert From Buffer** to display the Motion Capture Conversion Parameters dialog.
3. Adjust parameters, then click OK.

**To compare raw and filtered trajectories:**

1. Select a biped and turn on **Show Buffer** Trajectory on the Motion Capture rollout.
2. Click **Trajectories** on the Display rollout.

As you select various biped parts, two trajectories are displayed. The yellow trajectory represents raw motion capture data in the motion capture buffer; the purple trajectory represents the filtered data.

**To use Show Buffer:**

1. Create a biped.
2. Use **Load Motion Capture File** on the Motion Capture rollout to import a motion-capture file.
3. Turn on **Show Buffer** on the Motion Capture rollout.

A red stick figure appears, representing the raw motion-capture data.
Play the animation; the animation of the biped representing filtered motion-capture data and the red stick figure play back together.

Tip: For a very accurate visual comparison between raw motion capture data and filtered data, toggle Show/Hide Objects on the Display rollout to hide the biped. Toggle Show/Hide Bones in the same rollout to display only biped bones (the yellow stick figure), then play the animation with Show Buffer turned on. The two stick figures move together, and any discrepancies are easily spotted.

To learn how to use Show Buffer with the Fit To Existing parameter in Motion Capture Conversion Parameters rollout, see To use Fit To Existing to import a motion capture file (page 2–1071).

To import a motion-capture file:

1. Select a biped.

2. If necessary, click Load Marker Name File on the Motion Capture rollout (see MNM Files (page 3–973)).

   Note: This step is not required if the marker or joint names in the motion-capture file adhere to the character studio marker naming convention.

3. Click Load Motion Capture File.

   The Open dialog opens.

4. Choose a file type: BVH, BIP, or CSM.

5. Select a file and click Open.

   The Motion Capture Conversion Parameters dialog (page 2–1070) displays.

6. Select the filter options you want, and click OK.

   The biped adapts itself to the motion data. If Footstep Extraction is turned on, footsteps appear.

   Note: Load raw marker data (No Key Reduction, Freeform) to enable the marker calibration buttons.

   Tip: Use a biped that does not have a mesh attached to it with Physique. Import motion-capture data with the idea of then saving a BIP file that can be used for any character. If skeletal scale information is loaded from a motion-capture file, a mesh with the Physique modifier applied might deform unnaturally.

7. If a marker file was loaded, turn on Show Markers as a visual aid for biped scale and limb correction.

   If correction is necessary, adjust biped scale first. Keyframe adaptation takes place in order to accommodate a biped scale change.

   The remaining steps in this procedure are optional, unless you need to calibrate motion-capture files.

8. Click Talent Figure Mode and use Non-Uniform Scale or Rubber Band Mode (on the Biped rollout) to size the biped to the displayed markers.

9. Click Talent Figure Mode again to exit the mode.

   Key Adaptation takes place when you exit Talent Figure mode. Now, biped limb positions relative to the markers can be adjusted.

10. Align the biped limbs to the markers, if necessary, and then click Adjust Talent Pose to compute the offset for the entire animation.

11. Use Save Talent Figure Structure and Save Talent Pose Adjustment to save a size and position offset to a FIG and a CAL file, respectively.

   Load these files in the Motion Capture Conversion Parameters dialog when you import similar marker files in the future.
At this point, you can use Convert From Buffer to extract footsteps and reduce keyframes. Both scale and position adjustments will be incorporated. Save the motion as an optimized BIP file.

**Interface**

**Load Motion Capture File**—Key reduce and extract footsteps from raw motion-capture data. Load BIP, CSM, or BVH files. After you open a file, the *Motion Capture Conversion Parameters dialog (page 2–1070)* opens. Following are descriptions of settings in the Open dialog.

**Files of type**—

- **BIP**—Filters the raw version of the motion-capture data that ships with 3ds Max. These are in a BIP format. Filter standard BIP files to convert footstep animation to a freeform animation; extract footsteps from a freeform animation; and to loop a BIP file.
- **BVH**—BioVision motion-capture data file. Contains the “actor’s” skeletal and motion information. Once the motion-capture data is filtered and adjusted, save it as a BIP file for later use.
- **CSM**—Imports a character studio marker file (ASCII format file). Optionally, load a Marker Name file (MNM), a Talent Structure file (FIG), and a Talent Pose file (CAL) before loading a CSM file. Marker files should be loaded with no key reduction and no footstep extraction to enable the calibration controls.

**Restructure biped to match file (BIP files only)**—Turn on to change the biped structure to match the structure stored in the BIP file. The file loads with the stored biped structure. This is an Open dialog option.

This option is unavailable when you load a BIP file into a clip or onto a biped that is in Edit Clip mode, because all the clips in the motion flow would have to be adapted.

**Set lowest starting foot height to Z=0 (BIP files only)**—Sets the lowest starting foot height to Z=0. This is an Open dialog option. Default=on.

In 3ds Max, the height of a motion clip can be retained. This is important if you want to retain the height of a motion clip for motions adapted to characters of different sizes. If, for example, the character is jumping off a rock, and you want to retain the Z position of the character, you would turn this option off. Leave this option off if Motion Flow motions must be blended that begin and end at different heights, such as three clips that have the character mounting a bicycle, riding the bicycle, and dismounting the bicycle.

Turning off this option can, however, cause a jump in the motion during motion flow transitions. Turn this on for smooth transitions in Motion Flow mode. If adaptation takes place, the height is set so that the lowest foot at frame 0 starts at the Z=0 height. This lines up clips along the Z-axis and creates smooth transitions.

First load raw marker data and turn on Show Markers to help you decide if calibration is necessary. If both scale and position calibration are necessary, calibrate scale first (Talent Figure mode) and then calibrate limb position. 3ds Max adapts biped keys after biped scale is changed in Talent Figure mode. Orient the biped limbs relative to the markers and click Adjust Talent Pose to apply this offset to the entire animation. Save Talent Figure Structure and Talent Pose to a FIG and a CAL file, respectively. Load a FIG and a CAL
before loading a marker file that requires the scale and position offsets contained in these files.

Note: Calibration files can be loaded in the Motion Capture Conversion Parameters dialog before filtering marker files.

- **Convert from Buffer**—Filters the most recently loaded motion-capture data. This data is stored in the motion-capture buffer. Displays the Motion Capture Conversion Parameters dialog.

The most recently imported motion-capture file is stored in its raw form in the motion-capture buffer. Convert From Buffer provides a quick way to try new conversion parameters in the Motion Capture Conversion Parameters dialog.

- **Paste from Buffer**—Pastes a frame of raw motion-capture data to the selected parts of the biped.

After importing a motion-capture file, you might discover a subtle movement has been lost in the process of reducing keyframes. Paste From Buffer can add a keyframe from the raw motion-capture data to a selected biped body part to restore this motion. Turn on Auto Key before using Paste From Buffer, or click Set Key after using Paste From Buffer to store the new position in a key.

- **Show Buffer**—Displays raw motion-capture data as a red stick figure.

Use Show Buffer to compare raw and filtered motion-capture data. Ideally, the motion of the biped and the red stick figure are very similar. If this is not the case, alter the filter parameters and import the motion-capture file again, or select a biped object and use Paste From Buffer at selected frames to restore the lost motion.

Raw motion-capture data is buffered for the currently loaded or most recently imported motion-capture file, allowing easy comparison of the raw and filtered motion data. Show Buffer displays a red stick figure representing the raw buffered data; compare this to the filtered motion of the biped during playback.

- **Show Buffer Trajectory**—Displays buffered raw motion-capture data as yellow trajectories for the selected biped body parts.

Use Show Buffer Trajectory to display a trajectory based on the buffered raw motion-capture data for any biped body part. Use this in combination with Show/Hide Trajectories on the Display rollout to see how closely the raw and filtered data match.

This assumes a motion-capture file has been imported.

- **Batch File Conversion**—Converts one or more CSM or BVH motion-capture files to filtered BIP format. Displays the Motion Capture Batch File Conversion dialog (page 2-1075).

- **Talent Figure Mode**—After loading a raw marker file, turn on Talent Figure mode to scale the biped relative to the markers. Calibration for the entire marker file takes place when you exit Talent Figure mode.

Keyframe adaptation takes place in order to accommodate the new biped scale; because of this, you should adjust the biped scale before adjusting the biped position relative to the markers.

Use Rubber Band mode on the Biped rollout and Non-Uniform Scale to size the biped in Talent Figure mode.

Ideally, you will not need to use this feature. When loading a motion-capture file, 3ds Max attempts to extract the appropriate figure scale from the given data. Use Talent Figure mode only if the extracted scale of the biped doesn’t match the scale of the original talent. Even minor differences in scale will alter the motion.
Note: Calibration controls are enabled only when a marker or BVH file is imported in its raw form. Do not use key reduction or extract footsteps when you import a marker file for the first time.

**Save Talent Figure Structure**—After changing the biped scale in Talent Figure mode, you can store the changes into a FIG file. Use this file in the Motion Capture Conversion Parameters dialog to adjust marker files created by the same actor.

**Adjust Talent Pose**—After loading a marker file, use Adjust Talent Pose to correct the biped position relative to the markers. Align the biped limbs to the markers, then click Adjust Talent Pose to compute this offset for all the loaded marker data.

**Save Talent Pose Adjustment**—Saves a Talent Pose adjustment as a CAL file.

Save a CAL file after adjusting the biped relative to the markers. A CAL file is used for processing marker files that require the same adjustment. A CAL file can be loaded in the Motion Capture Conversion Parameters dialog during marker file importation.

**Load Marker Name File**—Loads a Marker Name (MNM) file to map incoming marker names in motion-capture files (BVH or CSM) to the character studio marker naming convention. Displays the Marker Name dialog.

**Load a CSM marker file**—Browses for a marker file for use with a CSM file.

**Load a BVH marker file**—Browses for a marker file for use with a BVH file.

When a BVH file is loaded, checks for and reports unknown track names, but loads the file anyway. Reports if any required tracks were not in the file and if so aborts the file load

**Use**—Uses the marker name file when importing motion capture files

If necessary, load a Marker Name File before loading a BVH or CSM file. Marker Name files are bundled with Character Studio to map marker names in popular third-party marker files. Edit these ASCII files if the marker files you have use unique names for markers.

Note: For BVH and CSM file specifications, see the BVH.rtf and CSM.rtf documents on the program disc.

**Show Markers**—Opens the Marker Display dialog (page 2–1075), with settings for specifying how markers are displayed.

Marker and marker names are displayed around the biped. You can use these to spot and adjust discrepancies; for example, the biped elbow position relative to the elbow marker. For information on how to correct these discrepancies, see Talent Figure mode and Adjust Talent Pose.

Marker Files (page 3–969)

---

**Motion Capture Conversion Parameters Dialog**

Create or select a biped. > Motion panel > Motion Capture rollout > Load Motion Capture File button > Open a file. Load motion capture data. > Motion panel > Motion Capture rollout > Convert from Buffer button

Motion-capture and marker data typically have keys at every frame. Filtering motion-capture data reduces keys, making the job of altering or personalizing the motion data much simpler.
Other filtering options include footstep extraction, applying the skeletal structure stored in the motion-capture file to the biped, looping the data, importing a portion of the motion-capture file, and selecting tracks to load.

**Motion-Capture Buffer**

Any file imported using Load Motion Capture File is stored in its raw (nonfiltered) form in the motion-capture buffer. This buffer is used to try new filtering options with the Convert From Buffer command, and to paste keys from the raw motion-capture data to the biped using Paste From Buffer on the Motion Capture rollout. The Show Buffer command displays a stick figure that represents the buffered data.

You can create your own library of imported and optimized motion-capture data by saving .bip files for use with other characters or as part of a longer script in Motion Flow mode. Use a biped that has no mesh attached to it with Physique. You import the data, adjust it to your liking, and save it as a .bip file. You can also run standard .bip files through this filtering process to create loops or to extract footsteps from a freeform animation.

**Note:** Marker files contain position data. Regular motion-capture files contain joint rotation data.

**biped.ini Parameters**

The biped.ini text file in the \plugcfg directory has parameters for smoothing the values of motion-capture joint angles for the body’s center of mass, the spine, and the head during import. The lines appear as below:

- MocapHeightSmoothing=0
- MocapBodyHorzSmoothing=0
- MocapBodyRotSmoothing=0
- MocapSpineSmoothing=0
- MocapHeadSmoothing=0

Higher values of smoothing will cause the importer to filter and "smooth out" the data using a gaussian filter, taking out spikes and jerks in the motion. These values must be integers, and can range from 0 to any high number, but practical values would probably always be less than 10. For most cases, smoothing is not needed, so the default values are set to zero.

**Procedure**

To use Fit To Existing to import a motion-capture file:

Use a motion-capture file that contains footsteps and other motion. A handspring motion would be ideal for this example.

1. Select a biped.
2. Click Motion panel > Motion Capture rollout > Load Motion Capture File.
4. Set Footstep Extraction to On, then click OK. The motion-capture file loads.
5. Select Motion Capture rollout > Show Buffer to display raw motion-capture data as a red stick figure, then click Play.

During the “hand spring” period of the playback, the hands on the red stick figure representing the raw motion data touch the ground. The biped, using the filtered data, is positioned higher and cannot reach the ground. Dynamics calculates the biped higher than the raw motion data because the footsteps before and after the handspring are so far apart in time. Creating a freeform period in Track View — Dope Sheet and reloading the same file using the Fit To Existing option will match the biped’s position to the motion-capture position during the handspring.

6. Find the Footsteps track for the biped in Track View.
7. Right-click the footsteps area of the Track View Edit window, then select Edit Free Form (No Physics) in the Footstep Mode dialog.

8. Click the “handspring” area between the footsteps. It turns to a solid yellow.

Motion-capture data will replace the keys in this freeform period.

9. Reload the same motion-capture file using the Fit To Existing option on the Motion Capture Conversion Parameters dialog.

The freeform area created in Track View is replaced with motion-capture data. The biped closely matches the red stick figure during the handspring part of the playback.

### Interface

- **Motion Capture File**—Displays the file to be imported.
- **Footstep Extraction**—Motion capture data can be applied to the biped in one of three ways:
  - **None: Freeform**—No footsteps are extracted. For swimming or flying motion data, footstep extraction is not necessary. For a traditional approach to character keyframing, use this option to keyframe the biped without footstep or Biped Dynamics; this is essentially a freeform animation.
  - **On**—Extracts footstep.
    - Direction and style of the motion-capture data are easily edited.
    - Allows changes to the toe structure of the biped after import; footsteps will readjust the character’s motion to maintain correct foot-toe-ground contact at all times, a common problem associated with motion-capture import.
    - Inappropriate “sliding feet” in the motion data are corrected.
  - **Fit to Existing**—Fits to existing footsteps.
    - Use with motion data that has both footstep motion and flying, swimming, falling, or tumbling motions.
    - First load the motion data using Perform Footstep Extraction. Create a freeform period for the flying, swimming, or falling portion of the data in Track View, and then reload the same motion capture file using the Fit to Existing option. The freeform area is loaded with data from the motion capture file without the influence of biped dynamics.
- **Conversion**—Chooses the type of key processing.
  - **Use Key Reduction**—Reduces keys for simpler key editing.
  - **No Key Reduction**—Does not reduce keys. Use this on files that are already key reduced or if you want to work with all the data in a raw motion-capture file.

Note: Marker files imported for the first time should be loaded with no key reduction or
footstep extraction to enable the calibration controls on the Motion Capture rollout.

- **Load Buffer Only**—Does not apply the data to the biped, but loads the data to the motion-capture buffer only. Use this either to compare your edited version with the original or to paste postures from the motion-capture buffer to the biped in the scene.

  Tip: To compare the filtered data with raw motion-capture data, use Show Buffer on the Motion Capture rollout (page 2–1065) rather than turning off key reduction.

**Up Vector**—Sets the vertical axis used in the motion-capture data.

**Scale Factor**—Multiplies the stored talent size by this value and size the biped accordingly.

**Footstep Extraction group**

Options here are active when Footstep Extraction is on.

**Extraction Tolerance**—Sets the sensitivity of footstep extraction. **character studio** determines if the footstep is there by checking that the foot does not move beyond the distance determined by the Extraction Tolerance value. Smaller numbers are more sensitive and extract more footstps. The value is a percentage of foot length.

The default value is 0.15. Increase this value to 0.2 or 0.25 if too many footsteps are generated.

**Sliding Distance**—Creates a sliding footstep (page 2–1064) when positional tolerance is reached. This value is a percentage of foot length. By default, the foot must slide its own distance (100), before a sliding footstep is created.

Use this with motion-capture files that contain sliding feet. A sliding footstep can be created manually by setting IK Blend > 0 for a biped foot at a "touch" state key (biped foot first touches a footstep).

Note: Sliding footsteps display as a footstep with a line through the center.

**Sliding Angle**—Creates a sliding footstep (page 2–1064) when rotational tolerance is reached. This value is in degrees; the default is set high (360 degrees). The foot must make a complete turn before a sliding footstep is created.

Use this with motion-capture files that contain feet that pivot, as in a dance motion.

Note: Sliding footsteps display as a footstep with a line through the center.

**Only Extract Footsteps Within Tolerance**—Turns on Z-axis Tolerance. These controls filter out footsteps that do not fall within a given range of the ground plane. Use this when filtering motions, such as hopping or pitching a baseball, in which a foot might come off the ground and remain stationary, but its position is not intended as a footstep.

- **Tolerance**—Value is a percentage of leg length.
- **From Z Level**—Set a Z value (ground).

**Flatten Footsteps to Z=0**—Moves extracted footsteps to Z=0. Use this to flatten out minor differences in the height of the extracted footsteps.

**Load Frames group**

![Load Frames](image)

**Start**—Start importing at this frame. Default is frame 0, the first frame.

**End**—Stop importing at this frame. Default is the last frame of the clip.

**Loop**—Loop the data by the value set here.
This is relative. Succeeding loops start where the previous loop left off. The clips are not blended and may require editing unless the original clip was designed to loop.

Use this for clips designed to loop.

Note: This often works best if Footstep Extraction is tuned off.

Key Reduction Settings group

Key reduction keeps the original motion intact and intelligently filters out more than 80 percent of the keys in the motion-capture file, making the process of altering the biped animation much simpler.

Use the Tolerance and Minimum Key Spacing settings to fine-tune key reduction for a specific track (body part). Specify whether or not to filter a track in the Filter column.

These settings are available only if Conversion is set to Use Key Reduction.

<table>

</tbody>
</table>

Tolerance—Sets the maximum angular or positional deviation for a track.

Values are in units of translation for position tracks, and in degrees for rotation tracks.

Minimum Key Spacing—Sets the minimum number of frames between keys.

Tolerance is computed first, then Minimum Key Spacing computes further key reduction.

A Minimum Key Spacing value of 10 for the head track ensures that no two keys are closer than 10 frames for this track.

Filter—Turn off to prevent filtering of the motion capture data into a track. When this is off, there is no key reduction for the track.

Set All—Forces all tracks to the values set in these fields.

Higher values here can determine how much key reduction is possible while preserving the original motion.

Limb Orientation group

The biped elbow and knee hinge joints are perpendicular to the triangles formed by the shoulder-elbow-wrist and hip-knee-ankle respectively. Resolve errors in the motion-capture data that break this rule by using either the angle or point method.

Angle—Moves the knee or elbow position to create the biped joint key.

Point—Rotates the shoulder-elbow-wrist or hip-knee-ankle to create the biped joint key.

Auto—Auto reads exact hand and foot positions from the motion-capture data; character studio then places the knees and elbows in a natural position. For marker files involving running and walking, this option can clean up the data nearly
instantly, regardless of how many markers were used and where they were placed.

Talent Definition group

Loads a Figure Structure File (.fig) and a Pose Adjustment file (.cal) prior to importing a marker file. Typically you correct a marker file by importing it and adjusting the biped scale and limb positions relative to the markers, then saving a .fig and a .cal file using Save Talent Figure Structure and Save Talent Pose Adjustment on the Motion Capture rollout. These files can then be loaded in the Talent Definition area when importing marker files created by the same actor in a motion capture session.

Figure Structure—Loads a .fig file.
Pose Adjustment—Loads a .cal file.
Browse—Browses for a .fig or .cal file.
Use—Use either or both the .fig and .cal files to adjust marker files during a marker file import procedure.
Load Parameters—Loads a motion capture parameter file (.moc).
Save Parameters—Saves a motion capture parameter file (.moc).

Interface

Source File Selection—Opens a dialog where you can specify motion-capture files to convert. Use [Shift]-click to select all files between two that you click. Use [Ctrl]-click to add individual files to the selection.

Destination Directory—Specifies the directory in which to store the filtered files.

Specify Conversion Parameters — Lets you choose how to specify conversion parameters:

- Specify Conversion Parameters Once—Imported files use a single set of conversion parameters.
- Specify Parameters For Each File—You specify conversion parameters for each file.

Marker Display Dialog

Create or select a biped. > Motion panel > Motion Capture rollout > Show Markers button

The Marker Display dialog lets you specify how markers from .csm files are displayed in the viewports. For further information on markers and .csm files, see Character Studio Marker Files (page 3–920).

Interface

Marker Display

- Show Recognized Markers
  - on selected objects
  - on all objects
- Show Prop Markers
- Show Unrecognized Markers

OK
Show Recognized Markers—When on, displays the markers that character studio recognizes.

- **On Selected Objects**—Displays the markers on selected objects only.
- **On All Objects**—Displays the markers on all objects.

Show Prop Markers—Enables the display of markers on prop bones (page 2–1065).

Show Unrecognized Markers—Displays the markers that character studio does not recognize.

---

**Physique**

Use the Physique modifier to attach a skin to a skeleton structure such as a biped. The skin is a 3ds Max object: it can be any deformable, vertex-based object such as a mesh, a patch, or a shape. When you animate the skeleton with skin attached, Physique deforms the skin to match the skeleton's movement.

Animating the underlying skeleton enables you to animate a single contiguous model of a character that bends, creases, and bulges about an arbitrary number of joints within the attached skeleton.

With Physique, you can define how the skin behaves when it deforms. For example:

- You can make portions of the skin solid, excluding them from Physique’s deformation, though solid portions still move along with the root node of the skeleton they are attached to. These solid portions are said to be root vertices.
- You can make portions of the skin deformable. They move with the deformation spline, the smooth curve running through the links of the skeleton they are attached to.
- You can make portions of the skin rigid, directly moving along with the skeleton they’re attached to.
- You can add bulges to simulate bulging muscles. Bulges are controlled by editable cross sections of the skin, and by bulge angles that you set.
- You can add tendons to distribute the effect of one bone’s motion to areas of the skin other than those around the bone itself.
- You can save Physique data to a Physique (.phy) file, preserving data common to all objects sharing a given Physique modifier. Later, you can reload the data file, either to restore the data that belongs to a particular skin or portion of skin.

Physique works with bipeds created and animated using the Biped plug-in, and with 3ds Max hierarchies, including the Bones systems. Physique also works with bones that are not in a hierarchy and splines.

**See also**

Posing the Biped (page 2–847)

---

**Using Physique**

**Creating a Skin**

A mesh deformed by a skeletal structure is called a skin. In character studio, Physique is a modifier you apply to a skin to make it deformable by the biped, or by another skeletal structure. The images below show meshes for different skeletons.
Meshes for Physique

A skin used with Physique can be any 3ds Max object that has vertices or control points. Specifically, a skin can be:

- An editable mesh or editable poly object. This is the most commonly used type of object for Physique. Often, it has been collapsed from an object with modifiers, or a compound object.
- An uncollapsed object with modifiers or a compound object.
- A parametric geometry primitive such as a cylinder.
  Geometric primitives are useful mainly for simple applications of Physique; for example, a cylinder with two bone links to depict an arm.
- A patch object.
- A spline or text shape.
- A NURBS object.
- A Free From Deformation (FFD) modifier.
- A mesh object you import from another application such as AutoCAD®.

Tip: Although you can apply Physique to a compound object or an object with modifiers, you should collapse the stack before applying Physique, if possible. This will maximize performance and reduce the amount of work you’ll need to do to get Physique working properly. An exception is the Optimize modifier, which can be useful for improving performance when applied below Physique on the stack.

Warning: After you collapse a compound or modified object, you can no longer edit it parametrically. If you work extensively with complex meshes of this sort, you can save two .max files: one to contain the original, editable objects and modifiers, and the other to contain only the collapsed mesh.

You can create a figure’s skin out of several objects. For example, you could have separate objects for the torso, legs and arms. In this case, select all the objects and apply Physique to all of them at once.

Posing the Skin

When you create a skin to use with a biped figure, you should pose the arms and legs of the skin in a standard reference pose.

Mesh in reference pose for use with bipeds

Use the following positions when you create the reference pose:

- Spread the legs somewhat apart, at a parade rest position.
- Spread the arms wide, level with shoulder height. The hands should be level with the arms, not dangling: palms facing down, fingers straight and slightly spread apart.
- Position the head so it will face in the correct direction when you load the biped’s at-rest
standing pose. If the skin and biped are for a figure that stands erect, position the head normally. If the character stoops forward, for example, a chimpanzee, make the head face upward so that it will face forward after the spine is bent.

As a general rule, create a reference pose that has the limbs outstretched, but otherwise represents the character’s natural at-rest posture.

**Skin Simplicity**

The degree of detail on the model makes a difference in how well it works for skinning. On one hand, your skin must have a sufficient number of vertices so Physique can deform it smoothly. On the other hand, the fewer vertices the mesh has, the easier it will be for you to adjust Physique for the mesh. In addition, a highly complex mesh can slow your system’s performance when working with Physique.

If you plan to use an Editable Poly mesh, create the mesh with evenly-sized, rectangular polygons. Avoid using long, triangular polygons, as these do not deform smoothly with Physique. These attributes are particularly important around the hip and shoulder areas.

A common workflow is to create the simplest possible version of the mesh, apply Physique to it, and apply the MeshSmooth modifier above Physique on the stack. This makes Physique as easy as possible to work with, but retains mesh smoothness for rendering.

If you want to use a particular mesh but its polygons violate these guidelines, use 3ds Max to add or delete edges and polygons as needed before applying Physique to the mesh. Usually, these rules are not so important for the facial area of the model, where little deformation will take place with Physique.

For example, the character shown below was originally modeled as designed, but with no regard for the best polygon distribution for Physique. The numerous odd-shaped polygons (especially around the hips), and the pose with the legs too close together, would have made this model difficult to work with after Physique was applied.

The model was altered to work better with Physique by deleting edges and vertices, and reshaping many of the polygons in the hip area. The model was also altered to make the character assume the reference pose.
After MeshSmooth is applied to the simplified mesh, renderings of the two models look identical. However, the second model works much better with Physique.

**Using Physique with a Biped**

The skeleton to which you attach a skin using Physique can be a 3ds Max hierarchy, bones in a hierarchy, bones not in a hierarchy and splines. Physique deforms the skin based on the relative position of the bone or links in the hierarchy. Specifically, it uses the length of each link and the angle between two connected links; it can also use the scale of a link.

The skeleton hierarchy can also be a 3ds Max system object that defines a behavior as well as a hierarchy. Three kinds of objects that are especially useful with Physique:

- Bipeds are provided by **character studio**.
- Bones are a standard Systems object provided with 3ds Max.
- Splines can be used rather than a “bones” hierarchy.

You create both bones and bipeds using the Systems object category on the Create panel.

Bones are useful for facial animation, a face with moving lips for example, or for non-bipedal characters. Bipeds are the system of choice for humanoid and other bipedal characters.

Usually you create the Physique skin before you create the skeleton, because you must adapt the skeleton’s dimensions to the dimensions of the skin, in order to optimize vertex assignment to the links in the hierarchy.
Using Physique with 3ds Max Bones

3ds Max bones with or without the IK Controller can be used with the biped for various effects. They can be used with Physique to add extra links and envelopes for any character, or to animate assemblies on a robot or mechanical character. Bones can also be added to animate extra appendages, a hat, a jaw and so on.

Note: If 3ds Max bones using the IK Controller are linked to the biped, the Auto Key button must be left on while the biped is positioned.

Two examples of compressible bones.

In the top image, 3ds Max bones are used to animate the linked piston assemblies. The bottom image shows 3ds Max bones used for added control when Physique is applied. In both cases the bones compress automatically as the biped is positioned.

Bones That Compress

One way to use bones with the biped is to use the Select and Link tool on the 3ds Max toolbar to link the root of the bone to one part of the biped and have the bone End Effector follow another part of the biped. As the biped moves these bones compress and expand.

In the image of the mechanical leg, piston objects are linked to the bones. As the bones compress and expand, they also animate the linked piston assembly. As the bones compress and expand in the abdominal area in the bottom image, the envelopes created by Physique for the bones compress and expand to animate this area on the mesh.

IK Solution

In the IK Controller Parameters rollout, you specify the accuracy of the IK solution and the frame duration of the solution. For bones that compress, you generally want an accurate solution to ensure that the bone follows the end effector perfectly, without any drift. In the image of the rollout Position has a value of 0, the least amount of allowable distance (Rotation is at its default value of 1, the Rotation End Effector is not used in this example). Iterations is set high, ensuring that that the solution is accurate, even if the character is scaled down a great deal. Start and End Time should span the animation.
There are many ways to use bones with the biped. You could automatically animate the bending of a hose that is attached to a character’s shoulder and mouth when the biped head rotates, for example. Bones attached to the biped create links and envelopes when Physique is applied; these extra Physique links offer localized skin control if necessary.

Procedures
To make compressible bones (bones with end effectors):
1. Create a bones system with end effectors.
2. Link the root of the bone to the appropriate biped object.
3. On the Motion Panel specify an End Effector Parent.
4. Specify another part of the biped.
5. On the Motion Panel set the Position Threshold to 0.
6. On the Hierarchy panel > IK > Sliding Joints rollout, turn on all the sliding parameters.
7. Animate the character.
   The bones expand and compress with the motion of the character.

To add a bone after Physique is applied using Reinitialize:
1. Turn on Figure mode.
2. Add a bone where it is needed.
3. Link the root node of the bone to the biped.
4. On the Physique rollout, click Reinitialize.
5. On the Physique Initialization dialog, click Initial Skeleton Pose and then click Include New Bones.
   Vertex Link Assignment turns on also.
6. Click Initialize.
7. Adjust envelopes in Sub-Object Envelope.
8. Turn off Figure mode.
   If you want the end of the bone to follow the biped, select the bone and delete the bone end effector in the Motion Panel.

This bone is used to animate the character’s nose.
To add a bone after Physique is applied using Add (Add Bone):

1. Turn on Figure mode.
2. Add a bone where it is needed.
3. Link the root node of the bone to the biped.
4. On the Physique Bones rollout, click Add.
5. In the viewports, click a bone. Repeat until all bones are added.
6. Adjust envelopes.
7. Turn off Figure mode.

Using Physique with 3ds Max Objects

The skeleton to which you attach a skin using Physique can be a 3ds Max hierarchy, bones in a hierarchy, bones not in a hierarchy, and splines. Physique deforms the skin based on the relative position of the bone or links in the hierarchy. Specifically, it uses the length of each link and the angle between two connected links; it can also use the scale of a link.

The skeleton hierarchy can also be a 3ds Max system object that defines a behavior as well as a hierarchy. There are two kinds of objects that are especially useful with Physique:

- Bones are a standard Systems object provided with 3ds Max. Bones can either be hierarchically linked or floating.
- Splines can be used rather than a “bones” hierarchy.

You create bones using the Systems object category on the Create panel.

Bones are useful for facial animation, a face with moving lips for example, or for non-bipedal characters.

Usually you create the Physique skin before you create the skeleton, because you must adapt the skeleton’s dimensions to the dimensions of the skin, in order to optimize vertex assignment to the links in the hierarchy.

Floating Bones

Floating bones are bones that are not linked together and know nothing about each other. By adding floating bones to Physique, you can deform the mesh by animating the bones. This is in contrast to using Attach To Node and clicking the root of a hierarchy, like the biped pelvis. For Attach To Node to work all the bones should be linked together.
Applying and Initializing Physique

Spline-Based Physique Deformation
In addition to the biped and 3ds Max bones, Physique supports spline and NURBS curves for mesh deformation. By animating vertices on a spline, you can animate the mesh. You can use this technique for facial animation or to deform any mesh.

To control a mesh with a spline:
1. Place a spline inside a mesh.
2. Select the mesh and add the Physique modifier.
3. In the Physique Floating Bones rollout, click Add and select the spline in the viewports.
4. Select the spline, turn on Vertex Sub-Object, and move the spline vertices to animate the mesh.

Procedure
To attach a mesh to a bones hierarchy using Physique:
1. Select or create a bones hierarchy.
2. Position the bones hierarchy inside the mesh.
   Tip: When you use a bones hierarchy with Physique, use frame 0 as your "figure mode." Don’t include frame 0 in your animation. Use it as the place where you position the bones and fit them to the mesh.
3. Select the mesh.
4. Go to the Modify panel. Use the Modifier List to apply Physique to the mesh.
5. Click to turn on Attach To Node. In a viewport, select the root bone in the bones hierarchy.
   The Physique Initialization dialog (page 2–1111) is displayed.
6. Click Initialize, accepting the default settings.
   When you use Attach To Node to attach a Physique skin to a hierarchy, the Physique Initialization dialog appears.
   Note: This dialog also appears when you want to reset Physique settings by clicking Reinitialize in the Physique rollout.

Applying and Initializing Physique
After you have created a skin and a skeleton, and fitted the skeleton to the skin, you apply the Physique modifier to the skin. The process entails these steps:
• Selecting the mesh
• Turning on Figure mode (if a biped is used)
• Adding the Physique modifier to the stack
• Attaching the Physique skin to the skeleton
• Initializing Physique
Physique initialization settings affect how envelopes are created and blending is handled. The Link Settings, Joint Intersections, and Cross Sections rollouts are used later to change default settings globally. For this reason, the Vertex-Link rollout is open when the dialog appears. This is where you determine the following default settings:

- Whether envelopes should be used to manage the vertex-to-link assignments
- Whether Physique uses deformable or rigid envelopes to manage the vertex-to-link assignments
- Number of links considered for blending

See also

Physique Rollout (page 2–1106)

**Previewing Motion**

After you have attached the skin to the skeleton, Physique deforms the skin when the skeleton is animated. From this point on, you can preview animation to see how the Physique skin deforms and whether you can use it in a finished animation or need to correct and refine it further.

Very likely, you’ll need to adjust some of the default envelope settings to ensure all vertices are being properly handled. It’s by moving the skinned character in the viewports that you’ll see vertex assignment problems.

A stray vertex on the right elbow not encompassed by an envelope.

See the Envelope Sub-Object (page 2–1130) topic for procedures and interface.

Tip: Physique skins are usually too large for 3ds Max to play them back in real time at 30 frames per second. However, speed improvements in character studio will allow fluid motions of many skinned meshes. When you attempt to play back at 30 fps, 3ds Max may drop frames during playback, which makes it hard to see how Physique has animated the skin. Use the Time Configuration dialog to turn off real time playback. The animation plays back more slowly than usual, but it plays every frame.

Tip: You can also specify which elements of the characters not to display in the viewports, and thereby speed up redraw. See Physique Level of Detail Rollout (page 2–1108).

For a skin attached to a complicated skeleton such as a biped, you will almost always need to correct some vertex assignments before the skin animates correctly. Most often, you’ll do so simply by adjusting the envelope’s shape. See .
Envelopes and Vertex Assignments

Envelopes

Envelopes are Physique’s primary tool to control skin deformation. Envelopes define an area of influence about a single link in the hierarchy and can be set to overlap adjacent links. Vertices that fall in the overlap area of the envelopes are weighted to produce smooth blending at joint intersections. Each envelope comprises a pair of inner and outer bounds, each with four cross sections.

Deformable and Rigid Envelopes

There are two envelope types: deformable and rigid.

- Deformable envelopes influence vertices they encompass to follow the deformation spline created through the hierarchy. Only the vertices encompassed by deformable envelopes can be affected by bulge angles or tendons.

- Vertices in a rigid envelope are linked to the node (the bone) and move in an immobile relationship to the link. Vertices in a rigid envelope, however, are deformed (blended) in the overlap area of other envelopes. There is a twist parameter in Link Sub-Object that can be enabled in a rigid envelope. This allows the rigid envelope to twist along the length of the link.

Deformable envelopes (above); Rigid envelopes (below)

Typically, you use deformable envelopes when you attach a mesh to the biped pelvis to produce a soft, flexible skin. Later you reassign certain links, such as the character’s head, to the rigid envelope to minimize the deformation. For special cases, you can turn on both deformable and rigid envelopes for the same link. This advanced feature allows you to average the effect of the two types of skin deformation for additional firmness in the skin. The forearms and legs are sometimes good candidates for this.
Blending Between Links

Blending controls specify the influence of overlapping envelopes on vertices contained within the overlap area. By the actual shape of adjacent envelopes, you can control the degree of influence each has on blending at the overlap area.

You can further control the number of envelopes that participate in the blending effect, or whether no blending takes place at all. Where you specify no blending, a vertex in an overlap area is influenced by a single link only.

Inner and Outer Bounds

Where a vertex falls within the inner and outer bounds determines the percent of influence of the attached link(s). Vertices that fall within the inner bound have a weight of 1. Vertices that fall between the inner and outer bound have a weighted value that falls off to 0 at the outer bound.

Vertices are color-coded in the viewports according to their weight; the color is based on parameters you specify in the Blending Envelope Display Options Dialog (page 2–1125).

See also

Envelope Sub-Object (page 2–1130)

Adjusting Default Envelope Shape

When you want to address vertex-linking anomalies, the first step is to resize or reposition the envelope about the problem link. Most often, the problem is an envelope that is too small to surround, and thereby influence, certain vertices.

This can happen because your biped character misaligns slightly with the mesh, or the link lengths used to create envelopes with unbounded bones systems links were insufficient to surround all vertices attached to the link.

Another potential source of problems is overlapping inner bounds. This can sometimes create too strong a deformation at the joint.

You’ll note problems with vertices as you preview motion. It sometimes looks like vertices got left behind when the link they were supposed to be attached to moves in 3D space. In fact, that’s just what is happening: they weren’t assigned to any link at all, and remain where they were at the initial skeletal pose: the pose of the mesh and its skeleton at the time Physique was applied and initialized.

The other case would be vertices being moved too much, resulting in a dent in the mesh. You’d fix this by decreasing the overlap of the envelopes affecting a joint.
Stray vertices (above) reassigned to correct link(s) by modifying envelope shape (below).

Procedures

To adjust default envelope shape:

1. In the Selection Level group of the Blending Envelopes rollout, turn on Link. In a viewport, select any link.
2. In the Parameters group, turn on the Inner, Outer or Both option and then increase the value of Radial Scale until the outer envelope just surrounds the character mesh.
   Note: With Both turned on, both the inner and outer bounds scale together.
3. Increase the Parent Overlap value until the inner (red) envelope appears through the mesh.
4. If necessary, decrease the Falloff value to strengthen this envelope.

To adjust envelopes around the biped’s pelvis:

1. In the Selection Level group, turn on Link. In a viewport, select the middle link.
2. In the Parameters group, turn on Both, and then increase the value of Radial Scale until the outer envelope just surrounds the mesh in pelvis area.

The Biped Triangle Pelvis option was used in this model. Triangle Pelvis creates additional links from the legs to the lower spine.

Top: The default envelope from the pelvis to the lower spine object is too small.
Middle: Mesh appears “scrambled” because the pelvis doesn’t control all the vertices that surround it.
Bottom: Increasing the envelope size corrects the mesh problem in the pelvis area.
Note: With Both turned on, both the inner and outer bounds scale together.

3. Increase the Parent Overlap value until the inner (red) envelope appears through the mesh.
4. If necessary, decrease the Falloff value to strengthen this envelope.
5. To finish correcting the pelvis area, adjust the Overlap of the thigh and buttock envelopes.

To select and edit cross sections:

1. On the Selection Level rollout, turn on Cross Section.
2. In the Envelope Parameters group, turn on Inner or Outer if you want to work with cross sections solely in that part of the envelope. Turn on Both to be able to work on both Inner and Outer cross sections at the same time.
3. Turn on Select Object on the Main toolbar, and in a viewport, click the cross section you want.

As you move the cursor over a selectable cross section, it changes to a plus shape, letting you know the object at that location is selectable.

By default, selected cross sections are yellow. (You can customize this color with the Blending Envelope Display Options dialog (page 2–1125).)

You can use \[\text{Ctrl}\]+click to add other cross sections to the selection set.

4. Use Radial Scale to resize the selected cross section, and the transform tools to move, rotate, and scale it.
5. To move to the adjacent cross section within the current bound, click Next or Previous.

Tip: You can also use the Control Point level to individually transform cross section control points.

To copy an envelope and its settings to a mirrored link (for example, from one thigh to the other):

1. Select the source link.
2. In the Edit Commands group, click Copy. The envelope settings are saved in a buffer.
3. Select the mirror link, and then in the Edit Commands group, click Paste. The envelope is applied to the opposite link, but without mirroring. It is now the currently selected envelope.
4. In the Edit Commands group, click Mirror. The selection flips about the mirror axis.
5. Use the Rotate transform on the Main toolbar to rotate the selection to its final orientation.

Envelope Sub-Object (page 2–1130)
Fine-Tuning Envelopes (page 2–1088)

Fine-Tuning Envelopes

Once you have adjusted inner and outer bounds of envelopes at the Envelope Sub-Object level, you may find you need still finer control: choose either the Cross Section or Control Point selection level in the Blending Envelopes rollout.

Using Cross Sections

Both inner and outer envelope bounds are like hulls about ribs, the cross sections. For each envelope, there are by default four cross sections you can use to alter the envelope’s shape.
Customizing Vertex Assignments

Using Control Points

By default, each cross section consists of four control points. You can use these control points to alter the shape of a single cross section. The control points define the shape (perimeter) of the section. Moving one point affects the shape between itself and its neighbors on each side.

Rotating and Scaling

Control points are internally positioned using cylindrical coordinates, that is a distance from the link at some angle around the link. To move a control point, you must scale it to the correct distance from the link and then rotate it into the orientation you desire. The move tool actually serves the dual function of rotating and scaling at the same time.

See also

Envelope Sub-Object (page 2–1130)

Customizing Vertex Assignments

Use Vertex sub-object controls to:

- Override vertex-link assignments currently in effect.
- Change the blending type and weight.
- Assign vertices to their links yourself, bypassing Physique’s envelope method for vertex-link assignment.

You might want to reassign link assignments in effect about adjacent fingers, for example, even after working to reshape envelope size and position. You may find that you need greater control in areas where adjacent envelopes overlap:
perhaps movement in the ring finger is causing unwanted movement in some vertices for the middle finger. You’d use Vertex sub-object controls to remove ring-finger vertices from the middle finger links, in effect reassigning them solely to the ring-finger links.

When you choose Vertex as the sub-object to edit in the Physique modifier, the Physique Selection Status and Vertex-Link Assignment (page 2–1150) rollouts appear.

**Envelope Display Options**

**Interactive Redraw**
By default Interactive Redraw, an option in Envelope and Bulge sub-object levels, is turned off. After changing an envelope the mesh is refreshed on mouse up. Turn this option on for interactive viewing of how envelopes and bulges are affecting vertices. As you adjust the envelopes, the vertices move to show the effects of the resized envelopes.

**Changing Display Options**
You can change the display settings for envelopes and their component parts. Click the associated color sample to open the Color Selector and change color setting for:

- Inner and outer bounds on both deformable and rigid envelope types.
- Differently weighted vertices, as they fall within the inner bound, or between it and the outer bound.
- Selected cross sections and control points.
- Turn on or off the associated check box to determine whether any of the above envelope components are displayed.
- Number of sides for inner and outer bounds. The default is 4.

Choose Initial Skeletal Pose (page 2–1099) if you want to work in the position of the mesh and its skeleton at the time Physique was applied. Returning to this pose can be useful if the display becomes confused with the effects of unassigned vertices when the character moves through an animation.

Fine-Tuning Envelopes (page 2–1088)

---

**Working with Deformable Envelopes**
Once you’ve got the deformable envelopes working the way you want to control overall skin deformation, you may want to adjust the finer aspects of skin control:

- Skin bending, twisting, sliding, and scaling about single links are controlled at the Link sub-object level. See Adjusting Link Parameters (page 2–1091).
- Link sub-object primarily controls the deformation spline (page 3–927). You use Link sub-object options to affect the shape of the spline and the smoothness of the skin. See Adjusting Link Parameters (page 2–1091).
- Crease behavior where links meet and bend is controlled at the Link sub-object level with Joint Intersection (page 2–1140) parameters.
- Muscle bulges as your character’s limbs move through a range of motion are controlled at the Bulge sub-object level. See Creating Bulges (page 2–1094).
- Skin stretching, generally between non-contiguous links, is controlled at the Tendon sub-object level. Tendons provide a secondary movement (a pulling or stretching) based on links farther up or down the skeleton. See Creating Tendons (page 2–1096).
Working with Rigid Envelopes

Vertices influenced by a rigid envelope follow the link itself rather than the deformation spline, like deformable vertices do. Low vertex-count models used for games are typically connected to the skeletons with rigid envelopes to simplify export to game engines. In such a case, each vertex can be simply described as assigned to a specific link. It can be located by giving a length along the link, a distance from the center of the link, and an angle around the link. As the link is transformed, all the vertices assigned to the vertex are uniformly transformed. This makes it simple for game engines to move the character’s skin.

The vertices move equally with the controlling link, so the skin appears rigid. For instance, in the case of a flexing arm, the skin between the wrist and elbow tightly follows the movement of the forearm, with no change in the spacing between vertices. The skin between the elbow and shoulder tightly follows the upper arm. Vertices around the elbow influenced by both links, smoothly blend to an average position between the two changed links.

Rigid and deformable envelopes can be mixed on a given character. You might, for instance, use deformable envelopes for most of the character, but choose rigid for the head and for a suit of armor around the torso.

Note: In Link sub-object, you can turn on twisting for rigid envelopes. As the wrist twists the vertices on the forearm will twist also.

- Tendons Sub-Object (page 2–1147)

See also
- Envelope Sub-Object (page 2–1130)

Working with Both Deformable and Rigid Envelopes

You can assign both Deformable and Rigid to a given link. For example, you might assign both to the shins, and size the envelopes differently to gain the benefits of both.

First, size the deformable envelope to affect the whole lower leg area and smoothly transition into the thigh and ankle areas. Next, you define a smaller rigid envelope to encompass the stiff unbendable section of the shin. Increase the weight of the rigid envelope to balance its effect against that of the deformable envelope.

Some users might use both envelopes as a way to have a bone affect two completely separate regions of a mesh. The envelopes are scaled so that the deformable envelope influences certain vertices on one side of the link and the rigid envelope affects the other side.

See also
- Envelope Sub-Object (page 2–1130)

Adjusting Link Parameters

Physique creates a continuous spline through each of the joints in the hierarchy. The spline is represented by an orange line within the object. It maintains continuity through each joint: as a joint angle changes, the spline passing through the joint remains a smooth curve. Physique relies on the deformation spline to obtain smooth bends of the skin object. Physique offers bias and tension controls to adjust the shape of the deformation spline.
You can use controls at the *Link sub-object level* (page 2–1135) to adjust the skin behavior about a given link. These link parameters define how the skin deformation behaves, relative to the motion of the underlying skeleton.

There are four kinds of *link parameters* (page 2–1136):

- **Bend parameters** affect the curvature of the deformation spline through the joint at a given link. As a result the skin deformation can range from more angular at the joint to more like a stiff rubber tube.

- **Twist parameters** control how the skin deforms when a joint rotates along its length, as in turning a doorknob. Consider, for example, winding up the rubber band on a toy airplane propeller; Twist parameters determine how the twist is distributed along the link and across the joint. Twist parameters apply to link rotation whose axis is the same as the axis along the length of the link.

- **Sliding parameters** control how the skin moves along the length of a link as a joint rotates. On the outside, the side where the angle is greater than 180 degrees, the skin moves toward the joint. On the inside, the side where the joint angle is less than 180 degrees, the skin moves away from the joint. The sliding effect tightens the outside to keep detail at the joint and prevent the facets of the mesh from moving apart. It relaxes the inside to prevent the mesh from bunching up at the joint.

- **Radial Scale parameters** affect the influence on the skin caused by scaling links of the skeleton. Certain settings, such as Breathe and Stretch, react to scaling of the skeleton, but only with standard 3ds Max bones or a 3ds Max hierarchy. *Note:* Bipeds and 3ds Max IK controllers don’t support scaling.

Link Scale provides a way to globally scale all the vertices influenced by the link. *CS Amplitude* scales the effect of bulge cross sections across the entire link. It can be used for animated scaling of the bones or for general mesh adjustments. The intent is not to edit the character itself, but rather the effect the bones have on it.

You set Link parameters at the sub-object level, in the *Physique Link Settings rollout* (page 2–1136).

### Partial Blending and Weight Assignments

Most often, you will want to use envelopes to correct the way skin behaves as the biped moves. However, you can override envelopes by manually assigning vertex properties. For example, you can remove the influence of inappropriate links from selected vertices. You can also change the weight distribution between links for a single vertex by using type-in weights.
In Cases where No Envelopes Use Partial Blending (the Default)

Vertex \( v \) is assigned to links \( l_1, l_2, \) and \( l_3 \), and the weights for these links are: \( w_1 = 0.2, w_2 = 0.3, \) and \( w_3 = 0.4 \).

In a non-partial blended case, the sum of these vertex weights is \( w_1 + w_2 + w_3 = 0.9 \) (less than 1.0).

With partial blending off, Physique will normalize the weights so they sum to 1.0. For example:

\[
\begin{align*}
\text{w1'} &= \frac{w_1}{w_1+w_2+w_3} = \frac{0.2}{0.9} = 0.2222222... \\
\text{w2'} &= \frac{w_2}{w_1+w_2+w_3} = \frac{0.3}{0.9} = 0.3333333... \\
\text{w3'} &= \frac{w_3}{w_1+w_2+w_3} = \frac{0.4}{0.9} = 0.4444444...
\end{align*}
\]

so

\[
w_1' + w_2' + w_3' = 1.0
\]

In Cases where All Envelopes Use Partial Blending

The weight fill-in for vertices with a weight less than 1 will always fill with the weight of the root. Whenever a vertex is assigned to a group of links, all of which are partially blended, then the remaining weight will be assigned and blended with the root link.

This works well for a case where you want partial deformation falling off to no deformation. An example would be a static head, where you are deforming the head for facial expressions, but the head itself remains in place.

For example: vertex \( v \) is assigned to links \( l_1, l_2, \) and \( l_3 \). The weights for these links are: \( w_1 = 0.2, w_2 = 0.3, \) and \( w_3 = 0.4 \).

The sum of these vertex weights is \( w_1 + w_2 + w_3 = 0.9 \) (less than 1.0). We need an additional fill-in weight (\( wf \)). The fill-in weight is determined by \( 1.0 - (w_1+w_2+w_3) = 0.1 \), or 10%. Physique fills in with weight \( wf \) from the root (leaving the vertex partially undeformed).

The resulting deformation will be \( w_1'l_1 + w_2'l_2 + w_3'l_3 + wf'\text{root} \). The root portion of this deformation is essentially an undeformed portion that simply follows the root of the skeleton.

In Cases where Some Envelopes Use Partial Blending and Some Do Not

The vertex weight fill-in in overlap areas will be based on the percentage of partial and non partial weights. For example, if the total weight of non partial links is 80% of the total summed partial and non partial weight, then 80% of the fill-in will be more of the non partial deformation. The remaining 20% fill-in will come from the root.

Example: If Vertex \( v \) is assigned to links \( l_1, l_2, \) and \( l_3 \), the weights for these links are: \( w_1 = 0.2, w_2 = 0.3, \) and \( w_3 = 0.4 \).

Let’s assume \( l_1 \) and \( l_2 \) are nonpartial, and \( l_3 \) is partial. The nonpartial weight is \( w_1 + w_2 = 0.5 \); the partial weight is \( w_3 = 0.4 \); then nonpartial weight is \( 0.5/(0.5+0.4) = 0.5555555, \) or 56%; and the fill-in weight is still \( 1.0 - 0.9 \) or \( wf = 0.1 \).

The program fills in with 56% of \( wf \) with more of the nonpartial blended links. The remaining 44% of \( wf \) is filled in with the root as in the partial blended case. This provides a smooth transition between the partial and nonpartial links.

Bulges

For some animations, simply attaching the skin and correcting its vertex assignments results in an animated skin you can use in final renderings. For other animations, you might need to give the skin more realistic movement, for example, muscles that bulge.

Physique lets you simulate an underlying musculature for the skin by adding tendons (page 2–1096) and bulges:
• Bulges change the skin’s profile to simulate bulging muscles. You create the bulge by establishing bulge angles, relationships between cross-sectional slices of the skin and specific poses of the skeleton joint. Imagine a cross section to be a slice through the skin’s mesh, perpendicular to the link. By making changes to cross sections, you in turn distort the shape of the mesh. Bulges in your character can be constructed by associating certain poses with related changes to the cross sections, in other words by defining bulge angles.

At any joint angle, you can define a bulge angle, and you may define as many bulge angles as needed. The bulge angle consists of the current orientation of the joint together with any defined cross sections. In addition, you can adjust the influence of a bulge angle. Physique considers all the bulge angles as the character moves. The resulting bulge is created by interpolating the effects of the various bulge angles having some influence at the current joint angle.

For example, to create a bulging biceps muscle, in Bulge sub-object level, on a selected link, insert a cross section near the center of the upper arm. Pose the arm into a flexed position, with the angle between upper and lower arms at 90 degrees or less. Insert a bulge angle and adjust the cross section so that it distorts the mesh appropriately. In the viewports and in the Bulge Editor (page 2–1114), you can edit the shape of the bulge to look like a flexed biceps muscle: higher and wider above the bone than below it. Now as the elbow bends from a straight orientation up and toward the shoulder, Physique bulges the biceps appropriately.

Note: The resulting bulge for any given frame in an animation is determined by the interpolated effects of all bulge angles for the link, based on the relationship of each bulge angle to the current joint angle. Bulge angles are not directly associated with keyframe parameters, but are relative to the skeleton’s behavior.

See also

Bulge Sub-Object (page 2–1141)

Creating Bulges

Bulges simulate bulging muscles. Physique creates bulges based on bulge angles and cross section shapes you specify, not on keyframe settings. You create a bulge by:

• Reposing the character to a position where the bulge will have its greatest effect. This can just be a matter of using the time slider to scrub to that place in a loaded motion file.

• Setting a bulge angle between two links, the currently selected link and its child link in the hierarchy. The bulge angle is the angle of the joint where the bulge has its full effect. When the joint has a different angle, Physique interpolates so the bulge can grow as the joint flexes toward that angle. See Setting Bulge Angles (page 2–1095) for more information.

Note: The resulting bulge for any given frame in an animation is determined by the interpolated effects of all bulge angles for the link, based on the relationship of each bulge angle to the current joint angle. Bulge angles are not directly associated with keyframe parameters, but are relative to the skeleton’s behavior.

• Apply only as much detail as you need to get the effect you want for a particular scene in your animation. This is probably the best approach when the Physique animation is meant to be used only once, or is not the main focus of the animation.

• Define a fully deformable character, with bulges for its entire range of motion. This is probably the best approach when you intend to reuse the Physique character in an ongoing series of animations, for example, or in a video game that has a variety of character action.
Setting Bulge Angles

Bulge shape is interpolated as joint movement approaches a bulge angle.

- Creating and shaping the cross sections associated with the bulge angle. A link’s cross sections and its profile are spline controls of the shape of the skin. To create and shape cross sections, see Shaping the Bulge (page 2–1096).

Each bulge angle affects both neighboring links. Therefore, each link contains a set of cross sections for each bulge at both its parent and child joint angles. For example, the forearm link can be deformed by bulge angles associated with both the elbow and wrist joints.

- Adjusting bulge parameters, including the joint intersection parameters. Bulge parameters control the smoothness and the strength of the bulge and are found at the Bulge sub-object level.

Joint intersection parameters control how the skin behaves when bulges would overlap each other if there were no collision detection for skin vertices. They are in a Physique rollout for Link sub-objects. See Reinitializing Physique Settings (page 2–1098).

See also

Bulge Sub-Object (page 2–1141)

Setting Bulge Angles

A bulge angle associates an angle value and a name. By default, each link has one bulge angle whose default name is the name of the link followed by “Bulge 0”. The default bulge angle’s initial angle value is the angle between the link and its child when you first attach Physique to the skeleton.

Bulges are effective because they grow and shrink as the joint moves. The initial bulge angle defines one shape that the skin can deform to; this would normally be like a default musculature. With no other bulge angles defined, the skin would always look like the first bulge angle, regardless of pose. Additional bulge angles provide the other shapes the mesh can deform to.

In the simple case of a flexing biceps muscle, one bulge angle defines the relaxed position and another defines the muscle in its flexed pose. Both are exposed so you can add definition to the default character. As in a biceps muscle, a heavily-muscled character might have some shape even in a relaxed pose. This lets you change the baseline without disturbing the original mesh. You can actually use Physique bulge cross sections to model your character.

The cross section deformation for a given link is determined by interpolating between the contributions of all bulge angles that affect the link. This includes bulge angles for both the link’s parent joint angle and its own (child) joint angle. Each bulge angle’s contribution is determined by:

- Influence (how far away the bulge angle is from the current joint angle rotation)
- Power (an ease based on the influence of the angle)
- Weight (the relative strength of the bulge angle)
Keep in mind that bulge angles can be set for arbitrary rotations, and are not limited to single-axis hinge joints.

**See also**
*Bulge Sub-Object (page 2–1141)*

---

**Fine-Tuning Bulges**

The *Bulge Editor (page 2–1114)* duplicates many of the controls available at the Bulge sub-object level. It gives you a focused, two-dimensional view of the current bulge settings.

**Shaping the Bulge**

Once you've inserted the bulge angle, and recorded the angle setting, you then shape the bulge by inserting and adjusting cross sections. You can either move and scale the cross sections, or adjust each one's shape using control points.

**Adding More Poses to Your Character**

For more complex body movements, you may need to add bulges for different positions. Overall, you might want to build a generic character that works in a number of situations, regardless of the type of motion.

Some examples are:

- Moving the character into several extreme poses.
- Putting the arms high over the head and bending them into different positions.
- Making the character squat and lifting the legs into various positions.
- Adding bulge angles to the links at places where real muscles would bulge.

Once the skin reacts well to the full range of motions, you can then place the character into a less demanding pose and it should work perfectly.

---

**Tendons**

Tendons tie links together, extending the effect of moving one link to another link where the tendon is based. Their effect is similar to that of tendons in a body.

For example, raising an arm usually stretches the skin along the same side of the body. To get this effect using Physique, you could base a tendon on a spine link, then attach it to the upper arm or collarbone, so when the arm lifts, the skin around the torso stretches as well.

**See Creating Tendons (page 2–1096)** for more information about creating tendons.

**See also**
*Tendons Sub-Object (page 2–1147)*

---

**Creating Tendons**

Like tendons in an actual body, *tendons in Physique (page 2–1147)* link one bone to another. They spread the effect of moving one link to the skin around a different link. Tendons can improve the realism of skin movement when it is animated by Physique.

Basically, a tendon consists of base points that live on a cross section near the skin. A base point is attached to another link on the skeleton that pulls it. As the tendon base point is pulled, it deforms the skin around it. Several parameters control how much the point is pulled in each direction.

You insert the tendon cross section at the location where you want the skin to stretch. You then attach it to the link that influences the movement.

Each link can contain several tendon cross sections, and each control point may be attached to a separate link. In a practical application, however, such as in the area below the armpits, you
Creating Tendons

might have two control points attached to each of
the left and right clavicles.

**Procedures**

**To create and attach a tendon:**

1. Go to the Tendons sub-object level. In the
Selection Level group of the Tendons rollout,
turn on Link.
2. In a viewport, select a link.
3. In the Insert Settings group, click to turn on
Insert.
4. In a viewport, position the cursor over the link.
The cursor changes to a small star.
5. Click to create cross sections on the link.
6. Click to turn off Insert.
   Tip: You can also right-click in a viewport to
turn off tendon creation.
7. In the Selection Level group, turn on Cross
Section.
8. Use the Rotate tool to rotate the cross
section so the control points are positioned in
useful places.
9. In the Tendon Parameters group, use the Radius
spinner to scale the cross section radially so the
control points fall close to the surface of the
skin.
10. In the Selection Level group, turn on
Control Point, then in a viewport, select one
or more control points.
11. In the Edit Commands group, turn on Attach,
then in a viewport, click a different link.
   Tendons span the area between the links.
12. Adjust the Pinch, Pull, and Stretch settings to
adjust the skin behavior.
13. Adjust the Upper and Lower Boundary
settings to control the extent of the effect on
neighboring links.

**To attach a tendon to another link:**

1. In the Selection Level group of the Tendons
rollout, turn on Control Point to make it the
active selection level.
2. In a viewport, select one or more of the tendon’s
attach points.
   Click a point to select it; use [Ctrl]-click to add
points to the selection; or drag a rectangular
region to select multiple points.
3. In the Edit Commands group, turn on Attach.
4. In a viewport, click the link to which you want
to attach the tendon.
   In the viewports, red lines appear showing the
tendon’s connection from its base to the other
link. The skin mesh might also deform as a
result of attaching the tendon.
   Tip: The tendon can have fixed attach points
that are not connected to another link. These
are useful for giving some rigidity to the skin,
as when (in an actual body) a bone lies close
to the skin’s surface. For example, you might
leave two fixed attach points on either side
of a character’s chest area, to simulate the
effect of the sternum. When all tendons are
attached to other links, the skin over the base
link can have a "squishy" appearance when
it is animated. This is appropriate for some
animated characters, but not for others.

**To delete a tendon:**

1. At the Link selection level in the Tendons
sub-object, select the link that has the tendon
you want to remove.
2. In the Insert Settings group, click Delete.
Saving and Loading Physique Data

You can save Physique data to a Physique (.phy) file to save data common to all objects that share a given Physique modifier.

Later, you can reload the data file, either to restore the data that belongs to a particular skin or portion of skin, or to transfer the Physique of one skin (or portion) to a different one.

Physique Rollout (page 2–1106)
Physique Load Specification Dialog (page 2–1123)

Reinitializing Physique Settings

When you need to reset vertex, envelope, and other skin parameters on a Physique mesh, click Reinitialize to display the Physique Initialization dialog. Using controls in this dialog, select the category to update, and apply the new global settings.

For example, if you’ve added a new bone to the hierarchy and want it included and influenced by the Physique modifier, use the reinitialization mechanism to effect its inclusion. Or maybe you’ve repositioned the biped structure relative to the mesh, you’d need to reinitialize Physique settings to recognize those changes.

Reinitializing with changed settings applies them as new defaults in the areas you choose. Reinitializing without changing settings on the Physique Initialization dialog is a method of erasing unsatisfactory changes you’ve made to the Physique settings, again in those areas you specify.

See also

Reinitialize Physique (page 2–1113)
Working with an Initial Pose

At times, you'll need to alter the fit of the hierarchy in the Physique mesh, or change its structure. To do so, you change the default, initial pose, which Physique uses as a reference for various operations, including reinitializing.

- For a biped, you change the structure in Figure mode, then reinitialize the Initial Skeleton Pose.
- For a Bones system with the HD IK solver, there is a Show Initial State check box in the Motion panel, on the IK Controller Parameters rollout.
- For any other hierarchy, use frame 0 for the initial pose. Be sure your animation does not affect the position of the skeleton in frame 0.

Procedure

To load a file created with different system units:

Note: If the System Unit Scale has a value that is different from that of the file you are loading, 3ds Max prompts you to rescale the scene. If you do so, any objects that have a Physique modifier exhibit a double scaling. Do the following:

1. Select the object.
2. Reinitialize with both Initial Skeletal Pose and Vertex Settings (the last check box) turned on.

See also

Figure Mode (page 2–982)

Improving Interactive Performance

Physique is multithreaded and optimized for modifier stack changes below the Physique modifier.

Level of Detail Controls

The controls in the Physique Level of Detail rollout (page 2–1108) help you optimize performance while working with Physique, by letting you specify which skin deformations are refreshed automatically in viewports. The more complex the skin object, the more effective these controls can be at speeding up your work.

Note: The 3ds Max renderer also heeds Level of Detail settings. Don't forget to reset these controls before the final render.

Turning Blending On and Off

When Physique is first initialized, the Blending Between Links parameter in the Physique Initialization dialog (page 2–1111) is set to N Links (page 3–978). This means that every envelope must be considered when determining the influence on any vertex (page 2–1123). You can reinitialize with No Blending (or only 2, 3, or 4 links) to reduce this calculation permanently, although at the cost of losing some or all blending at the joints.

Note: Setting to No Blending is advise only for those developing characters to be used by real-time game engines.

You can also set No Blending at the Vertex sub-object level. You can temporarily disable Link Blending on the Physique Level of Detail rollout, on the Modify panel.

Using the Optimize Modifier with Physique

The standard 3ds Max Optimize modifier allows you to reduce the level of mesh detail in order to increase display performance and speed up screen refreshes. Optimize can be helpful with Physique when you work with complicated skin objects such as detailed biped figures.

There are stack update options that determine how the stack is updated. See the Physique Level of
Detail rollout (page 2–1108) for a reference on the stack update options.

**Warning:** If the current stack update option is Reassign Globally, any modifier in the stack below Physique causes Physique to reevaluate vertex assignments each time the stack is changed. While this technique will improve performance in one way, it will hurt performance if you need repeatedly to make changes down in the stack.

**Procedure**

To optimize skin objects:

1. Select the skin.
   
   If the skin consists of multiple objects, select all of its component objects.

2. Apply an Optimize modifier to the skin.
   
   The Optimize modifier’s Parameters rollout appears on the Modify panel.

3. In the Optimize group of the Parameters rollout, increase the value of Face Threshold.
   
   As you increase Face Threshold, Optimize reduces the number of faces in the mesh.

The optimized mesh displays more quickly and speeds up your work with Physique. However, it doesn’t show full detail, and sometimes an optimized skin does not animate correctly, because of the reduced number of vertices.

**Tip:** Always turn off Optimize before you render the animated skin.

---

**Scaling a Character**

Using standard 3ds Max scale transform tools, you can adjust a biped’s posture by scaling the size of its links. You must be in Figure mode to scale the biped links. If you try to scale a biped without going into Figure mode, nothing happens.

**Procedures**

To scale a biped that has a mesh attached to it by using Physique:

1. Select the biped.

2. On the Motion panel, on the Biped rollout, turn on Figure mode.

3. On the Structure rollout, change the biped’s height.
   
   The biped and mesh scale together.

To reinitialize a scaled mesh:

Reinitializing a scaled mesh might be necessary if you use Initial Skeleton Pose in Physique. In this case, the mesh appears at its size before scaling. To correct for this, perform the following steps:

1. On the Modify panel, either make Physique inactive, or highlight the skin so the active level is below the Physique modifier in the stack.

2. Scale and move the mesh until it matches the biped or bones.

3. Re-enable Physique, or highlight its name once more in the stack display.
   
   The mesh will get large because it is doubly scaled.

4. Reinitialize with Initial Skeleton Pose turned on.
   
   The mesh will shrink to the size you set during scaling.

---

**Facial Animation**

As an alternative to morphing, Physique can be used effectively for detailed facial animation when a character’s face is set up with extra links. By setting up 3ds Max bones or other objects at appropriate locations on the mesh head, you can define a skeletal structure for moving the facial features.
Facial Bone Structure

A common skeletal structure for the face includes:

- Bones to make the upper and lower lips open and close.
- Bones to push the outer corners of the mouth, as for a smile.
- Bones to make the eyes open and close.
- A bone to control the jaw opening and closing.
- The main head bone going straight up from the neck to the top of the head. This bone controls the head overall, and any vertices not affected by bones on the eyes, mouth and jaw. Use this bone to bend the head forward or backward.

Tip: If you’ve never set up a facial bone structure before, refer to a text on character animation for information on the facial bones needed to create various expressions.

In general, the lower lip bones should be linked to the jaw, and upper lip, jaw and eye bones should be linked to the main head bone.

You can also use splines linked to the biped head to deform the mesh. You can add a spline to a character that already has Physique applied by using Add in the Physique Bones rollout and clicking the spline in a viewport.
If you use objects other than 3ds Max bones, you must create dummy objects at the end of each object used as a bone, and link each one to its corresponding bone before applying Physique. This is necessary because Physique extends links to the end of the second-to-last object in the hierarchy, not the last. In other words, if you don't create and link the dummy objects to the bones, Physique will not extend links to the ends of the bones.

Mesh objects that are to be animated along with the face, such as the eyes and hair, should not be linked to the bone structure until after Physique is applied. If you link them beforehand, Physique will treat them like bones. You can link these objects to the main head bone after you apply Physique.

**Separate or Connected Head**

There are two ways a setup like this could be used with a character body: The head could be attached to the body mesh, or it could be separate.

If possible, use a head that is separate from the body mesh. For human characters, this often works fine; most character animation doesn’t provide a view of the underside of the neck, so
your viewers will most likely never notice that they’re separated. If you use a separate head, it will be easier to control the facial animation.

If you use a separate head, apply Physique to the head mesh alone. Click Attach to Node and pick the main head bone. Check the links to make sure they extend to the ends of the bones. Then, link the main head bone to the biped head.

If the character’s head is connected to the mesh, link the main head bone to the biped head before applying Physique. Alternately, you can use the biped’s head as the main head bone, linking the facial bones directly to the biped’s head. When you apply Physique and click Attach to Node, pick the biped’s COM as usual.

After applying Physique to the head or the entire structure, you can adjust envelopes and vertex assignments for the facial bones as you would for any biped bone.

**Animating the Facial Structure**

After you apply Physique to the structure, you can animate it by rotating or moving bones. 3ds Max manipulators (page 2–27) are useful for setting up a custom user interface for bone animation.

**Facial Animation**

Facial expressions animated with Physique and facial bones.

**Tip:** Hierarchies other than bipeds can’t use Figure mode, so special consideration is needed to establish the initial skeletal pose. Position the facial bones in the “at rest” position at frame 0, and start keyframing the face at frame 1 or later.

You can perform lip sync animation by loading a sound track in Track View. By scrubbing the time slider, you can locate a sound and keyframe the dummies to appropriate positions.

**Procedure**

To isolate lip vertices from influence by inappropriate links:

When working with a complicated facial bone structure, envelopes for the lower lip are bound to affect vertices in the upper lip, and vice versa. In general, this can be corrected in at the Vertex sub-object level:

1. Select the head and on the Modify panel go to the Vertex sub-object level.
2. Turn on Initial Skeletal Pose
3. Turn on Select, region-select vertices of the lower lip, then click Remove From Link.
4. Select the links of the upper lip, and click Lock Assignments.
5. Region-select vertices of the upper lip, and click Remove From Link.
6. Select links of the lower lip, and click Lock Assignments.

Physique and Modifiers

Combining Physique with Other Modifiers

Although you can apply Physique to an object with modifiers, this can affect performance. If you use other animated modifiers in combination with Physique, this reduction is unavoidable. If the other modifiers are not animated, you can collapse the stack to remove modifiers prior to Physique. This can significantly improve performance.

How Physique reevaluates vertices coming up the stack depends on the stack update options.

Stack Update Options

In Physique, there are three stack update options available from the Physique Level of Detail rollout (page 2–1108) to determine how Physique handles animated vertices coming up the modifier stack.

Add Change

Add Change adds in the changes from the stack and then applies mesh deformation. No vertex remapping or reassigning is done. This is the default option, and usually will give you the deformation that you want. There is no performance degradation from Physique.

Remap Locally

Remap Locally resets vertex position on the spline used for bending and the link position used to interpolate twist. Use this option when vertices are sliding along the length of the spline, and you want them to bend and twist based on the spline position but don’t want the weights to change.

Reassign Globally

Reassign Globally does a complete vertex reassign for each frame. Use this option when vertices are moving to different envelopes and you want them reassigned to the new envelopes. This option should rarely be used. The only reason would be if vertices are sliding along a link and you want the twist to be interpolated based on the new position.

Using Physique with Changing Geometry

Physique can effectively handle dynamically changing geometry. That is, if the geometry coming through the modifier stack to Physique changes, Physique dynamically adjusts to accommodate the changes to the geometry, while maintaining its own parameter settings, including manual vertex assignments. This is why, when using Optimize, you can effectively change the resolution of the geometry deformed by Physique.

Only in situations where the changes dramatically increase the density of data is there ever a need to manually adjust vertex assignments. Physique remembers your manual vertex assignments, and uses these assignments to reassign vertices when the geometry changes.

Physique and Free Form Deformations (FFDs)

Physique can be applied to a Free-Form Deformation (FFD) space warp, which in turn can animate a mesh that is bound to the FFD. For
example, you could use this technique to animate a credit card or a box of cereal.

**Procedures**

**To apply Physique to an FFD to animate the entire mesh:**

1. Place an FFD (Box) space warp around the mesh to deform. The box should be large enough to encompass the mesh. The number of control points you use for the FFD can be fine-tuned later by going back down in the stack to the FFD to adjust the number of control points.
2. Select the FFD and apply the Physique modifier.
3. Click Attach To Node, and then click the biped pelvis or the root node of your bone structure.
4. If necessary, select the FFD space warp and adjust the vertex assignments of the control points so they are assigned to the proper links. This can be done in the same way as done using Physique with a mesh, only there are fewer assignments to deal with. Although fewer assignments provide smoother surface deformation with the FFD, control points and their link assignments must be thoughtfully placed.
5. Use Bind To Space Warp on the main toolbar to bind the mesh to the FFD space warp.
6. Link the mesh to the biped pelvis, or root node of the bone structure, so it follows the skeleton and FFD as they move around the scene.

**To use an FFD to complement the effects of Physique on a portion of a character mesh:**

Tip: You can use this procedure to animate clothes or amorphous shapes.

1. Place an FFD (Box) space warp around the mesh to deform. The box should be large enough to encompass the mesh. The number of control points you use for the FFD can be fine-tuned later by going back down in the stack to the FFD to adjust the number of control points.
2. Select the FFD and the mesh and apply a Physique modifier to both.
3. Click Attach To Node and in a viewport, click the biped pelvis.
4. Select the mesh only, and add a Mesh Select modifier to the mesh above Physique in the modifier stack.
5. Go to the Vertex sub-object level (or Control Vertex), and select the set of vertices (or CVs) that lie inside the FFD space warp you are using.
6. While in Vertex sub-object level, bind the mesh to the FFD space warp. Now only the selected vertices or CVs will be affected by the FFD.
7. With the mesh selected, highlight the Physique level in the stack, and assign all vertices or CVs affected by the space warp as blue (rigid). These should be the same vertices or CVs selected in step 5, above.
8. Assign the rest of the vertices or CVs that fall outside the FFD as deformable, in the same way you normally assign vertices to links (page 2–1150) with Physique.
9. Select the FFD space warp. If necessary, adjust the vertex assignments of the control points so they are assigned to the proper links. You do this in the same way as you do when using Physique with a mesh, except there are fewer assignments to deal with. Although
fewer assignments provide smoother surface deformation with the FFD, control points and their link assignments must be thoughtfully placed.

Physique User Interface

Physique User Interface

Select a mesh. > Modify panel > Modifier List > Physique. > Modify panel > Floating Bones, Physique, and Physique Level of Detail rollouts

Physique is a modifier. Controls for Physique appear on the Modify panel. The Physique and Floating Bones rollouts are for attaching the mesh to the biped, splines, or bones. Controls in the Physique Level Of Detail rollout are for troubleshooting envelopes, bulges, and tendons. The sub-object controls are for fine-tuning envelopes, creating and adjusting tendons and bulges, and for vertex editing.

See also

Physique (page 3–994)
Physique (page 2–1076)

Physique Rollout

Select an object that has the Physique modifier applied to it. > Modify panel > Physique rollout

You use the buttons on the Physique rollout to link a mesh to a biped, a bones hierarchy, or a spline; to reinitialize the Physique parameters on a mesh; to open the Bulge Editor (page 2–1114); and to load or save Physique (PHY) files.

Procedures

To attach a mesh to a biped using Physique:

1. Select or create a biped.

2. Go to the Motion panel. On the Biped rollout, click to turn on Figure mode.

3. Position the biped inside your character mesh.

4. Select the mesh.

   Important: If the mesh is made of multiple objects, select all of them.

5. Go to the Modify panel. Use the Modifier List to apply Physique to the mesh.

6. On the Physique rollout, click to turn on Attach To Node. In a viewport, select the biped’s pelvis object.

   The Physique Initialization dialog (page 2–1111) is displayed.

7. Click Initialize, accepting the default settings.

   By default, the Object Bounding Box option is selected: Physique sizes envelopes to approximate the biped limbs.

8. Experiment with animating the biped, and adjust envelopes around problem areas. Use the Envelope sub-object level to edit the newly created envelopes.

To attach a mesh to a bones hierarchy using Physique:

1. Select or create a bones hierarchy.

2. Position the bones hierarchy inside the mesh.

   Tip: When you use a bones hierarchy with Physique, use frame 0 as your "figure mode."
Don't include frame 0 in your animation. Use it as the place where you position the bones and fit them to the mesh.

3. Select the mesh.

4. Go to the Modify panel. Use the Modifier List to apply Physique to the mesh.

5. Click to turn on Attach To Node. In a viewport, select the root bone in the bones hierarchy.

   The Physique Initialization dialog displays.

6. Click Initialize, accepting the default settings.

7. Experiment with animating the bones, and adjust envelopes around problem areas. Use the Envelope sub-object level to edit the newly created envelopes.

To add a bone after you've already used Attach To Node:

1. Link the bone to the biped, then click Reinitialize.

2. Select the mesh, then go to the Modify panel. On the Physique rollout, click Reinitialize.

   The Physique Initialization dialog is displayed.

3. On the dialog, in the Initialize group at the upper left, click to turn on Initial Skeleton Pose. The toggle Include New Bone becomes available. Click to turn on Include New Bone, and then click Initialize.

To save Physique data:

1. With Physique active on the Modify panel, click Save Physique File on the Physique rollout. A file save dialog is displayed.

2. Enter a name for the new Physique file, and then click OK.

To load Physique data:

1. With Physique active on the Modify panel, click Open Physique File on the Physique rollout.

   A file open dialog is displayed.

2. Choose the Physique (PHY) file to open, and then click OK.

   A Physique Load Specification dialog is displayed.

3. Use the dialog to choose the kind of data to load, and then use the lists to match links in the PHY file with links in the scene.

   Important: The number of links selected from the file (left column) must match the number of links in the active Physique modifier (right column).

4. Click OK.

   Physique updates the links you chose with the data that was saved.

Interface

Attach to Node—Attaches the mesh objects to the biped or to a bones hierarchy.

Important: Put the biped in Figure mode and fit it to the mesh character before you click Attach To Node.

Turn on Attach To Node, then in a viewport, click the biped's pelvis or the root node of a bones hierarchy.

Note: If you click a biped's center of mass instead of its vertex, Physique corrects this by attaching to the pelvis instead.
After you select a node in the viewports, the *Physique Initialization dialog (page 2–1111)* is displayed. Accept the default values in this dialog, then click Initialize. Physique traverses the biped or bone hierarchy, and creates an *envelope (page 2–1130)* for each link it finds. (It can include additional bones that are linked to the biped.) The envelopes control Physique’s influence on the vertices of the mesh. When the hierarchy is animated, the mesh vertices move along with it.

**Reinitialize**—Displays the Physique Initialization dialog and resets any or all of the Physique attributes to the default values. For example, reinitializing (page 2–1113) with the Vertex Settings option selected reestablishes the relationship of a vertex and its original position relative to the Physique deformation spline. Settings for vertex-link assignments, bulges, and tendons can be reset from this dialog.

**Bulge Editor**—Displays the Bulge Editor (page 2–1114), which is a graphical alternative to the Bulge sub-object level for creating and editing bulge angles.

**Open Physique File**—Loads a saved Physique (.phy) file, which stores envelope, bulge angle, link, tendon, and vertex settings.

When you click Open Physique File to load a .phy file, the *Physique Load Specification dialog (page 2–1123)* is displayed. Select the links you want to import in the list on the left of the dialog, and apply them to the links you select in the list on the right of the dialog.

Any aspect of your Physique work can be loaded into any other character. You can choose from Link Settings, Bulges, Tendons, and Envelopes. You can also apply links from the file to differently named links in the current scene. For example, save and reload a .phy file to copy a bulge angle created on one character to a link on another character.

**Tip:** A bulge created on a bones hierarchy can be loaded and applied to Physique links created using a biped.

**Note:** Loading a .phy file will not overwrite locked vertices. If you want to overwrite them, you must either go to the Vertex sub-object level and unlock them, or reinitialize and turn on the option Vertex - Link Assignments.

**Save Physique File**—Saves a Physique (.phy) file, which contains envelope, bulge angle, link, and tendon settings.

**About Physique**—Displays a dialog that shows version and copyright information about Physique.

---

**Physique Level of Detail Rollout**

Controls in the Physique Level Of Detail rollout not only optimize the viewports, but also affect the rendered result. The primary purpose of this rollout is for troubleshooting. After creating bulge angles and tendons, you can turn off their influence to see exactly what they add to the deformation of the skin. This rollout also has controls for how changes in the modifier stack below Physique are handled.

**Tip:** Choose Deformable and turn on all its parameters during editing; this allows you to spot problem areas. Choose Rigid for the fastest viewport redraw.
**Procedure**

**To troubleshoot bulges and tendons:**

1. Select the mesh of a character that has bulges or tendons.
2. Go to the Modify panel.
3. On the Physique Level Of Detail rollout, in the Skin Update group, make sure Deformable is chosen.
4. Turn Bulges off, then on. Do the same with Tendons.
   Examine the mesh with and without the influence of bulges and tendons.
5. Use the Bulge Editor or the sub-object levels to adjust bulge and tendon settings.

**Interface**

**Renderer**—When chosen, settings in the Skin Update group affect rendered images.

**Viewports**—When chosen, settings in the Skin Update group affect viewports.

**Skin Update group**

**Deformable**—When chosen, Physique deformation is active. Deformable yields the highest-quality rendering. The Deformable toggles are unavailable unless Deformable is chosen.

- **Joint Intersections**—Turn off to remove joint intersection influence. Joint intersection influence allows the mesh to overlap itself; for example, at the elbow and knee joints. Default=on.
- **Bulges**—Turn off to remove any bulge angle influence. Default=on.
- **Tendons**—Turn off to remove any tendon influence. Default=on.
- **Skin Sliding**—Turn off to remove skin sliding influence. Default=on.
- **Link Blending**—Turn off to remove the influence of link blending. Default=on.

**Rigid**—When chosen, forces all vertices to use Rigid assignments rather than Deformable. This is an easy way to isolate deformation problems. It also provides the quickest viewport redraw speed. You might choose this option while adjusting the animation of your skeleton.

- **Link Blending**—Turn off to remove the influence of blending on rigid links. This toggle is unavailable unless Rigid is chosen. Default=on.

**Stack Updates group**

The controls in this group handle changes to vertex count that arise from (nonanimated) changes to the modifier stack.

If the vertex count changes, vertices are reassigned globally. Add Change adds in changes based on the vertices’ initial position. The other options reset the initial position at each frame to do the
remapping and reassigning. For this reason, turning on Add Change or making nonanimated stack changes should always be done at the initial position (Figure mode or frame 0).

**Add Change**—Adds in changes from the stack and then applies Physique deformation. No vertex remapping or reassigning is performed. Default=on.

This option will generally give you the deformation you want. There is no performance penalty (from Physique) when this option is used.

**Remap Locally**—For deformable vertices, this resets the vertex position on the Physique deformation spline used for bending, as well as the link position used to interpolate twist. For rigid vertices, this option resets the link position used to interpolate twist. Default=off.

When vertices are sliding along the length of the spline and you want them to bend and twist based on the spline position, but don’t want vertex weights to change, turn this option on.

**Reassign Globally**—Re-weights, and resets the position on the spline used for bending for moved vertices globally. The vertex link assignment, weighting, and spline position are reset for all moving points on every frame. (This is equivalent to Physique 2.2.) This option is like reinitializing on every frame. Default=off.

When vertices are moving to different envelopes and you want them reassigned to the new envelopes, use this option.

**Hide Attached Nodes**—Toggles the display of the underlying skeletal system. This allows you to hide and unhide the biped, for example.

---

**Floating Bones Rollout**

Select an object that has the Physique modifier applied to it. > Modify panel > Floating Bones rollout

“Floating” bones provide a way to use Physique without using a biped character. The Floating Bones rollout specifies the splines, bones hierarchy, or unattached bones you are using to deform a mesh. For example, Physique lets you animate a mesh by animating spline vertices or a bones system. When you attach the spline or parent bone to Physique, it creates envelopes for the selected spline or bones.

**Procedure**

**To have a spline influence a mesh:**

1. Create a spline and place it within a mesh that has Physique applied.

2. Select the mesh, and go to the Modify panel.

3. On the Floating Bones rollout, click Add. A Select Bones dialog is displayed.

4. Use the Select Bones dialog to select the spline.

5. Animate the spline vertices to animate the mesh.

**Tip:** If you want to control the mesh by animating bones, follow the previous steps using bones instead of a spline.
Add—Displays a Select Bones dialog so you can select splines or bones to use with Physique.

Reset—Resets splines or bones in their initial position: Reset reassigns vertices, but leaves envelopes as is.

Delete—To delete a spline or bone, click to highlight its name in the list, and then click Delete.

* Not available for customization in the Customize User Interface dialog.

Physique Dialogs

Physique Initialization Dialog

Select an object that has the Physique modifier applied to it. > Modify panel > Physique rollout > Click Attach to Node. > Select a root object in a viewport. > Physique Initialization dialog

Select an object that has the Physique modifier applied to it. > Modify panel > Physique rollout > Click Reinitialize. > Physique Initialization dialog.

Use the Physique Initialization dialog to specify link parameters and the type and size of envelopes to create for Physique links. This dialog is displayed under two circumstances:

- When you apply Physique initially, using Attach To Node on the Physique rollout (page 2–1106) on the Modify panel.
- When you click Reinitialize on the Physique rollout.
Creating Physique Links and Envelopes for the First Time

When you use Attach To Node to attach the mesh to a skeleton for the first time, you can use parameters on the Vertex-Link Assignment rollout (page 2–1123) to specify envelope parameters. In most cases, the default parameters on the Vertex-Link Assignment rollout work well as a starting point for envelope type, envelope sizing, and blending between links.

Normally, you want deformable envelopes. Blending Between Links is set to N Links (a vertex can be influenced by all envelopes that overlap it). The Object Bounding Box option is chosen by default, and bases the size of the envelopes on the size of biped limbs or bone diameters.

Link Settings, Joint Intersections, and Cross Section Rollouts

Controls on these rollouts match those found in bulge sub-object (page 2–1141) and link sub-object (page 2–1135) and are used here to set default values. Unless you want to change the default settings for all link parameters and bulges, you do not need to change the settings in these rollouts.

Initialization group

The Initialization check boxes are normally unavailable and not changeable during initialization. Although these options are unavailable, they are all turned on by default (except Include New Bones) for initialization, since all these settings are new when you use Attach To Node for the first time.

These check boxes become available when you click Reinitialize on the Physique rollout. See Reinitialize Physique (page 2–1113) for a description of the controls in this group.

Link Settings rollout

The Link Settings rollout contains the default link values that will be assigned to all links. See Link Sub-Object (page 2–1135) for a command reference.
Joint Intersections rollout
The Joint Intersections rollout contains default joint intersection values that will be assigned to all links. See Link Sub-Object (page 2–1135) for a command reference.

Cross Sections rollout
The Cross Sections rollout (page 2–1125) sets the default Bulge Angle parameter settings for new bulges.

Vertex-Link Assignment Rollout
On the Vertex-Link Assignment rollout (page 2–1123) you can choose to create new envelopes and pick the type of blending between links.

Reinitialize Physique
Select an object that has the Physique modifier applied to it. > Modify panel > Physique rollout > Click Reinitialize.

To reinitialize, select the mesh, open the Modify panel, and click Reinitialize. A dialog warns you to put the skeleton into the initial position. Click OK to reinitialize, and save the file after you have done so.

See also
Physique Initialization Dialog (page 2–1111)

Interface

Initialization group
Initial Skeleton Pose—Uses the current hierarchy position (for example, the biped pose) as the default pose for defining how the skeleton fits inside the skin. The current pose becomes the new initial pose, replacing the pose used when you first attached the mesh to the biped. Default=off.

Note: This toggle does not reassign vertices that you reassigned manually unless you also turn on Vertex-Link Assignments.

When using Physique with a biped, turn on Initial Skeleton Pose if you want to use Figure mode to reposition the biped relative to the mesh; for example, to reposition the biped shoulder joints.
It is helpful first to turn off the Physique modifier, using the lightbulb icon in the modifier stack display. This lets you use Figure mode to scale and rotate the biped limbs independent of the mesh skin. Use this option after you scale a character (see Scaling a Character (page 2–1100)).

- **Include New Bones**—Creates new links for any new object (bone) linked to the biped. Use this to add a bone to a mesh that has the Physique modifier applied. This toggle is unavailable unless Initial Skeleton Pose is on. Default=off.

**Link and Joint Settings**—Resets link parameters and joint intersection parameters to their default values. Link parameters include Bend, Twist, Sliding, and Radial Scale values. For Radial Scale, this includes Scale, Amplitude, Stretch, and Breath. Default=off.

When this option is on, you can set new default values in the Link Settings rollout (page 2–1136) and the Joint Intersections rollout (page 2–1140).

- **Bulges**—Resets bulge angles to the default values. By default, one bulge angle is created per link. Turning on Bulges deletes any new bulge angles you might have created. Default=off.

When this option is on, you can set new default values for cross sections in the Cross Sections rollout (page 2–1125).

- **Tendons**—Resets tendons to the default values. Turning on Tendons deletes any tendons you might have created. Default=off.

- **Vertex-Link Assignments**—Re-evaluates which vertices fall within each envelope. (This can vary from the original default settings, depending on whether you have made changes to the envelopes.) Turning on Vertex-Link assignments also removes any custom vertex assignments. Turn on Vertex-Link Assignments if you want to replace all manual vertex reassignments with the default vertex assignments. Default=off.

When this option is on, you can set new default values in the Vertex-Link Assignment rollout (page 2–1123).

**Vertex Settings**—Recalculates vertex parameters at the link to which each vertex is assigned. Turning on Vertex Settings does not reassign manually reassigned vertices. Use this option when you have changed the link parameters and want to recompute the vertex parameters based on these changes. This check box is automatically turned on if you turn on either Initial Skeleton Pose or Vertex-Link Assignments. Default=on.

---

### Bulge Editor

Select an object that has the Physique modifier applied to it. > Modify panel > Physique rollout > Click Bulge Editor.

Creating and editing cross sections allows you to “bulge” the mesh. The Bulge Editor is an alternative to using the Bulge sub-object level to create and edit bulge angles. The difference is that the Bulge Editor allows you to create, select, and edit cross sections in schematic Cross Section and Profile views. Using the Bulge sub-object level, creating and editing bulge angles takes place in the viewports. All of the parameter changes you make in the Bulge Editor are also reflected on the mesh in the viewports.

On the Modify panel, you access the Bulge Editor from the Physique rollout (page 2–1106), from the Bulge rollout at the Bulge sub-object level (page 2–1141), or from the Link Settings rollout at the Link sub-object level.

Note: The Bulge Editor works exclusively with bulge angles. To create and edit Tendons, use the Tendons sub-object level (page 2–1147).
Using an Animation to Preview Limb Orientations

For easier creation of bulge angles, you should create a simple animation that moves the limb into extreme orientations. In the case of the human arm, you might set keyframes with the arms down against the body; extended to the sides; bent at the elbows; and finally, more relaxed with the hands touching the shoulders. By scrubbing the time slider, you can easily choose one of many intermediate or extreme orientations. This saves time when you create Bulge Angles, because you won’t need to exit Physique to manipulate the skeleton to change the orientation of the mesh. You can create and set multiple Bulge Angles without ever leaving the Bulge Editor or Bulge sub-object level.

Procedures

To create a new bulge angle using the Bulge Editor:

1. Click the Bulge Editor button at the top level of the Physique modifier, or at the Link or Bulge sub-object level.

   The Bulge Editor is displayed.

   Tip: Accessing the Bulge Editor at the Bulge sub-object level provides the added benefit of letting you work in either the Bulge Editor or the Bulge rollout interchangeably.

2. In a viewport, click to select a link.

3. On the Bulge Editor toolbar, click Insert Bulge Angle.

   Physique creates a new bulge angle. The number of the bulge angle name in the Current Bulge Angle field increments.

4. Type a descriptive name in the Current Bulge Angle field.

   Tip: It is a good idea to change the color of the newly created bulge angle. Do this by clicking Bulge Angle Color at the Bulge sub-object level, and selecting a color with the Color Selector.

5. If no appropriate cross sections exist, then on the Bulge Editor toolbar, click Insert CS Slice. Click the Profile view to create and position a cross section.

   The cross section is created at the location you clicked.

6. In the viewports, rotate the joint to the desired angle.

   This is most easily done by creating a preview animation, as described in Using an Animation to Preview Limb Orientations (page 2–1115): just move the time slider to a frame that has the angle you want. Otherwise, you will have to exit the Bulge sub-object level, select the appropriate limb, and rotate it. For example, to bulge the biceps on a biped, you might rotate the biped forearm to ninety degrees.

7. “Bulge” the mesh by editing cross section control points using the Bulge Editor’s Cross Section view.

   As you scale or move control points in the Cross Section view, the mesh “bulges” in the viewports.

8. On the Bulge Editor toolbar, click Set Bulge Angle on the Bulge Editor toolbar.

   Physique saves the current angle of the joint. When the joint angle is reached, the mesh bulges. By default, Physique creates one bulge angle when it is first attached to the mesh. So to make an arm or leg that bulges when biped joints are rotated, you need to create and set only one additional bulge angle.
To change a bulge angle value:

1. On the Bulge Editor, make sure the bulge angle you want to reset is displayed in the Current Bulge Angle field.
2. In a viewport, change the angle between the active link and its child link.
   Rotate a biped limb or use the time slider to move to a frame that has the limb rotated correctly.
3. On the Bulge Editor toolbar, click Set Bulge Angle.
   The angle of the joint is set for the displayed bulge angle. When the biped limb rotates to this angle, the mesh bulge effect is at full strength.

To choose a specific bulge angle for editing:

1. Expand the Current Bulge Angle drop-down list (click the downward pointing arrow at its right).
   The full list of bulge angle names appears.
2. Click the name of the bulge angle you want to edit.
   The Bulge Editor’s Cross Section and Profile views update to show the cross sections associated with the newly selected bulge angle.

To delete a bulge angle:

1. Expand the Current Bulge Angle drop-down list (click the downward pointing arrow at its right).
   The full list of bulge angle names appears.
2. Click the name of the bulge angle you want to delete.
3. On the Bulge Editor toolbar, click Delete Bulge Angle.

Note: You can’t delete the default bulge angle: a link must always have at least one bulge angle defined.

To add a cross section:

1. On the Bulge Editor, make sure that the bulge angle you want to edit is displayed in the Current Bulge Angle field.
2. On the Bulge Editor toolbar, turn on Insert CS Slice.
3. In the Profile view, click the link at the point where you want the cross section to be added.
   The cross section is created at the location you clicked.
   Tip: You can also add cross sections to the child link.

To delete a cross section:

1. In the Profile view, click to select a cross section.
   The selected cross section turns red.
2. On the Bulge Editor toolbar, click Delete CS Slice.
   Note: You cannot delete the default cross section at the joint between the link and its child.

To make a cross section the active cross section:

- In Profile view, click a cross section to select it.
  The selected cross section displays in Cross Section view. You can change its shape by selecting and editing control points in Cross Section view. This will bulge the mesh at the location of the cross section.

To select multiple cross sections:

You can change parameters for multiple cross sections by selecting them and then adjusting parameters in the Cross Sections panel (page 2–1121).
1. On the Bulge Editor toolbar, turn on Select And Translate CS.

2. In Profile view, click to select a cross section.

3. Select additional cross sections by doing one of the following:
   • Use Ctrl-click to add cross sections to the selection.
   • Drag a rectangular region in the Profile view. All cross sections that the region surrounds or crosses are selected.

Tip: Use Alt-click to remove a cross section from the selection.

To move cross sections along the link:
Moving a cross section repositions where on the mesh a bulge occurs.
1. Select the cross sections to move.
2. On the Bulge Editor toolbar, click Select And Translate CS.
   Tip: If you are moving a single cross section, you can skip step 1 and click the cross section after you click Select And Translate CS Slice.
3. Drag left or right in the Profile view to move the cross section (or cross sections) left or right.
   Note: You cannot move cross sections through each other.

To copy and paste cross sections:
1. Select the cross section to copy.
2. On the Bulge Editor toolbar, click Copy Selected CS.
3. Select a cross section to paste over.
4. On the Bulge Editor toolbar, click Paste Selected CS.
   The cross section you pasted now has the shape of the cross section you copied.

Note: You can copy a cross section and paste it to a similar cross section on another link. Create a bulge angle and an appropriate cross section on the target link before pasting. If necessary, use Mirror Selected CS after pasting.

To change the shape of a cross section:
1. In the Profile view, click to select a cross section.
2. In the Cross Section view, use the transform tools to move, scale, or rotate the cross section’s control points.
   You can also add or delete cross section control points.
   You can also use freehand drawing to add control points.

To change the Profile view orientation:
1. In the Cross Section view, move the cursor to the outer end of the orientation bar.
   The cursor changes to a shape like the Cross Section view.
2. Drag to rotate the orientation bar.
   When you release the mouse, the Profile view updates to show the profile at the angle of the orientation bar.

Interface
Chapter 14: character studio

Toolbar

Select, Scale, and Rotate Control Points—Lets you select, scale, and rotate control points of a cross section in the Cross Section view.

This is comparable to using the Move transform on geometry in viewports. Control points are simultaneously scaled and rotated around the link, which in effect "moves" them.

Select a cross section in the Profile view first. Then select and move control points in the Cross Section view to change the bulge.

Select and Rotate Control Points—Lets you select and rotate control points in and around the center of the link in Cross Section view.

This does not twist the mesh. If the cross section is not a circle, a bulge migrates around the mesh.

Select and Scale Control Points—Lets you select and scale control points about the link’s center in the Cross Section view.

If all cross section control points are scaled, the mesh bulges uniformly.

Draw Control Points—Lets you add control points by drawing freehand in the Cross Section view. The shape of the bulge changes based on the shape you draw.

In the Cross Section view, you can draw the cross section interactively, placing control points at each resolution step. You can freeze existing control points by selecting them in the Cross Section view and holding down the [Ctrl] key as you draw.

Note: The number of control points created depends on the cross section Resolution (see Cross Sections panel (page 2-1121)).

Tip: You can also use this tool in Profile view. When you draw in Profile view, you change the profile of the bulge while placing a control point on each cross section of the bulge angle. This is useful mainly when the bulge angle uses multiple cross sections. You can rotate the orientation bar to draw whichever profile you desire. (Imagine the Cross Section view being like drawing around the arm, and the Profile view like drawing along the length of the arm.)

Insert Control Points—Lets you insert control points by clicking the cross section in the Cross Section view. A single control point is created each time you click.

Adding control points and changing their position lets you sculpt the cross section and control exactly where a bulge occurs on the mesh.

Delete Control Points—Deletes control points. First select the control points in the Cross Section view, and then click this button.

Previous Link and Next Link—Move to the next or previous link in the hierarchy. The Cross Section and Profile views update to display the appropriate bulge geometry.

Important: Profile view displays the parent link on the left and the child link on the right.

Mirror Selected CS—Mirror the cross section across the vertical plane running between the green profile reference points at the top and bottom of Cross Section view. In other words, clicking this button causes the bulge to appear on the opposite side of the link.

Select and Translate CS—Lets you select and move a cross section along its link. The bulge on the mesh migrates up and down the link as the cross section is moved.
**Insert Cross Section Slice**—Lets you insert a cross section by clicking Profile view in the location you want the cross section to appear. A new cross section is created where you clicked, on either the parent or the child link.

Extra cross sections give you more control of how and where the mesh bulges.

**Delete Cross Section Slice**—Deletes the currently selected cross section. First, select the cross section in Profile view.

**Copy Selected CS**—Copies the selected cross section.

You can copy a cross section from one link to another link. Create a new bulge angle with an appropriate cross section in the target link first, then copy the cross section parameters form the source cross section, select the target cross section, and click Paste Selected CS.

**Paste Selected CS**—Pastes copied cross section parameters onto another cross section.

First, select a cross section in Profile view, and click Copy. Then select another cross section in the Profile view, and click Paste.

**Set Bulge Angle**—Associates the effect of the current bulge angle with the skeleton’s current joint angle.

First, set the joint to the orientation at which you want the bulge to appear, then click this button. During animation, whenever the joint rotates near this angle, the mesh will bulge.

**Insert Bulge Angle**—Adds a new bulge angle for the selected link.

The Current Bulge Angle field displays a bulge angle name with the number incremented. You can enter a descriptive name for any new bulge angle; for example, Arm at 90.

By default, one initial bulge angle is created when Physique creates links. Only one additional bulge angle will allow you to bulge the mesh. You can create more bulge angles for further control, if you like.

**Delete Bulge Angle**—Deletes the current bulge angle. The current bulge angle displays in the Current Bulge Angle field.

First select a bulge angle in the Current Bulge Angle dropdown, and then click Delete Bulge Angle.

**Select Nearest Bulge Angle**—When on, selects the bulge angle nearest to the current joint angle.

If a joint bends over time, you can use this button in conjunction with the time slider to select a bulge angle. If you play the animation, you can see the Current Bulge Angle field change to reflect the bulge angle nearest to the current angle of the selected link and its child (if two or more bulge angles for the limb exist).

**Current Bulge Angle field and drop-down list**—Displays the current bulge angle. You can choose a bulge angle from the drop-down list to edit the bulge or change its name. To change the name, simply enter a new one in the edit field.

Tip: When you create a bulge angle, give it a descriptive name.

When you create a new bulge angle by clicking Insert Bulge Angle, this field displays the default bulge angle name, which is the previous name with its sequence number incremented.
Cross Section view

Cross Section view displays an outline of the active cross section. In Profile view (page 2–1120), the active cross section is shown in a bright red color. In Cross Section view, you can edit cross sections to bulge the mesh.

Note: It is possible to select multiple cross sections in Profile view using either a rectangular selection region or Ctrl+click. This allows you to enter settings on the Cross Sections panel (page 2–1121) for all selected cross sections at once. Only one active cross section, however, can be viewed and edited in Cross Section view. (Selected but inactive cross sections are shown in a dark red color in the Cross Section and Profile views.)

These are the elements of the cross section display:

- **Gray square at center**—Represents the link at the center of the cross section.
- **Control points**—When unselected, are shown as small black crosses on the control spline. When selected, they are shown as black squares with a white center.
- **Resolution lines**—Display as gray lines that surround the link radially. Control points snap to these lines as they are positioned.

You can increase or decrease the resolution by changing the Resolution setting. This control is on the Bulge rollout in Bulge Sub-Object. The Cross Section view, however, always displays 36 resolution lines.

- **Red line**—The control spline for the active cross section.

  The shape of the spline determines where mesh deformation occurs.

- **Green line**—Represents actual mesh deformation. (Typically this is less exaggerated than the control spline.)

  When you drag the time slider or play an animation, this updates according to the angle of the limb and the bulge angle parameters.

- **Orientation bar**—The bright yellow radius indicates the orientation of the “slice” shown in profile view. Profile view always shows a vertical profile of Cross Section view, indicated by the green dots at the top and bottom of the view, just outside the circle that contains the resolution lines. By default, the orientation bar is level at 3 o’clock. You can change the Profile view orientation by dragging the end of the orientation bar (the cursor changes to a miniature cross section). This lets you view different angles of the bulge in Profile view.

Profile view

Use Profile view to select, move, and copy cross sections on the selected link and its child. Highlight a cross section in Profile view to display and edit it in Cross Section view (page 2–1120).
Profile view is a schematic profile of two links. The currently selected link is on the left, and its child link is on the right. If the selected link is an end link, the outline of the right half of the Profile view turns gray.

Cross sections are shown as vertical bars across the profile. The active cross section is red. Unselected cross sections are white. Cross sections that are selected but not active are dark red.

You can use a rectangular selection region or Ctrl+click to select multiple cross sections. Although only one cross section at a time is active in Cross Section view, you can use the Cross Sections panel (page 2–1121) to change parameters for multiple cross sections.

Profile view shows a profile of the bulges you create. As in Cross Section view, the control spline is red and the deformation spline is green.

The profile is always a vertical profile of the Cross Section view. You can drag the orientation bar in Cross Section view to change the angle of the profile.

To insert a new cross section, turn on Create CS Slice and then click Profile view to set the cross section’s location.

You can use the Draw tool in Profile view to change the control spline by freehand drawing. Drawing updates the cross section shapes.

**Bulge Angles panel**

At the right of the Bulge Editor are two panels for setting parameters. Use the Bulge Angles panel to change bulge settings for the currently active bulge angle.

Note: These parameters are the same as those in the Bulge Angle Parameters group on the Bulge rollout at the Bulge sub-object level. Changing a value in one location changes it in the other.

**Influence**—The range of angles through which the bulge influences the skin. Range=0 to 180. Default=90 degrees.

For example, if you’ve set a bulge angle for the joint at 90 degrees, an Influence value of 40 means that the bulge effect begins to appear when the rotating joint reaches 50 degrees (90 minus 40) or 130 degrees (90 plus 40).

**Power**—Controls how smoothly or abruptly the bulge takes effect.

At 0, the bulge takes effect immediately, without interpolated easing. As values increase, the bulge eases in gradually. A value of 10 will bulge the mesh abruptly when the set angle is reached. Range=0 to 10. Default=2.5.

**Weight**—Increases the effect of the current bulge angle relative to the effect of any other bulges. Range=0.0 to 100.0. Default=1.0.

**Cross Sections panel**

At the right of the Bulge Editor are two panels for setting parameters. Use the Cross Sections panel to change the cross section settings for a particular link.
Note: These parameters are the same as those in the Cross Section Parameters group on the Bulge rollout at the Bulge sub-object level. Changing a value in one location changes it in the other.

Cross Sections—Click to display the Cross Sections panel.

**Sections**—Sets the number of cross sections for the selected link.

Tip: Rather than manually inserting cross sections in Profile view, use Sections to create cross sections. For a thigh or biceps bulge, you might need only one additional cross section in the middle of the link.

**Divisions**—Sets the number of control points on the selected cross sections. By default, control points are evenly distributed around the cross section control spline.

**Resolution**—Sets the number of radial divisions around the cross section. Control points snap to the nearest resolution line.

**Entire Link**—When on, selects all cross sections for all bulge angles in the selected link. Use this to globally change parameters for all cross sections on a link.

Entire Link also affects Copy Selected CS and Paste Selected CS. While Entire Link is on, Copy Selected CS copies all cross sections for all bulges, and Paste Selected CS pastes all cross sections for all bulges. Entire Link is useful for copying all the bulges from one arm or leg to another.

Note: When you turn on Entire Link, a number of toolbar controls, including the Current Bulge Angle name field, become unavailable. On the Bulge rollout at the Bulge sub-object level, the Current Bulge Angle changes to read “Entire Link.”
Physique Load Specification Dialog

Select an object that has the Physique modifier applied to it. > Modify panel > Physique rollout > Click Open Physique (.phy) File. > Choose a file. > Physique Load Specification dialog

This dialog appears after you have chosen a Physique (.phy) file to load. It lets you specify which information you want to obtain from the file.

Interface

At the upper left of the dialog are check boxes that let you specify which kind of data to load. Turn off a check box to avoid loading that kind of data.

Link Settings—Loads link parameters. Default=on.
Bulges—Loads cross sections and bulge angles. Default=on.
Tendons—Loads tendons. Default=on.
Envelopes—Loads envelopes. Default=on.
Locked Vertices—Loads locked vertices.
All Links—Selects all links to load.

This button is enabled only if the number of saved links equals the number of open links. Click to select all links in both lists. If All Links is disabled, you must choose links by hand. Click the name of a link in a list to select it. Before you click OK, the number of links to load must equal the number of links to update.

No Links—Deselects all links in both lists.
After deselecting all links, you must select the links to load and to update, before you click OK.

Selected Links From File and Selected Links In Modifier—At the left of the dialog is a list of the links that were saved in the file, and at the right is a list of links in the currently open Physique skin and skeleton. You can choose which links to update with the saved data.

Physique Initialization Rollouts

Vertex-Link Assignment Rollout

Select an object that has the Physique modifier applied to it. > Modify panel > Physique rollout > Click Attach to Node. > Select a root object in a viewport. > Physique Initialization dialog > Vertex-Link Assignment rollout

On the Vertex-Link Assignment rollout, you can choose to create new envelopes and pick the type of blending between links.
Deformable—Creates deformable envelopes for the links. Default=chosen.

Deformable envelopes determine vertex-link assignment based on the deformation spline that Physique creates through the links.

Rigid—Creates rigid envelopes for the links. Default=not chosen.

Rigid envelopes determine vertex-link assignment based upon the linear links in the hierarchy.

Blending Between Links—This drop-down list lets you choose how links are initially blended. Default=N Links.

Tip: Typically, you should leave this set to the default of N Links.

- N Links—Vertices are influenced by all overlapping envelopes.
- No Blending—Vertices are influenced by only one (1) link. This allows a mesh with the Physique modifier applied in character studio 1 to work with character studio 3. Choose No Blending if you are developing characters for a game engine that doesn’t support blending, or if you intend to use strictly character studio 1-style vertex-link assignments.

- 2, 3, or 4 Links—Vertices are influenced by more than one link, but the number of links is limited to 2, 3, or 4, depending on your choice. Choose one of these options if you are developing characters for a game engine whose support of blending is limited.

Radial Falloff Envelopes group

Create Envelopes—When on, creates envelopes for the links. When off, envelopes are not created. Default=on.

Note: With no envelopes, you have to use hand-weighting for vertices. If you want to add envelopes when a model has none, reinitialize Physique.

- Object Bounding Box—Envelope size is based on the size of objects in the hierarchy, such as biped limbs, or bones.
- Link Length—Each envelope has a Radial Scale that is one-third of the length of the link.
- Overlap—Sets how far the envelopes overlap. Default=0.1.
- Smooth—Sets the distance between the inner and outer bounds of an envelope by scaling the outer boundary. Range=0.0 to 10.0. Default=0.75.
- Falloff—Sets the rate of falloff between the inner and outer boundary of an envelope. The falloff rate is a Bezier function. Range=0 to 10. Default=0.5.
Cross Sections Rollout

Select an object that has the Physique modifier applied to it. > Modify panel > Physique rollout > Click Attach to Node. > Select a root object in a viewport. > Physique Initialization dialog > Cross Sections rollout

Select an object that has the Physique modifier applied to it. > Modify panel > Physique rollout > Click Reinitialize. > Physique Initialization dialog > Cross Sections rollout

The Cross Sections rollout lets you globally set how cross sections are initialized.

**Interface**

**Number**—Sets the initial number of cross sections per link. Default=2.

**Control Points**—Sets the initial number of control points per cross section. Default=4.

**Radial Snap**—Sets the initial number of snap positions per cross section (this is the value labeled "Resolution" in the Bulge Editor (page 2–1114) and at the Bulge sub-object level (page 2–1141)).

Sub-Object Options Dialogs

Blending Envelope Display Options Dialog

Select a mesh that has the Physique modifier applied to it. > Modify panel > Envelope sub-object level > Blending Envelopes rollout > Display group > Click Display Options.

This dialog lets you customize how Physique displays envelope blending at the Envelope sub-object level.

**Interface**

![Blending Envelope Display Options Dialog](image)

**Note:** All check box settings except Control Points are on by default.
Selected Deformable Envelope and Selected Rigid Envelope groups

These two groups have the same controls. By default, deformable envelopes are shown in red, and rigid envelopes are shown in green.

**Inner Envelope**—The check box toggles viewport display of inner envelopes. Click the color swatch to change the viewport color of the inner envelope boundary.
- **Sides**—Sets the number of inner envelope sides shown in the viewport display.

**Outer Envelope**—The check box toggles viewport display of outer envelopes. Click the color swatch to change the viewport colors of the outer envelope boundary.
- **Sides**—Sets the number of outer envelope sides shown in the viewport display.

**Weighted Vertices**—The check box toggles viewport display of weighted vertices. Click a color swatch to change viewport colors of weighted vertices in a particular percentage range.

Selected Envelope Cross Sections group

**Cross Sections**—Toggles viewport display of cross sections. Click the color swatch to change the viewport color of selected cross sections.

**Control Points**—Toggles viewport display of control points. Click the color swatch to change the viewport color of selected control points.

**Bezier Patch Handles**—Click to set the viewport color of Bezier patch handles.

---

### Exclude Envelopes Dialog

Select an object that has the Physique modifier applied to it. > Modify panel > Bulge sub-object level > Select an envelope. > Blending Envelopes rollout > Edit Commands group > Click Exclude.

At the *Envelope sub-object level* (page 2–1130), this dialog lets you exclude links from influencing other links. For example, you can exclude the right thigh link from influencing the left thigh link. Or, rather than scale the index finger envelopes to avoid influencing middle finger vertices, you might exclude the middle finger links from the index finger links.

**Tip:** You can leave this modeless dialog open while you choose links in the viewports.

**Note:** If you have a Physique model created with character studio 1 or 2, excluding links will not work until you *reinitialize Physique* (page 2–1113) using the initial skeleton pose. In the Physique Initialization dialog, make sure Vertex-Link Assignments is turned on.

### Interface

**Exclude Envelopes list (left side)**—Displays the links available for exclusion. Selected links are not in this list.
Exclude Envelopes for Selected Link list (right side)—Displays envelopes to exclude from the current link selection. The text field displays the name of the selected link, or “Multiple Links Selected.”

Right arrow—Select links in the Link Envelopes List on the left, then click the right arrow to add them to the Exclude Envelopes For Selected Link list on the right.

Left arrow—Select links in the Exclude Envelopes For Selected Links list on the right, then click the left arrow to remove them from the exclusion list.

Display Subtree—When on, the Link Envelopes list increments links according to their level in the hierarchy. This visual aid can help you to find and select links. Default=off.

Clear—Clears all links from the Exclude Envelopes For Selected Link list.

Bulge Angle Display Properties Dialog

Select a mesh that has the Physique modifier applied to it. > Modify panel > Bulge sub-object level > Bulge rollout > Display group > Click Display Options.

This dialog lets you customize how Physique displays bulge angles at the Bulge sub-object level.

Interface

Bulge Angle Display group

Sides—Specifies the number of sides the bulge angle envelope displays in the viewports. Default=4.

Scale—Specifies the scale of envelope display in the viewports. Default=1.1.

Default Color—Click to change the bulge angle envelope color in viewports.

Active Viewport Display group

Selected Cross Sections—The check box toggles the display of selected cross sections. Default=on.

Click the color swatch to change the display color of selected cross sections displayed in viewports.

Selected Control Points—The check box toggles the display of selected control points. Default=on.

Click the color swatch to change the display color of selected control points displayed in viewports.

Orientation Bar—The check box toggles the display of the orientation bar. Default=on.
Click the color swatch to change the color of the orientation bar displayed in viewports.

Note: The orientation bar is displayed in the viewports when the Bulge Editor is open.

**Profile**—The check box toggles the display of the profile. Default=on.

Click the color swatch to change the color of the profile displayed in viewports.

Note: The bulge profile displays in the viewports when the Bulge Editor is open.

---

### Tendon Display Options Dialog

Select a mesh that has the Physique modifier applied to it. > Modify panel > Tendons sub-object level > Tendons rollout > Display group > Click Display Options.

This dialog lets you customize how Physique displays tendons at the Tendons sub-object level.

#### Interface

**Physique: Tendon Display Options**

- Tendon Cross Sections
- Tendon Attach Points
- Tendon Attached Links

Selected Tendon Elements group

- Cross Sections
- Attach Points
- Attached Links

---

**Tendon Attach Points**—The check box toggles the display of tendon attach points. Default=on.

Click the color swatch to change the color of attach points displayed in viewports.

**Tendon Attached Links**—The check box toggles the display of attached links. Default=on.

Click the color swatch to change the color of attached links displayed in viewports.

**Selected Tendon Elements group**

**Cross Sections**—Click to change the viewport color of selected cross section.

**Attach Points**—Click to change the viewport color of selected attach points.

**Attached Links**—Click to change the viewport color of selected attached links.

---

### Type-In Weights Dialog

Select a mesh that has the Physique modifier applied to it. > Modify panel > Vertex sub-object level > Vertex-Link Assignment rollout > Vertex Operations group > Click Select by Link. > Click a link in a viewport. > Lock Assignments > Click Type-In Weights.

Lets you enter a weight for selected locked vertices. To use this dialog, select one or more vertices, then lock them, click Type-In Weights to display the Type-In Weights dialog, use the lists in the dialog to select a link, and then change the weight to that link in order to position the vertices (vertex positions update in viewports as the weight changes).

Note: You’ll primarily use Type-In Weights to correct flaws on low- to medium-resolution meshes. On a high-resolution mesh, adjusting envelopes should be used to correct deformation.

Tip: Adjust weights for stubborn vertices that fall in blended regions between two or more envelopes. Subtle adjustments can be made to the vertex
weights of specific links that would be difficult to achieve by adjusting envelopes alone.

**Interface**

- **Link Name**—Use the drop-down list to select a link and display the vertex weight to that link.
- **Currently Assigned Links Only**—When chosen, displays only those links that presently influence the selected vertices.
- **All Links**—When chosen, displays all available links.
- **Weight**—Displays the vertex weight for the active link (the link currently displayed by the Link Name list). Use the spinner to change the weight value, if necessary.
- **Absolute**—Uses an absolute value for vertex weight.
- **Normalized**—This option is unavailable in character studio.
- **Relative Scale**—Uses relative values for vertex weights.

This is the mode of choice when you work on multiple vertices. If a particular link is not having a strong enough effect on the selected vertices, you should lock them, open the Type-In Weights dialog, select the link, and choose Relative Scale. Then you can enter relative values in the Weight field. For example, entering 1.0 leaves weights the same, while entering 2.0 would double the effect of the selected link on the selected vertices.

**List of links**—Displays a list of links, with weight values at the right. The weight field is blank when it displays absolute weights. (When more than one vertex is selected, each is likely to have a slightly different weight.) Click a link in this list to select it.

---

**Physique Modifier Sub-Object Levels**

**Physique Sub-Objects**

Select an object that has the Physique modifier applied to it. > Modify panel > In the modifier stack display, expand the Physique sub-object hierarchy.

The Physique modifier has five different sub-object levels. Each kind of sub-object has various controls.

- **Envelope (page 2–1130)**
  
  Envelopes define a link’s area of influence on mesh vertices.

- **Link (page 2–1135)**
  
  Links are the segments of the Physique deformation spline (page 2–1135). Link
sub-object controls adjust the way link movement affects the mesh.

- **Bulge (page 2–1141)**
  Bulge controls are for creating flexing muscles.

- **Tendons (page 2–1147)**
  Tendons provide a way for multiple links to affect an area of the mesh.

- **Vertex (page 2–1150)**
  For Physique, Vertex controls let you fine-tune the influence of envelopes.

### Physique Selection Status Rollout

This rollout appears for all of the Physique sub-object levels. For all levels except Vertex, it shows the name of the hierarchy object associated with the active link. For the Vertex sub-object level, it prompts you to “Select Vertices” unless Select By Link or Assign To Link is active, in which case it displays the name of the hierarchy object associated with the active link, as it does at other sub-object levels.

### Envelope Sub-Object

Use Envelope sub-objects to adjust the way skin behaves. Each link has an envelope, and the shape of the envelope determines which vertices are affected by the link’s movement. An envelope has an inner and an outer bound: outside these bounds, vertices are not affected. Inside these bounds, the envelope’s influence is strongest at the inner bound. A Falloff setting lets you control how quickly influence falls as it approaches the outer bound.

Envelopes also control blending: they provide smooth deformation of the skin across joints. Vertices that fall between overlapping envelopes receive influence from each, thus creating a smoothly blended transition. The outer bounds of the envelopes of adjacent links should overlap enough to provide a smooth blend at the joints. You can adjust the relative strength of envelopes, giving one link’s envelope more influence than another.

At the Envelope sub-object level, in addition to the settings already mentioned, you can adjust an envelope’s Radial Scale. This is useful for making sure the envelope encloses vertices along the length of the link. The settings for Strength, Falloff, Radial Scale, and Overlap are grouped under *Envelope Parameters* (page 2–1133).

Envelopes have cross sections. You can add cross sections to refine the shape of an envelope, and you can move or scale a cross section’s control points to change the cross section’s shape. (Cross sections are also used to create *bulges* (page 2–1141).)

Tip: You can also use tools on the Main toolbar to adjust envelopes. For example, you can use Non-Uniform Scale on envelopes and cross sections, or use Select And Move to move envelopes, cross sections, or control points on cross sections.

### Workflow

The goal is to modify the envelopes so each vertex in the mesh is encompassed by at least one link’s envelope.

Usually the first adjustment is to assign a rigid envelope to the character’s head. A rigid envelope blends with other envelopes but retains the shape of the mesh. The head should not deform with the deformation spline.
With Initial Skeletal Pose turned on, check that the envelopes enclose all areas of the mesh. If you turn off Initial Skeletal Pose, the character adopts its animated position at the current frame. Use an animation that stretches the character around, such as a run or dance motion. Find a frame where the envelopes need adjusting, and edit the envelope parameters. Changing the envelopes with the character in an animated position will always reference the Initial Skeletal Pose.

These are some frequently encountered problems with the default vertex assignment:

- Vertices that don’t follow the skeleton.
  
  To correct this, increase the Radial Scale of an envelope’s outer boundary.

- Vertices at joints get pushed or dented in.
  
  Too many envelopes might be affecting these vertices. Try reducing the Radial Scale of the inner bound, and reduce the Overlap values of the links on both sides of the joint.

- Bending appears too linear or broken at the joint.
  
  Increase the envelope’s outer Overlap value toward the link on the other side of the joint.

Some further adjustments are described in the “Procedures” section that follows.

Note: An envelope does not need to enclose Patch tangent handles. It needs to enclose only the patch vertices. This relieves you from having to scale the envelopes to a large size to encompass tangent handles.

**Procedures**

*See Adjusting Default Envelope Shape (page 2–1086)*

**Interface**

Controls for Envelope sub-objects are on the Blending Envelopes rollout.
Chapter 14: character studio

- **Link**—Turn on to select links in the viewports and edit the selected link’s envelope parameters. For example, you might turn on Link, select a biceps link, [Ctrl]+click to add the opposite bicep to the selection, then edit envelope parameters for both links at the same time.

- **Cross Section**—Turn on to edit envelope cross sections, changing the envelope’s shape and thus its area of influence. For example, you might turn on Cross Section, select a cross section on the inner or outer boundary of an envelope, and then move or scale it. You might Non-Uniform Scale the cross section of a collar envelope so it avoids vertices in the chest area.

- **Control Point**—Turn on to edit the control points on a cross section. For example, you might turn on Control Point, select a point on a cross section of an envelope, and move the point to change the envelope’s shape and area of influence.

- **Previous and Next**—Click to move to the next or previous link, cross section, or control point, depending on which selection level is active.

**Active Blending group**

- **Active Blending**
  - **Deformable**—When on, enables a deformable envelope for the selected links. Default=on.

By default, deformable envelopes are shown in red.

- **Rigid**—When on, enables a rigid envelope for the selected links. Default=off.

**Important:** You can have both a deformable and a rigid envelope turned on for the same link. Normally, you use one or the other. By non-uniform scaling the rigid and deformable envelopes for one link, you can position one envelope on top of the other. For example, you could control the shoulder with a rigid envelope and the armpit with a deformable envelope. Both envelopes can also be turned off for a link.

- **Partial Blending**—Turns on partial blending for the selected links. Leave either a deformable or rigid envelope on, and then turn on Partial Blending. Physique calculates the weights of each link on a given vertex. If Partial Blending is off, and the total weight is less than 1, Physique normalizes the combined weight to 1. If Partial Blending is on, the weights are allowed to remain at a value of less than 1. The remainder is filled in by the root node, the equivalent of no influence. See *Partial Blending and Weight Assignments* (page 2–1092) for a detailed explanation of how the program calculates these values.
Partial Blending on all the deformable envelopes for the bones in this character’s jaw allows smooth mesh deformation when the bones are moved.

Envelope Parameters group

Envelope type drop-down list—Shows the type of the selected envelope. If the link has both a rigid and a deformable envelope, you can use this list to choose which envelope’s parameters you are adjusting.

**Strength**—Changes the strength of the envelopes. Range=0.0 to 100.0. Default=1.0.

Strength applies to both the inner and outer envelope bounds.

Used primarily for areas where envelopes overlap, and you want one to be more influential than the other.

**Falloff**—Changes the rate of falloff between the inner and outer bounds of an envelope. This is a Bezier curve function. Range=0.0 to 1.0. Default=0.1.

Vertices within the inner bound are fully influenced (weight=1.0) and those beyond the outer bound get no influence from the link (weight=0.0). Falloff determines the rate at which the influence falls off from 1.0 to 0.0.

The Inner, Outer, and Both buttons determine whether the controls that follow, Radial Scale, Parent Overlap, and Child Overlap, apply to the envelope’s inner bound, its outer bound, or both at once. First, use the buttons to choose which bounds to adjust, then change values in the spinners.

**Inner**—Turn on to change the values of the inner bound.

**Outer**—Turn on to change the values of the outer bound.

**Both**—Turn on to change the values for both inner and outer bounds at the same time.

When Both is selected, the values displayed for Radial Scale and Parent and Child Overlap reflect the values for the *inner* bound.

**Radial Scale**—Radially scales the envelope bounds. Range=0.0 to 100.0. Default=1.0.
Parent Overlap—Changes the envelope’s overlap with the parent link in the hierarchy. Range= -1.0 to 10.0. Default=0.1.

A value of 0.0 causes the end of the envelope to fall on the joint. Values less than 0.0 bring the envelope inside the link, and values above 0.0 will overlap onto the adjoining link.

Child Overlap—Changes the envelope’s overlap with the child link in the hierarchy. Range= -1.0 to 10.0. Default=0.1.

A value of 0.0 causes the end of the envelope to fall on the joint. Values less than 0.0 bring the envelope inside the link, and values above 0.0 will overlap onto the adjoining link.

Display group

Interactive Redraw—When on, Physique dynamically updates the mesh while you adjust envelopes. When off, the mesh updates only when you enter a final value (you press Enter or Tab, or release the mouse). Default=on.

Initial Skeletal Pose—When on, puts the mesh character in the pose it was in just before Physique was applied. Default=off.

Display Options—Clicking this button displays the Blending Envelope Display Options dialog (page 2–1125), which lets you customize envelope display.

Shaded—Toggles shaded display of vertex weights in the viewports. Default=off.
Select an object that has the Physique modifier applied to it. > Modify panel > Link sub-object level

Use parameters at the Link sub-object level to change how deformation around joints occurs. When a joint in the skeleton bends or rotates, Physique, by default, deforms vertices uniformly on either side of a joint. You can change these defaults by using the tools at the Link sub-object level. For example, you can adjust the amount of skin sliding that occurs along a limb as the limb bends, or change the angle of the crease between the upper arm and chest.

The deformation spline displays as a yellow curve that runs through the mesh.

Like a spline object, the deformation spline created by Physique is a continuous curve through several points. While a spline object runs continuously from vertex to vertex, the deformation spline is a smooth curve running from joint to joint. The Bend, Bias, and Tension spinners can change the shape of the curve, much as you can rotate or scale the handles at a spline vertex.

The deformation spline also takes into consideration twisting and scaling of the skeleton’s links. At the Link sub-object level, you take control of the behavior of the deformation spline, and subsequently gain full control of the skin’s behavior relative to the skeleton’s movement.
Interface

Link Settings Rollout (page 2–1136)

Joint Intersections Rollout (page 2–1140)

Link Settings Rollout

Select a mesh that has the Physique modifier applied to it. > Modify panel > Link sub-object level > Link Settings rollout

Controls on the Link Settings rollout let you adjust the behavior of the selected link.

See also

Joint Intersections Rollout (page 2–1140)

Active—When on, activates the selected link. Default=on.

Turning off Active makes the link unavailable for vertex assignment, meaning that the link has no influence on any vertices. Vertices within range of this link are not influenced by it, and can be “picked up” by other nearby envelopes, or can be manually assigned (without blending) to any other link. Turning off Active makes Physique ignore the link as if it were never part of the skeleton.

Continuity—Maintains a smooth transition across the joint from the parent link to the current link. Default=on.
When Continuity is on, the effect of the link parameters passes smoothly across the joint to the connected link. When Continuity is off, Bend, Twist, and Radial Scale settings are limited to the current link, which produces an abrupt transition across the joint. This is analogous to breaking the spline handles on a spline shape.

![Bulge Editor](image)

**Bulge Editor**—Displays the Bulge Editor (page 2–1114). The Bulge Editor displays bulge cross sections schematically, letting you create and edit bulge controls.

**Reinitialize Selected Links**—Reinitializes the link and its vertex parameters based on the current link parameter settings. Clicking Reinitialize Selected Links does not change vertex assignments or manual reassignments.

For example, increasing the tension of a link can cause the spacing to change for the link’s cross sections. Reinitialize Selected Links smoothes the spline, and makes cross section spacing even again.

Think of the skin being snugly stuck to the link. As the link parameters change, the vertices can bunch up or stretch out. Clicking Reinitialize lets the skin “slip” to its original shape, establishing a new relationship to the deformation spline.

**Bend group**

![Bend](image)

**Tension**—Sets the smoothness of a joint. Tension affects the curvature of the deformation spline through the joint. A low value, near 0.0, makes the spline linear and creates a sharp angle at the joint, like bending a hinge. High values, near 2.0, make the spline smooth through the joint, creating a rounded joint, like bending a firm hose. Range=0.0 to 2.0. Default=0.5.

**Bias**—Displaces the pivot point about which vertices are bent. Bias pushes the effect along the spline toward one side of the joint or the other. The default value of 0.5 centers the bend at the joint. Values lower than 0.5 move the pivot onto the child link. At 0.0, the bend effect is limited to the selected link. Range=0.0 to 1.0. Default=0.5.

**Twist group**

![Twist](image)

Twist parameters control the way the skin deforms when a joint rotates along its length, as in turning a doorknob.

**Use Twist for Rigid**—When on, twist is used for rigid as well as deformable envelopes. Default=off.

Turn off for the rigid envelope for a character’s head: the head should not twist along the length of the link. You might want to turn this on for the forearm or upper-arm link if you’re using rigid envelopes.

**Tension**—Values lower than 1.0 concentrate the effect closer to the joint. Values higher than 1.0 move the effect away from the joint. Range=0.0 to 2.0. Default=1.0.

**Bias**—Shifts the distribution of the twist from one side of the joint to the other. The default value of 0.5 twists the selected link and the child link equally. Values greater than 0.5 shift the twist to the child link. Range=0.0 to 1.0. Default=0.5
Sliding group

Skin sliding parameters control the amount of skin sliding that occurs when a joint rotates. Without skin sliding, vertices closest to the joint tend to compress on the inside and stretch apart on the outside, generally revealing the segments of the mesh. Outside sliding causes the vertices around the joint to move toward the joint, preventing localized stretching on the side that is greater than 180 degrees. Inside sliding causes the vertices to relax and slip away from the joint, preventing bunching of vertices on the side having an angle less than 180 degrees.

Tip: Use sliding for knees and elbows.

**Inside**—As values increase, skin moves away from the joint. Range=0.0 to 1.0. Default=0.0 (no inside sliding).

**Outside**—As values increase, skin moves toward the joint. Range=0.0 to 1.0. Default=0.0 (no outside sliding).

**FallOff**—As values increase, the effect is localized to the joint. Range=0.0 to 1.0. Default=0.5.

Radial Scale group

Radial Scale parameters expand or contract the skin by scaling the radial distance perpendicular to the link. They apply to any combination of user-definable scale, bulge settings, or link length.

**Tension**—Values between 0.0 and 1.0 concentrate the effect closer to the joint. The effect is closest to the joint when Tension is 0.0. Values greater than 1.0 move the effect away from the joint. Range=0.0 to 2.0. Default=0.5.
**Bias**—Shifts the effect of radial scaling. At the default value of 0.5, scaling affects both the selected link and the child link. Values lower than 0.5 shift the scaling effect onto the selected link, and values greater than 0.5 shift scaling onto the child link. At 0.0, expansion and contraction are limited to the selected link. At 1.0, expansion and contraction are limited to the child link. Range=0.0 to 1.0. Default=0.5.

**Link Scale**—Scales the entire link radially, independent of the effect of any cross sections. At 1.0, the link is “actual size” and this setting has no effect. Other values increase or decrease the radial scale of the link. Range=0.0 to 10.0. Default=1.0.

**CS Amplitude**—Cross section amplitude has no effect unless the link has bulge angle cross sections. At 0.0, cross section deformation is turned off. Values greater than 1.0, up to the maximum of 10.0, exaggerate the effect of cross sections. Default=1.0.

**Stretch**—When on, preserves the volume of the link’s skin when the length of the link changes. The effect is similar to stretching or squeezing a material that is only partly elastic, such as a tough rubber hose. Default=off.

**Breathe**—When on, scaling a skeleton node changes the radial scale of the link’s skin. When off, scaling a node has no effect on the scale of the skin. Default=off.
Joint Intersections Rollout

Select a mesh that has the Physique modifier applied to it. > Modify panel > Link sub-object level > Joint Intersections rollout

When a joint bends, the skin can "collide." Without collision detection, it can overlap unrealistically. This is especially likely when one or both of the links have bulges. The joint intersection controls can detect skin collisions and correct overlap by creasing the skin.

By default, Physique draws a crease plane that bisects the joint and prevents vertices from each link from crossing the crease plane. The result can be a somewhat unnatural flattening of the bulges along the plane. Physique therefore provides controls that let you modify the effect of the crease plane.

Properly adjusted crease plane

You can modify the effect of the joint creases at both ends of the selected link. These joints are the parent’s joint and the link’s joint. Blend From and Blend To points define the distance along the link that is affected by the crease plane.

- The parent’s joint is between the selected link and its parent. The parent’s joint is numbered 0.
- The link’s joint is between the selected link and its child. The link’s joint is numbered 1.

For the link’s joint, the joint is at 1.0 and the crease plane has an effect from the joint to the Blend To point. Between Blend To and Blend From, the crease plane has a partial effect, adjusted by the Bias setting. Vertices at locations greater than the Blend To point are not affected by the crease plane.

For the parent joint, the joint is at 0.0 and the crease plane has an effect from the joint to the Blend From point. Between Blend From and Blend To, the crease plane has a partial effect, adjusted by the Bias setting. Vertices at locations less than the Blend From point are not affected by the crease plane.

Procedure

To adjust joint intersection parameters:

1. With Physique active on the Modify panel, go to the Link sub-object level.
2. In a viewport, click the link you want to work with.
3. Select Active for the crease you want to manipulate: choose Crease At Parent’s Joint or Crease At Link’s Joint.
5. Select the opposite link and adjust the opposite set of joint intersection parameters.

For example, if you are working with the joint between the selected link and its child (such as the biceps link), turn on Active for Crease At Link’s Joint and change settings. Then select the child link (the forearm) and activate its Crease At Parent’s Joint. Adjustments to the Parent’s Joint for this link affect the other side of the same crease.
Both the parent’s and the link’s joint have the same controls:

**Active**—Turns off the effects of the joint intersection controls. When this box is cleared, Physique makes no compensation for overlapping bulges. Default=off.

**Blend From**—The area between Blend From and Blend To contains vertices that are partially affected by the crease plane. These vertices will be shifted, but not as much as those between the crease plane and the point where this joint begins to blend (Blend From in the parent’s case, Blend To in the link’s case). The distance of the vertices from the crease plane determines the exact amount of shifting. Vertices within the blend region that are closer to the intersection plane are shifted more than the vertices further away from it. Default=0.0.

**Blend To**—Indicates the distance beyond which the crease plane has no effect. Default=1.0.

**Bias**—Sets the strength of the crease plane effect within the blended region. A value of 0.0 means that the intersection plane will have no effect within the blended region; a value of 1.0 means that it will have a full effect within the blended region. Default=0.25.

---

**Bulge Sub-Object**

Select an object that has the Physique modifier applied to it. > Modify panel > Bulge sub-object level

After you have edited envelope sub-objects (page 2–1130) for good overall mesh deformation, you can create bulges to simulate muscle contraction and expansion when a character’s joint rotates.

A bulge angle requires two links: the selected link, and the child link of that selection (for example, an upper arm and forearm). The joint that separates the two is referred to as the *bulge joint*. Any rotation applied to this joint becomes the angle used to center the effect of a bulge angle.

Physique creates a single default bulge angle for each bulge joint in the attached skeleton. The angle of this joint is that of the initial skeleton pose. This is the pose the skeleton had when the Physique modifier was applied to the skeleton, or when you use Reinitialize (page 2–1113) and turn on Initial Skeleton Pose in the Physique Initialization dialog. To create a bulge, you need to add only a single additional bulge angle. You can add further bulge angles to refine the bulge effect.

**Workflow to Create a Biceps Bulge**

The overall steps for creating a biceps bulge are:

- Insert a new bulge angle.
  
  Give the new bulge angle a custom name and color.
- Set the bulge angle at a point where the joint is flexed; for example, at 90 degrees.
- Insert a cross section on the upper arm.
- Use control points (or the Bulge editor (page 2–1114)) to shape the bicep bulge.
The following paragraphs elaborate these steps.

Above: Default bulge angle at the initial pose. 
Below: Bicep bulges at the custom bulge angle of 90 degrees. The new bulge angle has been assigned a red color.

To create a biceps bulge angle, go to the Bulge sub-object level. In the Selection Level group, turn on Link. Select the upper arm link, then click Insert Bulge Angle; the bulge angle name increments from 0 to 1 in the Current Bulge Angle field, indicating that a new bulge angle has been created. Type a descriptive name for the new bulge angle in the Current Bulge Angle field; for example, Arm at 90.

Click Bulge Angle Color and select a color for the newly created bulge angle. When Select Nearest Bulge Angle is active, the bulge angle color changes as the joint bends; this is a good visual indicator of which angle has the most influence at any given frame.

Scrub the time slider to a frame where the arm is bent to 90 degrees, then click Set Bulge Angle (you can also rotate the joint).

Note: The Set Bulge Angle command records only the angle between the biceps and forearm, not the frame number where that angle occurs. The bulge will occur at any frame where the elbow is at the bulge angle.

In the Selection Level group, click Cross Section. Then in the Cross Section Parameters rollout, click Insert. In a viewport, position the cursor over the upper arm link, and click to place the new cross section for the biceps.

On the Selection Level rollout, click Control Point. To shape the cross section, move the cross section control points in the viewports, creating a bulge. Click Play. The biceps should grow as the angle of the character’s arm approaches 90 degrees. If Select Nearest Bulge Angle is active, the bulge angle gizmos change colors, depending on which angle has the greatest influence.

Go to the Link selection level and use Copy, Paste, and Mirror to create an identical bulge angle for the opposite arm.

Tip: When you use Physique with a biped, load a .bip file that will rotate the character’s limbs. Turn on In Place mode before you scrub the time slider to locate appropriate limb angles. This keeps the character (the biped) in the viewports.

Bulge Editor

The Bulge Editor (page 2-1114) duplicates many of the controls at the Bulge sub-object level. The benefit of using the Bulge Editor is that bulge angle data is represented graphically, and provides an alternative way of creating, selecting, and editing cross sections. Rather than editing cross section control points in the viewports to "bulge" the mesh, you might prefer to open the Bulge Editor and move control points in the Bulge Editor’s Cross Section view.

Procedures

To create a new bulge angle on a selected link:

1. With Bulge sub-object active, turn on Link in the Selection Level group.
2. Select a link in a viewport.
3. Click Insert Bulge Angle.
This creates a new bulge angle. The name in the Current Bulge Angle field increments.

Note: By default, one bulge angle is created by Physique in the initial skeletal pose; the arm is usually straight in this pose.

4. In the Current Bulge Angle field, enter a name, such as **Arm at 90**.

5. Click the Bulge Angle Color swatch and choose a color in the color selector. This makes identification easier.

Now you need to set a joint angle for the newly created bulge angle.

6. Move the time slider until the joint is at the desired angle.

If the skeleton is not yet animated, you can exit the Bulge sub-object level, rotate the skeleton’s joint until it is at the desired angle, then return to the Bulge sub-object level.

7. Click Set Bulge Angle. The joint angle between the link and its child is recorded (for example, if a biped’s upper arm link is selected, Set Bulge Angle records the angle created by the upper arm and the forearm.)

8. In the Selection Level group, turn on Cross Section. Then in the Cross Section group, click Insert. In a viewport, click the link at the point where you want the new cross section to be.

9. Scale the cross section or move its control points to create the bulge.

To move individual control points, use the Control Point selection level.

10. Enter **80.0** in the Influence field.

If the bulge angle is for a biceps bulge when the forearm and upper arm create a 90-degree angle, the bulge begins to appear at 10 degrees.

To copy all Bulge angles from one link to its opposite:

1. Go to the Bulge sub-object level.

2. In the Selection Level group, turn on Link. In a viewport, select a link to copy.

3. Choose Entire Link from the Current Bulge Angle drop-down list.

4. In the Cross Section Parameters rollout, click Copy.

5. In a viewport, select the opposite link.

6. In the Cross Section Parameters rollout, click Paste, and then click Mirror.

All the bulge angles from the first link are pasted to the opposite link, then mirrored.

To choose a specific bulge angle for editing:

1. Click the arrow of the Current Bulge Angle drop-down list.

2. Click the name of the bulge angle you want to edit.

The viewports update to show the cross sections associated with the newly selected bulge angle.

To change a bulge angle value:

1. Make sure the bulge angle’s name is displayed in the Current Bulge Angle drop-down list.

2. Move the time slider to a frame that displays the angle you want to record, or use transforms to change the angle between the active link and its child link.

3. In the Bulge Angle Parameters group, click Set Bulge Angle.

To delete a bulge angle:

1. Click the arrow of the Current Bulge Angle drop-down list.
The full list of bulge angle names is displayed.

2. Click the name of the bulge angle you want to delete.

3. Click Delete Bulge Angle.

You can't delete the default bulge angle: a link must always have at least one bulge angle defined.

To use Select Nearest Bulge Angle:
The Select Nearest Bulge Angle button can help you identify the bulge angle that has the greatest effect at the current pose.

1. In the Selection Level group, click Select Nearest Bulge Angle.

2. Scrub the time slider or rotate the joint.

   The bulge angle named in the drop-down list changes to show the most influential bulge at each skeleton pose.

**Interface**
Controls for the Bulge sub-object level are on the Bulge rollout.
Link—Turn on to select links in the viewports. The Copy, Paste, and Mirror commands are enabled for links.

Cross Section—Turn on to select and edit cross sections in order to "bulge" the mesh. The Insert, Delete, Copy, Paste, and Mirror commands are enabled for cross sections.

Control Point—Turn on to edit cross section control points.

Previous and Next—Click to select the next or previous link, cross section, or control point, depending on the selection level.

Bulge Editor—Click to display the Bulge Editor (page 2–1114), which lets you create and edit bulge angles using the schematic Cross Section and Profile views.

Select Nearest Bulge Angle—Turn on to select the bulge angle nearest to the current joint angle. If a joint bends over time, this lets you use the time slider to select a bulge angle. If you click Play, you can see the Current Bulge Angle field change to reflect the nearest bulge angle to the current angle of the selected link and its child (if two or more bulge angles for the limb exist).

Rock A Forearm Bulge 0

Current Bulge Angle (field and drop-down list)—Displays the current bulge angle. You can enter a descriptive name for a newly created bulge angle. When you click Insert Bulge Angle, this field displays the new bulge angle name. Use the drop-down list to select other bulge angles.

Entire Link—This choice in the Current Bulge Angle drop-down list selects all cross sections for all bulge angles in the active link. Use this to change cross section settings globally for a link.

This also affects the Copy and Paste commands. While Entire Link is chosen, Copy Cross Section copies all cross sections for all bulges, and Paste Cross Section pastes all cross sections for all bulges.

Tip: Entire Link is useful for copying all the bulges from one arm or leg to another.

Bulge Angle Color—Click the color swatch to change the color of the current bulge angle. Giving each bulge angle a different color is a convenient way to distinguish between them.

Bulge Angle Parameters group

Set Bulge Angle—Changes the angle value to the skeleton’s current joint angle on the current bulge angle (visible in the Current Bulge Angle field in the Selection Level group). First use Move or Rotate in a viewport to change the angle between the selected link and its child, then click Set Bulge Angle.

Insert Bulge Angle— Adds a new bulge angle for the selected link. The Current Bulge Angle field displays a bulge angle name with the number incremented. You can enter a descriptive name for a new bulge angle, such as Arm at 90.

By default, one Bulge Angle is created in the Figure mode pose when Physique creates links. Only one additional bulge angle is needed to bulge the mesh. You can create more bulge angles for further control, if you want.
**Delete Bulge Angle**—Removes the current bulge angle from the selected link.

You cannot delete the default bulge angle.

**Influence**—The range of angles through which the bulge influences the skin. Range =0 to 180. Default=90 degrees.

For example, if you’ve set a bulge angle for the joint at 90 degrees, an Influence value of 40 means that the bulge effect begins to appear when the rotating joint reaches 50 degrees (90 minus 40) or 130 degrees (90 plus 40).

**Power**—Controls how smoothly or abruptly the bulge takes effect. At 0.0, the bulge takes effect immediately, without interpolated easing. As values increase, the bulge eases in gradually. A value of 10.0 will bulge the mesh abruptly when the set angle is reached. Range=0 to 10.0. Default=2.5.

**Weight**—Increases the effect of the current bulge angle relative to the effect of any other bulges.

Range=0.0 to 100.0. Default=1.0.

**Cross Section Parameters group**

**Sections**—Sets the number of cross sections for the selected link.

**Divisions**—Sets the number of control points around the cross section. By default, control points are evenly distributed around the circumference of the cross section.

**Resolution**—Sets the number of radial divisions around the cross section. Control points snap to the nearest resolution line.

Note: The buttons that follow, Insert, Delete, Copy, Paste, and Mirror, work according to which level is active in the Selection Level group.

**Insert**—Creates a new cross section or control point.

**Delete**—Deletes the active cross section or control point.

**Copy**—Copies the active link (with its bulge angles) or cross section.

**Paste**—Pastes a link (with its bulge angles) or cross section.

To copy and paste all the bulge angles from one link, choose Entire Link from the Current Bulge Angle drop-down list, and then click Copy. Select the opposite link and click Paste. Click Mirror to mirror the pasted link parameters.

**Mirror**—Mirrors bulge angles and cross sections on bulge angles. If necessary, you can then use Select And Rotate to orient the bulge angles and cross sections.

**Display group**

**Interactive Redraw**—Turn on to deform the mesh in real time while you edit cross sections in the viewports. Turn off to update the mesh only when you release the mouse. Default=on.

Tip: Turn off Interactive Redraw when working on a slow system, or with a dense mesh that takes a long time to compute.
Initial Skeletal Pose—When on, puts the mesh into its original pose; that is, the pose it was in when Physique was first applied. Default=off.

Display Options—Click to display the Bulge Angle Display Properties dialog (page 2–1127), which lets you customize the viewport display of bulges.

Tendons Sub-Object

Select an object that has the Physique modifier applied to it. > Modify panel > Tendons sub-object level

While envelopes provide smooth skin deformations, tendons provide additional stretching in much the same way that actual human tendons do. For example, you might create pulling in the wrist (several joints away) when the fingers are moved. After adjusting the envelope sub-objects (page 2–1130) for good mesh deformation, you can use tendons to control the amount of skin stretching across multiple links.

Workflow Example

To create a tendon from the spine to the upper arm, go to the Tendon sub-object level. Select a spine link. In the Insert Settings group, click to turn on Insert, and then click the selected link to position the tendons. A tendon cross section is added to the link. Turn off Insert.

In the Selection Level group, turn on Cross Section. Using the Rotate tool (on the Main toolbar), rotate the cross section so its control points are in useful locations. In the Tendon Parameters group, use the Radius spinner to scale the cross section radius so the control points fall close to the surface of the skin.

In the Selection Level group, turn on Control Point. Select a control point on the spine tendon's cross section, click Attach, and then click the arm link. A tendon stretches from the spine to the arm.

Finally, adjust the values of Pull, Pinch, and Stretch to refine the movement of the skin.

Tendons connecting upper chest to arms

Procedures

See Creating Tendons (page 2–1096)

Interface

Controls for Tendon sub-objects are on the Tendons rollout.
Chapter 14: Character Studio

### Tendons

<th>![Image]</th>
</tr>
</thead>
</table>

- **Link**—Click to select a link.
- **Cross Section**—Click to select and edit tendon cross sections.
- **Control Point**—Click to edit control points on tendon cross sections.
- **Previous and Next**—Click to go to the previous or next link, tendon cross section, or control point (depending on the active selection level).

#### Insert Settings group

<table>
<thead>
<tr>
<th>Insert Settings</th>
<th>![Image]</th>
</tr>
</thead>
</table>

- **Sections:** Sets the number of base cross sections for the tendon. Default=1.
- **Attach Points:** Sets the number of attach points around the tendon’s base cross section. Default=6.
- **Resolution:** Sets the radial resolution around the base cross section. Attach points are constrained to one of the radial resolution lines. Default=60.

**Insert**—Turn on to insert a new cross section on the selected link, or to insert a control point on a cross section. The action depends on the active selection level: Link, Cross Section, or Control Point.

**Delete**—Click to delete the selected cross section or control point.
The action depends on the active selection level: Link, Cross Section, or Control Point.

**Tendon Parameters group**

<table>
<thead>
<tr>
<th>Tendon Parameters</th>
<th>Radius</th>
<th>Pull</th>
<th>Pinch</th>
<th>Stretch</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
</tr>
</tbody>
</table>

**Radius**—Scales attach points relative to the center of the cross section. Default=The average circumference of the skin where the tendon base is located.

**Pull**—Defines the strength of pull along the length of the link. Default=1.0.

**Pinch**—Defines the amount of pinch around the link circumference of the tendon base. Default=1.0.

**Stretch**—Defines the amount of stretch toward the attached link. Default=1.0.

The Pull, Pinch, and Stretch values work together to control, along a particular dimension, the strength of the one link (the attached link; call it link B) on vertices assigned to another link (the link where the tendon cross sections are inserted; call it link A). Vertices on link A behave as if they were under the influence of link B.

Pull, Pinch, and Stretch can all range from -2.0 to 2.0. At the default value of 1.0, the tendon’s effect is full strength. Reducing the value of these parameters to a value between 0.0 and 1.0 reduces the strength of the tendon’s effect. At values below 0.0, the tendon deforms the skin in the opposite direction. Pull, Pinch, and Stretch values between 1.0 and 2.0 cause an exaggerated effect, which is not usually needed for realistic effects.

Tip: Setting Stretch less than 0.0 can be useful in regions where movement typically pulls the skin inwards, as in the collarbone area or the buttocks.

Tip: As a general rule, leave the tendon values at 1.0 when the tendon is attached to a nearby link. For example, leave them at 1.0 between the upper spine (at the chest) and the arms. Reduce the Pull, Pinch, and Stretch values to reduce the tendon’s effect when the tendon is attached to a more distant link. For example, reduce them between a lower part of the spine and the arms.

**Edit Commands group**

<table>
<thead>
<tr>
<th>Edit Commands</th>
<th>Attach</th>
<th>Detach</th>
</tr>
</thead>
</table>

**Attach**—To attach a point, select the point, click to turn on Attach, then in a viewport, click a different link.

**Detach**—At the Control Point selection level, detaches the tendon of the selected control point. At the Cross Section selection level, detaches all of the cross section’s attached control points. At the Link selection level, detaches all attached tendons on all cross sections of the selected link.

**Upper Boundary Conditions group**

<table>
<thead>
<tr>
<th>Upper Boundary Conditions</th>
<th>Connect to Child Link</th>
<th>Upper Bound</th>
<th>Pull Bias</th>
<th>Pinch Bias</th>
<th>Stretch Bias</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
</tr>
</tbody>
</table>

**Connect to Child Link**—When on, allows tendons to affect the child link. This lets you connect tendons across several links. Otherwise, there is a boundary between the links where no tendon effect occurs. Default=off.

**Upper Bound**—Sets the upper boundary overlap. Upper Boundary values greater than 1.0 affect the child link. Default=1.0.
Warning: Tendons that span several links can conflict with joint intersection parameters. In these cases, go to the Link sub-object level (page 2–1135), and turn off Active to deactivate the joint intersection parameters for the joints that the tendon spans. (These controls are in the Joint Intersections rollout (page 2–1140).)

Pull Bias, Pinch Bias, Stretch Bias—Set the upper boundary falloff effect for these tendon parameters. Values of 0.0 have no effect. Increasing the value shifts the Pull, Pinch, or Stretch effect toward the child. Default=0.5.

Lower Boundary Conditions group

Connect to Parent Link—When on, allows tendons to affect the parent link. This lets you connect tendons across several links. Otherwise, there is a boundary between the links where no tendon effect occurs. Default=off.

Lower Bound—Sets the lower boundary overlap. Lower Boundary values less than 0.0 affect the parent link. Default=0.0.

Warning: Tendons that span several links can conflict with joint intersection parameters. In these cases, go to the Link sub-object level (page 2–1135), and turn off Active to deactivate the joint intersection parameters for the joints that the tendon spans. (These controls are in the Joint Intersections rollout (page 2–1140).)

Pull Bias, Pinch Bias, Stretch Bias—Set the lower boundary falloff effect for these tendon parameters. Values of 0.0 have no effect. Increasing the value shifts the Pull, Pinch, or Stretch effect toward the parent. Default=0.5.

Display group

Interactive Redraw—Turn on to deform the mesh in real time while you edit cross sections in the viewports. Turn off to update the mesh only when you release the mouse. Default=on.

Tip: Turn off Interactive Redraw when working on a slow system, or with a dense mesh that takes a long time to compute.

Initial Skeletal Pose—When on, puts the mesh into its original pose; that is, the pose it was in when Physique was first applied. Default=off.

Display Options—Click to display the Tendon Display Options dialog (page 2–1128), which lets you customize the viewport display of tendons.

Vertex Sub-Object (Physique)

Select an object that has the Physique modifier applied to it. > Modify panel > Vertex sub-object level

Most often, you will want to use envelopes to correct the way skin behaves as the biped moves. However, you can override envelopes by manually assigning vertex properties. For example, you can remove the influence of inappropriate links from selected vertices. You can also change the weight distribution between links for a single vertex by using type-in weights.

Procedures

Tip: You don’t have to work locally, one link at a time. You can use region selection to select groups of vertices or groups of links, working with areas of the body and its skeleton all at once.
To check vertex assignments:
1. Go to the Vertex sub-object level.
2. In the Vertex Operations group, click to turn on Select By Link.
3. Make sure all three Vertex Type buttons are on.
4. In a viewport, click a link.
Physique displays the vertices assigned to that link. If any vertices assigned to the link are out of place, reassign them to a different link, as described in the procedures that follow.
5. Repeat step 4 for other links in the skeleton.

To remove a link's influence on vertices:
For example, you might want to remove the influence of the index finger links from the vertices of the middle finger.
1. Go to the Vertex sub-object level.
2. Turn on Select and select vertices in the viewports.
3. In the Vertex Operations group, turn on Remove From Link.
4. Click a link in a viewport.
The vertices are removed from that link's influence.
Note: You can click additional links to remove their influence as well.
5. In the Vertex Operations group, turn on Lock Assignments.
You must use Lock Assignments to ensure that these envelopes will not influence these vertices if envelope parameters are adjusted later.

To override vertex assignments manually:
This technique is used when envelope assignments are inappropriate, and you want to have specific vertices influenced by a specific link.
1. Go to the Vertex sub-object level.
2. Make sure all three Vertex Type buttons are on, and then in the Vertex Operations group, click to turn on Select By Link.
Observe the assignments and determine which vertices are incorrectly influenced. Also note if the vertices are red (deformable) or green (rigid).
Note: Blue vertices do not fall within the influence of any link and are thus assigned to the root.
3. Turn on Select, and in a viewport, select only the out-of-place vertices.
Note: Alternatively, you can use Alt-click to deselect the vertices that are in the correct place.
4. In the Vertex Type group, click to turn off Rigid Vertices and Root Vertices. Leave Deformable Vertices on.
5. In the Vertex Operations group, click Remove From Link.
6. In the viewports, click each link that you want no longer to influence the selected deformable vertices.

To remove deformable vertices from a link's influence:
1. Go to the Vertex sub-object level.
4. In the Vertex Type group, choose only the type of vertex assignment you want to use: deformable (red) or rigid (green.)

5. Choose No Blending from the Blending Between Links drop-down list.
   This setting will disregard the effects of blending envelopes and vertex weights, and let you assign the selection to any link manually.

6. In a viewport, click the link you want to influence the vertex.
   Note: When you assign deformable vertices, some vertices might turn blue; they are assigned to the root instead of the link you clicked. To assign these vertices as correctly deformable vertices, simply use Ctrl+click with the neighboring parent or child link. If the blue vertices now turn red, they are deformable.

7. In the Vertex Operations group, click Lock Assignments to preserve the manual assignment.

To make vertices rigid:
1. Go to the Vertex sub-object level.

2. Turn on Select, and in a viewport, select the vertices you want to make rigid.

3. In the Vertex Operations group, click to turn on Assign To Link.

4. Turn on Rigid Vertices (green) in the Vertex Type group, and turn off Deformable and Root Vertices.

5. Choose No Blending from the Blending Between Links drop-down list.
   This setting will disregard the effects of blending envelopes and vertex weights, and let you assign the selection to any link manually.

6. In a viewport, click the link these vertices are to be assigned to.

7. In the Vertex Operations group, click Lock Assignments.
   Small squares around the selected vertices indicate that the vertices are locked.

Interface
Controls for vertices in a mesh controlled by Physique are on the Vertex-Link Assignment rollout.
Note: This is not the same as the rollout used by the Physique Initialization dialog.
Vertex Type group

There are three vertex types, differentiated by color:

- **Red**—Deformable vertices that follow Physique’s deformation spline.

- **Green**—Rigid vertices that do not deform but just follow the link they are assigned to.

- **Blue**—Vertices attached to the root node. Physique uses this color when it isn’t sure which link to assign the vertices to. These vertices don’t deform but follow the center of mass object. You should reassign blue vertices to be either rigid or deformable.

While a button of the appropriate color is turned on, you can select vertices of that color. Turn off a button to avoid selecting vertices of that color. You can’t turn off all three buttons at once.

Blending Between Links drop-down list

This list provides several options:

- **N Links**—Vertices within all overlapping envelopes are influenced.

  While this option is active, vertices can be assigned only to the envelopes they fall within. Envelopes are used by Physique in this case to define the blended weight of each vertex.

- **No Blending**—Vertices are influenced by only one link, as in character studio 1. This is useful as a general default if you are developing characters for a game engine that doesn’t support blending. At the Vertex sub-object level it is useful to override blending weights defined by envelopes, and assign vertices to links as either Rigid or Deformable.

  For example, after selecting vertices of the skull and face, turn on No Blending, turn on Rigid vertices, turn on Assign To Link, and then click the head link. This will override the head envelope vertex assignments and assign these vertices as rigid to the head link. Use Lock Assignments to lock any changes (see below).

- **2, 3, 4 Links**—Vertices are influenced only by the specified number of closest links. This is useful when developing characters for a game engine with limited blending.

Vertex Operations group

- **Select**—Selects vertices using the selection tools on the main toolbar.

- **Select by Link**—Selects vertices by link.

- **Assign to Link**—Assigns the selected vertices to a link.

  To assign the currently selected vertices to a link, turn on Assign To Link and then click the link.

  Assign To Link has a dependency on the envelopes defined for each link, and you must set Blending Between Links to "No Blending" to override
Chapter 14: character studio

this. After vertices are assigned manually in this way, use Lock Assignments to keep them from being reassigned inadvertently during subsequent operations.

Note: You must select or assign a link by clicking the link; you can’t use the Select Objects dialog to select or assign a link while you use Physique to work with vertices.

Remove from Link—Remove the selected vertices from a link.

Note: Select, Select By Link, Assign To Link, and Remove From Link will act only on vertices specified by the red, green, and blue Vertex Type (“+”) buttons.

Lock Assignments—Locks vertex assignments.

Lock will prevent any changes from being made to the weights and blending presently assigned to the selected vertices. After any manual assignment of vertices, they should be locked. Before using type-in weights, vertices must be locked. When manipulating envelopes in difficult areas of the character, you might choose to lock vertices that are working well before changing the envelopes to affect other vertices.

Note: If additional data, such as more vertices, comes up the modifier stack, Physique notes the proximity of new vertices to the locked vertices. It then locks the new vertices based on proximity. Already locked vertices will not be unlocked.

Unlock Assignments—Unlocks vertex assignments.

Click Unlock Assignments on selected locked vertices prior to reassigning them to another link, or changing their blending settings.

Type-In Weights—Displays the Type-In Weights dialog (page 2–1128), which you use to enter a weight for selected locked vertices; only the weight for locked vertices can be changed.

To use this feature: select one or more vertices, then lock them. Click this button to display the Type-In Weights dialog, select a link from the drop-down list, and change the weight of that link to position the vertices (vertex positions update in the viewports as the weight changes).

You can use type-in weights for stubborn vertices that fall in blended regions between two or more envelopes. Subtle adjustments can be made to the vertex weights of specific links that would be difficult to achieve by adjusting envelopes alone.

Tip: Type-In Weights is useful mainly for correcting flaws in low- to medium-resolution meshes. On a high-resolution mesh, adjusting envelopes should be used to correct deformation.

Hide—Hides the selected vertices

Unhide All—Unhides all vertices.

Initial Skeletal Pose—When on, puts the mesh into its original pose; that is, the pose it was in when Physique was first applied. Default=off.

Crowd Animation

The crowd-animation system in character studio is designed to simulate the behavior of real-life crowds. A crowd simulation emulates real-life situations by animating delegates (page 3–928) (helper objects that act as representatives). You
Creating a Crowd System

The following is a basic procedure for creating and using a crowd system:

1. Add a Crowd helper (page 2–1157) object.

   ![Crowd helper](image)

   The crowd helper is the controlling object for the entire crowd simulation.

2. Create a Delegate helper (page 2–1157) object.

   ![Delegate helper](image)

   This is a prototype for your crowd; a representative member.

3. On the Modify panel > Motion rollout (page 2–1183), set appropriate speed and turning limits for the delegate.

   ![Motion rollout](image)

   The delegate will move according to the set speed and turning limits.

These topics provide further explanation of the principles of crowd animation:

- Creating a Crowd System (page 2–1155)
- Creating Crowd Helpers (page 2–1157)
- Adjusting Delegate Parameters (page 2–1159)
- Assigning Behaviors (page 2–1159)
- Directing Delegates (page 2–1162)
- Obstacle Avoidance (page 2–1164)
- Changing Delegate Orientation and Speed (page 2–1167)
- Solving the Simulation (page 2–1168)
- Linking Objects to Delegates (page 2–1169)
- Cognitive Controllers (page 2–1170)
- Biped Crowds (page 2–1172)
- Non-Biped Crowds (page 2–1179)
This is analogous to defining how a particular animal or object moves. Is it a bird, a fish, a slug, or an airplane?

4. Make clones of the delegate, either with 3ds Max clone tools, or by scattering delegates (page 2–1157).

5. Create 3ds Max objects to be used with behaviors, such as grids or objects to seek or avoid. These objects often correspond to objects in your scene. For example, you could create a grid in an open doorway to attract delegates, or a box at an obstacle to repel delegates.

6. Add one or more behaviors (page 2–1159). Modify each behavior’s settings to be appropriate for the members of your crowd.
7. Solve the simulation.
8. Watch the solved simulation. If it needs correction, make changes to behaviors or delegate parameters. Solve again, and continue until the simulation works as intended.
9. Create the objects that will follow the delegates, and align and link them to delegates (page 2–1169).

Creating Complex Simulations
The process described above creates a simple crowd simulation. You can also use other tools to further control the simulation:

- Use cognitive controllers (page 2–1170) to cause delegates to switch behaviors based on their proximity to objects in the scene, time elapsed in the simulation, and other factors.
- Use motion synthesis (page 2–1179) to cause different portions of the linked object’s animation to be used based on delegate speed, rotation, and other factors.
- Use bipeds and a motion flow network to animate the bipeds with delegates. See Biped Crowds (page 2–1172).

Creating Crowd Helpers
The crowd system in character studio uses two helper objects: Crowd and Delegate. The first step in creating a crowd simulation is the creation of these helpers. The crowd helper serves as the command center for setting up and solving crowd simulations, while delegates provide stand-ins for animated objects. The crowd helper controls are used to animate the delegates, then later you link objects to delegates to create the finished scene.

Crowd Helper
A crowd helper object appears in viewports as blue tetrahedron. The location and size of the crowd helper does not affect the simulation. For the easiest workflow, create the crowd helper with a relatively large size, and place it where you can easily select it. You’ll rarely need more than one Crowd helper object per scene.
Delegate Helpers

The Crowd system in character studio uses Delegate helper objects as intermediaries between the crowd simulation and the influenced objects. A delegate is a non-rendering pyramid-shaped object. Its apex points in the direction the crowd system uses as “forward” when it moves the delegate around.

Use one delegate per object to be animated by the crowd system. You can add delegates one by one, or use any of the standard 3ds Max methods for cloning objects, including Shift+clone and the Array function. However, the Crowd object offers a convenient Scatter Objects (page 2–1189) function that lets you clone delegates and distribute the clones over a surface or within a volume, with options for orientation and scaling.

Procedures

To create a Crowd helper object:

1. On the Create panel, click Helpers.
2. Click Crowd, and drag the helper object to a convenient size.
   Tip: Make the crowd helper object large enough so you can easily select it in two or more viewports. The size of the helper does not affect the crowd simulation in any way.

To create a Delegate helper object:

1. On the Create panel, click Helpers.
2. Click Delegate. Drag in a viewport to set the delegate position, and then drag vertically to set the size.
   Tip: The delegate always points “up” in the viewport you add it in. So if you want it to point “forward,” that is, toward the positive Y direction in the World coordinate system, you should create it in the Top viewport.

To clone and scatter delegates:

1. Create a Crowd helper and a Delegate helper.
2. Decide how to distribute the delegate clones, and create an object to define how the clones are to be positioned: a grid object, a primitive box or sphere, a shape, or any object to serve as a surface. Alternatively, you can choose to distribute clones in a circular area without the use of a distribution object.
3. Select the Crowd object and access the Modify panel.
4. Click the Scatter Objects button to open the Scatter Objects dialog (page 2–1189).
5. On the Clone tab, set the number of clones to create, and select the object to clone.
6. Click Generate Clones.
   This produces the specified number of clones in the same location. To vary positions, orientations, and/or sizes, proceed with the following steps.
7. On the Position tab > Placement Relative To Object group, choose a distribution option. Click the None button, and then select the distribution object you created earlier.
   Alternatively, to distribute delegates in a circular area, choose Placement In Area group > In Radial Area and set a center and radius.
8. Click Generate Locations.
   This distributes the clones.

9. On the Rotation tab, choose which of the cloned object’s local axes are to look forward and up. Optionally, specify source and target objects for the clones’ orientations, as well as limits for randomized deviations from the calculated orientation.

10. Click Generate Orientations.

11. On the Scale tab, for each axis, specify Average, Deviation, and, optionally, Same As settings and a random seed.

12. Click Generate Scales.
   At this point, you’re basically finished. However, to create a series of randomized positions, orientations, and/or sizes for clones, follow the next two steps and repeat as necessary.

13. On the All Ops, turn on Positions, Rotations, and/or Scales. To vary the randomized positions, rotations, and/or scales, turn on the corresponding Inc Seed check boxes.

14. Click the Scatter button.
   You can combine the cloning, position, rotation, and scale functions in one operation by setting the options on their respective tabs without clicking the Generate buttons, and then using the All Ops tab to apply any or all scatter operations simultaneously. Also, you can use the All Ops tab > Select Objects To Transform to specify any objects to scatter; not just clones.

See also
Crowd Helper Object (page 2–1187)

Adjusting Delegate Parameters
Delegate parameters define the nature of their motion. You can change delegate parameters in one of two ways:

- To adjust parameters for an individual delegate, select the delegate, access the Modify panel, and adjust parameters. For descriptions of parameters, see .

- To adjust parameters for several delegates at once, select the crowd helper object, access the Modify panel, and click Multiple Delegate Editing to access the Edit Multiple Delegates dialog (page 2–1197).

The speed parameters let you describe a delegate’s average speed and maximum acceleration. You can also define how much a delegate slows down as it turns or goes upward, and how much it speeds up when it goes down.

Turning parameters let you indicate how quickly a delegate can turn, and how much it can turn upward and downward. And banking parameters describe how much and how quickly a delegate banks and its banking limit.

All of these parameters work together to describe different types of creatures. A small fish, for instance, can turn more quickly than a large bird. A fish’s speed would not be affected when the fish traveled up or down, but a bird’s speed might be altered by its upward or downward direction.

Crowd Helper Object (page 2–1187)

Assigning Behaviors
In the real world, different crowds exhibit diverse behaviors, and even members of the same crowd can conduct themselves in various ways. Included
with the **character studio** Crowd system is an assortment of behaviors that let you simulate a range of crowd activities.

Behaviors let you assign procedural activity types to delegates, which in turn affect objects linked to delegates. You can associate any number of behaviors with each crowd object (page 2–1187), and then link delegates and teams of delegates to each behavior. A specific behavior assigned to a Crowd object belongs only to that crowd; it cannot be assigned to any other crowds.

Following is a list of available behaviors:

- **Avoid Behavior** (page 2–1211)—Prevents delegates from colliding with objects in the scene, or with each other. Avoidance can use any combination of turning, braking/stopping, repelling, and vector field.

- **Orientation Behavior** (page 2–1214)—Applies a fixed orientation or orientation range to delegates, so they face a specific direction instead of toward the destination. You can specify orientation in absolute terms, or relative to the direction the delegate currently faces.

- **Path Follow Behavior** (page 2–1216)—Restricts motion to a spline or NURBS curve; options include back-and-forth patrol-type movement.

- **Repel Behavior** (page 2–1218)—Forces delegates to move away from a target.

- **Scripted Behavior** (page 2–1220)—Uses MAXScript to specify behavior.

- **Seek Behavior** (page 2–1220)—Moves delegates toward a target or targets.

- **Space Warp Behavior** (page 2–1221)—Uses any dynamics-oriented space warp to control movement, including wind and gravity. Vector Field, a crowd-specific space warp that lets delegates avoid irregularly shaped objects while following their contours, is included with **character studio**.

- **Speed Vary Behavior** (page 2–1222)—Lets delegates change speed for more realistic movement.

- **Surface Arrive Behavior** (page 2–1223)—Lets delegates move toward and land on a surface, with custom speed and acceleration parameters.

- **Surface Follow Behavior** (page 2–1226)—Delegates move along a surface, which can be animated. Also, you can specify whether the delegates are to move straight ahead or skirt hills and depressions.

- **Wall Repel Behavior** (page 2–1227)—Uses a grid to repel delegates; ideal for keeping objects inside an enclosed, straight-sided room.

- **WallSeek Behavior** (page 2–1229)—Uses a grid to attract delegates. You can use this as a doorway for crowd-controlled bipeds to walk through.

- **Wander Behavior** (page 2–1231)—Induces a realistic semi-random movement for characters such as shoppers at a mall.

**Tip:** If you need custom behaviors, you can create your own with scripting.

The first time you add a behavior to the scene, a new rollout appears for the behavior below the Setup rollout. This rollout lets you change settings for the behavior. Certain behaviors, such as Seek and Avoid, let you specify "target" objects.

**Tip:** Behaviors are assigned generic names by default. It’s a good idea to rename them with more meaningful descriptors; for example, "Seek Ball" or "Avoid Fire".

To display the rollout for a different behavior in the scene, choose it from the drop-down list in the Behaviors group. To see the controls available in the rollout for a behavior type, follow the link from its entry in the above list.

In addition to the controls available in behavior rollouts, you can use the **Behavior Assignments**
Assigning Behaviors

1161

and Teams dialog (page 2–1200) to turn behaviors on and off (with the Active check box), and for all behaviors except Avoid, Orientation, and Surface Follow, you can set and animate Weight. The Active status is animatable for all behaviors.

Using Behaviors

To use a behavior, you apply it to a delegate or a team of delegates using the Behavior Assignments and Teams dialog (page 2–1200). In this dialog, each assignment of a behavior to a delegate is given a weight. You can modify and/or animate these weights to influence the simulation.

Behavior assignment weights can profoundly effect a simulation. When applying two or more behaviors to the same delegate, the weights define the relationship between the behaviors, making one more or less powerful than the other. One way to visualize a behavior assignment weight is to examine the behavior’s force vector during a crowd simulation. The vector’s length indicates the behavior’s weight upon the delegate.

Each behavior has its own parameters which appear in the Behavior rollout, available in the Crowd object’s Modify panel. These parameters describe how the behavior works, and can sometimes contribute to the behavior’s strength as well. For instance, Seek, Repel, Wall Seek, and Wall Repel, all have specific volumes of influence. Outside these volumes they have no effect and essentially have a weight of zero. This rollout lets you specify whether or not you wish to see behavior’s force vector dynamically displayed during a Crowd simulation, and what color that vector should be.

When working with the Crowd system, it is critical to play with behavior assignment weights, as well as each behaviors’ parameters. Typically, you run the simulation repeatedly, changing the weights and parameters to get the desired result.

A few behaviors cannot be weighted. These are Avoid, Surface Follow, and Orientation. Avoid and Surface Follow take over after all of the other behaviors have been applied to a delegate. They can take stringent measures to affect the delegate, possibly overpowering other behaviors in order to meet their constraints. Orientation simply sets the delegate’s facing direction. It cannot be weighted and does not apply a force.

Behavior Tips

A few helpful things to know about behaviors in character studio:

• You can create conditional behavioral systems with Crowd’s Cognitive Controller feature. This uses the MAXScript scripting language to determine when to effect a transition from one behavior to another; we’ve provided a number of sample scripts for you to learn from and adopt to your own simulations in Cognitive Controller Editor (page 2–1206) and State Transition Dialog (page 2–1208).

• The Behavior rollout appears immediately after the Crowd object > Setup rollout in the Modify panel. However, it doesn’t show up until you’ve added at least one behavior to the crowd object.

• The Crowd panel displays only one Behavior rollout at a time. To access a different one, choose its name from the drop-down list at the bottom of the Crowd object’s Setup rollout.

• As with most scene entities in 3ds Max, it’s a good idea to give behaviors custom names, such as “Seek Doorway” or “Follow Hilly Surface.” You do this by clicking the behavior’s name in the Setup rollout and entering a new one from the keyboard.

• The default behavior settings may not always give the ideal results. The optimal settings depend vary with the particulars of your simulation setup; in many cases, if not most, you’ll need to experiment with the settings to
get the results you want. In some cases, you might need to animate settings as well.

One particularly useful feature of the delegate is its ability to display, using colored vectors, the strength and direction of the various forces acting upon it during solution of the crowd simulation. Each force can have a unique, identifying color. For example, the Seek behavior uses green by default, while the Wander behavior uses aqua. You can change these colors to any you like.

If a simulation isn’t proceeding as expected, you can debug it by observing the vectors during the solution. And if the solution occurs too quickly, you can use the Step Solve feature to solve the simulation one frame at a time.

**Procedure**

**To use assign behaviors to delegates:**

This example shows how to create a basic crowd simulation with delegates and behaviors.

1. Run 3ds Max or reset the program.
2. Add a Crowd object and one or more Delegate objects to the scene. In general, add delegates in the Top viewport so that they point forward. The Crowd object’s location is immaterial.
3. Select the Crowd object and open the Modify panel.
4. On the Setup rollout > Behaviors group, click the New button.
5. In the Select Behavior Type dialog, click a behavior and then click OK to close the dialog.
   A Behavior rollout appears for the behavior you chose.
6. If the behavior requires a target object or objects, such as Seek, click the None button and then select an object, or click Multiple Selection and select several objects.
7. Change other behavior settings as necessary.
8. Create and modify additional behaviors as necessary.
9. On the Setup rollout, click the Behavior Assignment button.
10. In the Assignment Design group, the two upper lists should each contain a single entry: the delegate on the left, and the behavior on the right. Select both items.
11. Click the New Assignment button to the right of the Assignment Design group. It’s a vertical button with five right-pointing arrows.
   This adds the new assignment to the list in the Behavior Assignments group.
12. Accept the changes and the OK button to close the Behavior Assignments and Teams dialog.
13. On the Modify panel, scroll down to the Solve rollout and click the Solve button.

Keys are created as follows: The delegate turns to point toward the sphere, banking as it turns, and then moves directly toward the sphere. When it reaches its target, it moves slightly beyond the sphere, and then repeats the turn-and-move motion until the end of the simulation. To prevent this, try starting with the two objects farther apart, or animating the sphere’s position.

Directing Delegates

One of the purposes of behaviors is to move delegates in a particular direction over the course of the simulation. These behaviors can be used to direct delegates:

- The Seek behavior (page 2–1220) is one of the most commonly used behaviors in the crowd system. With this behavior, you can cause delegates to move toward a specific object. The seek object can be animated, and the delegates will follow it.
• The Wall Seek behavior (page 2–1229) causes delegates to seek a rectangular area. Compare with the Seek behavior, which causes delegates to seek an object’s pivot point.

• The Path Follow behavior (page 2–1216) is also useful for pushing delegates in a specified direction. With this behavior, delegates follow a path but can “stray” from the path by a specified distance, creating slightly random motion along the path.

• With the Surface Arrive behavior (page 2–1223), delegates seek one or more objects as they do with the Seek behavior, but you can cause delegates to stop when they reach a target.

• You can use the Surface Follow behavior (page 2–1226) to cause delegates to move along a surface.

• With the Space Warp behavior (page 2–1221), you can use a vector field to push delegates around the field to avoid obstacles. See Obstacle Avoidance (page 2–1164).

After setting up a behavior, you must use Behavior Assignments (page 2–1200) to assign the behavior to a delegate or team.

Procedures

To use the Seek behavior:

1. Select the crowd helper and access the Modify panel.

2. In the Setup rollout > Behaviors group, click New. Choose Seek Behavior from the pop-up list.

   The Seek Behavior rollout appears below the Setup rollout.

3. In the Seek Behavior rollout (page 2–1220), click None to add one seek object, or click Multiple Selection to designate more than one object for the delegates to seek.

4. Change the default settings as desired.

To use the Wall Seek behavior:

1. On the Create panel, click Helpers, and click Grid. Create a grid in the scene.

   Tip: For best results, do not use Mirror to copy a grid to be used with behaviors. Use Shift+Clone instead.

2. Move and rotate the grid to position it.

   Tip: The Wall Seek behavior attracts delegates to the grid in the direction of grid’s local Z axis. With the grid still selected, use the Local coordinate system to see the direction of the Z axis in viewports; the axis arrow points in the direction of the positive Z axis. Checking the Z-axis direction will speed the process of setting up the behavior.

3. Select the crowd object, and add a Wall Seek behavior.

4. In the Wall Seek Behavior rollout, click None, and pick the grid.

5. Choose Positive Axis to cause the delegates to be attracted to the Z-axis side of the grid. You can also choose Negative Axis to attract delegates to the opposite side of the grid, or Both to attract them to both sides.

6. If you want delegates to be attracted to the grid only when they are within a specified area in front of the grid (rather than when they are anywhere in the scene), turn on Use Distance. Use the Inner Distance and Outer Distance parameters to set the area in which delegates will be attracted to the grid. Turn on Display Distance to see the distance in viewports.

To use the Path Follow behavior:

1. On the Create panel, click Shapes. Create a shape to be used as a path for delegates.

2. Add a Path Follow behavior to the Crowd object.
3. In the Path Follow Behavior rollout, click the None button and pick the shape for the delegates to follow.

4. Set the Radius parameter to the number of units by which delegates can stray from the path. Change other settings as desired.

To use the Surface Arrive behavior:
1. Add a Surface Arrive behavior to the Crowd object.
2. Add an object or objects to serve as the target surface to the scene.
   Note: If you use multiple objects, delegates will arrive at the surface of the closest object.
3. In the Surface Arrive Behavior rollout, click None or Multiple Selection to designate the one or more target objects.
4. Use the settings in the Location group to determine where the delegate will stop when it reaches a target object.
5. Use the settings in the Approach group to determine how the delegate will behave when it approaches the target.

To use the Surface Follow behavior:
1. Add a Surface Follow behavior to the Crowd object.
2. Add an object or objects to serve as the follow surface to the scene.
   Note: If you use multiple objects, they must intersect to form a contiguous surface. Each delegate will move to the closest surface, follow it to the next closest that it encounters, and then start following that one, and so on.
3. In the Surface Follow Behavior rollout, click None or Multiple Selection to designate the object or objects whose surface(s) the assignees are to follow.
4. If you like, use the settings in the Projection Vector group to force delegates to move in a specific direction.

Obstacle Avoidance

An important part of crowd behavior is avoidance of obstacles. Think of an obstacle as anything that impedes a crowd member’s progress. Examples of obstacles include walls, telephone poles, and fences, as well as other crowd members. Encountering such objects can cause avoidance behavior, which consists of any combination of slowing down, turning, and stopping.

There are several ways to implement avoidance in character studio, including:
- The Avoid behavior (page 2–1211) is one of the most commonly used behaviors. Use this behavior to cause crowd members to avoid other crowd members, or spherical objects in the scene. It works by creating a spherical volume of avoidance around the avoided object, so it doesn’t accommodate irregular objects.
  The Avoid behavior is unlike any other behavior in Crowd. After all the other behaviors exert their forces on the delegates, Avoid takes over and has the power to turn, slow down, and even stop a delegate in order to make it avoid an obstacle.
- Use the Wall Repel behavior (page 2–1227) to cause crowd members to avoid broad, flat objects such as walls and fences. You can set a maximum distance for the repel effect, and describe the rate at which the force away from the wall increases as a delegate approaches the wall.

Unlike the Avoid behavior, which can stop or slow down a delegate, Wall Repel simply exerts a force on the delegate to turn it away from the wall. It does not guarantee wall avoidance. You must work with it’s distance
and falloff parameters, as well as its weight in the Assignments and Teams dialog, to control its strength.

- Use the *Repel behavior* (page 2–1218) to cause crowd members to turn away from an object. It works exactly like Wall Repel except that it uses a spherical volume rather than a plane. You can set a maximum distance for the repel effect, and describe the rate at which the repel force increases as the delegate approaches the obstacle.

*Repel* exerts a force on the delegate to turn it away from the obstacle. It does not guarantee avoidance. You must work with its Distance and Falloff parameters, as well as its weight in the *Behavior Assignments and Teams dialog* (page 2–1200), to control its strength. *Repel* can be used instead of the Avoid behavior as a simple avoidance technique for non-terrestrial creatures such as fish or birds.

- Use a *Vector Field* (page 2–1241). This is a special type of space warp that crowd members can use to move around irregular objects such as a curved, concave surface. You can use the Vector Field space warp in conjunction with the Avoid behavior to make delegates slow down when they approach a complex object, and then go around it. This guarantees that the delegate will not pass through the obstacle’s surface.

  You can also use the Vector Field space warp in conjunction with the *Space Warp behavior* (page 2–1221). This simply exerts a force on the delegate that mimics the contours of the object. It does not assure that the delegate will not pass through the surface of the obstacle. You can use a Vector Field with both the Space Warp and Avoid behaviors to combine their effects.

### Procedures

**To use the Avoid behavior:**

1. Add an Avoid behavior to the Crowd object.
2. In the Avoid Behavior rollout, use the None button or the Multiple Selection button to designate the target object or objects to avoid.
   
   Tip: To make an entire team of delegates avoid each other, choose all delegates in the team. The crowd system will cause each delegate to avoid all others except itself.
3. Turn on Display Hard Radius to see the radial avoidance area in viewports. Adjust the Hard Radius to the appropriate size for your delegates.
4. Adjust the Brake Pressure to determine whether a delegate will slow down when it encounters an avoided object.
5. Adjust the Look Ahead parameter to determine how many frames ahead each delegate will look to determine the best way to avoid others.
6. Use *Behavior Assignments* (page 2–1200) to assign the behavior to a delegate or team.

**To use the Wall Repel behavior:**

1. On the Create panel, click Helpers, and click Grid. Create a grid in the scene.
   
   Tip: For best results, do not use Mirror to copy a grid to be used with behaviors. Use *Shift* + Clone instead.
2. Move and rotate the grid to position it.
   
   Tip: The Wall Repel behavior repels delegates from the grid in the direction of grid’s local Z axis. With the grid still selected, use the Local coordinate system to see the direction of the Z axis in viewports; the axis arrow points in the direction of the positive Z axis. Checking the Z-axis direction will speed the process of setting up the behavior.
3. Select the crowd object, and add a Wall Repel behavior.
4. In the Wall Repel Behavior rollout, click None, and pick the grid.
5. Choose Positive Axis to cause the delegates to be repelled from the Z-axis side of the grid. You can also choose Negative Axis to repel delegates from the opposite side of the grid, or Both to repel them from both sides.

6. If you want delegates to be attracted to the grid only when they are within a specified area in front of the grid (rather than when they are anywhere in the scene), turn on Use Distance. Use the Inner Distance and Outer Distance parameters to set the area in which delegates will be attracted to the grid. Turn on Display Distance to see the distance in viewports.

7. Use Behavior Assignments (page 2–1200) to assign the behavior to a delegate or team.

To use the Repel behavior:
1. Add a Repel behavior to the Crowd object.
2. In the Repel Behavior rollout, use the None button or the Multiple Selection button to designate the object or objects that are to repel delegates.
3. Change the default settings as desired.
4. Use Behavior Assignments (page 2–1200) to assign the behavior to a delegate or team.

To add a Vector Field space warp:
Adding a Vector Field space warp object works the same as adding a Box geometry primitive.
1. On the Object Type rollout, click Vector Field.
2. Drag in a viewport to set the initial dimensions.
   - If using the Cube creation method, this sets all three dimensions simultaneously.
   - If using the Box creation method, release the mouse button, and then move the mouse vertically to set the height.
3. Click to create the space warp.

To use a Vector Field space warp with delegates:
This procedure presents general guidelines for using the Vector Field space warp with delegates in a crowd simulation.
1. Create an object to serve as an obstacle. This object must be an editable mesh or geometric primitive; it can have modifiers.
2. Add a Vector Field space warp.
3. Position and scale the space warp lattice so that it encloses the obstacle object.
   The lattice should be significantly larger than the object. The object should be located roughly at the lattice center.
4. In the Lattice Parameters rollout, increase the Length Segs/Width Segs/Height Segs settings so that the lattice segments intersect the object at reasonable intervals.
   To determine appropriate Segs settings for your obstacle objects, first examine the object complexity. If the obstacle has a lot of detail, and you want that detail reflected in the vector field, then you need a relatively high lattice resolution.
5. Click the Obstacle Parameters rollout > Compute Vectors group > Vector Field Object button (initially labeled “None”), and then in a viewport, click the object that will act as an obstacle in the crowd simulation.
   This specifies the obstacle object. The range volume grid appears on the object’s surface as an olive-colored wireframe.
6. Increase the Obstacle Parameters rollout > Compute Vectors group > Range setting.
   As you increase this setting, you’ll see the range volume grid expand. The range volume should enclose the space in which crowd members need to start turning in order to avoid the object.
7. Turn off Display group > Show Lattice and Show Range so that the vector field will be more easily visible when generated.
8. Turn on Display group > Show Vector Field.
9. In the Compute Vectors group, click the Compute button. This generates the vector field.

Tip: To make the vector lines more evident, increase the Display group > VectorScale setting.

The vectors appear as blue lines surrounding the obstacle object. One vector is computed for each lattice intersection within the range volume grid. Each vector matches the normal of the object at the point on the object’s surface closest to the lattice point.

The vector force falls off with distance from the object, as shown by the progressively shorter vector lines toward the grid perimeter.

10. Add Crowd (page 2–1187) and Delegate helper objects.
11. Select the Crowd object and open the Modify panel.
12. In the Setup rollout > Behaviors group, click New.
13. In the Select Behavior Type dialog that is displayed, choose Space Warp Behavior, and then click OK.
14. In the Space Warp Behavior rollout that appears, click the button (initially labeled “None”), and then in a viewport, click the Vector Field space warp.

Tip: You might find it easier to use Select By Name to select the space warp.
15. In the Setup rollout, click the Behavior Assignments button, and use the Behavior Assignments And Teams dialog (page 2–1200) to assign your delegate or delegates to the space warp behavior.

16. Add any other objects or behaviors appropriate to the simulation.
17. Select the Crowd object, and then solve the simulation by clicking the Solve rollout > Solve button.
18. Fine tune the behavior associated with the Vector Field space warp by adjusting the Lattice parameters (page 2–1242) and Obstacle parameters (page 2–1242).
19. Continue computing the vector field and then solving the simulation after each adjustment. In certain cases you might need to animate the vector field parameters to keep objects within the field.

### Changing Delegate Orientation and Speed

You can use the Orientation behavior (page 2–1214) to change the direction in which a delegate moves, and the Speed Vary behavior (page 2–1222) to vary delegates’ speed or make them stop moving altogether.

After setting up a behavior, you must use Behavior Assignments (page 2–1200) to assign the behavior to a delegate or team.

### Procedures

**To use the Orientation behavior:**

1. Select the crowd helper and access the Modify panel.
2. In the Setup rollout > Behaviors group, click New. Choose Orientation Behavior from the pop-up list.
   
   The Orientation Behavior rollout appears below the Setup rollout.
3. To restrict the heading orientation with respect to the delegate’s current heading, turn on Heading group > Relative. To restrict the
heading to a specific direction or range, leave Relative off.

4. To restrict the pitch orientation with respect to the delegate's current pitch, turn on Pitch group > Relative. To restrict the pitch to a specific direction or range, leave Relative off.

5. Change the other default settings as desired.

To use the Speed Vary behavior:
1. Add a Speed Vary behavior to the Crowd object.
2. Adjust the Center and Deviation as needed to control delegate speed. Change other settings as desired.

Solving the Simulation

After you have set up behaviors for delegates, you must solve the simulation to generate keyframes on delegates. You solve the simulation by selecting the crowd object and clicking Solve in the Solve rollout (page 2–1232).

In order to generate the simulation as quickly as possible, delegate keys are saved after the solution is run, so there might be a pause between the end of the solution and return of control of the software to you. Also, any objects linked to delegates are hidden during the simulation.

You will most likely have to solve a simulation several times before it is correct. Watch the animation after the solution is calculated, correct behaviors or delegate parameters as necessary, then solve again.

You can speed up the solution calculation time by decreasing the frequency of keyframes or screen updates. You can also view the solution one frame at a time to help pinpoint trouble areas.

Procedure

To solve a simulation:
1. Set up a crowd simulation with a crowd helper, delegates and behaviors. See Assigning Behaviors (page 2–1159).
2. Select the crowd helper.
3. On the Modify panel, in the Solve rollout, set the Start Solve and End Solve parameters to set the start and end frames for the solution.
4. Click Solve.

Tip: To use the keyboard shortcut for the Solve button, turn on the Keyboard Shortcut Override Toggle and then press the S key to run a solution.

Wait a few moments while the solution is calculated. The progress bar at the bottom of the screen tells you the status of the solution process.

To speed up the solution time:
1. Under Save every Nth Key, set the Positions and Rotations parameters to a higher number, such as 5.

This causes the simulation to set delegate keyframes every five frames rather than at every frame.

2. Increase the Solve rollout > Display During Solve group > Frequency setting to a higher number, such as 100.

This will cause the display to update with the new delegate locations only every 100 frames.

To troubleshoot the simulation:
In a crowd simulation, it is not uncommon for a short portion of the animation to have a unique problem that doesn’t appear on other frames. Use Step Solve to analyze short portions of your simulation when things don’t go as expected.
1. Move the time slider to the frame at which you want to start solving one frame at a time.

2. Click Step Solve.

To use the keyboard shortcut for the Step Solve button, turn on the Keyboard Shortcut Override Toggle and then press the T key to run a solution in step mode.

You can start at any frame. Zoom in to examine the vectors of misbehaving delegates.

3. Press the spacebar to solve the simulation one frame at a time.

4. Press Esc to exit Step Solve mode.

**Linking Objects to Delegates**

You can link objects or bipeds to delegates to make them follow the simulated animation.

You can link objects to delegates with 3ds Max linking. Alternatively, the crowd system has a tool for automatically aligning and linking objects with delegates.

When you want to use bipeds with delegates, you associate bipeds with delegates rather than link them. This approach enables the bipeds to use a motion flow network to determine their motion during the simulation. For an explanation of how to set up a biped crowd simulation, see *Biped Crowds (page 2–1172)*.

**Procedures**

*To link objects to delegates:*

1. Set up a crowd simulation with a crowd helper and delegates. See *Creating Crowd Helpers (page 2–1157)*.

2. Create a series of objects to follow the delegates. Tip: In a later step, you will align each object’s local Y axis to point in its corresponding delegate’s forward direction. For this reason, you should take care to make sure your objects’ local Y axes point in the direction you consider to be “forward”. The easiest way to do this is to set up one object with its Y axis pointing in the forward direction, then clone the object.

3. Select the crowd helper, and access the Modify panel.

The Object/Delegate Associations dialog (page 2–1196) appears.

5. Click Add under the Objects list to add objects to link with delegates.

6. Click Add under the Delegates list to add delegates to link with the objects you added in the previous step.

Each object in the Objects list will be associated with the delegate in the same position in the Delegates list. If necessary, reorder either list manually by highlighting entries and using the Shift Up/Shift Down buttons; these are the arrow buttons between the two lists.

7. Click Align Objects with Delegates to align each object with its corresponding delegate.

The objects on the Objects list are moved and rotated to align with delegates. Each object’s local Y axis points in the delegate’s forward direction.

8. Click Link Objects to Delegates.

9. Click OK to exit.

*To associate bipeds with delegates:*

1. Set up a crowd simulation with a crowd helper and delegates.

2. Create several bipeds, one for each delegate.

3. Select the crowd helper, and access the Modify panel.
   The Associate Biped with Delegates (page 2–1199) dialog appears.
5. Click Add under the Bipeds list, and choose the bipeds to add to the list.
6. Click Add under the Delegates list, and choose the delegates to associate the bipeds with.
7. Turn on Set Delegates to Use Biped.
   This will turn on the Use Biped option for each delegate, which is a requirement for biped crowd simulations.
8. Choose Make Specified Associations to associate each biped with its corresponding delegate listed on the dialog. Alternatively, choose Associate Delegates With Closest Biped to associate each delegate with the biped nearest to it in the scene.
9. Click Associate to make the associations, and click Close.
   Unlike regular objects, bipeds are not aligned with delegates immediately. Each biped will align with its respective delegate when the simulation is solved.

   Note: In order for a biped crowd simulation to solve correctly, it must have a motion flow network for the bipeds to follow. See Biped Crowds (page 2–1172).

**Cognitive Controllers**

You can use the cognitive controller feature to cause crowd members to change behaviors during a simulation depending on the circumstances. For example, a character could wander randomly until it comes within a certain distance of a target, at which point it could head straight for the target.

In technical terms, cognitive controllers let you influence crowd simulations with scripted conditionals, effectively implementing a form of artificial intelligence. You use the Cognitive Controller editor (page 2–1206), a flowchart-style editor (much like the Motion Flow Graph dialog (page 2–1045)) to set up a network of behaviors and behavior combinations, known as states. Then you then apply MAXScript-based transitions that specify when delegates are to move from one state to another. Even with a relatively simple setup, you can create simulations that make your characters appear to be living, conscious beings, making decisions as they move through the scene.

You can find procedures describing various examples of cognitive-controller transitions in the State Dialog (page 2–1207) topic:

- Testing a particle system parameter (page 2–1209)
- Testing an object position
- Testing an atmospheric property (page 2–1209)
- Testing the distance between two objects
- Testing a modifier parameter
- Testing another delegate’s behavior (page 2–1209)

**Procedure**

**To set up and use a cognitive controller:**

This procedure describes a typical setup routine for creating and using a cognitive controller. The procedure assumes basic knowledge of crowd simulation setup. For more information about crowd setup, see Crowd Helper Object (page 2–1187) and Setup Rollout (page 2–1188).

1. Create a scene containing a crowd object and one or more delegates. See Creating Crowd Helpers (page 2–1157).
2. Create at least two behaviors. See Assigning Behaviors (page 2–1159).
3. Open the *Cognitive Controller* editor (page 2–1206).

4. Click the New button to create a cognitive controller.

   *Character Studio* gives the controller the default name of "Cognitive Controller." It’s recommended that you give more descriptive names to cognitive controllers, such as "Seek/Wander." Do this by clicking on the name in the text box and editing it from the keyboard.

5. Click in the editor window to create and place a state. Continue clicking in different places to add as many states as necessary.

6. Right-click a state to open the *State* dialog (page 2–1207).

7. Again, it’s recommended that you give more descriptive names to states, which you can do in the State dialog. Click the name (State or State#) in the text box and edit it from the keyboard.

   Next, define a behavior or behaviors for each state.

8. Click the Add button.

9. In the Select Behaviors dialog, choose one or more behaviors.

   If you choose multiple behaviors, you can specify different weights for each in the State editor. For example, you can combine a Seek behavior at full weight with a Wander behavior at half weight, so that the delegate will meander slightly as it seeks the target.

10. Close the Select Behaviors dialog, and then close the State editor.

11. Repeat steps 6–10 as necessary to define behaviors for the other states in the controller.

Next, use Create Transition to define the sequence of states during the simulation.

12. Decide on the sequence in which the states are to occur.

13. Click the Create Transition button.

14. Drag a line from one state to the next in the order that they are to execute. Click a state to create a transition from itself to itself.

   A transition arrow appears, pointing from the "source" state to the "destination" state.

   Each state can have any number of incoming and outgoing transitions. Specify different transition conditions for each to create as complex a state diagram as necessary.

   Next, use the State Transition dialog to define a conditional for each transition.

15. Right-click a transition line.

16. In the *State Transition* dialog (page 2–1208), enter the name of the transition condition, and then click the Edit MAXScript button.

17. Use the MAXScript editor window to enter or load a script that defines the condition or conditions under which the transition is to occur.

   Typically, this is a function that tests a condition and returns 1 (if true) or 0 (if false).

   *Note:* See this topic in the online *User Reference* for sample MAXScript code for this function.

18. Use the State Transition dialog to set other parameters such as priority and duration.

19. Use the *Behavior Assignments and Teams* dialog (page 2–1200) to assign the cognitive controller to delegates or teams.

   *Note:* Crowd doesn’t let you use multiple cognitive controllers with a delegate. You can assign them, but when you solve, the software notifies you that it will use only the first assigned cognitive controller.

Using Motion Synthesis
You can create advanced, complex crowd simulations in character studio with motion synthesis, which lets the software adjust the simulation results dynamically to account for differing conditions. Two different forms of motion synthesis are available: one for non-bipedal crowds, and a second for the more exacting requirements of biped crowds.

See also
Biped Crowds (page 2–1172)
Non-Biped Crowds (page 2–1179)

Biped Crowds
The biped crowd is a special case of crowd simulation necessitated by the complex nature of legged animal movement. Biped locomotion exhibits intricate dynamics and exacting IK foot constraints. As such, the smoothly curving trajectories computed from delegate motion parameters, while suitable for birds, fish, insects, and snakes, are not rich enough to animate the microstructure of bipedal motion. Therefore, several features in Crowd are focused on the special needs of bipeds.

In order to generate the required level of nuance, animated motion clips form the basis for the repertoire of biped movements. In other words, during a Biped/Crowd simulation, the delegates have no effect over the motion of the Biped, they only set goals to be achieved using clips available in the Motion Flow graph. With this approach, known as motion synthesis, the animator can precisely control details in the motion either by using hand animation or employing motion capture to produce a set of clips that describe how a member in the crowd behaves.

For example, if you wanted to animate a crowd of marathon runners making their way through the streets of a city, you would need motion clips for various kinds of walking, running, jogging, resting, drinking water, cheering, etc. In effect, each of the motions you might expect to see in a marathon race could be represented as a clip. But motion must be more than a fragmented collection of clips. You must also consider how motions might be sequenced. Which motion transitions are possible from a given motion clip?

To best understand this process, study this topic and follow the procedure Using bipeds in a crowd simulation (page 2–1175).

Motion Flow Network and Possible Scripts
Biped’s Motion Flow (page 2–1043) functionality provides the mechanism for defining how separate motions fit together into a fluid animation. In effect, the motion flow network describes which motions can follow from other motions. Once the motion flow network is defined, a broad set of animated actions is possible by following different paths through the network. In Biped, a path through the network is called a motion flow script.

For example, shown below is a motion flow network used in the sample file walkers.max. You can find this file in the cstudio\tutorials\biped_crowds folder in your 3ds Max path. This folder also contains the BIP files used in the motion flow network. You can access these files only if you have installed tutorials.
on your hard disk. For information on installing tutorials, see the Installation Guide.

![Motion Flow Graph](image.png)

This is a fairly simple network of possible motions, because the characters can only start, stop, turn at 90 degree angles left and right (walk_L90 and walk_R90), and do an about-face (walk_180). However, for more natural crowd interaction, it’s advisable to expand the motion flow network to include shorter, more finely tuned variations such as turning at 45 degree increments, moving in different directions while facing the same way, loitering motions, and moving at different speeds.

The Biped Motion Library has a comprehensive list of clips for you to experiment with.

Tip: You can create motion clips that curve slightly to the left and right by applying Biped’s footstep-bending operation to straight-line motion clips. If the clips are motion captured, you should employ footstep extraction during import in preparation for the bending operation. Adding clips that turn slightly will let the biped crowd simulation make minute corrections in heading in order to achieve goal locations more precisely.

Motion flow graphs that work best incorporate fine-tuned transitions. A good way to check your motion-flow transitions is by building test scripts as you build the graph: Add clips to the graph, add the necessary transitions, and optimize the transitions. Optimizing transitions works well as a starting point and, more often than not, produces the smoothest transitions. Next, make a new script that uses your transitions, and use the script to tweak the motion flow until the feet don’t slide.

The Shared Motion Flow Networks feature lets many bipeds use a single motion-flow network. Therefore, it’s practical to make motion-flow networks large without taxing your computer’s memory.

### Delegate-Directed Behavioral Goals

You can give a biped a behavioral goal by associating it with a delegate in the Crowd system, and then assigning behaviors to the delegate.

For example, in the walkers.max sample, the behavioral goals of each of the biped’s delegates are to:

- Move toward the sphere using the Seek behavior.
- Avoid hitting each other using the Avoid behavior.

During a biped crowd simulation, the software attempts to compute the best motion flow script for each biped member of the crowd that satisfies the behavioral goals of its associated delegate. In other words:

- The biped’s crowd delegate defines the behavioral goals of the biped.
- The possible motions to reach those goals are defined by the biped’s motion flow network.
- The Crowd object’s Solve operation computes the script, or path through the motion flow network, that best meets the goals of the biped’s delegate.

So in the walkers.max sample, the simulation will always choose the best available walking clip in the network that directs the biped’s delegate toward the sphere. Each biped’s script evolves as the crowd “Solve” computes. This is somewhat like a real-time "game engine" in that the crowd solver’s
choice of the next best clip for a given biped is restricted by that biped’s currently active clip.

**Biped Crowd Avoidance, Priority, and Backtracking**

Because bipeds in crowds are always following motion flow scripts, the avoidance behavior for bipeds works differently. Unlike ordinary delegates, biped delegates can move only along motion flow-scripted paths, so if a collision takes place, the software will *backtrack* to the previous clip in the current script and find another path. This may take some time to compute when complex crowd interactions are present since a single backtrack may not be enough. The computation will explore all paths from a given backtracking clip, and if that fails, it will backtrack to the previous clip, and so on, until a solution is found.

In the example, if the current script of a biped is:

```
walk_start
walk
walk_L90
```

and a collision is encountered during the *walk_L90* clip, the biped will backtrack to the end of the *walk* clip and attempt to try a different clip in place of the failed left turn. If that fails, it will try the next best choice, and so on.

**Tip:** The inclusion of stopping and loitering motions in the motion flow network is sometimes helpful in preventing excessive backtracking since stopping is always an effective way to avoid collisions in a tight situation. In general, the more variation in speed and direction that is possible, the more quickly the backtracking feature will find a solution.

In order to make the backtracking computationally manageable, the biped crowd members are computed one at a time, in order of **priority** (*page 2–1235*). Thus, the crowd interaction is accumulated with each successive biped added to the animation. In other words, each waits its turn to compute its complete animation, which entails avoiding the bipeds that have been computed before it. It follows that bipeds with the lowest priorities generally encounter the most collisions, since they must steer around all the bipeds that have higher priorities.

**Preparing Characters for a Biped Crowd**

To create a biped crowd simulation, you will need several bipeds. Because the crowd simulation factors in each biped’s leg length when applying clips to the biped, your simulation will be more accurate if your bipeds are the correct size from the start.

One straightforward workflow would be:

- In a separate file, create or acquire a few character models for your scene.
- Skin the characters with Physique or with another method, such as the 3ds Max Skin modifier.
- Clone the characters and change something about each one, such as the color of clothing or hair, and the character’s height. See **Scaling a Character** (*page 2–1100*).
- Give each character a unique name that will allow you to identify it in the simulation to some degree. Example: BigMan02, LittleGirl03. See **Naming the Biped** (*page 2–847*).
- For each character, disable the MeshSmooth modifier or other modifiers above Physique that add polygons.
- Hide the character meshes and leave the bipeds visible.

This setup makes it easy to merge the characters into the crowd scene. When characters are merged, the meshes themselves will be hidden, which will improve system performance.
Preparing Motions for a Biped Crowd

The clips you use for a biped crowd simulation can be loaded from the CD that comes with character studio, imported from motion capture files, or created from scratch.

The integrity of transitions between clips in the motion flow network is very important when creating a biped crowd simulation. When creating transitions for a single biped, it's a simple matter to correct individual transitions after the motion flow script has been created. With a crowd, having to correct transitions for each biped after the simulation is complete would be extremely time-consuming. It is much more efficient to ensure your transitions are correct before starting to solve the simulation.

One way to make this process easier is to set up all motions so each has an ideal transition of exactly the same number of frames, such as 10 or 15. Then you can optimize transitions for this length, and all or most transitions will work flawlessly.

To check transitions, create a simple script for one biped using several transitions in the graph. Check the motion and work with transitions individually until they look right. You might not catch all bad transitions with this method, but you'll catch most of them. A “bad” transition would be one where the feet skip or hop when they should be walking, or any other undesirable change that occurs during a transition. See Customizing Transitions (page 2–1034).

After solving the biped crowd simulation the first few times, check again for bad transitions you might have missed the first time around. After a few simulations, most likely you will have found all or nearly all the bad transitions.

Restrictions

Some features of the crowd system are not designed to work with biped crowds. These behaviors and parameters have no effect on the crowd’s movements when bipeds are used with the simulation.

- Vector fields
- The Look Ahead parameter in the Avoid behavior

Procedures: Using Bipeds in a Crowd Simulation

The following sequence of procedures gives the basic steps for creating and saving a motion flow graph, assigning several bipeds to delegates, and then sharing the motion flow graph among the bipeds so that the software automatically creates separate motion flow scripts for each biped, based on the behaviors assigned to its delegate.

Note: These procedures assume you know how to animate bipeds with footsteps and keyframe methods, and save the animations as BIP files. To prepare for using Shared Motion Flow, you should create and save a range of biped motions such as start, walk, turn right, turn left, stop, and wait. See Loading and Saving BIP Animation (page 2–920).

The first step is to create an appropriate motion flow graph and save it to disk.

To create the shared motion flow:

1. Add a biped, and then open the Motion panel.
2. Click the Biped rollout > Motion Flow Mode button.
3. Click the Motion Flow rollout > Show Graph button.
4. In the Motion Flow Graph toolbar, click the Create Multiple Clips button.

This displays an Open dialog that lets you select any number of BIP files from the same
directory to add simultaneously to the motion flow graph. Use `Click+Shift+click` (click, and then `Shift+click`) to choose several contiguous files, and `Ctrl+click` to choose non-contiguous files.

5. Choose the BIP files you want the software to use for motion synthesis, and then click the OK button.

The files are added to the graph as clips. Each clip is automatically named after the file from which it’s derived.

Note: For best results, especially with simulations in which bipeds are to turn at different angles, use as many different turning clips as possible. A minimal setup would include separate left-turn and right-turn walks at angles of 45, 90, 135, and 180 degrees.

The next step is to add transitions among the clips so **character studio** knows which actions can proceed to and from other actions. You can do this manually for greater control, but for initial testing, you can save time by letting the software add and optimize transitions automatically.

6. Click the **Synthesize Motion Flow Graph** button. This uses the first 30 percent and the last 30 percent of each motion to create transitions.

The graph now shows arrows to and from each clip, as well as from each clip to itself. If you like, delete transitions that obviously don’t belong, such as the ones from the stop and start clips to themselves.

Alternatively, you can use **Create Transition** to set up a custom graph.

7. **Optimize the transitions. See Transition Optimization Dialog (page 2–1058).**

When you solve the simulation, Crowd automatically generates a motion flow script for the biped, based on this graph. When you have a graph with multiple clips, as in this case, it chooses the starting clip for the script from one or more clips you designate as random start clips.

If you want to check the integrity of transitions before continuing, do so now. See **Customizing Transitions (page 2–1034).**

8. **Click the Select Random Start Clips button, and then click a clip.**

This tells the software to start the script with this clip, and uses the default probability of 100 percent that the clip will be chosen.

If you want the various bipeds to start with different clips, select multiple random start clips by pressing and holding the `Ctrl` key as you click. The default Random Start Probability setting of 100 for all clips means that the software will choose randomly among them for a starting clip for each biped’s script.

To change the likelihood of starting with specific clips, right-click a clip and modify its Random Start Probability setting. For example, say you want to start each biped’s script with any of three clips: clips A, B, and C. You want clip A to be chosen twice as often as clip B or C. In that case, using the Random Start Clips tool, you’d first click clip A, and then `Ctrl+click` clips B and C. Then you’d right-click each in turn, assigning a Random Start Probability of 60 to clip A, and 30 to both clips B and C.

Note: The Probability values are arbitrary; what counts is their ratios. For example, values of 80/40/40 or 20/10/10 would work the same.

Note: You can also set and change random starting clips and start probabilities in the **Motion Flow graph** after loading the MFE file.
into the Shared Motion Flow dialog, described later in this procedure.

Note: If a motion flow script already exists for a biped, for example after you’ve solved a crowd simulation, the software can use the first clip in the script for subsequent solutions.

9. In the Motion Flow rollout, click the Save File button, and save the graph in the MFE format.

The next step in using bipeds in a crowd simulation is to create the simulation.

To set up the crowd simulation:
1. Reset 3ds Max.
2. Set up a crowd simulation with any number of delegates, using behaviors appropriate to the crowd scene you want to create. Do not use bipeds at first; work with delegates only to rough out the motion of the crowd members.
   Tip: When first starting out with motion synthesis, use smaller crowds of eight or so delegates.
3. Solve the simulation and adjust the settings as necessary to obtain the desired motion.
4. Merge bipeds and characters into the scene, and associate each delegate with a different biped using the delegate’s Motion Parameters rollout (page 2–1183) > Biped group settings.
   You must select the biped’s center of mass (COM) object (typically named Bip0#), as indicated by the mouse cursor turning into a crosshairs icon when it’s over the COM in the active viewport.
5. Turn on Use Biped for each delegate.
   Tip: To link up any number of delegates with bipeds, all at the same time, select the Crowd helper object and click the Setup rollout > Biped/Delegate Associations button (page 2–1199). Use the dialog to connect the pairs and turn on Use Biped for each delegate. See Linking Objects to Delegates (page 2–1169).
6. Set the biped/delegates to use a random start clip as the first clip. You can set this simultaneously for multiple delegates with the Edit Multiple Delegates dialog (page 2–1179).

To apply the shared motion flow:

Next, you use the Shared Motion Flow function to apply the saved motion flow graph to the bipeds.
1. Select any biped and open the Motion panel.
2. Click the Biped rollout > Motion Flow Mode button.
3. Click the Motion Flow rollout > Shared Motion Flow button.
4. In the Shared Motion Flow dialog, click the New button.
   This creates a new shared motion flow and assigns it a default name. You can change the name if you like.
   Next, load a motion flow file.
5. Click the Parameters group > Load .mfe button, and use the Open dialog to load a motion flow file. Typically, this would be the one you saved earlier in the procedure.
   Next, specify the bipeds that will share this motion flow.
6. In the Parameters group, click the Add button, and use the Select dialog to specify the bipeds that will share the motion flow.
   For your convenience, the Select dialog shows only center of mass objects for the bipeds in the scene.
   After you click the Select button, the bipeds appear in the dialog, in the list under "Bipeds Sharing this Motion Flow."
7. To correctly share a motion flow, bipeds’ legs must be scaled the same. If any of the bipeds are scaled differently than the one you started with, an alert appears, and then, when you click the OK button in the alert box, the wrong-scale bipeds are noted as such in the list. At this point, you can select one of the bipeds in the list, and then click the Set Shared Motion Flow Scale button to match the others’ scale to that biped. Or you can click one of the Reset Wrong Scales buttons to rescale the wrong-scale bipeds or just their legs. Be sure to take one of these measures before proceeding.

One more step in the Shared Motion Flow dialog is necessary: You must activate Motion Flow mode for all the bipeds sharing the motion flow. A special button in the dialog lets you perform that action in one step.

8. Click the Put Multiple Bipeds in Motion Flow button. This activates Motion Flow mode for all the bipeds sharing the motion flow.

9. Click the OK button to exit the dialog.

To offset the delegates and test the simulation:
Delegate-controlled bipeds can begin their animation with their motion flow scripts’ first clip, if it exists, or with a random motion clip. But when you load a motion flow file into the Shared Motion Flow dialog, any scripts in the file are ignored. Thus, delegate-associated bipeds using motion flow in an unsolved crowd simulation have no existing scripts, and you must specify that they use the random start clip that you set in the motion flow. You do this via the delegates.

1. Use the Edit Multiple Delegates dialog > Biped group to specify Random Start Clip for all the delegates.

Solve the simulation.

2. Select the Crowd object, and go to the Modify panel.

3. In the Solve rollout, set the desired End Solve frame.

4. Click Solve to run the simulation.
Crowd solves the simulation.

5. Check the solved simulation by dragging the frame slider and/or playing back the animation.

To fine-tune the simulation:
Chances are good that adjustments will be required. You can resolve problems in a number of different ways: Change the behavior and/or motion flow setups, change delegate parameters, and so on.

If you find that bipeds are colliding and interpenetrating, you can take advantage of Crowd’s special Priorities and Backtracking features. In fact, it is strongly recommended that you use both options for most Crowd/Biped simulations.

1. Use the Priority rollout (page 2–1235) controls for assigning different priorities to your delegates. Typically, delegates at the head of the crowd should have the highest priorities (that is, the lowest Priority settings).

2. In the Solve rollout > Biped/Delegates Only, turn on Use Priorities, and then turn on Backtracking. If you’ve solved previously, it’s a good idea to turn on Delete Keys Before Solve as well.

Now, when it solves the simulation, Crowd solves for one biped/delegate at a time, starting with the lowest-priority biped/delegate. As it solves for each subsequent biped/delegate, it looks for collisions, and when the occur, it backs up the solution to the end of the previous clip, and if necessary, previous clips, and then tries different paths through the motion flow graph. This method can take longer, which is
why Backtracking is off by default, but it's often the best way to resolve problems with colliding bipeds.

Non-Biped Crowds

Motion synthesis in character studio lets the software derive character motion from a combination of crowd behaviors and either motion flow networks, when animating bipeds (see Biped Crowds (page 2–1172)), or clip controllers, when working with non-bipedal creatures. In the latter case, using the Global Motion Clip and Master Motion Clip controllers, you can animate groups of creatures such as birds, butterflies, schools of fish, and insects. You can create clip controllers either as block controllers in Track View, or, more directly, with the Crowd helper controls on the Global Clip Controllers rollout.

Two Approaches to Animation

You can animate your creature either in place with looping animation but no transformational motion (such as a bird flapping its wings), or you can incorporate transformational motion into the animation as well (the bird moves upward while flapping its wings). In-place cyclic motion lends itself to flying or swimming motions like birds and fish, while adding lateral motion lends itself to crawling type animation where feet should be planted on the ground and not sliding. Depending on which you use, you toggle options on the Motion Clips tab of the Synthesis dialog. In both cases, you use crowd delegates driven by behaviors to motivate the creatures, which are linked to those delegates.

Note: To animate a model for motion synthesis, apply modifiers to the model and animate their parameters. Modifiers such as Bend, Taper, Wave, and Xform produce animation you can use with motion synthesis. Do not use sub-object animation, such as animation of vertices on an Editable Mesh object.

Cyclic In-Place Animation

First you create a creature with a few short loop cycles, like the beating of wings, gliding, turning left and turning right. This creature is assigned as the Global Object or the master object from which the motion clips will be derived. Then clones of the original creature are created. The clones are positioned and linked to delegates. States are created to select which clips will play based on a state.

For example, if a bird (delegate) is pitching up or accelerating, the fast-beating clip is used; if the bird (delegate) slows to a stop, the wings-at-rest clip is used, and so on. During synthesis, the software determines which state should be active depending on the speed and direction of the delegates. An active state determines which clip should be applied to the clones of the original object. Clips are blended together to create the animation. Available states are speed, acceleration, pitch, pitch velocity, heading velocity, or script (MAXscript).

Animation with Lateral Motion

For multi-legged creatures that walk, you can animate lateral motion as well as the cyclic motion of the legs moving. This is done to ensure that the creatures' feet do not slide as they move. The software then uses the lateral motion information to create a state that perfectly matches the actual motion. The software then strips the actual motion out. When a delegate approaches the speed and heading recorded in that state, the appropriate motion clip is triggered. This technique minimizes sliding feet.

Use the character studio crowd tools to create the initial motion for the delegates. Use a seek or avoid behavior to steer birds, for example. Your
object with the loop animation is then copied and
the copies are linked to the delegates to create the
complete animation. The delegate handles the
path and the clip controllers handle the looped
animation.

You can create Master Motion Clip and Global
Motion Clip in Track View by assigning a
controller to the available controller under Block
Control. It is, however, simpler to use the Crowd
helper controls on the Global Clip Controller
rollout to apply and use the clip controllers.

Synthesis Dialog (page 2–1246)
ClipState Dialog (page 2–1253)

Global Motion Clip
Global Motion Clips store the clips to be shared
among multiple Master Motion Clips, which are
assigned to the cloned objects during synthesis.
Global Motion Clips also contain the logic for
performing motion synthesis on a collection of
objects with trajectories and states associated with
clips. Controls for motion synthesis are found in
the Synthesis dialog.

The way the motion clip keys are scaled and
ordered depends upon user-defined states. Each
state contains one or more motion clips that will
be played when the state is active.

Master Motion Clip
Master Motion Clips are controllers that contain
motion clips, or individual clips of animation.
These motion clips are sequenced to create
animation, and overlap slightly with automatic
blending to smooth the transitions between clips.

Procedure

To use Motion Synthesis with non-bipedal creatures:
All of the work involved in copying and
synthesizing clips takes place using controls in the
Synthesis dialog (page 2–1246). This dialog has
three tabs: Motion Clips, State, and Synthesis.

This procedure assumes that the global object is
static and has animation that loops. For creatures
with many legs, you can animate lateral motion
on the global object and then strip out the lateral
motion with the Synthesis dialog. This latter
approach serves to minimize foot sliding in a
multi-legged creature.

1. Animate an object.
   Create animation in one position, like a bird’s
   beating wings. Create a variety of animation
   like a gliding motion (wings still), wings beating
   slowly, and so on. To animate the object, apply
   modifiers and animate their parameters.
   This will be the Global object, from which
   animation clips will be derived.

2. Using the Create panel > Helpers > Object Type
   rollout, add a Crowd object and a Delegate
   object.
   Create the objects in the Top or Perspective
   viewport.

3. Use Scatter Objects (page 2–1189) in Crowd
   function to clone the delegate and optionally
distribute the clones (you can also distribute
   them manually).
   Make sure you end up with an equal number of
   delegates and animated object clones.
   Next, associate and link the objects to the
   delegates.

4. On the Setup rollout, click the
   Object/Delegate Associations button.
   The Object/Delegate Associations dialog (page
   2–1196) appears.
5. Add the objects and delegates into their respective columns.

6. Click Align Objects With Delegates, and then click Link Objects To Delegates, and then click OK to exit the dialog.

   The objects align themselves with the delegates and are linked to the delegates.

   Next, animate the delegates with behaviors. See Assigning Behaviors (page 2–1159) for information on using behaviors.

   When you solve the simulation, the cloned objects follow the delegates, which are guided by behaviors. You then generate motion synthesis based on the delegate movement.

7. Select the Crowd object. On the Modify panel > Global Clip Controllers rollout, click New, and use the Select dialog to select the Global object from step 1.

   The object appears in the Global Clip Controllers rollout list.

8. In the list, click the object, and then click the Edit button.

   The Synthesis dialog displays. Its name is that of the object.

9. On the Motion Clips panel, turn off all check boxes in the From Global Object and Remove Local groups.

   Use these options only if your original object has lateral motion to coordinate with footsteps.

10. On the Motion Clips panel, click New.

    This opens the MotionClip Parameters dialog, which lets you set the name, color, and frame range for a motion clip.

11. Choose a descriptive name and a frame range for the motion clip.

    For example, frames 0 through 10 might be your glide animation.

12. Continue to define clips using different frame ranges from the Global object’s animation. Give the clips descriptive names.

    Next, you define states whose parameters determine when motion synthesis is to use each clip.

13. Click the State tab, and then click New State.

    A new state is added to the drop-down list at the top of the Synthesis States group. Give the state a descriptive name. In many cases, the state can use the same name as the motion clip that’s to be associated with it.

    Next, you specify the state’s parameters; that is, how the delegate should be moving when the associated object is to use its motion clip. For example, your glide motion should be active only if acceleration is less than 0.

14. Click Edit Properties and define how the software should activate the clip, based on any combination of speed, acceleration, and so on. Click each appropriate tab, turn on its Use ... check box, and set parameters. Click Exit to exit the dialog.

    When using a range, make sure the Min setting is lower than the Max setting. For example, when using a negative range such as -180 to -10, enter the number with the higher absolute value (-180) as the Min setting.

    You should already have several motion clips. Now you need to associate a clip with this state. For example, if you’ve defined a state whose acceleration is less than 0, you might associate the Glide clip with it.

15. In the MotionClips group, click Add Clip, and in the Select MotionClip dialog, highlight a clip and click OK.

16. Repeat steps 14 and 15 for each state to be used in motion synthesis.

17. Go to the Synthesis panel, click New Master Motion Clip, and add all of the cloned objects.
18. Click Auto Blend All and then click Synthesize All.

The synthesis occurs as a progress bar displays. When the synthesis is completed, the Synthesis dialog reappears. You can now view the ClipState parameters’ ranges and average values by clicking State panel > Edit properties. This is useful in fine-tuning state properties.

Click OK to exit the Synthesis dialog.

19. Click Play. It’s not necessary to re-solve the simulation.

The objects follow the delegates and are animated using clips that are activated according to delegate motion and the states you created.

Crowd Animation User Interface

Crowd animation lets you simulate the behavior of crowds of people, animals, or other beings parametrically, using several different types of objects. The topics that follow describe the user interface for setting up a crowd simulation.

• The Crowd helper object (page 2–1187) includes facilities for replicating and grouping objects and assigning behaviors (page 2–1200) to objects and groups. The Crowd object works directly on delegate helper objects, and indirectly on bipeds and other objects via delegates.

• Cognitive controllers (page 2–1206) can change delegate behavior based on circumstances in the simulation.

• Motion synthesis (page 2–1241) uses animation from the linked object based on delegate orientation, speed and other factors.

Crowd Shortcuts

To enable the character studio keyboard shortcuts, turn on the Keyboard Shortcut Override toggle (page 3–872).

All character studio keyboard shortcuts activate when the Motion panel is active and the Keyboard Shortcut Override button is active.

Delegate Helper Object

Create panel > Helpers > Object Type rollout > Delegate

The Delegate is a special helper object used in crowd animation. It serves as an agent for motion created by a Crowd object (page 2–1187) and its behaviors. The Crowd object controls a delegate or delegates, whose motion can then be imparted to a biped or other object. Delegates cannot be rendered.

The delegate object is shaped like a pyramid. By default, the point of the pyramid indicates the forward direction, the delegate's local Y axis.

The delegate object uses the following rollouts:

Geometry Parameters Rollout (page 2–1183)
Motion Parameters Rollout (page 2–1183)

Also, you can set parameters for multiple delegates simultaneously, optionally with random variation, using the Crowd object’s Edit Multiple Delegates dialog (page 2–1197).

See also
Creating Crowd Helpers (page 2–1157)
Crowd Helper Object (page 2–1187)

Geometry Parameters Rollout

Create panel > Helpers > Object Type rollout > Delegate > Geometry Parameters rollout

Select a Delegate object. > Modify panel > Geometry Parameters rollout

Use these parameters to modify the delegate object’s size.

Interface

Width, Depth, Height—Sets the width, depth, and height of the Delegate object. These fields also act as readouts when you create the delegate.

Note: The Delegate is a helper object, and thus cannot be rendered. Thus the size of the Delegate object is primarily for use in scene setup, and for determining bounding box extents.

Motion Parameters Rollout

Create panel > Helpers > Object Type rollout > Delegate > Motion Parameters rollout

Select a Delegate object. > Modify panel > Motion Parameters rollout

The Motion Parameters rollout lets you specify a Delegate object's characteristics, including speed, acceleration, and other factors. It also lets you associate the delegate with a biped.

Important: When using delegates with bipeds, only the settings in the Biped group have any effect in the simulation, because Biped gets all its speed and turning information from motion flow clips and behaviors.

Note: You can set any or all motion parameters simultaneously for a number of delegates with the Edit Multiple Delegates dialog (page 2–1197).
Interface

## Velocity Color
When Show Velocity is on, uses the specified color to draw a vector in the delegate’s center during the simulation solution. The vector length indicates the delegate’s relative speed. Default=black.

## Active
The delegate object is subject to control by a Crowd object. Default=on.

## Show Forces
The forces being applied to a delegate by any applicable behaviors are drawn as vectors whose length indicates the extent of the forces and whose orientation shows the direction in which the behavior is influencing the delegate to move. Default=on.

For example, if the delegate is affected by a Space Warp behavior (page 2–1221) and a Wander behavior (page 2–1231), the vectors (using default colors) are yellow and blue-green, respectively. These vectors are visible only during solution of the crowd simulation.

## Show Velocity
Uses the Velocity Color (see above) to draw a vector whose length depicts the delegate’s relative speed. This vector is visible only during the solution of the crowd simulation. Default=off.

## Show Cog Control States
During a solution, a text label appears next to the delegate showing the name of the cognitive controller (page 2–1170) state or transition that currently directs its behavior, if any. Default=on.

## Constrain to XY Plane
The delegate remains at its initial height (position on the world Z axis) throughout the simulation. When off, the delegate’s height can change during the simulation, for example when seeking an object at a different height. Default=on.

## Bound Box of Hierarchy
When on, the Avoid behavior (page 2–1211) uses the bounding box of the delegate and all of its children to perform its behavior. Default=on.

### Speed group

#### Average Speed
Specifies the delegate’s baseline velocity in 3ds Max units (or the current unit type) per frame. Default=5.0.

The delegate’s speed can be modified during the simulation by a variety of factors, such as a linked biped’s built-in speed and Deviation settings in a behavior.

#### Max Acceleration
Multiplied times Average Speed to determine the maximum acceleration. Default=0.1.

For example, given the defaults of 5.0 for Average Speed and 0.1 for Max Accel, the acceleration or deceleration at any moment can be no greater than 0.5 units/frame/frame.

#### Deceleration Weight
Specifies how much a delegate should slow down when turning.

The higher this setting, the more the delegate slows down when it reaches the turn angle (see following...
parameter). A value of 0 specifies no slowdown; a value of 1 tells the delegate to stop. Default=0.3.

The algorithm computes a value, d, which goes linearly from 0 to (1 - Decel Weight) as the turn angle of the delegate goes from 0 to the Turn Angle specified by the user. The speed of the delegate is then multiplied by d. For example, when the delegate turns at the Turn Angle or greater, its speed will be multiplied by (1 - Decel Weight), slowing it down as much as possible based on this parameter. When the delegate is not turning at all, its speed is not affected by the Decel Weight. When the delegate is turning at half the specified Turn Angle, d = Decel Weight / 2, so its speed will be multiplied by (1 - Decel Weight / 2).

As a practical example, take a delegate traveling at 10 units/frame. Decel Weight is set to 0.4, and At Turn Angle is set to 30. When the delegate has turned 15 degrees (half the At Turn Angle), the effective deceleration weight is 0.2. Subtract that quantity from 1 to get 0.8, and then multiply that times the delegate's speed to get 8 units per second halfway into the turn. At the full turn (30 degrees), the delegate travels at 6 units per frame.

At Turn Angle—Specifies the turn angle at which Decel Weight's full slowdown effect is applied. Default=10.0.

If the current turn angle is less than At Turn Angle, the algorithm divides the latter by the former, and then divides the Decel Weight setting by the result to derive the effective deceleration weight.

Decel(eration) Weight—Specifies how much the delegate should slow down when moving at an upward slant. Default=0.1.

See Decel Weight for a full explanation.

At Incline Angle—Specifies the upward slant angle at which Decel Weight's full slowdown effect is applied. Default=90.0.

Accel(eration) Weight—Specifies how much the delegate should speed up when moving at a downward slant. Default=0.1.

See Decel Weight for a full explanation, taking into account that Accel Weight produces a speedup effect rather than a slowdown. Thus, the effective acceleration weight is added to 1, not subtracted from it.

At Decline Angle—Specifies the downward slant angle at which Accel Weight's full speedup effect is applied. Default=90.0.

Turning group

<table>
<thead>
<tr>
<th>Turning</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Max Turn Velocity</td>
<td>30.0</td>
</tr>
<tr>
<td>Max Turn Accel</td>
<td>3.0</td>
</tr>
<tr>
<td>Max Incline</td>
<td>90.0</td>
</tr>
<tr>
<td>Max Decline</td>
<td>90.0</td>
</tr>
</tbody>
</table>

These parameters affect the delegate’s turning behavior; that is, how it changes direction in response to forces applied by crowd behaviors.

You can use the Orientation behavior (page 2–1214) to affect how a delegate turns and banks, independently of the actual path taken.

Turning applies to objects moving both on the ground and in the air.

Max Turn Velocity—Specifies the maximum number of degrees a delegate can turn per frame. Applies both to heading and pitch. Default=30.0.

Max Turn Accel—Specifies how much the delegate's heading or pitch angle can change per frame. This controls angular acceleration and deceleration. For smooth turns, keep it relatively low. Default=3.0.

Tip: If a delegate exhibits sluggish turning behavior during a simulation, try increasing Max Turn Velocity, Max Turn Accel, or both.
**Max Incline**—Specifies the maximum number of degrees a delegate can turn upward at any given frame. For example, most birds can’t fly straight up, so you might set this to 45 for a bird. Default=90.0.

**Max Decline**—Specifies the maximum number of degrees a delegate can turn downward at any given frame. Default=90.0.

For example, for a bird that can’t fly straight up but can fly straight down, you might set to Max Incline to 45 and Max Decline to 90.

**Banking group**

These parameters affect the delegate’s banking behavior; that is, how it tilts around its front-back axis as it changes direction while moving. Banking typically applies to objects moving in the air or on water, but can also apply to ground-based objects such as one- or two-wheeled vehicles.

**Max Bank**—Specifies the maximum number of degrees a delegate can bank. Default=30.0.

**Max Bank Velocity**—Specifies the maximum number of degrees a delegate can bank per frame. Default=3.0.

**Bank per Turn**—The number of degrees the delegate will bank as a function of the turn angle at the current frame. For example, if Bank Per Turn=1, the delegate will bank one degree for every degree it is turning at a given frame. Default=1.0.

**Biped group**

![Biped parameters](image)

These parameters relate to the use of bipeds associated with delegates. In order to have a biped exhibit character animation as it follows the delegate’s course, you must use motion flow methods. For a procedure, see *To use bipeds in a crowd simulation* (page 2–1175).

**Use Biped**— Associates the delegate with a biped (specified with the None button), and causes the delegate’s speed to be determined by that of the biped’s existing motion. Its behavior (for example, seeking another object) remains defined by a crowd object.

Note: This button is not available until a biped is designated via the None button.

**None (label)**—Click this button and then select a biped to be associated with the delegate’s motion.

You can select a biped by clicking it in a viewport, by clicking its center of mass object (e.g., bip01), or with the Select Object dialog, opened by clicking the toolbar button Select By Name (you cannot use the Selection Floater). Thereafter, the name of the biped object appears on the button.

Tip: When using the viewport, the mouse cursor changes to a crosshairs when positioned over a biped’s center of mass.

**Start Frame**—Specifies the frame at which the biped’s first clip will begin to play.
If, when several bipeds share the same starting clip, you vary this setting per biped, they won’t walk in lockstep formation. This is most useful when you take advantage of the ability of the Edit Multiple Delegates dialog (page 2–1197) to randomize the start frame for each delegate.

Priority—Sets the delegate priority, which determines the order of solution in biped/delegate simulations.

For details, see Priority Rollout (page 2–1235).

First clip choice method—Determines which motion clip in the shared motion flow graph Crowd initially uses to animate the biped linked with the delegate.

- First clip of current script—Uses the first clip in the biped’s motion flow script, if a script exists. If this option is chosen, but there is no script, an error message is generated.
- Random start clip—Uses the random start clip or clips specified in the shared motion flow graph, if random start clips have been designated. If this option is chosen, but no random start clips have been designated, an error message is generated.

Crowd Helper Object

The Crowd helper object acts as the command center for controlling crowd simulations in character studio. In most cases, you won’t need more than one Crowd object per scene.

The Crowd object provides the following rollouts:

Setup Rollout (page 2–1188)
Solve Rollout (page 2–1232)
Priority Rollout (page 2–1235)
Smoothing Rollout (page 2–1238)
Collisions Rollout (page 2–1240)
Geometry Rollout (page 2–1240)
Global Clip Controllers Rollout (page 2–1241)

Crowd Behaviors

The Crowd object also lets you add behaviors to the scene, choose the current behavior from a list, and provides a rollout for modifying that behavior. Behaviors provided with character studio include:

- Avoid Behavior (page 2–1211)
- Orientation Behavior (page 2–1214)
- Path Follow Behavior (page 2–1216)
- Repel Behavior (page 2–1218)
- Scripted Behavior (page 2–1220)
- Seek Behavior (page 2–1220)
- Space Warp Behavior (page 2–1221)
- Speed Vary Behavior (page 2–1222)
- Surface Arrive Behavior (page 2–1223)
- Surface Follow Behavior (page 2–1226)
- Wall Repel Behavior (page 2–1227)
- Wall Seek Behavior (page 2–1229)
- Wander Behavior (page 2–1231)

See also

Creating Crowd Helpers (page 2–1157)
Chapter 14: character studio

Setup Rollout

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout

Select a Crowd object. > Modify panel > Setup rollout

The Setup rollout of the Crowd helper object contains controls for setting up crowd functions.

Interface

A number of functions are available from a row of buttons at the top of the Setup rollout:

- **Scatter**—Opens the Scatter Objects Dialog (page 2–1189).
- **Objects/Delegate Associations**—Opens the Object/Delegate Associations dialog (page 2–1196).
- **Biped/Delegate Associations**—Opens the Associate Biped With Delegates dialog (page 2–1199).
- **Multiple Delegate Editing**—Opens the Edit Multiple Delegates dialog (page 2–1197).
- **Behavior Assignments**—Displays the Behavior Assignments and Teams dialog (page 2–1200).
- **Cognitive Controllers**—Displays the Cognitive Controller editor (page 2–1206).

Behaviors group

Use these controls for adding, removing, and renaming behaviors.

- **New**—Launches the Select Behavior Type dialog (page 2–1205). Choose a behavior and then click OK to add the behavior to the scene. Then use the Behavior Assignments and Teams dialog (page 2–1200) to assign the behavior to a delegate or delegates in the scene.

  The first time you add a behavior to the scene using this command panel, a new rollout appears for this behavior below the Setup rollout. This rollout lets you change settings for the behavior. To display the rollout for a different behavior in the scene, choose it from the drop-down list in the Behaviors group.

  Following is a list of available behaviors:

  - **Avoid Behavior** (page 2–1211)
  - **Orientation Behavior** (page 2–1214)
  - **Path Follow Behavior** (page 2–1216)
  - **Repel Behavior** (page 2–1218)
  - **Scripted Behavior** (page 2–1220)
  - **Seek Behavior** (page 2–1220)
  - **Space Warp Behavior** (page 2–1221)
  - **Speed Vary Behavior** (page 2–1222)
  - **Surface Arrive Behavior** (page 2–1223)
  - **Surface Follow Behavior** (page 2–1226)
  - **Wall Repel Behavior** (page 2–1227)
  - **Wall Seek Behavior** (page 2–1229)
  - **Wander Behavior** (page 2–1231)

- **Delete**—Deletes the current behavior.

  If the behavior is currently in use, that is, it’s assigned to a delegate or team, either directly in the Behavior Assignments and Teams dialog (page 2–1200) or indirectly through a cognitive
controller, a small dialog appears asking you to confirm the deletion. If you delete a directly assigned behavior, its assignment is removed from the scene. If you delete a behavior used in a cognitive controller, it is removed from the state to which it was assigned.

**Behaviors List**—Lists all behaviors in the current scene (added with New). Select a behavior from the list to have its rollout appear below the Setup rollout.

Note that behaviors that appear in this list aren’t necessarily assigned to any delegates active in the crowd simulation. Likewise, a behavior whose rollout appears below the Setup rollout isn’t necessarily active or assigned. To assign delegates and/or activate behaviors, use the *Behavior Assignments and Teams dialog* (page 2–1200).

You can rename a behavior by first selecting it from the list, and then clicking its name and entering a new one from the keyboard. It’s a good idea to give descriptive names to behaviors; for example, *Avoid Red Team*.

Note: If you add the first behavior in the scene from the *Behavior Assignments and Teams dialog* (page 2–1200), the text box remains empty and no rollout for the behavior appears. To edit the behavior, choose it from the list.

---

**Scatter Objects Dialog**

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > Scatter Objects

Select a Crowd object. > Modify panel > Setup rollout > Scatter Objects

The Scatter Objects dialog of the Crowd helper object includes facilities for creating crowds by cloning objects, such as delegates. It also lets you distribute the clones and other objects within a radial area, along a shape, across a grid object or surface, or within a box or sphere. You can also specify various orientation and scaling options for scatter objects.

**Interface**

**Clone panel**

Contains the basic options for cloning an object.

**Object to Clone (None)**—Click this button, and then select an object in the scene to be cloned.

**How Many**—Specifies the number of clones to be generated.

**Copy/Instance/Reference**—Lets you specify how the object is cloned. It can be cloned as a copy, an *instance* (page 3–958), or a *reference* (page 3–1002).
Clone Hierarchy—When on, all objects linked to the selected object are cloned as well, with the hierarchical structure retained intact for each clone.

Clone Controllers—When on, any controllers (that is, animation) associated with the selected object are cloned as well.

Generate Clones—Click this button to create the specified number of clones of the object whose name appears on the Object To Clone button.

Cloned objects are all created in the same location; to distribute them, you must set distribution options on the Position panel, and then click the Generate Locations button.

After you generate clones, the original object and its newly created clones are scatter objects; that is, they're selected in the list in the All Ops panel (Select Objects To Transform), and are thus subject to subsequent operations on the Position, Rotation, and Scale panels. You can change this selection via the All Ops panel > Select Objects to Transform function or by generating clones again.

Contains options for positioning objects using a reference (distribution) object. You can distribute objects randomly over the surface of a grid or other object, along a shape, or within the volume of a box or a sphere. You can choose only one option from the first two group boxes.

Placement Relative to Object group

On Grid/Inside Sphere/Inside Box/On Surface/On Shape—Choose the appropriate item before selecting the reference object.

- On Grid distributes the scatter objects over the surface of a grid object.
• Inside Box and Inside Sphere distribute the scatter objects within the volume of a primitive box or sphere object, respectively.

• On Surface distributes the scatter objects over the surface of any renderable object. For example, you can create a landscape object for use as a distribution surface by applying a Noise modifier to a patch grid.

• On Shape distributes the scatter objects along a shape object: a spline or NURBS curve. If the shape consists of more than one curve, Scatter uses the lowest-numbered curve (typically the first one added).

Offset—When using On Surface, specifies a consistent distance above the surface (using surface normals) for distribution. Available only when On Surface is chosen.

Grid/Box/Sphere/Surface/Shape (None)—Click this button, and then select an object in the scene to be used as a reference object. Listed objects are limited to the chosen category.

Note: With the Grid, Box, and Sphere choices, you can use only a grid helper object, a primitive sphere, or a primitive box as a reference object. A primitive sphere or box that has been converted to an editable mesh object can’t be used as a reference object. Also, the appropriate radio button (see the first item in this group) must be chosen before you select a reference object.

Placement in Area group

Contains options for positioning scatter objects in a radial area, without using a reference object.

In Radial Area—Distributes the scatter objects randomly in a spherical or circular arrangement, using the remaining controls in this group box.

Center—Specifies the center of the distribution in world coordinates.

Radius—Specifies the maximum distance from the center within which objects are to be positioned.

In XY Plane—Specifies that objects are to be distributed on the world XY plane only, resulting in a disc-like array.

Spacing group

Include children’s bounding boxes in spacing calculations—When on, all of a hierarchical scatter object’s sub-objects are considered when determining spacing. When off, only the selected object is considered.

Spacing—Specifies the minimum distance between scatter objects. The Spacing setting is multiplied by the size of the object’s bounding sphere to determine how close objects can get. If Spacing is left at 1.0, the default, objects normally cannot be positioned within each others’ bounding spheres. If Spacing is set to 2.0, objects are separated by a distance equal to or greater than the size of the bounding sphere.

Rand Seed—Specifies a seed value for randomizing scatter objects’ locations. If, for example, you use the same value for clones of a delegate and then a master object, each pair ends up in the same place. If a scene has more than one crowd, each should use a different seed to avoid having identical configurations.

Generate Locations—Click this button to produce a set of locations for all scatter objects; that is, cloned objects or objects selected with the Select Objects to Transform button.

Inc(rement) Seed—When on, and you click the Generate Locations button, Scatter adds 1 to the Rand Seed value, and redistributes the objects using the new random seed. Default=on.
Chapter 14: character studio

Rotation panel

Contains options for orienting scatter objects. You can specify alternative forward and up axes, plus a target object toward which the objects will point. In addition, you can specify a source object; when using both source and target objects, the objects are rotated so they're parallel to the line between the two.

Local Axes group

Use these settings to designate alternative forward and up axes. The default settings match the delegate axes.

Forward—+/-/X/Y/Z: Specifies which axis of the objects points forward, for use with the Look At Target option. When the + button is active, the default condition, the positive chosen axis is used. Click the + button to use the negative axis.

Up—+/-/X/Y/Z: Specifies which axis of the objects points upward; this axis is aligned with the world Z-axis. When the + button is active, the default condition, the positive chosen axis is used. Click the + button to use the negative axis.

Note: You cannot specify the same axis as Local Forward and Local Up simultaneously. If you choose an axis for one that’s already chosen for the other, the software switches the other to a different axis.

Look From group

Self/Selected Object—Determines the direction from which the objects look. By default, each object looks from its own position (Self), so that when several objects are looking at a single target, each is oriented differently. To orient each object so that it’s parallel to an imaginary line between two objects (the "from" object and the "to" object), choose Selected Object and specify the object with the (None) button.

None (label)—When choosing Selected Object as the Look From object, use this button to specify the "from" direction. Click the button, and then select an object from which the objects are to look.

Look At Target group

Current Orientation/Selected Object—Determines the direction toward which the scatter objects look. By default, each object retains its current orientation. To orient each scatter object so that it’s parallel to an imaginary line between two objects (the "look from" object and the "look at target" object), choose Selected Object and specify the object with the (None) button.
None (label)—Use this button to specify the "to" direction. Click the button, and then select an object toward which the scatter objects are to look.

Sideways Deviation—Sets a maximum deviation angle in degrees for the objects’ sideways orientation. If the scatter objects should look in an object’s general direction but may look at a spot to either side of the target, use Sideways Deviation to set the maximum amount by which they can deviate from the calculated angle. The actual deviation amount for each object is calculated at random, based on the Deviation settings and the Rand Seed setting. Range=0.0 to 180.0.

Up/Down Deviation—Sets a maximum deviation angle in degrees for the objects’ up/down orientation.

If scatter objects should look in an object’s general direction but may look at a spot above or below the target, use Up/Down Deviation to set the maximum amount by which they can deviate from the calculated angle. The actual deviation amount for each scatter object is calculated at random, based on the Deviation settings and the Rand Seed setting. Range=0.0 to 180.0.

Rand Seed—Specifies a seed value for randomizing the scatter objects’ orientations, based on the Deviation settings.

If you use the same value for clones of a delegate and then a master object, each pair ends up with the same orientation. If a scene has more than one crowd, each should use a different seed to avoid having identical configurations.

Generate Orientations—Click this button to produce a set of orientations for all scatter objects; that is, cloned objects or objects selected with the Select Objects to Transform button.

Inc(rement) Seed—When on, and you click the Generate Orientations button, Scatter adds 1 to the Rand Seed value, and reorients the scatter objects using the new random seed. Default=on.

Scale panel

Contains options for scaling scatter objects. You can apply uniform or non-uniform scaling, with optional per-axis deviation for scaling variation.

Each axis group has a "Same As" option that lets you scale that axis by the same amount as another. To prevent non-uniform scaling, set two axes to be the same as the third. For example, set scaling in the X group, and then in the Y and Z groups, turn on Same as X.

Warning: These controls can apply non-uniform scaling to objects, which may produce unexpected results when performing other operations within 3ds Max.
X group

Scale—Sets scaling on the X-axis as a multiplier. Default=1.0.

Deviation—Sets the maximum factor for randomization of scaling. For each scatter object, Deviation is multiplied by a random number between 0.0 and 1.0, and then added to the Scale multiplier.

Same As Y/Z—Lets you use the same scaling as on the Y- or Z-axis, whether explicit or randomized. When you specify an axis, the parameters group for that axis becomes unavailable.

Y group

Scale—Sets scaling on the Y-axis as a multiplier. Default=1.0.

Deviation—Sets the maximum factor for randomization of scaling. For each scatter object, Deviation is multiplied by a random number between 0.0 and 1.0, and then added to the Scale multiplier.

Same As X/Z—Lets you use the same scaling as on the X- or Z-axis, whether explicit or randomized. When you specify an axis, the parameters group for that axis becomes unavailable.

Z group

Scale—Sets scaling on the Z-axis as a multiplier. Default=1.0.

Deviation—Sets the maximum factor for randomization of scaling. For each scatter object, Deviation is multiplied by a random number between 0.0 and 1.0, and then added to the Scale multiplier.

Same As X/Y—Lets you use the same scaling as on the X- or Y-axis, whether explicit or randomized. When you specify an axis, the parameters group for that axis becomes unavailable.

Rand Seed—Specifies a seed value for randomizing the clones' scales, based on the Deviation settings. If you use the same value for clones of a delegate and then a master object, each pair ends up with the same scaling factor.

Generate Scales—Click this button to scale all scatter objects; that is, cloned objects or objects selected with the Select Objects to Transform button.

Inc(rement) Seed—When on, and you click the Generate Scales button, Scatter adds 1 to the Rand Seed value, and re-scales the scatter objects using the new random seed. Default=on.

All Ops panel

This panel lets you perform various permutations of cloning and transform operations in a single step, with or without successive randomization.

Operations group

Compute Clones—Turn on to clone the object chosen with the Object to Clone button. When you click the Scatter button, the object is cloned,
and then any specified transforms are applied to the clones.

Turning on Clones makes the Select Objects To Transform button unavailable. The object to clone and cloning parameters must be specified on the Clone panel (page 2–1189).

**Compute Positions/Rotations/Scales**—Any options in this column that are turned on when you click the Scatter button cause the respective transforms to be applied to the current selection (see Select Objects To Transform, below) according to the settings in the Position panel (page 2–1190), Rotation panel (page 2–1192), and Scale panel (page 2–1193).

**Inc(rement) Seed Positions/Rotations/Scales**—Any options in this column that are turned on cause the respective Rand Seed settings to be incremented by 1 each time you click the Scatter button.

Use this option to experiment with various randomized transform combinations for your clones.

**Select Objects to Transform**—Lets you designate objects to be affected by clicking the Scatter button.

Clicking this button opens a version of the Select dialog that’s unique to Scatter Objects functionality. If you’ve performed one or more cloning operations during the current session, the results of the most recent cloning are selected by default, including the original cloned object. For example, if you created 10 clones, 11 objects are selected. You can use the Select dialog to alter or replace this selection.

Note: The results of the most recent cloning operation remain selected even if you close and later reopen the Scatter Objects dialog.

**Scatter**—Performs any cloning and/or transforms that are turned on.

**Cancel**—Forgets any changes and closes the dialog.

**See also**

Creating Crowd Helpers (page 2–1157)

---

**Random Placement Difficulty Dialog**

This dialog appears when the software encounters difficulty placing cloned objects without overlapping using the Scatter Objects dialog (page 2–1189). The dialog text tells you how many attempts the software has made to place a specific object, and asks you if you want to try again.

**Interface**

<table>
<thead>
<tr>
<th>Random Placement Difficulty</th>
</tr>
</thead>
<tbody>
<tr>
<td>I have made 100 attempts to place Boat12. Would you like me to try again? If so, how many attempts should I make?</td>
</tr>
<tr>
<td>![Try Again](Try Again.png) ![How Many More Attempts](How Many More Attempts.png)</td>
</tr>
<tr>
<td>![Skip This One](Skip This One.png)</td>
</tr>
<tr>
<td>![Quit Trying](Quit Trying.png)</td>
</tr>
</tbody>
</table>

**Try Again**—Click this button to force the software to make N more attempts, where N is set in the How Many More Attempts field.

**Skip This One**—Instructs the software to stop trying to place the current object and proceed to the next.

**Quit Trying**—Aborts the Generate Locations process; no more objects will be placed.
Object/Delegate Associations Dialog

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > Associate Objects with Delegates

Select a Crowd object. > Modify panel > Setup rollout > Associate Objects with Delegates

You can use this dialog to link any number of delegate-object pairs. You can also use this dialog to align objects with delegates, optionally matching scaling factors as well. Lastly, you can specify that the objects use the delegates’ controllers.

Interface

Objects—Lists objects available for linking, specified using the Add function (see following item). You can select any number of objects from this list for subsequent removal.

Add—Click this to open the standard 3ds Max Select dialog, which lists all objects in the scene, including delegates. Make your selection, and then click the Select button to add the objects to the Objects list.

Remove—Deletes the highlighted object or objects from the list.

Shift Up/Shift Down—Use the arrow buttons between the two lists to move highlighted items higher or lower in the list.

When you click Align Objects With Delegates, Link Objects To Delegates, or Assign Delegate Controllers To Objects, the software creates associations between pairs of items at matching positions in the lists.

Delegates—Lists delegates available for linking, specified using the Add function (see following item). You can select any number of delegates from this list for subsequent removal.

Add—Click this to open the standard 3ds Max Select dialog, which lists all delegates in the scene. Make your selection, and then click the Select button to add the delegates to the Delegates list.

Remove—Deletes the highlighted delegate or delegates from the list.

Association via Linking group

Align Objects with Delegates—Aligns each object with its corresponding delegate by moving and rotating the object on its local axes. Each delegate’s local Y axis points in the forward direction, so aligned objects will be rotated so their Y axes point in the forward direction as well. This option works much like the 3ds Max Align feature.

Align Scale—When on, clicking Align Objects with Delegates sets each object’s absolute scaling factor to that of its corresponding delegates. This is useful if, for example, you’ve randomized delegates’ sizes with the Scatter Objects Scale panel (page 2–1193), and want the associated objects to match.
Link Objects to Delegates—Creates a hierarchy for each object-delegate pair, with the delegate as parent.

Association via Animation Replacement group

Assign Delegate Controllers to Objects—Copies each delegate’s controllers to the paired objects as an instance.

This is the same as using Track View > Copy Controller from the delegate, and then pasting the controller as an instance to the object. Does not link objects hierarchically with delegates.

Once you’ve set up the delegate animation the way you want it, if you then want to apply the animation to an object or objects en masse, use this function. You can then delete the delegates if you like.

OK—Implements any changes and closes the dialog.

Cancel—Eliminates any changes and closes the dialog.

Note: Clicking OK has no intrinsic effect; in order to implement any of the dialog functions, you must first click at least one of the Align/Link/Assign buttons.

Edit Multiple Delegates Dialog

The Edit Multiple Delegates dialog lets you define groups of delegates and set parameters for them. You can create and store up to 10 different configurations or settings combinations; each consists of one or more delegates and settings for the delegates. The parameters are mostly the same as those found in the delegate object’s Motion Parameters rollout (page 2–1183), with the following exceptions and additions.

- Each setting has an associated SET check box, which lets you determine whether the setting has any effect. When off (the default), the setting has no effect. When on, the setting affects the specified delegate or delegates when you click the Apply Edit button.
- Each numeric parameter has two Value settings and an associated Random check box, which lets you specify a random value within a specified range for each member of the group. By default, Random is off, and the Value 1 setting is applied for all parameters with SET turned on. If you turn on Random for a parameter, its Value 2 setting becomes available. If you then specify a different setting for Value 2, the software calculates a different random number between Value 1 and Value 2 for each delegate in the group.

Tip: To reset a parameter to a specific value for all delegates in a group after it’s been set to a random value within a range, turn off Random and turn on SET for the parameter, then set Value 1 to the desired value, and then click OK.

Procedure

To edit multiple delegates:

1. Select the Crowd object and open the Modify panel.
2. On the Setup rollout, click the Multiple Delegate Editing button.
   This opens the Edit Multiple Delegates dialog.
3. Optionally, in the dialog (bottom-left corner), choose a stored dialog setting to use from the 10 available settings.
4. If necessary, use the Delegates To Edit group box controls to add delegates to or remove them from the current setting.

5. Modify the remaining parameters as necessary. Be sure to turn on the SET check box for any parameters that are to change.

6. Click the Apply Edit button to make the changes and exit the dialog.

**Interface**

**Delegates to Edit group**
This group shows delegates belonging to the current settings combination in a list box and lets you add and delete members.

- **Add**—Click this button, and then choose delegates to add from the Select dialog.
- **Remove**—To remove delegates from the list, first choose the names of those to delete in the list box (drag to choose two or more contiguous names, or use **Ctrl** click to choose non-contiguous names), and then click Remove.

**Set Parameters from Animation group**
Use this function to obtain motion parameters from an animated object and apply them to all specified delegates. It affects only Average Speed, Max Accel, and the Turning parameters.

Because this one animation will set most of the parameters of the delegate, it should be representative of a whole range of motion of the delegate. For example, the object should turn and accelerate. The animation should be somewhat lengthy so that averages are calculated correctly.

- **Animated Object**—Specifies an animated object. Click this button, and then choose the object from the list in the Select dialog.
- **Set**—After specifying the animated object, click this button to apply its parameters to the delegate settings. Also turns on the SET check box for any affected parameters.

**General group**
Rather than numeric values, the settings in this group are on-off switches, except for the first, Velocity Color. To change Velocity Color, click the color swatch, use the Color Selector dialog to pick a new color, and then turn on the Velocity Color SET check box. To change any other setting in the General group, click the check box to the right of the setting, and then turn on the setting’s SET check box.

These settings are the same as those found in the delegate object’s *Motion Parameters rollout* (page 2–1183).

**Speed group**
These parameters are the same as those found in the delegate object’s *Motion Parameters rollout* (page 2–1183). For an explanation of the Random and SET check boxes, see the introduction to this topic.
Turning group

These parameters are the same as those found in the delegate object’s Motion Parameters rollout (page 2–1183). For an explanation of the Random and SET check boxes, see the introduction to this topic.

Banking group

These parameters are the same as those found in the delegate object’s Motion Parameters rollout (page 2–1183). For an explanation of the Random and SET check boxes, see the introduction to this topic.

Biped group

These parameters are the same as those found in the delegate object’s Motion Parameters rollout (page 2–1183). For an explanation of the Random and SET check boxes, see the introduction to this topic.

Stored Dialog Settings—Use this list to specify up to 10 different combinations of delegates and settings. To store a combination, choose a name from the list, and then specify the delegates and settings. To recall a combination, choose its name from the list. To rename a combination, choose its name from the list, and then highlight the name and edit it using the keyboard.

Check All Sets—Click this button to turn on all SET check boxes. This ensures that any changes you make in the dialog take effect when you click the Apply Edit button.

Apply Edit—Click Apply Edit to implement all changed settings and exit the dialog.

Close—Click Close to remember, but not implement, all changed settings and exit the dialog.

Cancel—Click Cancel to forget all changed settings and exit the dialog.

Associate Bipeds With Delegates Dialog

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > Biped/Delegate Associations button

Select a Crowd object. > Modify panel > Setup rollout > Biped/Delegate Associations button

Use this dialog to associate any number of delegates with an equal number of bipeds. Add delegates and bipeds to the two lists, and order them so the desired pairs are across from each other. Then choose Make Specified Associations and click the Associate button. Alternatively, you can remove existing delegate-biped associations, or simply associate each delegate with the biped nearest it in the scene.

Interface

Bipeds—Lists bipeds available for linking, specified using the Add function (see following item). You can select any number of objects from this list for shifting up or down, or deleting.

To clear highlighted items, control-click them.
Chapter 14: character studio

Add—Click this to open the standard 3ds Max Select dialog, which lists all bipeds in the scene that are not currently listed in the Associate Bipeds with Delegates dialog. Make your selection, and then click the Select button to add the delegates to the Objects list.

Remove—Removes the highlighted biped or bipeds from the list.

Shift Up/Shift Down—Use the arrows between the two lists to move highlighted items higher or lower in the lists.

When Make Specified Associations is chosen and you click the Associate button, the software creates associations between pairs of items at matching positions in the lists.

Delegates—Lists delegates available for linking, specified using the Add function (see following item).

You can highlight any number of objects from this list for shifting up or down, or deleting.

To clear highlighted items, control-click them.

Add—Click this to open the standard 3ds Max Select dialog, which lists all delegates in the scene that are not currently listed in the Associate Bipeds with Delegates dialog. Make your selection, and then click the Select button to add the delegates to the Delegates list.

Remove—Removes the selected delegate or delegates from the list.

Clear Associations—When this is on, and you click the Disassociate button, character studio eliminates any delegate-biped associations. Makes the Bipeds list and buttons unavailable.

Make Specified Associations—When chosen, and you click the Associate button, character studio associates each parallel delegate-biped pair in the two lists. That is, the first delegate is associated with the first biped, the second delegate with the second biped, and so on.

Associate Delegates With Closest Biped—When chosen, and you click the Associate button, character studio calculates the biped nearest each delegate in the scene and links the two together.

Set Delegates to Use Biped—When on, and you click the Associate button, the software turns on the Use Biped option for all delegates listed in the dialog.

Associate/Disassociate—Implements specified changes, calculates any random values, and closes the dialog. Button text changes to "Disassociate" when the Clear Associations option is chosen.

Close—Remembers any changed settings and closes the dialog. No new delegate settings are calculated or applied.

Cancel—Ignores any changes and closes the dialog.

Behavior Assignments and Teams Dialog

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > Behavior Assignments

Select a Crowd object. > Modify panel > Setup rollout > Behavior Assignments

The Behavior Assignments and Teams dialog lets you group delegates into teams (page 2–1204), and assign behaviors and cognitive controllers (page 2–1206) to individual delegates and teams. It also lets you modify existing assignments.

The dialog is modeless; while it's open, you can use the Modify panel to adjust behaviors and set up new behaviors, as well as animate assignments’ Weight settings.
Behavior Assignments and Teams Dialog

Note: Crowd doesn’t let you use multiple cognitive controllers with a delegate. You can assign them, but when you solve, the software notifies you that it will use only the first assigned cognitive controller.

Note: The Enable Flashing option helps you see which delegates are affected by different actions in this dialog. When it’s turned on, and you perform any of the following, the relevant delegates “flash” (highlight briefly) in the viewports:
- Click a delegate or team in the Assignment Design group
- Click an assignment in the Behavior Assignments group
- Add members to a team in the Teams group
- Remove members from a team in the Teams group

Procedures

To group delegates into a team:
1. In the Teams group, click the New Team button.
2. Use the Select Delegates dialog to designate the delegates in the team, and then click the OK button.
3. To change a team name, choose it from the drop-down list at the top of the Teams group, click on its name, and then use the keyboard to edit the text.
4. To remove team members, choose the team from the drop-down list at the top of the Teams group, select the members to remove from the lower list, and then click the Remove Members button.
5. To add team members, choose the team from the drop-down list at the top of the Teams group, click the Add Members button, and then use the Select Delegates dialog to designate the delegates to add.

To create a new behavior assignment:
This procedure gives the basic method for assigning a behavior or cognitive controller to a delegate or team.

1. If you want to assign the same behavior to more than one delegate, use the Teams group (page 2–1204) to collect delegates into teams. Note: You can still assign behaviors to an individual delegate, even if it belongs to one or more teams.
2. Make sure no existing assignments in the Behavior Assignments group are highlighted. If any are, [Ctrl]-click them to clear the selections.
   If assignments are highlighted, the software assumes you want to modify the existing assignments
3. In the Assignment Design group, select one delegate or team, and one or more behaviors or one cognitive controller.
   You can select only one item from either side of this group, with the exception of behaviors. If you choose multiple behaviors, the software creates a separate assignment for each.
   Note: When you select a delegate or team, it briefly highlights in the viewports to indicate the affected delegates.
4. Click the New Assignment button. This is the vertical button to the right of the assignment Design group, with five right-pointing arrows.
   This adds the assignments to the list in the Behavior Assignments group.
5. At this point, you can highlight an assignment, and then change its Weight setting, its Active status, delete it, or change the assignee and/or behavior/cognitive controller.
6. Click OK to accept the changes and close the dialog.
To modify an existing behavior assignment or assignments:

1. In the Behavior Assignments group, select the assignment or assignments to change.
   You can select multiple assignments by Ctrl + clicking for non-contiguous items or Shift + clicking for contiguous items, and then change the assignees or behaviors for all of them at once.
2. To change assignees, in the Assignment Design group, select a delegate or team.
3. To change the assigned behaviors, in the Assignment Design group, select a behavior or cognitive controller.
4. Click the Reset Assignment button. This is the vertical button to the right of the assignment Design group, with five right-pointing arrows.
5. Change the Weight setting and Active status as necessary.
6. Click OK to accept the changes and close the dialog.

Interface

Assignment Design group

Let's set up assignments by choosing a behavior or cognitive controller and a delegate or team to assign it to. Choose one item from the left side (upper or lower list), and one item from right side (upper or lower list). Then click the New/Reset Assignment button immediately to the right of the Assignment Design group (vertical button with five right-pointing arrows).

Tip: With the exception of Behaviors, you can choose only one item from either side of this group. To assign the same behavior to more than one delegate, the most efficient method is to use the Teams group (page 2–1204) to gather delegates into teams.

You can select multiple behaviors for a new assignment to a delegate or team. When you click New Assignment, the software creates a separate assignment for each highlighted behavior. For changing assignments, you're still restricted to choosing one behavior at a time. If you choose an existing assignment and multiple behaviors, the Reset Assignment button becomes unavailable.

Delegates—Lists delegates in the scene.
Behaviors—Lists existing behaviors.
To use a behavior that hasn't been added to the scene yet, click the New Behavior button at the bottom of this group.
Teams—Lists teams in the scene.
To create a new team, use the controls in Teams group box.
Cognitive Controllers—Lists existing cognitive controllers.
To create a new controller, click the Setup rollout > Cognitive Controllers (page 2–1206) button. You needn't first exit the Behavior Assignments and Teams dialog; when you close the editor, the new controllers are added to the Cognitive Controllers list.
Clear Selections—Deselects all highlighted items in the Assignment Design and Behavior Assignments groups.
Use this before modifying an assignment, to avoid possible confusion.

**New Behavior**—Opens the Select Behavior Type dialog (page 2-1205), which lets you add a behavior to the scene for use in an assignment.

To modify a new behavior, use the facilities available in the Crowd object’s rollouts.

**Note:** If you add the first behavior in the scene from this dialog, the text box in the Crowd object > Setup rollout remains empty, and no rollout for the behavior appears. To edit the behavior, choose it from the list.

**New Assignment/Reset Assignment**—Click to assign a behavior or behaviors or a cognitive controller to a delegate or team.

This vertical button with five right-pointing arrows on it is situated between the Assignment Design and Behavior Assignments group. It’s available only when two items in the Assignment Design group are highlighted (exception: Multiple behaviors can be highlighted). If no item in the Behavior Assignments group is highlighted, clicking the button creates a new assignment and adds it to the assignments list. If one or more items in the Behavior Assignments group are highlighted, clicking the button sets the highlighted assignments to use the highlighted delegate/team and behavior/cognitive controller combination.

### Behavior Assignments group

<table>
<thead>
<tr>
<th>Delegate/Team</th>
<th>Behavior/Cog</th>
<th>Weight</th>
<th>Active</th>
</tr>
</thead>
<tbody>
<tr>
<td>Team0</td>
<td>Avoid Behavior</td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>Team0</td>
<td>Space Walk Behavior 1.00</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**List box**—Displays all current behavior assignments, including team or delegate name, assigned behavior or cognitive controller, weight setting, and active status.

Items are sorted in alphabetical first by Delegate/Team name, and then by Behavior/Cog name. A dashed line appears before a list entry if it’s the first item for that delegate or team.

To modify or delete an assignment, choose it from the list, whereupon the software highlights the assigned components in the Assignment Design group. Make the changes using the remaining controls in this dialog.

**Note:** You can select multiple assignments from the list by [Ctrl]+clicking for non-contiguous items or [Shift]+clicking for contiguous items. To clear an item, [Ctrl]+click it.

**Weight**—The relative effect of the assigned behavior or cognitive controller. The higher an assignment’s Weight setting is than others’, the greater relative effect it will have. This setting is animatable. Default=1.0.
In most cases, you should keep Weight within a range of 0.0 to 1.0. Higher settings are available but shouldn’t be used unless absolutely necessary. Note: The Weight setting is not relevant to the Avoid (page 2–1211), Orientation (page 2–1214), or the Surface Follow (page 2–1226) behavior, and is thus unavailable for assignments using any of those three.

Active—When on, the assignment is currently in effect. When off, the assignment has no effect. This check box is animatable. Default=on.

Delete—Deletes the highlighted behavior assignment.

Teams group

![Teams group](image)

Lets you define, modify, and delete teams of delegates.

Note: You can toggle the display of this group box with the No Teams/Teams button below the Behavior Assignments group.

Drop-down list—Displays the name of the current team.

To view a different team, choose it from the list. To change a team name, click in the box and then use the keyboard to edit the text.

List box—Displays delegates in the current team.

New Team—Adds a team to the list, and opens the Select Delegates dialog (page 2–1205) to let you specify new team members.

The default team name is "Team," followed by a number, starting with "0" and counting up.

Delete Team—Deletes the current team.

Team members are not deleted from the scene.

Add Members—Lets you add members to the current team. Use the Select Delegates dialog (page 2–1205) to specify new team members.

Remove Members—Removes selected members from the team.

Removed members are not deleted from the scene.

Create/Change Selection Set—Adds the current team to the list of selection sets, accessible from the Named Selection Sets list on the Main toolbar.

If the current team already is a selection set, and you subsequently changed the team’s makeup, click this button to update the members in the Named Selection Sets list.

Enable Flashing—When on, and you click a list item in the dialog or create/modify a team, the relevant objects highlight briefly in the viewports to indicate which are affected. Default=on.

See the introductory note for details.

OK—Click this button to accept all changes and close the dialog.
No Teams/Teams—Toggles display of the Teams group box.

By default, the Teams group is displayed; click the No Teams button to turn it off. When it’s off, click the Teams button to turn it on. The state of the toggle persists only during the current session.

Select Behavior Type Dialog

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > Behavior Assignments > New Behavior

Select a Crowd object. > Modify panel > Setup rollout > Behavior Assignments > New Behavior

Use this dialog to select the type of behavior to be added to a Crowd object. The choices are:

Avoid Behavior (page 2–1211)
Orientation Behavior (page 2–1214)
Path Follow Behavior (page 2–1216)
Repel Behavior (page 2–1218)
Scripted Behavior (page 2–1220)
Seek Behavior (page 2–1220)
Space Warp Behavior (page 2–1221)
Speed Vary Behavior (page 2–1222)
Surface Arrive Behavior (page 2–1223)
Surface Follow Behavior (page 2–1226)
Wall Repel Behavior (page 2–1227)
Wall Seek Behavior (page 2–1229)
Wander Behavior (page 2–1231)

Select Delegates Dialog

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > Behavior Assignments > Choose or add a team. > Add Members

Select a Crowd object. > Modify panel > Setup rollout > Behavior Assignments > Choose or add a team. > Add Members

The Select Delegates dialog lets you designate delegates to be assigned to teams using the Behavior Assignments and Teams dialog (page 2–1200) for assigning crowd behaviors.

Interface

List box—Lists all delegates in the scene.
All—Selects all delegates in the list.
None—Deselects all delegates.
Invert—Inverts the current selection.
Selection Sets—Choose an item from this to select all members of the selection set. You must first have created a selection set from one or more delegates.
OK—Closes the dialog and implements changes.
Cancel—Closes the dialog and ignores changes.

Cognitive Controllers

The Cognitive Controller editor lets you combine behaviors into states. More importantly, it lets you sequence different behaviors (page 2–1159) and behavior combinations using state diagrams, where conditionals written in MAXScript impose changes in behavior. For example, you can specify that a character or object is to wander aimlessly until it comes within a certain distance of another object, whereupon it heads straight for that object. Or you can specify that one character is to avoid another only when the second character is avoiding the first.

Note: The MAXScript conditionals used in the cognitive controller typically consist of a single line of code. You can load and save them separately as .ms files, but they are also stored within the .max scene file in which they reside.

The editor interface consists of an icon-based toolbar above a window that contains the state diagram. When you first open the editor, no state diagrams exist. Begin by clicking the New button to create a new state diagram.

Tip: If you find yourself consistently assigning two or more behaviors to delegates or teams, you can save time by combining the behaviors into a single-state cognitive controller, or “behavior module,” and assigning that instead. The only disadvantage is that you can’t animate the weights of behaviors used in the cognitive controller, but you can work around that by using transitions.

Note: Crowd doesn't let you use multiple cognitive controllers with a delegate. You can assign them, but when you solve, the software notifies you that it will use only the first assigned cognitive controller.

See also
State Dialog (page 2–1207)
State Transition Dialog (page 2–1208)

Interface

Create State—Lets you create new states in the diagram. Click this button, and then click in the state diagram area to add states. A state appears as a rectangular box containing the name of the state. The first state you add is, by default, the first state in the controller that executes when the simulation is run. This is indicated by its red color; states you add subsequently are colored blue. To set a different state to execute first, use the Set Start State function.

You specify a state’s name and behaviors by editing the state. To edit a state, right-click it. This opens the State dialog (page 2–1207).

Create Transition—Lets you link states with transitions. Click this button, and then drag between two states to create the transition, starting...
with the earlier state. The transition appears as a black arrow pointing from the first state to the second. Alternatively, if you click a state with the Create Transition tool active, you create a transition that loops back to the state itself.

Right-click a transition to specify its characteristics and conditions by editing the transition. This opens the State Transition dialog (page 2–1208).

**Set Start State**—Normally the state that executes first in a cognitive controller is the one that was added first. Use this tool to choose a different state to execute first. The start state is red; the rest are blue.

Typically you would use this when you have a circular sequence of states, and you want to change which state executes initially.

**Move State**—Lets you move states around in the window by dragging them.

**Select State/Transition**—Lets you select states and transitions for subsequent deletion. Selected states have white outlines, and selected transition lines are white.

You can select multiple states by dragging a box around them. You can select multiple states and transitions by holding the Ctrl key as you click.

**Delete State/Transition**—Lets you delete one or more states or transitions. First select any combination of states and transitions to delete, and then click this button.

**(Name)**—Shows the name of the current state diagram. To display and/or edit another, choose it from the list.

To change a state diagram’s name, click the name in the box and use the keyboard to edit the text.

**New**—Adds a new cognitive controller. By default, cognitive controllers are named “Cognitive Controller” followed by a number, but you can change this to anything you like.

**Delete**—Deletes the current cognitive controller. This is an undoable operation.

---

**State Dialog**

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > Cognitive Controllers > right-click a state icon.

Select a Crowd object. > Modify panel > Setup rollout > Cognitive Controllers > right-click a state icon.

The State dialog lets you add behaviors to, and remove them from, a cognitive controller state in a crowd simulation, and specify weights for each behavior.

**Interface**

**State name**—Displays the name of the state.

To change the name, click this text and edit from the keyboard.
List—Displays the names of all behaviors associated with the state.

To remove a behavior or change its weight, click the behavior’s name, and then make the appropriate changes using the controls below the list.

Note: The order of behaviors in this list is immaterial; all behaviors execute simultaneously.

Add—Opens the Select Behavior dialog, which displays the names of all behaviors (page 2–1211) in the current Crowd object that are not associated with the current state. Select a behavior (use Shift and/or Ctrl to choose multiple behaviors), and then click OK.

Remove—Eliminates the highlighted behavior from the state.

Weight—Specifies the selected behavior’s relative influence in the state. Default=1.0.

The higher the weight in relation to other behaviors’ weights, the more evident the results of the behavior in the state. In most cases, you should keep Weight within a range of 0.0 to 1.0. Higher settings are available but shouldn’t be used unless absolutely necessary.

OK—Closes the dialog and implements changes.

Cancel—Closes the dialog and ignores changes.

State Transition Dialog

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > Cognitive Controllers > Right-click a transition line.

Select a Crowd object. > Modify panel > Setup rollout > Cognitive Controllers > Right-click a transition line.

These settings control how the software effects a transition from one state to another when using a cognitive controller (page 2–1206). For more detailed information, see To set up and use a cognitive controller (page 2–1170).

The Transition Script

The most important element of the transition is the MAXScript conditional script. This is a script associated with the controller that is executed once per frame, and can test any aspect or aspects of the scene and cause a transition or not, depending on whether the result of the test is successful (true, or 1) or unsuccessful (false, or 0).

The software executes scripts once per frame per assigned delegate, so objects and effects can be animated and still let delegates react with accuracy.

All scripts used in transitions use the following structure:

```
fn [FunctionName] delt =
[MAXScript code]
if [MAXScript conditional] then 1 else 0
```

The opening section contains "fn" (function) followed by the function name, which also must appear in the State Transition dialog, and then the input parameters "delt", and lastly "=" (".

The closing section contains a necessary MAXScript conditional, and then "then 1 else 0". This means: If the result of the conditional is true, then return 1 (that is, the transition is to take place), or if the result of the conditional is false, then return 0 (that is, the transition is not to take place). You could reverse the order of the numbers 1 and 0 ("then 0 else 1") so that the conditional being true would cause no transition to take place, and vice-versa. Lastly, the function must end with a close parenthesis: ")".

Following are some examples of scripts that can be used in cognitive controllers, along with brief
explanations. These are presented for you to modify and use in your own scenes.

Note: See this topic in the online User Reference for sample code to test an object position, test the distance between two objects, and test a modifier parameter.

Testing a Particle System Parameter

This sample script tests the number of particles emitted by particle system Spray01, and returns positive if the number equals 100.

```maxscript
fn TestParticles delt =
    if (particleCount $Spray01) == 100 then 1 else 0
```

Testing an Atmospheric Property

This sample script tests the Density parameter of a fog effect, and returns positive if it equals 50.

```maxscript
fn TestAtmos delt =
    atmos_fog = getAtmospheric 1
    print atmos_fog.density -- to:debug
    if (atmos_fog.density == 50) then 1 else 0
```

Note the second line, which assigns the fog atmospheric to a variable named "atmos_fog". This is necessary only for atmospheric effects; with most standard objects, you simply use the object name preceded by a $, as in the two previous examples. The "1" following the getAtmospheric command refers to the atmospheric's position in the Rendering Effects dialog > Effects list.

Once you've executed this assignment, you can obtain a list of the atmosphere's properties by entering this command in the MAXScript Listener:

```maxscript
ShowProperties atmos_fog
```

Also, the third line in the sample script isn't necessary for the cognitive controller; it simply prints the result of the test in the Listener window for debugging purposes.

Testing Another Delegate's Behavior

You might want to determine in a transition script which behavior is currently influencing a certain delegate. Crowd provides a MAXScript-based method for doing this. You can even check whether a particular delegate is specified as a target within that behavior. An example would be a cocktail party scene in which Betty avoids Harry if Harry is seeking Sally. But if Harry is avoiding Sally, then Betty will seek Harry.

The following example script is taken from the sample file `party.max`, which you can find in the Biped download available on this page, under 3ds Max 8 Tutorials – Scene and Support Files > Specialized. The scene uses a more complex scenario than the example described in the previous paragraph. Following is an overview, but to fully understand the setup, you should examine the scene. Study, in particular, the behavior assignments and cognitive controllers, which use a total of eight different transition scripts.

Six delegates are confined in a "room" defined by four grids, using a Wall Repel behavior. Delegates 1, 2, 3, and 5 simply wander at random during the simulation. However, delegate 4 uses a cognitive controller (cc1) that tells it to start wandering, and then switch to one of three Avoid behaviors if members of one of three arbitrary pairs of delegates come within 50 units of each other. Each of the Avoid behaviors targets a different group of three delegates, two of which include delegate 2. Delegate 6 is assigned a second cognitive controller (cc2) that uses the following script to tell it to switch to an Avoid behavior if delegate 4 is avoiding delegate 2. The heart of the script is this line in function `transfunc4`:

```maxscript
Note: See the online User Reference for this sample code.
```

Load the file, press [F11] to open the Listener window, and then solve. The Listener window
displays a message whenever delegate 4 is found to be avoiding delegate 2.

You can use this script as is in your own simulations to check for whether one delegate is avoiding a second by substituting the delegates' names in the above line, and also substituting the names of your Avoid behaviors in the list in transfunc4, adding or deleting lines as necessary.

The example script illustrates a second important point: Cognitive controller transition scripts can contain multiple functions. Crowd first executes the function specified in the State Transition dialog > Transition Condition field, and that function calls one or more additional functions in the script, which, of course, can also call functions. In this case, transfunc4 calls the first function, isDelegateAvoiding, passing it three parameters.

Lastly, the script contains a special function, getBehaviorType, that compares an input behavior against a list of known behaviors, and on a match, returns the known behavior. In this case, transfunc4 runs through the list of behaviors currently influencing Delegate04, testing each with getBehaviorType, and if an Avoid behavior is in effect, proceeds to check whether Delegate02 is an obstacle of that Avoid behavior. Use of this function is more efficient and flexible than testing for specific behaviors, especially if your scene contains many behaviors of the same type, or you’re constantly editing behavior settings. You can see the returned behaviors by removing the comment (double hyphen) from the beginning of the following line in transfunc4.

Note: See the online User Reference for this sample code.

### Interface

![Interface Image]

**Priority**—Sets the transition’s precedence.

When more than one transition tests true, the software uses the Priority setting to determine which transition occurs. It performs the transition with the lowest Priority setting. Thus, for example, a transition with a Priority setting of 0 takes precedence over one with Priority 1, and so on.

**Duration**—The number of frames the software takes to effect the transition between states.

**Ease In**—The rate at which the transition begins. Default=0.5. Range=0 to 1.0.

Lower values cause a more abrupt transition, while higher values cause a more gradual transition.

**Ease Out**—The rate at which the transition ends. Default=0.5. Range=0 to 1.0.

Lower values cause a more abrupt transition, while higher values cause a more gradual transition.

Note: The sum of the values for Ease In and Ease Out must be less than or equal to 1.0. The software won’t let you set a value for either parameter that would cause the sum to exceed 1.0. To increase the value of one parameter when its value equals
1.0 minus the other parameter, decrease the other parameter first.

**Transition Condition**—The name of the MAXScript function that specifies when/how the transition is to occur.

This name must also appear at the beginning of the main function in the script, after "fn". The script can contain additional functions that are called by the main function and each other.

**Edit MAXScript**—Opens an editor window for editing, saving, and loading the transition’s MAXScript script.

**OK**—Closes the dialog and implements changes.

**Cancel**—Closes the dialog and ignores changes.

---

**Behavior Rollout**

- Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > New button
- Select a Crowd object. > Modify panel > Setup rollout > New button
- Select a Crowd object. > Modify panel > Setup rollout > Choose a behavior.

The Behavior rollout appears in the Crowd object command panel after you first add a behavior to the scene using the Setup rollout. The rollout’s full name (for example: Avoid Behavior or Seek Behavior) depends on the current behavior, displayed in the text box in the Setup rollout. To display the rollout for a different behavior, choose the behavior from the drop-down list.

**Note:** If you add the first behavior to the scene from the **Behavior Assignments and Teams Dialog (page 2–1200)**, a behavior rollout does not automatically appear in the Crowd command panel. You must first choose the behavior from the drop-down list at the bottom of the Setup rollout.

Use the controls in this rollout to modify the behavior. Following is a list of available behaviors:

- **Avoid Behavior** (page 2–1211)
- **Orientation Behavior** (page 2–1214)
- **Path Follow Behavior** (page 2–1216)
- **Repel Behavior** (page 2–1218)
- **Scripted Behavior** (page 2–1220)
- **Seek Behavior** (page 2–1220)
- **Space Warp Behavior** (page 2–1221)
- **Speed Vary Behavior** (page 2–1222)
- **Surface Arrive Behavior** (page 2–1223)
- **Surface Follow Behavior** (page 2–1226)
- **Wall Repel Behavior** (page 2–1227)
- **Wall Seek Behavior** (page 2–1229)
- **Wander Behavior** (page 2–1231)

For a detailed description of specific behaviors, refer to the above topics. For an overall look at behaviors, see **Assigning Behaviors (page 2–1159)**.

---

**Behaviors**

**Avoid Behavior**

- Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > New button > Avoid Behavior
- Select a Crowd object. > Modify panel > Setup rollout > New button > Avoid Behavior

The Avoid behavior lets you specify any object or objects that delegates must keep away from.
As delegates approach designated objects during the crowd simulation, they steer clear of them while turning and/or braking as necessary. This behavior uses three different methods to let delegates avoid each other and other objects: Steer To Avoid, Repel, and Vector Field.

Steer to Avoid behavior is best used for animals that steer around each other at close proximity. Earthbound animals and fish typically do this. Steering motion may be sudden since its action is often engaged for relatively short periods of time.

By contrast, Repel avoidance behavior mimics the continuous action of a repellent magnetic field. Birds, bats and flying insects are best animated with large Repel fields so that they can smoothly avoid each other while maintaining a comfortable margin of error. Repel forces prevent intrusion from all sides, regardless of the direction of travel. Thus even animals that rely mainly on Steer to Avoid will also need some degree of Repel avoidance to maintain spatial separation when they are moving through dense traffic. The forces of Repel avoidance are always directed uniformly outward in a spherical shape.

Use Vector Field avoidance for cases where crowd members must avoid hitting the more complex shapes of arbitrary 3ds Max objects. The outward forces of the Vector Field avoidance can constructed to form the shape of any object. For example, suppose you want to animate a school of fish swimming around a sunken ship. In this case, a vector field can be created so that it extends the shape of the ship into the surrounding space. The field is computed by scan converting the ship's surface normals into a 3D lattice that surrounds the ship. These normals will extend into space as "beacons" in the 3D lattice, telling the fish how to best swim away from the shape of the ship. As the fish enter the space of the vector field lattice, they can be precisely repelled along an avoidance force directed away from ship's surface.

Note: In the explanations that follow, the word "target" is used to refer to the object or objects to be avoided.

### Interface

![Interface Image]

**None (label)**—Specifies a single target. Click this button, and then click the target object in the viewport. The target name then appears on the button.

If you've selected multiple targets using Multiple Selection (see next item), the word Multiple appears on the button. To see which objects are
Avoid Behavior

- **Multiple Selection**—Opens the Select dialog to let you designate multiple targets. When you have more than one target, you can set delegates to move toward the closest target in the group, or to a computed average of the target positions.

- **Look Ahead**—The number of frames in advance of the current frame that the software looks for potential collisions. Default=30.

- **Hard Radius**—Distance from the target's pivot point, in multiples of the delegate's bounding sphere, where no penetration should occur. Default=1.0.

  **Tip:** Because the hard radius' center is the pivot point, Avoid may not work as expected with target objects whose pivot point is not centered, such as the box primitive. For best results, use the Hierarchy panel > Adjust Pivot rollout controls to center the pivot to the object.

- **Display Hard Radius**—Enables display of a wireframe sphere that depicts the extent of the Hard Radius setting. Default=off.

### Steer To Avoid group

Steer To Avoid is used by delegates to steer precisely around anticipated future collisions based on the delegates’ current speed and direction. Delegates using this approach can pass very close to one another.

- **Detour Angle**—Maximum necessary turning angle relative to the direction of delegate's goal that delegate will steer to avoid rather than slow down and wait. Default=360. Range=0-360.  

  **Tip:** To disable turning for avoidance, thus allowing only braking, set Detour Angle to 0. This forces delegates to remain directed toward their goal so that they must slow down and wait until there is a clearing in front of them, much like an audience queuing to leave through an exit after a concert.

- **Brake Pressure**—Determines how strongly a delegate will react when it encounters an avoided object. Higher values make the delegate more likely to slow down or stop. Lower values will cause delegates to look for a way around the obstacle so they can keep going, sometimes causing delegates to veer off in unexpected directions. Default=2.0.

### Repel group

Repel is a general separation force that is based only on the spatial position. Delegates use this to keep from getting into situations where they might side-swipe each other or where they might get so close that Steer To Avoid is too difficult to achieve.

- **Strength**—Determines the strength of the repelling force; higher values result in greater repulsion force. Default=0.2. Range=0.0 to 1.0.

- **Radius**—Maximum distance from delegate's bounding sphere within which "repel" avoidance is sensed and carried out. Default=3.0.

- **Falloff**—The rate at which the strength diminishes between the Repel radius and the hard radius. A value of 1.0 indicates a linear falloff. Higher values cause the strength to fall off to zero more rapidly with distance, thus focusing its effect closer to the delegate's hard radius. Lower values reduce the rate of diminishment, with a Falloff setting of 0.0 indicating that the strength is the same at the Radius distance as it is at the Hard Radius. Default=3.0.

- **Display Repel Radius**—Enables display of a wireframe sphere that depicts the extent of the Repel setting. Default=off.

### Vector Field group

If you've applied a Vector Field space warp to an object in your scene, you can specify the vector field as an object to avoid. The distinction is this: When used with the Space Warp behavior (page 2–1221), delegates use the vector
field to steer around the object by being guided to travel perpendicular to the field’s vectors. When used with the Avoid behavior, the delegate simply moves away in the direction of the vectors.

Tip: Sometimes when using Avoid with a vector field, the behavior might seem to be "fighting” with other behaviors (such as Seek) over delegate movement, causing a halting and/or wavering motion. In such cases, try reducing Brake Strength and/or increasing Falloff.

**Strength**—Higher values result in more powerful influence. Delegates will be directed to move perpendicular to the field. Default=1.0. Range=0.0 to 1.0.

**Falloff**—Higher values cause vector field influence to fall off to zero more rapidly with distance, thus focusing its effect closer to the delegate’s hard radius. Default=8.0.

**Display During Solve group**

Use these switches for debugging a crowd simulation. During the solve, they display information about the simulation using graphical metaphors for different aspects of the Avoid behavior.

**Potential Collisions**—Displays a green line from the delegate to the location of a potential collision. Default=off.

**Repel Activity**—Displays a white line between the delegate and target when the repel force is in effect. Default=off.

**Look Ahead Radius**—Displays a sphere that shows the current distance used to check for potential collisions.

**Color Swatch**—Shows the color used to draw the Avoid force vector during the solution. Click the box to choose a different color. Default=red.

**Force**—When on, force exerted on one or more delegates by the Avoid behavior is drawn in the viewports as a colored line during the simulation solution. Default=on.

---

**Orientation Behavior**

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > New button > Orientation Behavior

Select a Crowd object. > Modify panel > Setup rollout > New button > Orientation Behavior

The Orientation behavior lets you control whether and how delegates rotate, independent of their direction of motion. Normally, a delegate always faces in the direction it’s moving. You can use the Orientation behavior to specify limits to the delegate’s rotational activity without affecting its path, which is generated by other behaviors. Use these settings, for example, to keep delegates facing in one direction while moving in another.

Note: These settings do not affect the path a delegate takes, which is produced by other behaviors such as Seek and Avoid. They influence only the direction it faces as it traverses the path.

### Heading group

Use these controls to affect how delegates turn on the vertical axis. By default, heading is absolute, with 0 specifying the positive X axis in World coordinates. Thus, -90 would specify the negative Y axis, 90 the positive Y axis, and 180 or -180 the negative X axis.

**Absolute heading as viewed from the top**

For example, if you wanted a delegate to be able to turn between the positive X axis and the positive Y axis, you would set Max Heading to 0 and Min Heading to 90.

You can also specify heading limits in amounts relative to the delegate’s heading at the time that the Orientation behavior takes effect by turning on the Relative check box.

**Relative**—When on, Heading settings are applied relative to the delegate's heading at the time the behavior takes effect. When off, settings are absolute. Default=off.

**Min Heading**—The minimum permissible heading. This number should be lower than the Max Heading value. Default=180. Range=-180 to 180.

**Max Heading**—The maximum permissible heading. This number should be higher than the Min Heading value. Default=180. Range=-180 to 180.

**Max Heading Velocity**—Specifies how much the delegate’s heading can change per frame. This controls angular acceleration and deceleration. Default=180.

**Head Response**—Determines how quickly the heading follows the direction the object is
moving in. A value of 1.0 indicates maximum responsiveness, and will point in the direction the delegate is moving (within the limits) while a lower value means that it is less responsive. Default=1. Range=0 to 1.

**Pitch group**

Use these controls to affect how delegates turn on the left-right axis.

**Relative**—When on, Pitch settings are applied relative to the delegate’s pitch at the time the behavior takes effect. When off, settings are absolute. Default=off.

**Min Pitch**—The minimum number of degrees a delegate can incline or decline. This number should be lower than the Max Pitch value. Default=-180. Range=-180 to 180.

**Max Pitch**—The maximum number of degrees a delegate can incline or decline. This number should be higher than the Min Pitch value. Default=180. Range=-180 to 180.

**Max Pitch Velocity**—Specifies how much the delegate’s pitch can change per frame. This controls angular acceleration and deceleration. Default=180.

**Pitch Response**—Determines how quickly the pitch follows the direction the object is moving in. A value of 1.0 indicates maximum responsiveness, so that will point in the direction the delegate is moving (within the limits) while a lower value means that it is less responsive. Default=1. Range=0 to 1.

**Banking group**

Use these controls to affect how delegates turn on the in-out axis. Banking is primarily a result of heading changes.

**Max Bank**—The maximum number of degrees the delegate can bank. Default=30.0.

---

**Max Bank Velocity**—The maximum number of degrees the delegate’s bank angle can change per frame. This controls angular acceleration and deceleration. Default=3.0.

**Bank per Turn**—The number of degrees the delegate will bank as a function of the turn angle at the current frame. For example, if Bank per Turn=1, the delegate will bank one degree for every degree it is turning at a given frame. Default=1.0.
Path Follow Behavior

Interface

None (label)—Click this button, then select a path object. Suitable path objects include splines and NURBS curves. If a path object contains more than one spline or curve, *character studio* uses the lowest-numbered element (usually the earliest created one).

Note: You can assign a path object only from the Modify panel.

Radius—The radial distance from the path, in units, within which the delegate stays while traversing the path. Default=20.0. Range=0.0 to 99,999.0.

Turning group

These parameters determine how delegates turn while following the path. Awareness determines how well a delegate anticipates turns in the path as it moves; you can apply random variation to Awareness with the Deviation setting.

Awareness—Specifies how "intelligent" the delegate is while traversing this path. A high Awareness setting means that it takes into account the curve of the path while moving and will try to anticipate changes. A low value for Awareness, on the other hand, means that the delegate notices the path only when leaving it. Default=0.5. Range=0.0 to 1.0.

Note: You can randomize awareness behavior with the Deviation and Seed settings.

Deviation—Specifies the maximum amount by which Awareness should vary. *character studio* takes a random number between the negative and positive values of the Deviation setting, multiplies it by the Awareness setting, and adds the result to Awareness. Default=0.5. Range=0.0 to 1.0.

Note: You can vary behaviors among different Path Follow behaviors that use the same Awareness and Deviation settings by changing the Seed value.

Starting Point

Determines where on the path the delegate begins to follow the path. The default choice is Beginning of Path.

Hint: To see a selected spline path’s start point, open the Modify panel and turn on any sub-object level; the start point is represented with a unique indicator. Also in the Modify panel, with closed curves, you can see the vertex ordering at any sub-object level by turning on Selection rollout > Display group > Show Vertex Numbers. To see a NURBS curve’s start point, go to the Curve sub-object level; the start point is indicated by a small green circle.
Beginning of Path—The delegate first moves to the start of the path before following it.

End of Path—The delegate first moves to the end of the path before following it. With closed curves, this is the same point as the beginning of the path.

Nearest Point—The delegate first moves to the closest point on the path and then follows the path from there.

Direction

Determine the direction the delegate takes initially when following the path. The default choice is Forwards.

Forwards—The delegate moves along path vertices in ascending order.

Backwards—The delegate moves along path vertices in descending order.

Action at End of Path

Determines what the delegate does when it reaches the path end. The default choice is Loop.

Loop—The delegate loops around the path, even if it isn’t closed. If Beginning of Path or End of Path is chosen, it returns to the path’s start or end point each time it finishes traversing the path. If Nearest Point is chosen, it returns to an arbitrary point determined by its position and the path shape.

Reverse—The delegate reverses direction at the end of the path. Use this choice to simulate a back-and-forth “patrol” behavior.

Continue—The delegate continues moving in the same direction it faced at the end of the path until the simulation ends or it’s acted upon by another force or behavior.

Seed—Specifies a seed value for randomizing Awareness. Default=1.

Color Swatch—Shows the color used to draw the Path Follow force vector during the solution. Click the box to choose a different color. Default=blue.

Display Force—When on, force exerted on the delegate(s) by the Path Follow behavior is drawn in the viewports as a vector during the simulation solution. Default=on.

Color Swatch—Shows the color used to draw the target icon. Default=dark blue.

Display Target—Enables display of the target icon, which appears during the solution when a new interim goal is calculated for the delegate. Default=on.

Target Scale—Specifies the overall size of the target icon. Default=5.0.

Repel Behavior

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > New button > Repel Behavior

Select a Crowd object. > Modify panel > Setup rollout > New button > Repel Behavior

The Repel behavior lets you specify any object or objects (sources) that will force delegates to move away from them. This is basically the opposite of the Seek behavior (page 2–1220). If you want delegates to back away from an object, as opposed to turning to face the direction they’re moving, use Repel in conjunction with the Orientation behavior (page 2–1214).

Note: Repel is set by default to work only within a specific radius around the source. If you want it to work at any distance, turn off Radius group > Use Radii.
Repel Behavior

**None (label)—** Specifies a single source. Click this button, and then click the target object in the viewport. The target name then appears on the button.

If you’ve selected multiple sources using Multiple Selection (see next item), the word Multiple appears on the button. To see which objects are designated as sources, click the Multiple Selection button.

**Multiple Selection—** Opens the Select dialog to let you designate multiple sources. When you have more than one source, you can set delegates to move toward the closest target in the group, or to a computed average of the source positions.

**Source of Repulsion group**

Determines repel activity when the behavior uses multiple sources. The default choice is Closest Source Only.

**Closest Source Only—** Each delegate is repelled by the closest of the assigned sources. Use this to have delegates assigned a single Repel behavior move away from sources in different directions.

**Average Of Sources—** All delegates move away from a common point determined by averaging all sources’ locations.

**Method group**

Determines whether delegate direction as influenced by the behavior is calculated by an angular method or a force method. Default=Force.

**Angle—** Applies a force to the delegate based on the angle between the delegate’s current direction and the direction it would need to take in order to be moving directly away from the source.

The magnitude of the force is greatest when the delegate is moving directly towards the source, and needs to turn around. It can be as little as 0 when the delegate is moving directly away from the source.

**Force—** Always applies a force directly away from the source. The magnitude of the force is constant.

**Radius group**

Use the Radius settings to activate the Repel behavior only when the delegates are within a specific distance from the target. The relative strength of the force increases from 0 percent at the outer radius to 100 percent at the inner radius.

**Use Radii—** When on, the behavior applies only to delegates closer to the target than the Outer Distance value. Default=on.

**Inner Radius—** The distance from the target at which the force is applied at full strength. Default=0.0.

**Outer Radius—** The distance from the target at which the force begins to be applied. Default=10.0.
Falloff—Default=2.0.

Display Radii—The radii are displayed when the force is active.

Color Swatch—Shows the color used to draw the Repel force vector during the solution. Click the box to choose a different color. Default=violet.

Display Force—When on, force exerted on the delegate(s) by the Repel behavior is drawn in the viewports as a vector during the simulation solution.

Scripted Behavior

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > New button > Scripted Behavior

Select a Crowd object. > Modify panel > Setup rollout > New button > Scripted Behavior

The Scripted behavior lets you create custom behaviors using MAXScript. A scripted behavior can incorporate one of three behavior types: Force, Constraint, or Orientation.

For detailed information on scripting behaviors, see the MAXScript reference, available from the Help menu.

Interface

Behavior Type—Choose Force, Constraint, or Orientation.

Script Context Name—Specify a name for the script.

Edit MAXScript—Click to open an editor window.

Seek Behavior

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > New button > Seek Behavior

Select a Crowd object. > Modify panel > Setup rollout > New button > Seek Behavior

The Seek behavior lets you specify any object or objects as a stationary or moving target for delegates. Delegates move toward the target during the crowd simulation while turning as necessary.

Interface

None (label)—Specifies a single target. Click this button, and then click the target object in the viewport. The target name then appears on the button.
If you've selected multiple targets using Multiple Selection (see next item), the word Multiple appears on the button. To see which objects are designated as targets, click the Multiple Selection button.

**Multiple Selection**—Opens the Select dialog to let you designate multiple targets. When you have more than one target, you can set delegates to move toward the closest target in the group, or to a computed average of the target positions.

**Seek Target group**
Determines seek activity when the behavior uses multiple targets.

**Closest Target Only**—Each delegate seeks the closest of the assigned targets. Use this to have delegates assigned a single Seek behavior move in different directions.

**Average Of Targets**—All delegates move toward a common point determined by averaging all targets' locations.

**Method group**
Determines whether delegate direction as influenced by the behavior is calculated by an angular method or a force method. Default=Angle.

**Angle**—Applies a force to the delegate based on the angle between the delegate’s current direction and the direction it would need to take in order to be moving directly toward the target.

The magnitude of the force is greatest when the delegate is moving away from the target, and needs to turn around. It can be as little as 0 when the delegate is directly approaching the target.

**Force**—Always applies a force directly towards the target. The magnitude of the force is constant.

**Radius group**
Use the optional radius settings to activate the Seek behavior only when the delegates are within a specific distance from the target. The relative strength of the Seek behavior increases from 0 percent beyond the outer radius to 100 percent at the inner radius.

**Use Radii**—When on, the Seek behavior applies only to delegates less than the Outer Radius distance from the target. Default=off.

**Inner Radius**—The distance from the target at which Seek is applied at full strength. Default=0.0.

**Outer Radius**—The distance from the target at which Seek begins to be applied. Default=10.0.

**Falloff**—Default=2.0.

**Display Radii**—The radii are displayed when the force is active.

**Color Swatch**—Shows the color used to draw the Seek force vector during the solution. Click the box to choose a different color. Default=green.

**Display Force**—When on, force exerted on the delegate(s) by the Seek behavior is drawn in the viewports as a vector during the simulation solution. If Use Radii is turned on, the radii are also displayed when the force is active.

---

**Space Warp Behavior**

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > New button > Space Warp Behavior

Select a Crowd object. > Modify panel > Setup rollout > New button > Space Warp Behavior

The Space Warp behavior lets space warps, such as wind or gravity, influence a crowd simulation. You can use it to apply space warps in the Forces
and Particles & Dynamics categories to crowd members.

In particular, use the Space Warp behavior to tie delegates to a Vector Field space warp (page 2–1241), so that they avoid penetrating an irregularly shaped object while following its contours.

**Interface**

None (label)—Click this button, then select a space warp object.

Color Swatch—shows the color used to draw the Space Warp force vector during the solution. Click the box to choose a different color.

Display Force—When on, force exerted on the delegate(s) by the Space Warp behavior is drawn in the viewports as a vector during the simulation solution.

**Speed Vary Behavior**

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > New button > Speed Vary Behavior

Select a Crowd object, > Modify panel > Setup rollout > New button > Speed Vary Behavior

The Speed Vary behavior is useful for objects whose velocity changes at random as they move, such as sightseeing tourists. Its parameters let you specify how often a delegate should change speed, what speed range it should look at for a new speed, and how long it should accelerate to get to that new speed.

**Interface**

- **Time group**

  Period—Specifies how many frames should elapse before a new speed is chosen.

  Deviation—Specifies the maximum amount by which Period should vary.

  Each time a period ends, character studio takes a random number between the negative and positive values of the Deviation setting, multiplies it by the Period setting, and adds the result to Period. Default=0.5. Range=0.0 to 1.0.

- **Speed group**

  The mathematical formula for the new speed is as follows: new speed = (delegate's Average Speed*Center)*(1 + RN*Center Deviation), where RN is a random number between -1 and 1.

  Center—Specifies the speed the delegate should change to. Center is a multiplier: A value of 0.0 means to stop, a value of 1.0 means to move at its *average speed*, and a value greater than 1.0 means to move faster than its average speed. Default=1.0. Range=0.0 to 99,999.0.
Deviation—Specifies the maximum amount by which the delegate’s calculated speed (Average Speed*Center) should vary.

Each time a period ends, character studio takes a random number between the negative and positive values of the Deviation setting, multiplies it by the calculated speed, and adds the result to the calculated speed. Default=0.25. Range=0.0 to 99,999.0.

Accel Period—Specifies the rate at which the delegate’s speed should change in relation to the period length.

A value of 0.0 means that the transition to the new speed will proceed as quickly as possible, and a value of 0.5 means the transition will take half the period. A value of 1.0 means the transition will take the entire period. Default=0.5. Range=0.0 to 1.0.

Deviation—Specifies the maximum amount by which acceleration should vary.

Each time a period ends, character studio takes a random number between the negative and positive values of the Deviation setting, multiplies it by the Acceleration setting, and adds the result to Acceleration. Default=0.5. Range=0.0 to 1.0.

Seed—Specifies a value for randomizing the Speed Vary behavior.

Seed—Specifies a value for randomizing the Speed Vary behavior.

The Surface Arrive behavior is similar to the Seek behavior (page 2–1220) in that it lets you specify an object or objects as a stationary or moving target for delegates. The principal difference is that Surface Arrive can cause delegates to stop when they reach the target. You can also specify, to some degree, where the delegate will stop on the object, and how it will approach the target before stopping.

An example of a use for this behavior would be birds flying over a row of telephone poles, then each one landing on top of a different pole.
None (label)—Specifies a single target. Click this button, and then click the target object in the viewport. The target name then appears on the button.

If you’ve selected multiple targets using Multiple Selection (see next item), the word Multiple appears on the button. To see which objects are designated as targets, click the Multiple Selection button.

Multiple Selection—Opens the Select dialog to let you designate multiple targets.

When you have more than one target, you can set delegates to move toward the closest target in the group, or to a computed average of the target positions.

Arrival group

Specifies three aspects of the Surface Arrive behavior: Rate, Speed, and Distance.

Disable After Arriving—When on, turns off the Surface Arrive behavior after the delegate arrives at the surface. Default=on.

Rate—A multiple of the delegate’s Max Accel setting that specifies the acceleration with which it will try to arrive. A value of 1.0 means to use the full acceleration of the delegate. Default=0.5.

Deviation—Adds random variation to the Rate setting.

The actual deviation is calculated by multiplying the Deviation setting by a random number between -1 and 1, and then multiplying the result by the Rate setting. Default=0.0.

Speed—The speed at which to arrive, relative to the speed of the target. Default=0.0.

Deviation—Adds random variation to the Speed setting. Default=0.0.

The actual deviation is calculated by multiplying the Deviation setting by a random number between -1 and 1, and then multiplying the result by the Speed setting.
**Distance**—The maximum radial distance from the target within which the behavior will be active. Default=9999999.0.

Until the delegate is within this radius, the behavior has no influence.

**Deviation**—Adds random variation to the to the Distance setting.

The actual deviation is calculated by multiplying the Deviation setting by a random number between -1 and 1, and then multiplying the result by the Distance setting. Default=0.0.

**Location group**

**Offset**—Specifies a consistent distance from the calculated arrival point, based on the surface normal, for the delegate to use. Default=0.0.

**Facing**—When on, the delegate will try to arrive only at points on triangles on the surface that are facing it. Default=off.

**Random**—The software chooses a random point on the target surface as the arrival point.

When using the Random option, the software chooses arrival points for delegates once, at the beginning of the simulation. This is the default choice.

**Closest**—The software chooses the closest point on the target surface as the arrival point.

If Closest is chosen, but Every Frame is off, the software chooses arrival points for delegates once, at the beginning of the simulation.

**Every Frame**—When on, the software chooses arrival points for delegates at every frame. Available only when Closest is chosen. Default=off.

Every Frame is useful when the target object is rotating during the animation, but requires more time for calculation.

**Display Offset**—When on, shows the Offset distance as lines emanating from each vertex in the surface object, perpendicular to the surface.

**Approach group**

The Height and Descent settings together specify the path the delegate will take for its arrival. They allow for a wide range of behavior, from soft, gradual landings to direct helicopter-type descents.

In both cases, the actual deviation is calculated by multiplying the Deviation setting by a random number between -1 and 1, and then multiplying the result by the relevant value.

**Height**—Specifies a distance from the arrival point along its face normal.

This is the point that the delegate will go to first before descending to the arrival point.

**Deviation**—Adds random variation to the to the Height setting.

The actual deviation is calculated by multiplying the Deviation setting by a random number between -1 and 1, and then multiplying the result by the Height setting.

**Descent Start**—Specifies the distance between the delegate and the arrival point at which the descent should start.

Note: Be careful that Descent Start is set high enough that the delegate won't overshoot when descending because its speed is too high and deceleration too low, compared to when it should start descending.

**Deviation**—Adds random variation to the to the Descent Start setting.

The actual deviation is calculated by multiplying the Deviation setting by a random number between -1 and 1, and then multiplying the result by the Descent Start setting.
**Off This Normal**—When on, lets you set an approach vector to specify the angle at which the final approach occurs. Default=off.

**X/Y/Z**—Use these settings to specify the final approach vector in world coordinates. For example, the vector specified by the default settings of X=0, Y=0, Z=1 means that the delegates will approach the target along the vertical world axis.

**Seed**—Affects the random numbers used to calculate the Deviation settings.

For similar randomization among different Surface Arrive behaviors, use the same Seed value.

**Color Swatch**—Shows the color used to draw the target icon. Default=dark blue.

**Display Target**—Enables display of the target icon, which appears during the solution when a new interim goal is calculated for the delegate. Interim goals are created when using the Approach group settings. Default=on.

**Target Scale**—Specifies the overall size of the target icon. Default=5.0.

---

**Surface Follow Behavior**

The Surface Follow behavior moves delegates with respect to object surfaces, which can be still or animated. For example, you can apply an animated Noise modifier to a patch grid to simulate a choppy water surface, and objects guided by Surface Follow will stay on top.

Note: By default, a delegate influenced by Surface Follow picks a direction to move in at any given frame based on its current facing and the plane of the face it’s currently over. Thus objects moving up a hill, while seeking a point at the bottom of the other side of the hill, tend to turn left or right to skirt the hill, rather than following the upward slope. You can override this with the Projection Vector option.

**Interface**

- **None (label)**—Specifies a single "target" object to use as a surface. Click this button, and then click the target object in the viewport. The target name then appears on the button.

If you’ve selected multiple targets using Multiple Selection (see next item), the word Multiple appears on the button. To see which objects are designated as targets, click the Multiple Selection button. The Select dialog appears with designated targets highlighted.

**Multiple Selection**—Opens the Select dialog to let you designate multiple targets.
When you have more than one target, delegates initially move toward the closest target in the group, and then move over its surface until they encounter another target, at which point they switch to its surface, and so on.

**Projection Vector group**

These controls let you override the default direction calculated by the Surface Follow behavior by describing a virtual plane along which the delegate is to move. You do this by specifying a vector, in world coordinates, that’s perpendicular to the desired virtual plane.

For example, if you want the delegate, when it encounters a hill, to keep moving forward, straight up and over the hill, instead of skirting it, you would use the default Projection Vector settings: \( X=Y=0, Z=1 \). This vector is aligned with the world Z (vertical) axis, so it specifies a plane parallel to the world XY plane. Thus, the delegate always moves straight ahead while following the surface.

**Use Projection**—When on, Surface Follow calculates delegate direction from the specified vector, rather than using the default.

**XY/YZ**—Specifies a vector using world coordinates. Default=\( X=Y=0, Z=1 \). Range=-1.0 to 1.0.

If only one of these settings is not 0, then the projection vector is aligned with the non-zero axis. Combine non-zero settings to create angled planes for Surface Follow. For example, to create a virtual plane that’s rotated 45 degrees clockwise about world Y axis, set \( X=Z=1 \) and \( Y=0 \). Also, while you can set all three axes to 0, that specifies no vector, and so effectively turns off Use Projection.

**Position on Surface group**

**Offset**—Specifies the delegate’s distance above the surface, using the surface normal. Recalculated at each frame.

**Display Offset**—When on, shows the Offset distance as lines emanating from each vertex in the surface object, perpendicular to the surface.

**Color Swatch**—Shows the color used to draw the Surface Follow target (see Display Target, next) during the solution. Click the box to choose a different color.

**Display Target**—When on, the interim goal for each delegate influenced by the Surface Follow behavior is drawn in the viewports as a wireframe sphere during the simulation solution.

If the delegate starts out away from the surface to be followed, the target is most visible before the delegate reaches the surface; the target is then positioned along the surface edge. While the delegate is actually following the surface, the target is usually coincident with the delegate, because Surface follow sets a new destination only a frame or two ahead.

**Target Scale**—Sets the target size.

---

**Wall Repel Behavior**

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > New button > Wall Repel Behavior

Select a Crowd object. > Modify panel > Setup rollout > New button > Wall Repel Behavior

The Wall Repel behavior uses one or more grid objects to repel delegates. When influenced by the Wall Repel force, delegates turn until they’re heading away from the grid. It’s useful for keeping objects inside a straight-sided enclosure, such as a room in a building.

You can set the grids to repel from either side or both sides, and optionally specify a maximum distance for repelling. You can also set the behavior to act as though each grid extends infinitely along its plane.
Note: The Wall Repel behavior simply applies a force on the delegate in the direction opposite the wall; it does not guarantee that the delegate won’t go through the wall. If the delegate does go through the wall, adjust settings such as Inner and Outer Distance, and, in particular, try reducing Falloff.

**Method group**

Determines whether delegate direction as influenced by the behavior is calculated by an angular method or a force method. Default=Force.

**Angle**—Applies a force to the delegate based on the angle between the delegate’s current direction and the direction it would need to take in order to be moving directly away from the source.

The magnitude of the force is greatest when the delegate is moving directly towards the source, and needs to turn around. It can be as little as 0 when the delegate is moving directly away from the source.

**Force**—Always applies a force directly away from the source. The magnitude of the force is constant.

**Direction group**

Determines whether the grid repels from its positive-axis side, its negative-axis side, or both.

To determine which is the positive-axis side, select the grid, and then set the reference coordinate system to Local (the default system is View). Look at the grid in a viewport in which it appears edge-on. The side with the axis sticking out is the positive-axis side, and the opposite side is the negative-axis side.

**Tip:** For ease of setup, when building a “room” from grids, make sure they all point inward (or outward).

**Positive Axis**—The grid repels only from the positive-axis side.

**Negative Axis**—The grid repels only from the negative-axis side.

**Both Axes**—The grid repels from both sides.

**Distance group**

Use the distance settings to activate the Wall Repel behavior only when the delegates are within a
specific distance from the target. The relative strength of the behavior increases from 0 percent at the outer radius to 100 percent at the inner radius.

**Use Distance**—When on, the behavior applies only to delegates closer to the target than the Outer Distance value. Default=on.

**Inner Distance**—The distance from the target at which the force is applied at full strength. Default=0.0.

**Outer Distance**—The distance from the target at which the force begins to be applied. Default=10.0.

**Falloff**—The rate at which the repelling force diminishes between the Inner Distance and the Outer Distance. Default=2.0.

A value of 1.0 indicates a linear falloff. Higher values cause the strength to fall off to zero more rapidly with distance, thus focusing its effect closer to the Inner Distance. Lower values reduce the rate of diminishment, with a Falloff setting of 0.0 indicating that the strength is the same at the Outer Distance as it is at the Inner Distance.

**Display Distance**—Shows the inner and outer distance settings as grids offset from the target grid in the viewports. The Inner Distance grid is light blue, while the Outer Distance grid is blue-white. Default=on.

**Grid Spacing**—Alters the spacing of grid lines used to draw the Inner/Outer Distance grids. The lower the value, the closer the spacing. Default=500.

**End force at grid edges**—When on, the force emanates only from the grid object. When off, the force emanates from an imaginary infinite grid created by extending the grid plane in all directions.

**Color Swatch**—Shows the color used to draw the Wall Repel force during the solution. Click the box to choose a different color. Default=violet.

**Display Force**—The force, when activated, is drawn in the viewports as a wireframe rectangle during the simulation solution. Default=on.

---

**Wall Seek Behavior**

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > New button > Wall Seek Behavior

Select a Crowd object. > Modify panel > Setup rollout > New button > Wall Seek Behavior

The Wall Seek behavior uses a grid object to attract delegates. When influenced by the Wall Seek force, delegates turn until they’re heading toward the grid. It’s useful for moving objects toward a rectangular area, such as a doorway.

You can set the grid to attract from either side or both sides, and optionally specify a maximum distance for attraction. You can also set the behavior to act as though the grid extends infinitely along its plane.
### Interface

![Wall Seek Behavior Interface](image)

**Grid to seek**—Set the target grid by clicking the button (initially labeled “None”) and then selecting the grid. Thereafter, the grid’s name appears on the button.

**Method group**

Determines whether delegate direction as influenced by the behavior is calculated by an angular method or a force method. Default=Angle.

- **Angle**—Applies a force to the delegate based on the angle between the delegate’s current direction and the direction it would need to take in order to be moving directly toward the target.

  The magnitude of the force is greatest when the delegate is moving away from the target, to turn around. It can be as little as 0 when the delegate is directly approaching the target.

- **Force**—Always applies a force directly towards the target. The magnitude of the force is constant.

**Direction group**

Determines whether the grid attracts from its positive-axis side, its negative-axis side, or both.

To determine which is the positive-axis side, select the grid, and then set the reference coordinate system to Local (the default system is View). Look at the grid in a viewport and check the direction of the Z-axis arrow. This arrow determines the positive-axis direction. The opposite direction is the negative-axis direction.

- **Positive Axis**—The grid attracts only from the positive-axis side.
- **Negative Axis**—The grid attracts only from the negative-axis side.
- **Both Axes**—The grid attracts from both sides.

**Distance group**

Use the distance settings to activate the Wall Seek behavior only when the delegates are within a specific distance from the target. The relative strength of the behavior increases from 0 percent at the outer distance to 100 percent at the inner distance.

- **Use Distance**—When on, the behavior applies only to delegates closer to the target than the Outer Distance value. Default=on.
- **Inner Distance**—The distance from the target at which the force is applied at full strength. Default=0.0.
- **Outer Distance**—The distance from the target at which the force begins to be applied. Default=10.0.
**Falloff**—The rate at which the attracting force diminishes between the Inner Distance and the Outer Distance. Default=2.0.

A value of 1.0 indicates a linear falloff. Higher values cause the strength to fall off to zero more rapidly with distance, thus focusing its effect closer to the Inner Distance. Lower values reduce the rate of diminishment, with a Falloff setting of 0.0 indicating that the strength is the same at the Outer Distance as it is at the Inner Distance.

**Display Distance**—Shows the inner and outer distance settings as grids offset from the target grid in the viewports. The Inner Distance grid is light blue, while the Outer Distance grid is blue-white. Default=on.

**Grid Spacing**—Alters the spacing of grid lines used to draw the Inner/Outer Distance grids. The lower the value, the closer the spacing. Default=500.

**End force at grid edges**—When on, the force emanates only from the grid object. When off, the force emanates from an imaginary infinite grid created by extending the grid plane in all directions.

**Color Swatch**—Shows the color used to draw the Seek force vector (and, if used, the radii) during the solution. Click the box to choose a different color. Default=violet.

**Display Force**—When on, force exerted on the delegates by the Seek behavior is drawn in the viewports as a vector during the simulation solution. If Use Radii is turned on, the radii are also displayed when the force is active.

---

**Wander Behavior**

Create panel > Helpers > Object Type rollout > Crowd > Setup rollout > New button > Wander Behavior

Select a Crowd object. > Modify panel > Setup rollout > New button > Wander Behavior

The Wander behavior imparts a random motion to delegates, letting you simulate meandering activity in which delegates move and turn in a haphazard manner. It works by randomly picking a new direction, and then turning and moving in that direction. You can specify how often to pick a new direction, how far to turn, and how fast or slow to turn while moving.

Tip: The trajectory calculated by the Wander behavior varies significantly for each object to which it’s applied. To create a group of wandering delegates all using the same trajectory, apply the Wander behavior to a delegate, solve the simulation, and then replicate the delegate using the Scatter Objects (page 2–1189) facility with Clone Controllers turned on.

**Procedure**

**To use the Wander behavior:**

1. Add a Wander behavior to the Crowd object.
2. Change the default settings as desired. Probably the most important is Period, which sets the number of frames between changes of direction.
3. Use Behavior Assignments (page 2–1200) to assign the behavior to a delegate or team.
Chapter 14: character studio

Interface

### Time group

**Period**—Specifies how many frames should elapse before a new direction is chosen. Default=10.

**Deviation**—Specifies the maximum amount by which Period should vary. Each time a period ends, *character studio* takes a random number between the negative and positive values of the Deviation setting, multiplies it by the Period setting, and adds the result to Period. Default=0.5. Range=0.0 to 1.0.

### Turning group

**Angle**—Specifies how far to turn when changing direction. A small value means to change direction by only a small amount, while as the value approaches 1.0 the delegate will turn randomly in any direction. Default=0.5. Range=0.5 to 1.0.

**Turn Period**—Specifies how long over the current period it takes to turn. A value of 0.0 means that the delegate will rotate as quickly as possible to face a direction and then travel in that direction, while a value of 1.0 means the delegate will take the entire period to rotate in that direction. Default=0.5. Range=0.5 to 1.0.

**Deviation**—Specifies the maximum amount by which Angle should vary. Each time a period ends, *character studio* takes a random number between the negative and positive values of the Deviation setting, multiplies it by the Angle setting, and adds the result to Angle. Default=0.5. Range=0.0 to 1.0.

**Seed**—Specifies a seed value for randomizing the Wander behavior.

**Color swatch**—Shows the color used to draw the Wander force vector during the solution. Click the box to choose a different color.

**Display Force**—When on, force exerted on the delegates by the Wander behavior is drawn in the viewports as a vector during the simulation solution.

### Solve Rollout

Once you’ve set up the crowd simulation, use this rollout to set solution parameters and to solve the simulation. You can solve continuously or a frame at a time, starting at any frame.
Solve Rollout

**Interface**

<table>
<thead>
<tr>
<th>Solve</th>
<th>Step Solve</th>
</tr>
</thead>
</table>

- Simulation Start: 0
- Start Solve: 0
- End Solve: 100
- Delete Keys before Solve
- Save every Nth Key: Positions: 1, Rotations: 1

**Display During Solve**

- Update Display
- Frequency: 1
- Vector Scale: 10.0

**MAXScript**

- Use MAXScript
- Function Name: PerFrameFn
- Edit MAXScript

**Biped**

- Biped/Delegates Only
- Use Priorities
- Backtracking

---

**Solve**—Runs the crowd simulation continuously, applying all specified behaviors to delegates to which they are assigned. Solving a simulation overwrites any previous solutions.

To abort a solution in progress and save all keys generated up to that point, press the **Esc** key. Alternatively, with complex simulations, you can save time by pressing **Shift+Esc** to abort a solution without saving keys.

**Step Solve**—Runs the crowd simulation one frame at a time, starting at the current frame as specified by the time slider position. Press the **spacebar** to advance one frame.

To abort a solution in progress and save all keys generated up to that point, press the **Esc** key. When you do so, the software disregards any non-default settings for Save Every Nth Key. Alternatively, with complex simulations, you can save time by pressing **Shift+Esc** to abort a solution without saving keys.

Note: Step Solve always starts at the current frame; it disregards the Simulation Start setting.

**Simulation Start**—The first frame of the simulation. Default=0.

To make the solution repeatable, set this and keep it the same.

**Start Solve**—The frame at which you begin solving. Default=0.

This value must be greater than or equal to that of Simulation Start. If greater, the solve will begin in the middle of the simulation.

Start Solve should equal Simulation Start the first time you solve, so that when you set Start Solve to start in the middle of the simulation, the simulation up to that point will be correct.

Note: If you set Start Solve to a frame number lower than the first frame of the active time segment, **character studio** changes the first frame of the time segment to the Start Time value.

**End Solve**— Specifies the last frame considered for the solution. Default=100.

Note: If you set End Solve to a frame number higher than the last frame of the active time segment, **character studio** changes the last frame of the time segment to the End Solve value.
Delete Keys before Solve—Deletes the keys of active delegates in the range over which the solution takes place. Default=off.

This option leaves the first two keys so that the delegate doesn’t end up with no keys and then pop to its current position. This is a useful feature for biped crowds; it lets you watch each biped compute, one after another, without the ones not yet computed still performing their old animation.

Save every Nth Key—Lets you specify the number of position and rotation keys saved after the solution.

Positions/Rotations—The frequency with which keys are saved for delegate positions and rotations. If 0, no keys are saved. If 1, a key is saved every frame. If 2, a key is saved every other frame, and so on. Defaults=1.

Display During Solve group

Update display—When on, motion produced during solution of a crowd simulation appears in the viewports. Default=on.

Frequency—How often the display is updated during the solution. If 1, the update occurs every frame. If 2, the update occurs every other frame, and so on. Default=1.

Vector Scale—Globally scales all force and velocity vectors that are displayed during the simulation. Default=10.0.

Scaling vectors up helps to see them better when they are very small. It does not effect the simulation.

MAXScript group

This feature lets you execute a MAXScript script at each frame. Its primary purpose is for working with bipeds; specifically, to take advantage of available MAXScript calls to Biped that let you specify which clip the biped will be likely to choose next when using the shared motion flow feature.

With this feature, you can write a script that dynamically selects the biped’s next clip during the Crowd simulation, based on which clip is currently being used, the frame number, the proximity of other bipeds, or anything else that you can find out in a script. Of course, this scripting feature can be used for other purposes as well.

Use MAXScript—When on, a user-specified script is executed at each frame during the solution. Default=off.

Function Name—The name of the function to be executed. This name must also specified in the script.

Edit MAXScript—Click this button to open a MAXScript window for displaying and modifying the script.

Bipeds group

When solving simulations that use bipeds linked to delegates, it is strongly recommended that you use all three options in this group.

Biped/Delegates Only—When on, only biped/delegates are included in the computation. Also, the options to use priorities and backtracking become available. These options are available only for biped-only computations. Default=off.

Use Priorities—When on, biped/delegates are computed one delegate at a time, in order of their Priority values, from lowest to highest. Also, backtracking becomes available, and Step Solve becomes unavailable. Default=off.

Backtracking—Turns on backtracking functionality when solving a crowd simulation that uses bipeds. Default=off.

When Backtracking is on during the solution, in the case of an impending collision between bipeds, the Crowd system will back up the simulation to the beginning of the current clip, and then
try a different traversal of the lower-priority delegate/biped’s motion flow graph. If necessary, the system will back up two or more clips.

**Priority Rollout**

Create panel > Helpers > Object Type rollout > Crowd > Priority rollout

Select a Crowd object. > Modify panel > Priority rollout

The Crowd system uses the Priority rollout settings when solving a simulation involving bipeds associated with delegates. The Priority parameter is a positive integer assigned by the user to a delegate. When priorities are used, the Crowd simulation computes one biped at a time, based on its priority setting from lowest to highest; that is, a lower Priority setting means a higher priority. If the priorities of two biped/delegates are the same, the computation order of those two biped/delegates is randomly determined.

This topic describes the six different ways of setting a delegate’s priority, and how priorities might be put to use in different situations.

**Using Priorities**

If you have a large crowd all going in one direction, you would typically want the delegates in front to solve first. In that case, using Proximity To An Object or Proximity To A Grid would be useful in setting priorities.

In a case where you start with a circle of bipeds, and you want them all to wander and mingle, you might not care about the bipeds’ priorities. You could let them all have the same priority and let the system decide which goes first. However, it might be better to assign random priorities or make priorities unique, so that you are guaranteed the same order each time, and you can read the priority numbers to know what will happen next. This also lets you change the order if you need to.

Suppose you have two groups of bipeds, all of which are assigned random priorities. If you wanted to keep the priority relationships within each group, but make one group start after or before the other, you could use Increment Priorities to increment or decrement all the priorities in one group.

If none of the algorithms applies to your situation, you need some way to set the priorities by hand. It’s useful to be able to set them visually. That’s what the Assign By Picking method is for.
### Interface

#### Assign by Picking group

**Pick/Assign**—Lets you assign successively higher Priority values to any number of delegates by selecting each in turn in the viewport. The first delegate you select is assigned the Start Priority value. The Priority value assigned to each succeeding delegate you select is incremented by one.

To stop assigning priorities, right-click in a viewport or click the Pick/Assign button again.

Delegate priorities appear in viewports as black numerals attached to each delegate; they’re usually most easily seen in Wireframe views.

Note: You can undo and/or redo assignments during the process.

Tip: It’s possible to assign two or more delegates the same priority value using this method. In such a case, for more predictable behavior, use Make Priorities Unique so that delegates don’t share priorities.

#### Assign by Computation group

This group provides five different methods for assigning priorities to delegates, plus a button for selecting delegates to be affected by these methods.

**Delegates to Prioritize**—Lets you use the Select dialog to specify delegates to be affected by subsequent use of other controls within this group. Select the delegates with the Select dialog, and then click Select to exit the dialog. This selection applies only to Proximity assignments (that is, Proximity To An Object and Proximity To A Grid).

**Proximity to an Object**—Lets you assign priorities based on delegates’ distance from a specific object. To specify the object, click the None button, and then select the object on which priorities are to be based. Lastly, click the Assign button to compute and assign priorities. The delegate closest to the object is assigned the Start Priority value, and each subsequent delegate is assigned a higher Priority value.

**Proximity to a Grid**—Assigns priorities based on the grid's closest point to a delegate.

**Assign Random Priorities**—Assigns random values to delegates.

**Make Priorities Unique**—Ensures that no two delegates share the same priority.

**Increment Priorities**—Lets you increment the current priority by a specified amount.

**Increment**—Sets the amount by which to increment the priority.

**Set Start Frames**—Sets the start and end frames for the priorities assignment.

**Display Priorities**—Displays the priorities in the viewport.

**Display Start Frames**—Displays the start and end frames in the viewport.

### Start Priority—Sets the initial priority value.

Applies to the first four methods of setting priorities: Assign By Picking, Proximity To An Object, Proximity To A Grid, and Assign Random Priorities. Default=0.

Note: Priority is assigned in increasing order. Thus, a delegate with Priority value 0 goes before a delegate with Priority 1, 1 goes before 2, and so on.
successively farther delegate is assigned the next highest priority.

For any delegates that are equidistant from the object, the software assigns priorities randomly.

**Proximity to a Grid**—Lets you assign priorities based on delegates' distance from an infinite plane defined by a specific grid object. To specify the grid object, click the None button, and then select the grid object on which priorities are to be based. Lastly, click the Assign button to compute and assign priorities. The delegate closest to the grid object is assigned the Start Priority value, and each successively farther delegate is assigned the next highest priority.

For any delegates that are equidistant from the plane, the software assigns priorities randomly.

**Assign Random Priorities**—Assigns random priorities to the selected delegates. The range of priority values assigned lies between the Start Priority value and that value plus the number of selected delegates.

**Make Priorities Unique**—Ensures that all delegates have unique priority values. If two delegates share the same priority, one of them will be given a new priority value that differs from the rest.

**Increment Priorities**—Increments the priorities of all selected delegates by the Increment value.

**Increment**—Sets the value by which the Increment Priorities button adjusts delegate priorities. Use a negative Increment value to decrement priorities. Default=0.

**Set Start Frames**—Opens the Set Start Frames dialog (page 2–1237), for setting start frames based on assigned priorities.

**Display Priorities**—Enables the display of assigned priority values as black numerals attached to the delegates. Default=off.

**Display Start Frames**—Enables the display of assigned start frame values as black numerals attached to the delegates. Default=off.

When both Display Priorities and Display Start Frames are on, the two values are displayed side by side, separated by a slash symbol (/). The priority appears to the left of the slash and the start frame appears to the right.

### Set Start Frames Dialog

Create panel > Helpers > Object Type rollout > Crowd > Priority rollout > Set Start Frames button

Select a Crowd object. > Modify panel > Priority rollout > Set Start Frames button

When you include bipeds in a crowd simulation using a shared motion flow, you usually don't want them all walking in lockstep formation. You can avoid this by setting different start frames to vary the animation frame at which each biped starts moving using its initial motion clip. In most cases, you would set start frames in the same order as priority, so you don't get bipeds with earlier start frames stuck behind bipeds with later start frames. The Set Start Frames dialog lets you automatically assign start frames to delegates in the same order as priority.

This dialog assigns start frames to the delegates selected via the Delegates To Prioritize control. In general, you should first use a non-random method to assign priorities in the Priority rollout (page 2–1235), such as the Pick/Assign button or one of the Proximity options, and then assign start frames with this dialog. You can use the dialog to set a start frame for the highest-priority delegate (that is, the delegate with the lowest Priority setting), and then have start frames incremented randomly between two limits for the remaining delegates, based on priority order.
For instance, if you set Lowest Start Frame to 0, Minimum Number ... to 1, and Maximum Number to 3, you could get a start frame sequence like this: 0, 2, 5, 6, 8, and so on. If you want more regularly staggered start frames, set Minimum and Maximum to the same value. For example, with Lowest Frame=0 and Minimum/Maximum both set to 2, you'd get: 0, 2, 4, 6, 8, etc.

**Interface**

**Lowest Start Frame**—Sets the start frame assigned to the delegate with the lowest Priority setting.

**Minimum number of frames between consecutive start frames**—The smallest value the software will use to increment assigned start frames.

**Maximum number of frames between consecutive start frames**—The largest value the software will use to increment assigned start frames.

**Delegates with the same priority get the same start frame**—The software assigns the same start frame to any delegates with identical Priority settings. When off, the software randomizes the order of same-priority delegates’ start frames. Default=on.

**OK**—Assigns start frame values to selected delegates based on the dialog settings and priority order and closes the dialog.

**Cancel**—Closes the dialog without changing start frame values.

---

**Smoothing Rollout**

Create panel > Helpers > Object Type rollout > Crowd > Smoothing rollout

Select a Crowd object. > Modify panel > Smoothing rollout

Smoothing works on existing animation keys (that is, a solved simulation) to create more natural-looking animation. Use these controls if solving a crowd simulation results in abrupt position or rotation changes of animated objects. By default, smoothing works by reducing keys. As an option, it can also filter (average) existing animation keys to make changes more gradual, resulting in more natural motion.
Interface

- **Smoothing**
  - Select Objects to Smooth
  - Filter delegate selection
  - Whole Animation
  - Animation Segment
    - From: 0
    - To: 0
  - Positions
  - Rotations

Reduction group

- **Reduce**
  - Keep every Nth key
    - N: 2

Filtering group

- **Filter**
  - Past Keys: 2
  - Future Keys: 2
  - Smoothness: 4

**Perform Smoothing**

**Select Objects to Smooth**—Opens the Select dialog, which lets you specify which objects’ positions and/or rotations to smooth.

**Filter delegate selection**—When on, the Select dialog opened by the Select Objects To Smooth button shows only delegates. When off, it shows all scene objects. Default=on.

**Whole Animation**—Smoothes all animation frames. This is the default option.

**Animation Segment**—Smoothes only the frame ranges specified in the From and To fields.

**From**—When Animation Segment is chosen, specifies the first animation frame for smoothing.

**To**—When Animation Segment is chosen, specifies the last animation frame for smoothing.

**Positions**—When on, selected objects’ animation paths generated via the simulation are smoothed after the simulation has finished. Default=on.

**Rotations**—When on, selected objects’ rotations generated via the simulation are smoothed after the simulation has finished. Default=on.

**Reduction group**

- **Reduce**—Reduces the number of keys by keeping only every Nth key.

**Keep every Nth key—N**: Limits the amount of smoothing by keeping every other key (N=2), or every third key (N=3), and so on. Default=2.

**Filtering group**

Smoothing works by averaging the delegate’s current position and/or orientation with those several keyframes ahead and behind. All keyframes used in the calculation can be affected. These settings let you control the number of keyframes used and the extent of smoothing performed.

- **Filter**—When on, smoothing is performed using the remaining settings in this group.

- **Past Keys**—The number of keys prior to the current frame used for averaging position and/or rotation. Default=2.

- **Future Keys**—The number of keys after the current frame used for averaging position and/or rotation. Default=2.

- **Smoothness**—Determines the degree to which smoothing is performed. The higher the setting, the closer all keys involved in the calculation are moved toward the average value. Default=4.
The highest available Smoothness value is always 6. The lowest available value depends on the Past Keys and Future Keys settings.

**Perform Smoothing**—Click this button to carry out the smoothing operation.

*Note:* If neither the Reduce nor the Filter check box is turned on, no smoothing is performed.

**Collisions Rollout**

Create panel > Helpers > Object Type rollout > Crowd > Collisions rollout

Select a Crowd object. > Modify panel > Collisions rollout

During a crowd simulation, you can use this rollout to keep track of collisions defined by Avoid behaviors. A delegate whose hard radius as defined by the Avoid behavior intersects with the hard radius of anything it is avoiding is marked as having collided at that frame. If too many collisions occur, the simulation might not provide satisfactory results; in such cases, you might want to alter the simulation setup.

**Interface**

- **Hilite Colliding Delegates**—When on, delegates that collide are highlighted in the collision color.

  **Only during collisions**—Colliding delegates are highlighted only in frames in which they actually collide.

  **Always**—Colliding delegates are highlighted in frames in which they collide and all subsequent frames.

  **Collision Color**—The color swatch indicates the color used to highlight colliding delegates. To change the color, click the swatch and use the Color Selector dialog to set a new color.

  **Clear Collisions**—Clears collision information from all delegates.

  If you re-solve part of the simulation, new collision information for the recomputed frames will be computed. However, if you move a delegate manually, its collision information will remain the same, and may be incorrect. In such cases, use Clear Collisions to correct the collision information.

**Geometry Rollout**

Create panel > Helpers > Object Type rollout > Crowd > Geometry rollout

Select a Crowd object. > Modify panel > Geometry rollout

Use this parameter to modify the crowd object’s size.

**Interface**

**Icon Size**—Determines the size of the Crowd helper object’s icon.

This setting is primarily for visibility; it has no effect on the crowd simulation.
Global Clip Controllers Rollout

Create panel > Helpers > Object Type rollout > Crowd > Global Clip Controllers rollout

Select a Crowd object. > Modify panel > Global Clip Controllers rollout

Use global clip controllers when assigning non-biped animated objects (such as a bird flapping its wings) to delegates in a crowd simulation. Applications include synthesis of animation activity based on a variety of criteria, such as an object’s speed, acceleration, and pitch. This group of controls replicates the Track View controls for the same functionality. For an in-depth discussion of global clip controllers and related topics, see:

Non-Biped Crowds (page 2–1179)
Synthesis Dialog (page 2–1246)
ClipState Dialog (page 2–1253)

For a procedure covering clip controller usage, see:

To use Motion Synthesis with non-bipedal creatures: (page 2–1180)

Interface

(List)—Lists objects designated as Global Objects, whose controllers can be used as animation clips to control other objects (typically clones).

To designate an object as a Global Object, click the New button, and then select the object in the Select dialog.

New—To designate a Global Object and add it to the list, click this button, and then select the object in the Select dialog.

Edit—To modify a Global Object’s properties, click its name in the list, and then click this button. This opens the Synthesis dialog (page 2–1246).

Load—Loads a previously saved Global Motion Clip (.ant) file from disk.

Save—Stores the current Global Motion Clip settings on disk in the .ant file format.

Vector Field Space Warp

Create panel > Space Warps > Particles & Dynamics > Object Type rollout > Vector Field

A vector field is a special type of space warp that crowd members use to move around irregular objects such as curved, concave surfaces. The Vector Field gizmo, a box-shaped lattice, is placed and sized so that it surrounds the object to be avoided. The vectors are generated from the lattice intersections. These vectors are, by default,
perpendicular to the surface of the object to which the field is applied; if necessary, you can smooth them out with a blending function. The crowd members move around the object by traveling perpendicular to the vectors.

You can use the vector field as a *Space Warp behavior* (page 2–1221), as the source object for an *Avoid behavior* (page 2–1211), or both. When used together, delegates slow down when they approach a complex object, and then go around it. This guarantees that delegates will not pass through the obstacle’s surface.

The vector field includes settings for strength, falloff, and a push/pull effect, as well as options to display the lattice, the effective range, and the vectors.

The Vector Field space warp provides these rollouts:

*Create Method Rollout (page 2–1242)*

*Lattice Parameters Rollout (page 2–1242)*

*Obstacle Parameters Rollout (page 2–1242)*

**Create Method Rollout**

Create panel > Space Warps > Particles & Dynamics > Object Type rollout > Vector Field > Create Method rollout

The Create Method rollout for the Vector Field space warp lets you specify whether to create the vector field using the cube or box method.

**Interface**

**Cube**—Forces length, width, and height to be equal.

Creating a cube-shaped space warp is a one-step operation. Starting at the center of the cube, drag in a viewport to set all three dimensions simultaneously. You can change the individual dimensions in the Lattice Parameters rollout.

**Box**—Creates a standard box-shaped space warp from one corner to the diagonally opposite corner, with different settings for length, width, and height.

**Lattice Parameters Rollout**

Create panel > Space Warps > Particles & Dynamics > Object Type rollout > Vector Field > Lattice Parameters rollout

Select a Vector Field space warp. > Modify panel > Lattice Parameters rollout

Use these parameters to specify the Vector Field lattice size and number of segments.

**Interface**

**Length/Width/Height**—Specify the dimensions of the lattice. The lattice should be larger than the Vector Field object.

**Length Segs/Width Segs/Height Segs**—Specify the resolution of the Vector Field lattice. The greater the resolution, the higher the accuracy of the simulation.

**Obstacle Parameters Rollout**

Create panel > Space Warps > Particles & Dynamics > Object Type rollout > Vector Field > Obstacle Parameters rollout

Select a Vector Field space warp. > Modify panel > Obstacle Parameters rollout

A vector field (page 2–1241), generated around an *obstacle object*, allows crowd (page 2–1187) members to avoid that object in a scene. The field consists of a three-dimensional array of vectors which guide delegates or other objects around the obstacle. The settings in this rollout help determine how the vectors are generated and displayed, and how they affect other objects.
Note: Objects are subject to a vector field’s forces only if they are bound to the field with a Crowd object. For general usage guidelines, see *To use a Vector Field space warp* (page 2–1166).

**Interface**

**Display group**

The check boxes in this group let you enable and disable display of four different elements of the Vector Field space warp.

**Show Lattice**—Displays the vector field lattice, a yellow wireframe box. Default=on.

The vectors are generated at lattice intersections inside the vector field range.

**Show Range**—Displays the volume about the obstacle object within which vectors are generated, as an olive-colored wireframe. Default=on.

The range starts out the same shape and size as the obstacle object, and is typically enlarged with the Compute Vectors group > Range setting.

**Show Vector Field**—Displays vectors, which appear as blue lines emanating outward from lattice intersections within the range volume. Default=off.

**Show Surface Samples**—Displays short green lines emanating from sample points on the surface of the obstacle object. Default=off.

These appear only after you’ve *computed* the vector field. See *Sample Resolution* for more information.

**VectorScale**—Scales the vectors so they’re more visible or less obtrusive. Default=1.0.

Note: This setting does not affect the strength of the vectors; only their visibility.

**Icon Size**—Adjusts the size of the Vector Field space warp icon, a pair of crossed double-headed arrows. Increase the size for easier viewport selection. Default=original size originally drawn in viewport.

**Force group**

These parameters determine how the vector field affects objects within its volume.

Changing any of the Force group settings does not require that you recalculate the vector field.

Note: Using a vector field does not guarantee that delegates or particles remain at a particular distance from the obstacle. In some cases you might have to animate the Strength, Falloff, and/or Pull settings to keep delegates within the vector field.

**Strength**—Sets the degree of effect the vectors have on the movement of an object entering the
vector field. If *Show Vector Field* is on as you adjust Strength, you can see the vector lines change size in the viewports in real time. Default=1.0.

Note: Sometimes, after changing strength, vectors will be too large or too small. In such cases, adjust the *Vector Scale* parameter so that they display properly.

**Falloff**—Determines the rate at which the strength of the vectors falls off with distance from the surface of the object. Default=2.0.

A value of 0 will make all the vectors the same size. A value greater than 0 will make them get smaller as they get farther away from the object surface. A value less than 0 will make them get larger as they get farther away.

**Parallel/Perpendicular**—Sets whether the force generated by the vectors works parallel or perpendicular to the vector field. Default=Perpendicular.

Because the vectors are perpendicular to the object surface, and you typically would want delegates to travel parallel to the surface, you would normally use a perpendicular force.

**Pull**—Adjusts objects’ position relative to the field. Available only when Perpendicular is chosen. Default=0.0. Range=-1.0 to 1.0.

Objects moving perpendicular to a vector field sometimes tend to drift away from it, due to lack of subsampling. The Pull parameter helps to pull objects back. Pull values greater than 0 create a pulling force towards the source of the vector field vector. Values less than 0 pull the force towards the direction in which the vector field’s vector is pointing. A value of 0.0 produces a force perfectly perpendicular to the vector field’s vector.

### Compute Vectors group

**Compute Vectors**

- **Vector Field Object**—Lets you designate the obstacle object. Click this button, and then select the object around which the vector field is to be generated. Thereafter the object’s name appears on the button (which is intially labeled “None”).

Note: You can only use primitives and unmodified editable mesh objects as obstacles. Also, the object should be fully enclosed in the Vector Field lattice.

- **Range**—Determines the volume within which vectors are generated. Default=1.0.

The range is represented in viewports as an olive-colored wireframe that starts out the same size and shape as the obstacle object. Increasing the Range setting moves the wireframe away from the obstacle object in the direction of its surface normals.

In crowd simulations, the Range outline is where the delegates start to "see" the obstacle object, and begin to turn to avoid it. If your crowd members are penetrating the obstacle, or even just coming too close to it before turning, increase the Range setting. Also try increasing the Vector Field lattice resolution and/or the Sample Res setting.

- **Sample Res**—Acts as a multiplier of the effective sampling rate used on the obstacle object’s surface to calculate vector directions in the field. Default=1.
The basic sampling rate is determined by the program from the size of the lattice and the size of each polygon.

**Use Flipped Faces**—Causes flipped normals to be used during the computation of the vector field. Default=off.

By default, vectors are generated in the same direction as the obstacle object’s face normals, so that assuming these face normals point outward, objects move around its exterior in a crowd simulation. However, if you want objects to remain within an object’s interior, turn on Use Flipped Faces.

Tip: If you run a crowd simulation inside an object that is also being viewed from the inside, such as a room, you’ll probably want the object’s faces to point inward. In that case, use Editable Mesh/Edit Mesh > Surface Properties to flip the normals, and don’t turn on Use Flipped Faces.

**Compute**—Calculates the vector field.

Always recalculate the vector field after changing any parameters except those in the Force group.

**Blend Vectors group**

<table>
<thead>
<tr>
<th>Blend Vectors</th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Start Dist:</td>
<td>0.0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Falloff:</td>
<td>2.0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Blend segs X:</td>
<td>1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Blend segs Y:</td>
<td>1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Blend segs Z:</td>
<td>1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Blend</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Use the Blend Vectors parameters to reduce abrupt changes in the angles of neighboring vectors. For example, if you have a wavy surface, you might get wavy vectors very far out from the surface, which could adversely affect the simulation. Use Blend Vectors to correct this condition.

**Start Dist**—The distance from the object at which you want to start blending the vectors. Default=0.0.

**Falloff**—The falloff of the blend of the surrounding vectors. Default=2.0.

**Blend segs X**—The number of adjacent lattice points to blend on the X-axis. Default=1.

**Blend segs Y**—The number of adjacent lattice points to blend on the Y-axis. Default=1.

**Blend segs Z**—The number of adjacent lattice points to blend on the Z-axis. Default=1.

**Blend**—Click this button to implement the blending.

---

**Motion Synthesis**

The Crowd system in **character studio** can use two different types of **motion synthesis**, which lets the software adjust the simulation results dynamically to account for differing conditions. This section deals with the application of motion synthesis to non-bipedal crowds, such as a flock of birds.

You use two dialogs to set up non-bipedal motion synthesis:

- **Synthesis Dialog** (page 2–1246)
- **ClipState Dialog** (page 2–1253)

For information on using motion synthesis with bipeds, see **Biped Crowds** (page 2–1172).
Chapter 14: Character Studio

Synthesis Dialog

Select a Crowd object. > Modify panel > Global Clip Controllers rollout > New > Choose a GlobalClip object. > Select the object in the list. > Edit > Synthesis dialog > Motion Clips panel

Open Track View > Global Tracks > Block Control > GlobalClip Properties > Synthesis dialog

The Synthesis dialog is where you set up motion synthesis for non-bipedal crowd members. It uses three panels to split up the workflow. On the Motion Clips panel, you specify the global object from which the motion clips are to be derived; you also set up the motion clips here. Controls on the State panel let you set up states and link clips to states. The Synthesis panel controls let you blend clips and synthesize the motion for some or all crowd members.

The panels are:

Motion Clips Panel (page 2–1246)
State Panel (page 2–1248)
Synthesis Panel (page 2–1250)

See also

ClipState Dialog (page 2–1253)

Procedure

Usage of the Synthesis dialog is closely associated with usage of the ClipState dialog. For a procedure that combines both, see To use Motion Synthesis with non-bipedal creatures: (page 2–1180).
Interface

**Global Object**—Click Global Object and pick the object that contains the animation (all the clips) in the Select Global Objects To Copy dialog.

**Global Motion Clips group**

**List Window**—The list of motion clips. The clips that you create appear in this list.

**Edit Window**—Rename or change the color for the selected motion clip.

From Global Object group

**Create State**—Create a new state with parameters specific to the motion clip, such as speed, heading, acceleration, and so on.

**character studio** evaluates the motion and orientation of the object and creates a new state with parameters set accordingly.

**Remove Local X, Y, Z, Orientation**—Turn on any or all of these options to strip out transformation and orientation data from the motion clip.

The idea is to animate the global object with full lateral motion. **character studio** then creates states based on the actual motion of the global object. After the states are created, the animation is stripped from the object. When delegates linked to clones of the global object come close to the actual motion recorded in the state, then the appropriate state is used to trigger the motion clip.

This technique is used to minimize sliding feet. If you animate a creature with many legs, you should animate lateral motion as well as leg motion. Then you create clips that record and then strip out the lateral motion that you created. When the delegate approaches the speed and direction you created originally on the global object, then the leg motion clip will be activated by the state; leg motion will be accurate relative to speed, preventing sliding feet.

**New**—Lets you set up a new motion clip. Displays the *MotionClip Parameters* dialog (page 2–1252) where you can specify the name and duration of the clip.

This selects all active controllers.

**Modify**—Lets you modify a motion clip’s parameters. Highlight the clip to modify, and then click Modify. Displays the *MotionClip Parameters* dialog (page 2–1252), where you can specify the name and duration of the clip.

Also, if you’ve changed the animation on the Global Object, you can re-apply it to a clip simply
by clicking Modify and then clicking OK to close the dialog. The change will affect all the objects being synthesized.

**Copy to Object**—The keys from the highlighted motion clip are copied back to the Global Object. Deletes any existing animation keys in that part of the Global Object’s animation.

You can use this function in several ways. First, if you've changed the animation on the Global Object, you can restore it from a stored motion clip with Copy To Object. Also, if you've edited the clip in Track View (Global Tracks > Block Control > Global Motion Clip:: ...), you can apply it to the Global Object with Copy To Object.

**From Track View group**

**New**—Lets you create a motion clip from an animation track in Track View.

Specify a track in the Track View Pick dialog (page 2–1252). The MotionClip Parameters dialog (page 2–1252) displays upon exiting the Track View Pick dialog.

**Modify**—Lets you modify a motion clip in the list by changing the Track View track from which it's derived, as well as the name and duration.

Specify a track in the Track View Pick dialog (page 2–1252). The MotionClip Parameters dialog (page 2–1252) displays upon exiting the Track View Pick dialog.

**Add Selected**—Creates a motion clip from only the selected tracks in Track View.

**Delete**—Deletes the highlighted clip in the list.

**Load**—Loads a motion clip file (.clp). Displays the Load Motion Clip dialog. Use the Save command to create a .clp file.

**Save**—Saves a motion clip into a .clp file. Displays the Save Motion Clip dialog.

**OK**—Accepts changes and closes the dialog.

---

**State Panel**

Select a Crowd object. > Modify panel > Global Clip Controllers rollout > New > Choose a GlobalClip object. > Select the object in the list. > Edit > Synthesis dialog > State panel

Open Track View > Global Tracks > Block Control > GlobalClip Properties > Synthesis dialog > State panel

Controls on the State panel let you set up states for non-bipedal motion synthesis and link motion clips to states.

**See also**

Synthesis Dialog (page 2–1246)

Motion Clips Panel (page 2–1246)

Synthesis Panel (page 2–1250)
Interface

**Synthesis States drop-down list**—Displays the current state. Choose a state to modify from the list. You can change the state name by editing the text in the list window.

**New State**—Creates a new state and adds it to the list.

The default name is “ClipState,” optionally followed by a number. You can change the state name by editing the text in the window.

**Delete State**—Deletes the current state. This is undoable.

**Edit Properties**—Lets you modify the current state. Displays the ClipState dialog (page 2–1253) for the current state.

**Clear Properties**—Returns the state to the default settings and removes clips from the MotionClips window.

**MotionClips group**

**MotionClips window**—Displays motion clips used by the current state.

Use Add Clip to associate clips with the state. If you assign more than one clip to a state, the software picks the clips randomly during synthesis based on their respective weights.

**MotionClip Weight**—Determines the chance that a clip will be chosen during synthesis. Range=0 to 1000.

Highlight the clip in the list, and then set its weight. A higher weight means that a clip is more likely to be chosen.

**Add Clip**—Displays the Select MotionClip dialog. Highlight a clip and click OK to add a clip to the current state.

**Remove Clip**—Removes the highlighted clip from the current state.

**Precedence**—Sets the precedence for the current state. Range=0 to 1000.

If multiple states qualify for activation based on their properties, character studio uses the clip associated with the one with the higher precedence first. If more than one state has the same precedence, then the one with the greater weight is played first.

**Weight**—Specifies a weight value for a state.
If two states have the same precedence, the state with a greater weight will be given higher priority considered during random selection.

**Animation Start Percent**—Specifies where in the clip’s animation you want it to start playing when the state is active.

At the default value of 0, the animation will start once the state is active. If the value is 66, the animation will start playing two-thirds of the way in once the state becomes active. You can also randomize where the animation starts by specifying a Animation Start Deviation value other than 0.

**Animation Start Deviation**—You can randomize where the animation starts by specifying a Animation Start Deviation value other than 0. Range=0.0 to 1.0.

**State Active Percent**—Specifies the percentage of time the state needs to be valid over its interval in order for it to be selected. Range=0 to 100. Default=50.

**Clip Select Seed**—Changes how the random selections occur.

If the value stays the same, you are guaranteed to get the same random selections for that state.

**OK**—Accepts changes and closes the dialog.

### Synthesis Panel

Controls in the Synthesis panel are for adding objects to be synthesized, selecting blend transition points, and performing the synthesis. When you synthesize, different sequences of motion clips are applied to each specified object based on the behavioral motion of its delegate.

**See also**

- *Synthesis Dialog (page 2–1246)*
- *Motion Clips Panel (page 2–1246)*
- *State Panel (page 2–1248)*

### Interface

- **Master Motion Clips list**—Displays the objects to which the synthesized motion will be applied.
You can highlight any of these by clicking them, and select multiple items with \textbf{Ctrl}+click and \textbf{Shift}+click. Highlight all objects with the Select All button.

\textbf{New Master Motion Clip}—Displays the Select Object To Copy dialog. Use this to specify the objects to which the synthesized motion will be applied.

These objects must all be structurally identical to the Global Object. In effect, they should be clones.

\textbf{Remove Animation}—Strips the animation from the clones.

After making clones of the original animated object, you can strip the animation from the clones. During synthesis, motion is applied based on which state is active.

\textbf{Collapse Selected}—Collapses motion clips to keys on the highlighted objects.

This deletes the Master Motion Clip for that object. You can then edit keys and make changes to the animation manually in the scene.

\textbf{Synthesize Selected}—Analyzes the motion of the delegates linked to the highlighted objects in the Master Motion Clips list, determines which state definitions fit that motion throughout the animation, and applies the corresponding motion clips.

\textbf{Select All}—Selects all of the objects in the Master Motion Clips list.

\textbf{Synthesize All}—Analyzes the motion of the delegates linked to all objects in the Master Motion Clips list, determines which state definitions fit that motion throughout the animation, and applies the corresponding motion clips.

A progress bar displays during synthesis. When synthesis is completed, the Synthesis dialog reappears, and you can view the calculated minimum, maximum, and average values of delegate motion for the different state properties in the ClipState dialog. You can use these values to fine-tune the state properties.

\textbf{State Select Seed}—Sets a seed value for random state selection.

During synthesis, it’s possible that several states qualify for activation at the same time, in which case one state is chosen at random. The seed is used to modify the random value selected when determining which state to select.

\textbf{Synthesis Blend Parameters group} During synthesis, clips aren’t sequenced from end to end; instead, they partially overlap, with key blending or averaging occurring during the overlap intervals. This allows for smooth transitions between clips. During the blending or overlap period, weighting gradually shifts between the “from” and “to” clips, so the former’s keys predominate at the beginning of the blend, and the latter’s at the end.

You can specify explicitly how blending occurs between clips, or you can let the software calculate blending parameters automatically. To specify blending, use the drop-down lists to choose a pair of clips to blend between, and then set Blend Start to the frame in the “from” clip at which blending should begin. Alternatively, use Auto Blend or Auto Blend All to have \textit{character studio} determine the best blend points.

If you use Auto Blend, you can then see the calculated blend start point for each pair of clips by choosing the clips from the drop-down lists.

\textbf{From Clip list}—Lets you select the starting clip to blend; the clip to blend \textit{from}.

\textbf{To Clip list}—Lets you select the ending clip to blend; the clip to blend \textit{to}.

\textbf{Blend Start}—Displays the frame in the From clip at which the transition is to begin, whether the
default, calculated, or set manually, and lets you change the start frame.

**Auto Blend**—Automatically sets the Blend Start frame for the current From and To clips.

**Auto Blend All**—Automatically sets the Blend Start frames for all possible pairs of clips.

**OK**—Accepts changes and closes the dialog.

---

### MotionClip Parameters Dialog

Enter a clip name, frame range, and color using controls in the MotionClip Parameters dialog. The software determines which clips to trigger by states that you define on the State panel (page 2–1248).

**Name**—Enter a name for the new motion clip.

**Start**—Specifies the first frame of the animation clip from the Global Object.

**End**—Specifies the last frame of the animation clip from the Global Object.

**Color**—Click the color swatch and choose a color in the color picker. This color is used in Track View when displaying the clip.

---

### Track View Pick Dialog

Open the hierarchy and pick a track to use in the motion clip.
ClipState Dialog

Select a Crowd helper. > Modify panel > Global Clip Controllers rollout > New > Choose GlobalClip object. > Select object in list. > Edit > Synthesis dialog > State panel > New State > Edit Properties > Clip State dialog

Track View > Global Tracks > Block Control > GlobalClip Properties > Synthesis dialog > State panel > New State > Edit Properties > ClipState dialog

In character studio, in crowd animation with non-bipedal motion synthesis, a state is a particular property or set of properties of a delegate's animation; for example, the period during which it is pitched upwards and is decelerating. After determining the delegate's state, the motion synthesis engine chooses a motion clip for animating the object, or character, linked to the delegate; for example, a bird. When preparing a simulation that uses motion synthesis, you use the ClipState dialog to define states and associate states with motion clips.

You can define a state with any combination of these properties: speed, acceleration, pitch, pitch velocity, and heading velocity (plus a script). For each active property, you can specify a range or a unique value that triggers the clip for its respective state.

When you use a range, be sure to set the Min setting lower than the Max setting. For example, when using a negative range such as -180 to -10, enter the number with the larger absolute value (-180) as the Min setting.

You can see the delegates' actual ranges and average values for all properties after synthesizing the clips.

The dialog panels are:

- Speed Panel (page 2–1254)
- Acceleration Panel (page 2–1256)
- Pitch Panel (page 2–1257)
- Pitch Velocity Panel (page 2–1259)
- Heading Velocity Panel (page 2–1261)
- Script Panel (page 2–1262)

Note: The dialog contains more tabs than can fit across its top. To see additional tabs, click the left or right arrow button near the upper-right corner of the dialog.

You can enable and disable each state property individually. For example, you can tell the motion synthesis to consider only speed and pitch when analyzing delegate motion. For each of a state's active properties, you can designate a range of values between which a state can be activated.

Alternatively, you can specify a single, unique motion value to be used when a state is active, such as a speed of 50 units per frame. In addition, you specify the In and Out values of the parameter as it approaches and then passes through that unique value. These values are analogous to the tangents of a curve. For each, you can pick Anything, Decreasing, Increasing, or Constant. For example, an animation of an object that has just landed after flying might have a Unique speed value of 0.0 (the object isn't moving laterally), a decreasing In value (the object decelerated before landing) and a constant Out value (the object remains stationary). Taking off, on the other hand, would have an increasing Out value.

If you don't specify state parameters, the state is a default state. For example, if you want the motion synthesis engine to choose random motion clips for an object, and you don't care about what the speed or pitch is, you create default states, and the synthesis engine will randomly pick which clip is active.

Tip: When setting up states, it’s useful to know the extents of state property values for delegate motion in the scene, such as maximum and minimum speed. To determine these, set up the clips and states you want to use, set the ranges to any values,
and then synthesize (see the procedure below). After you synthesize, the different property panels of the ClipState dialog will show the actual ranges and average values of delegate motion. These values are saved with the scene.

Note: The default name of this dialog is "ClipState" because that’s the default name of the first state created on the Synthesis dialog > State panel. It’s the dialog invoked by clicking the Edit Properties button. If you rename the state, the dialog assumes the changed name.

**Automatic State Creation**

*character studio* can create states automatically if you turn on Create State on the Synthesis dialog > Motion Clips panel. You can use this feature if you created a creature that contains lateral motion as well as looping motion.

If you turn on all the options in the Motion Clips panel > Remove Local group, then *character studio* creates a state that reflects the actual heading, speed, and acceleration of your creature. When a delegate approaches the heading and speed contained in this state, it triggers the appropriate motion clip. This method prevents sliding feet when animating multi-legged creatures.

**See also**

*Synthesis Dialog* (page 2–1246)
Interface

Use Speed—Turn on to have the motion synthesis engine consider delegate velocity in determining whether to use the clip.

Range—Choose Range to have the motion synthesis engine activate the clip when the delegate's speed falls inside the specified range.

Range Display—After you synthesize the Master Motion Clips, displays delegates' minimum, average, and maximum speed.

Min—Set the minimum speed value for the range.

Max—Set the maximum speed value for the range.

Unique—Choose Unique to have the motion synthesis engine activate the clip when the delegate's speed matches a specific value, optionally with a rising, falling, or constant value before or after the specified value.

Value—Set a unique speed value.

In/Out—These radio buttons let you specify the behavior of the parameter before and after the unique value is met. For example, with a flying object, to trigger a landing animation clip you might set the unique value to 0, the In setting to Decreasing, and the Out setting to Constant. This means that the object has slowed down and then stopped, and is now stationary.

- Anything—Speed before or after the target value is not relevant.
- Decreasing—Speed decreases before or after it reaches the target value.
- Constant—Speed before or after the target value is constant.
- Increasing—Speed increases before or after it reaches the target value.

Scale Playback Speed group

These settings let you scale the rate at which the animation is played depending upon the speed of the delegate. By default, when Scale Animation is off, the object animation will always play at its normal rate. If you turn it on, you can then set a Base Speed, at which the animation should play at its normal rate, plus a percentage to specify how...
much the animation rate is modified by the actual delegate speed.

**Scale Animation**—Scales the clip’s animation based on speed.

For example, as a bird increases its velocity, its wings beat more rapidly. Scaling an animation scales the keys of the animation.

**Percentage**—Specify how much to alter the playback speed based upon the difference between the delegate’s speed and the Base Speed setting.

The formula used is this:

\[
\text{Animation Speed change \%} = (\text{current speed}/\text{Base Speed} - 1) \times \text{Percentage \%}
\]

For example, if a delegate is moving 50 percent faster than the base speed, and the Scale Percentage value is 50, then the playback speed is scaled up by 25 percent.

**Base Speed**—Specifies the delegate speed at which the animation should be played back at its normal rate.

### Acceleration Panel

To have delegate acceleration considered for motion synthesis, turn on Use Acceleration, choose Range or Unique, and then make the appropriate settings.

**Interface**

Acceleration is measured in units per frame per frame, where the unit is the current 3ds Max system unit. That is, the acceleration is determined by the rate at which the speed changes per frame.
Range Display—After you synthesize the Master Motion Clips, displays delegates’ minimum, average, and maximum acceleration.

Min—Set a minimum acceleration value for the range.

Max—Set a maximum acceleration value for the range.

Unique—Choose Unique to have the motion synthesis engine activate the clip when the delegate’s acceleration matches a specific value, optionally with a rising, falling, or constant value before or after the specified value.

Value—Set a unique acceleration value.

In/Out—These radio buttons let you specify the behavior of the parameter before and after the unique value is met.

Anything—Acceleration before or after the target value is not relevant.

Decreasing—Acceleration decreases before or after it reaches the target value.

Constant—Acceleration before or after the target value is constant.

Increasing—Acceleration increases before or after it reaches the target value.

Scale Animation—Scale the clip’s animation based on acceleration.

For example, as a bird accelerates, its wings beat more rapidly. Scaling an animation scales the keys of the animation.

Percentage—Specify how much to alter the playback speed based upon the difference between the delegate’s acceleration and the Base Acceleration setting.

The formula used is this:

Animation Speed change % = (current speed/Base Acceleration - 1 ) x Percentage %

For example, if a delegate is accelerating 50 percent faster than the base acceleration, and the Scale Percentage value is 50, then the playback speed is scaled up by 25 percent.

Base Acceleration—Specifies the delegate acceleration at which the animation should be played back at its normal rate.

Scale Playback Speed group

These settings let you scale the rate at which the animation is played, depending upon the acceleration of the delegate. By default, when Scale Animation is off, the object animation will always play at its normal rate. If you turn it on, you can then set a Base Acceleration, at which the animation should play at its normal rate, plus a percentage to specify how much the animation rate is modified by the actual delegate acceleration.

Pitch Panel

Select a Crowd helper. > Modify panel > Global Clip Controllers rollout > New > Choose GlobalClip object. > Select object in list. > Edit > Synthesis dialog > State panel > New State > Edit Properties > Clip State dialog > Pitch Panel

To have delegate pitch considered for motion synthesis, turn on Use Pitch, choose Range or Unique, and then make the appropriate settings.

Pitch is determined by the angle in degrees of the delegate about the world X-axis. In world coordinates, the delegate’s pitch is positive when it’s aimed upward, negative when it’s aimed downward, and 0 when it’s aimed parallel to the home grid.
Use Pitch—Turn on to have the motion synthesis engine consider delegate pitch in determining whether to activate the state.

Range—Choose Range to have the motion synthesis engine activate the clip when the delegate's pitch falls inside the specified range.

Range Display—After you synthesize the Master Motion Clips, displays delegates’ minimum, average, and maximum pitch.

Min—Set a minimum pitch for the range.

Max—Set a maximum pitch for the range.

Unique—Choose Unique to have the motion synthesis engine activate the clip when the delegate's pitch matches a specific value, optionally with a rising, falling, or constant value before or after the specified value.

Value—Set a unique pitch value.

In/Out—These radio buttons let you specify the behavior of the parameter before and after the unique value is met.

- **Anything**—Pitch before or after the target value is not relevant.
- **Decreasing**—Pitch decreases before or after it reaches the target value.
- **Constant**—Pitch before or after the target value is constant.
- **Increasing**—Pitch increases before or after it reaches the target value.

Scale Pitch Orientation group

These settings let you scale the pitch at which the animation is played, depending upon the pitch of the delegate. By default, when Scale Pitch is off, the animated object will pitch normally. If you turn it on, you can then set a Base Pitch at which the animation should play, plus a percentage to specify how much the Base Pitch is modified by the actual delegate pitch. If the Percentage is 100, then only the Base Pitch will be used; anything else will scale between the base pitch and the delegate pitch. This is useful for when birds and other objects elevate, but don't pitch up.
**Pitch Velocity Panel**

Select a Crowd helper. > Modify panel > Global Clip Controllers rollout > New > Choose GlobalClip object. > Select object in list. > Edit > Synthesis dialog > State panel > New State > Edit Properties > Clip State dialog > Pitch Velocity Panel

Track View > Global Tracks > Block Control > GlobalClip Properties > Synthesis dialog > State panel > New State > Edit Properties > ClipState dialog > Pitch Velocity Panel

To have delegate pitch velocity considered for motion synthesis, turn on Use Pitch Velocity, choose Range or Unique, and then make the appropriate settings.

Pitch velocity is determined by the rate of change in degrees per frame of the angle of the delegate about the world X-axis. In other words, pitch velocity measures how fast the delegate is changing its *pitch*.

**Scale Animation**—Scales the clip’s pitch based on delegate pitch.

**Percentage**—Specify how much to alter the pitch based upon the difference between the delegate’s pitch and the Base Pitch setting.

The formula used is this:

Pitch change % = (current pitch/Base Pitch -1 ) x Percentage %

**Base Pitch**—Specifies the delegate pitch at which the animation should be played back at its normal rate.

**Scale Playback Speed group**

These settings let you scale the rate at which the animation is played, depending upon the pitch of the delegate. By default, when Scale Animation is off, the object animation will always play at its normal rate. If you turn it on, you can then set a Base Pitch, at which the animation should play at its normal rate, plus a percentage to specify how much the animation rate is modified by the actual delegate pitch.

**Scale Animation**—Scales the clip’s animation based on pitch.

**Percentage**—Specify how much to alter the playback speed based upon the difference between the delegate’s pitch and the Base Pitch setting.

The formula used is this:

Animation Speed change % = (current speed/Base Pitch -1 ) x Percentage %

For example, if a delegate’s pitch velocity is 50 percent above its base pitch rate, and the Scale Percentage value is 50, then the playback speed is scaled up by 25 percent.

**Base Pitch**—Specifies the delegate pitch at which the animation should be played back at its normal rate.
Interface

Use Pitch Velocity—Turn on to have the motion synthesis engine consider pitch velocity in determining whether to activate the state.

Range—The motion synthesis engine activates the clip when the delegate's pitch velocity falls inside the specified range.

Range Display—After you synthesize the Master Motion Clips, displays delegates' minimum, average, and maximum pitch velocity.

Min—Set a minimum pitch velocity for the range.

Max—Set a maximum pitch velocity for the range.

Unique—Choose Unique to have the motion synthesis engine activate the clip when the delegate's pitch velocity matches a specific value, optionally with a rising, falling, or constant value before or after the specified value.

Value—Set a unique pitch velocity value.

In/Out—These radio buttons let you specify the behavior of the parameter before and after the unique value is met.

- Anything—Pitch velocity before or after the target value is not relevant.
- Decreasing—Pitch velocity decreases before or after it reaches the target value.
- Constant—Pitch velocity before or after the target value is constant.
- Increasing—Pitch velocity increases before or after it reaches the target value.

Scale Playback Speed group

These settings let you scale the rate at which the animation is played, depending upon the pitch velocity of the delegate. By default, when Scale Animation is off, the object animation will always play at its normal rate. If you turn it on, you can then set a Base Pitch Rate, at which the animation should play at its normal rate, plus a percentage to specify how much the animation rate is modified by the actual delegate pitch velocity.

Scale Animation—Scales the clip's animation based on pitch velocity.
**Percentage**—Specify how much to alter the playback speed based upon the difference between the delegate’s pitch velocity and the Base Pitch Rate setting.

The formula used is this:

\[
\text{Animation Speed change} \% = (\text{current speed/} \text{Base Pitch Rate} - 1) \times \text{Percentage} \%
\]

For example, if a delegate’s pitch velocity is 50 percent above its base heading rate, and the Scale Percentage value is 50, then the playback speed is scaled up by 25 percent.

**Base Pitch Rate**—Specifies the delegate pitch velocity at which the animation should be played back at its normal rate.

### Heading Velocity Panel

Select a Crowd helper. > Modify panel > Global Clip Controllers rollout > New > Choose GlobalClip object. > Select object in list. > Edit > Synthesis dialog > State panel > New State > Edit Properties > Clip State dialog > Heading Velocity Panel

To have delegate heading velocity considered for motion synthesis, turn on Use Heading Velocity, choose Range or Unique, and then make the appropriate settings.

Heading velocity is determined by the rate of change in degrees per frame of the angle of the delegate about the world Z-axis. In other words, heading velocity measures how fast the delegate is changing its heading.

### Interface

![Interface Image](image)

**Use Heading Velocity**—Turn on to have the motion synthesis engine consider heading velocity in determining whether to activate the state.

**Range**—Choose Range to have the motion synthesis engine activate the clip when the delegate’s heading velocity falls inside the specified range.
Range Display—After you synthesize the Master Motion Clips, displays delegates' minimum, average, and maximum heading velocity.

Min—Set a minimum heading rate value for the range.

Max—Set a maximum heading rate value for the range.

Unique—Choose Unique to have the motion synthesis engine activate the clip when the delegate's heading rate matches a specific value, optionally with a rising, falling, or constant value before or after the specified value.

Value—Set a unique heading rate value.

In/Out—These radio buttons let you specify the behavior of the parameter before and after the unique value is met.

· Anything—Heading velocity before or after the target value is not relevant.

· Decreasing—Heading velocity decreases before or after it reaches the target value.

· Constant—Heading velocity before or after the target value is constant.

· Increasing—Heading velocity increases before or after it reaches the target value.

Scale Playback Speed group
These settings let you scale the rate at which the animation is played, depending upon the heading velocity of the delegate. By default, when Scale Animation is off, the object animation will always play at its normal rate. If you turn it on, you can then set a Base Heading Rate, at which the animation should play at its normal rate, plus a percentage to specify how much the animation rate is modified by the actual delegate heading velocity.

Scale Animation—Scales the clip's animation based on heading velocity.

Percentage—Specify how much to alter the playback speed based upon the difference between the delegate's heading velocity and the Base Heading Rate setting.

The formula used is this:

Animation Speed change % = (current speed/Base Heading Rate - 1) x Percentage %

For example, if a delegate's heading velocity is 50 percent above its base heading rate, and the Scale Percentage value is 50, then the playback speed is scaled up by 25 percent.

Base Heading Rate—Specifies the delegate heading velocity at which the animation should be played back at its normal rate.

Script Panel

Select a Crowd helper. > Modify panel > Global Clip Controllers rollout > New > Choose GlobalClip object. > Select object in list. > Edit > Synthesis dialog > State panel > New State > Edit Properties > ClipState dialog > Script Panel

The script state option lets you create a MAXScript script that takes two parameters: node and time. The script typically tests one or more values, and then returns 1 if the condition (the result of the test) is true or 0 if it's false. This result determines whether or not the state is to be activated.

Scripts used by the clip controller are similar to those used by the cognitive controller (page 2–1206), with the exception that a special time-related statement is required.

In the following sample script, "del" is the delegate's node, and "t" is the time. The name of the scripted function, "stoppedScript," would also need to be entered into the name field in the Script panel of the ClipState dialog. Unlike cognitive
controller scripts, the statement "at time t" needs to be invoked because the animation is not running when the synthesis takes place.

```plaintext
fn stoppedScript del t = (  
  at time t  
  if del.pos.z < 65 then 1 else 0  
)
```

**Script**—Enter the name of the function defined by the script, also found at the start of the script.

**Edit Script**—Opens a MAXScript editor window that lets you edit the script.

### File Formats and Index of Procedures

**character studio File Formats**

**character studio** uses several proprietary file formats for various functions.

**BIP**—Motion file. Includes biped motion and the size of the original biped so motion can be accurately loaded to other bipeds. Can be loaded directly onto a biped, or used to combine motions with Motion Flow or the Motion Mixer. See *Loading and Saving BIP Animation* (page 2–920).

**FIG**—Figure file. Contains the sizes and poses of each biped body part, and overall biped size. Use this file to save and load a biped pose in Figure mode. See *Saving and Loading FIG Files* (page 2–855).

**CPY**—Copy file. Contains postures, poses and tracks you have copied with the Copy/Paste rollout. See *Copying and Pasting Postures and Poses* (page 2–910) and *Copying and Pasting Tracks* (page 2–926).

**MFE**—Motion Flow Graph file. Contains the motion flow graph, and a motion flow script if one was present for the biped upon saving. See *Saving, Loading, and Appending Motion Flow Graphs* (page 2–1032).

**MIX**—Motion Mixer file. Contains clip data, tracks and trackgroups, transitions between clips, track/clip weights, and scale, trim and time
warp information for edited clips. See Exporting Animation to the Biped (page 2–624).

**PHY**—Physique file. Contains information on envelope sizes and vertex weights set up with the Physique modifier. See Saving and Loading Physique Data (page 2–1098).

**STP**—Step file. Contains footstep data. See Loading and Saving STP Files (page 2–924).

**BVH, CSM, MNM**—These file formats contain motion-capture data. They are not specific to character studio. See BVH File (page 3–920), CSM File (page 3–925), or MNM File (page 3–973) in the glossary.

---

**Procedures**

These procedures appear elsewhere in this User Reference, in their associated topics. Here, they are organized by feature.

**Biped and Physique**

**Creating a Biped**

To delete a biped: (page 2–854)

To create a biped on a surface: (page 2–845)

To change the biped name upon creation: (page 2–847)

To change the biped name after creation: (page 2–847)

To create a Named Selection for the biped center of mass: (page 2–847)

**Loading and Viewing Motion**

To save animation you have created or imported to a BIP file: (page 2–921)

To load biped motion from an existing BIP file: (page 2–920)

To preview biped motion using biped playback stick figure: (page 2–929)

To preview biped motion using the full biped model: (page 2–929)

**Animating the Biped with Freeform**

To use pivots: (page 2–907)

To make a hand or foot follow an object: (page 2–908)

To anchor a hand or foot: (page 2–909)

**Animating the Biped with Footsteps**

To create footsteps automatically: (page 2–862)

To create multiple footsteps: (page 2–988)

To create footsteps beginning at the current frame: (page 2–864)

To make the biped walk up or down stairs: (page 2–992)

To make the biped walk in place: (page 2–992)

To make the biped walk backward: (page 2–992)

To prepare for manual footstep creation: (page 2–864)

To create footsteps manually, beginning at the current frame: (page 2–989)

To append footsteps onto the existing footsteps: (page 2–989)

To create footsteps using AutoGrid: (page 2–864)

To make the biped speed up as it walks: (page 2–992)

To activate footsteps: (page 2–865)

To deactivate footsteps: (page 2–866)

**Editing Footsteps**

To save footstep data: (page 2–925)

To move selected footsteps in time: (page 2–871)
To change the duration of a footstep: (page 2–871)
To scale keys in time: (page 2–871)
To prevent keys from changing when active footsteps are edited: (page 2–872)
To turn off Scale Stride mode: (page 2–922)
To display footstep tracks: (page 2–889)
To display footstep keys in Track View: (page 2–871)
To change the display of numbers of footstep keys: (page 2–871)
To convert an airborne period to freeform mode: (page 2–884)
To convert between footsteps and freeform animation: (page 2–885)
To create a purely freeform animation: (page 2–887)
To create a freeform animation from a footstep animation: (page 2–887)
To save footstep data: (page 2–925)
To copy footsteps to the buffer: (page 2–873)
To edit the footstep buffer: (page 2–873)
To splice the footstep buffer: (page 2–873)

Editing Biped Keys
To use In Place mode to adjust keyframes: (page 2–930)
To set the balance factor: (page 2–878)
To set ballistic tension: (page 2–882)
To set the IK Blend value of a key: (page 2–901)
To locate vertical center of mass keys: (page 2–881)
To set a Body Vertical key: (page 2–881)
To change TCB for a biped arm: (page 2–894)
To select and rotate multiple links: (page 2–895)

To rotate all links in the spine, neck, or tail: (page 2–895)
To change Dynamics Blend for multiple Body Vertical keys: (page 2–882)
To bend a biped trajectory: (page 2–915)
To edit keys on the Center of Mass trajectory: (page 2–915)
To edit biped trajectory keys in a viewport: (page 2–931)
To use In Place mode to adjust keyframes: (page 2–930)

Motion-Capture Data
To import a motion-capture file: (page 2–1067)
To import a marker file: (page 2–1063)
To use Fit To Existing to import a motion-capture file: (page 2–1071)
To use Convert From Buffer: (page 2–1066)
To compare raw and filtered trajectories: (page 2–1066)
To use Show Buffer: (page 2–1066)

Motion Flow
To create clips in the Motion Flow Graph: (page 2–1027)
To create multiple clips in the Motion Flow Graph: (page 2–1028)
To create transitions using From > To or To < From method: (page 2–1029)
To create transitions using Create All Transitions: (page 2–1029)
To optimize transitions in the Motion Flow Graph: (page 2–1030)
To create a Motion Flow script: (page 2–1031)
To save Motion Flow Editor files: (page 2–1032)
To load Motion Flow Editor files: (page 2–1033)
To append Motion Flow Editor files: (page 2–1033)
To manually customize transitions between two clips: (page 2–1034)
To automatically customize transitions between two clips: (page 2–1035)
To create a random script for one biped: (page 2–1036)
To customize transition “weighting” and setting a start clip: (page 2–1037)
Example: To create a unified motion: (page 2–1038)
Example: To share a random motion flow among multiple bipeds: (page 2–1039)
To apply a shared motion flow to a different group of bipeds: (page 2–1041)
To load a Motion Flow scene from another system: (page 2–1042)

Posing the Biped
To link a mechanical character to the biped (without Physique): (page 2–855)
To fit biped legs to the skin: (page 2–850)
To fit the spine to the skin torso: (page 2–850)
To fit both arms using copy/paste: (page 2–851)
To pose both arms simultaneously: (page 2–851)
To create a symmetrical pose by copying one side of the biped to the other: (page 2–851)
To copy a posture: (page 2–912)
To paste the posture: (page 2–912)
To copy a track from one biped to another: (page 2–927)
To copy the entire pose of a biped: (page 2–912)

To attach a mesh to a bones hierarchy using Physique: (page 2–1106)

Applying Physique
To attach a mesh to a biped using Physique: (page 2–1106)
To adjust default envelope shape: (page 2–1087)
To adjust envelopes around the biped’s pelvis: (page 2–1087)
To add a bone after you’ve already used Attach To Node: (page 2–1107)
To troubleshoot bulges and tendons: (page 2–1109)
To select and edit cross sections: (page 2–1088)
To copy an envelope and its settings to a mirrored link (for example, from one thigh to the other): (page 2–1088)
To copy all Bulge angles from one link to its opposite: (page 2–1143)
To use Select Nearest Bulge Angle: (page 2–1144)
To remove a link’s influence on vertices: (page 2–1151)
To check vertex assignments: (page 2–1151)
To remove deformable vertices from a link’s influence: (page 2–1151)
To override vertex assignments manually: (page 2–1151)
To make vertices rigid: (page 2–1152)
To have a spline influence a mesh: (page 2–1110)
To apply Physique to an FFD to animate the entire mesh: (page 2–1105)
To use an FFD to complement the effects of Physique on a portion of a character mesh: (page 2–1105)
To make compressible bones (bones with end effectors): (page 2–1081)
Procedures

To add a bone after Physique is applied using Reinitialize: (page 2–1081)
To add a bone after Physique is applied using Add (Add Bone): (page 2–1082)
To optimize skin objects: (page 2–1100)
To reinitialize a scaled mesh: (page 2–1100)

Bulges
To create a new bulge angle using the Bulge Editor: (page 2–1115)
To create a new bulge angle on a selected link: (page 2–1142)
To add a cross section: (page 2–1116)
To change the shape of a cross section: (page 2–1117)
To make a cross section the active cross section: (page 2–1116)
To choose a specific bulge angle for editing: (page 2–1116)
To change a bulge angle value: (page 2–1116)
To select multiple cross sections: (page 2–1116)
To move cross sections along the link: (page 2–1117)
To copy and paste cross sections: (page 2–1117)
To change the Profile view orientation: (page 2–1117)
To delete a bulge angle: (page 2–1116)
To delete a cross section: (page 2–1116)

Links and Tendons
To adjust joint intersection parameters: (page 2–1140)
To create and attach a tendon: (page 2–1097)
To attach a tendon to another link: (page 2–1097)
To delete a tendon: (page 2–1097)

Saving and Reusing Physique Information
To save Physique data: (page 2–1107)
To load Physique data: (page 2–1107)
To merge a skinned biped: (page 2–922)
To clone a skinned biped: (page 2–924)

Figure Mode
To work in Figure mode: (page 2–849)
To adjust the biped center of mass with Rubber Band: (page 2–833)
To rubber band an arm or leg link: (page 2–853)
To Scale a Biped and a Physique Mesh: (page 2–984)
To save a biped’s figure information to a file: (page 2–856)
To load a biped figure: (page 2–856)

Layers
To increment all keys using layers (global offset): (page 2–914)
To increment an interval of keys with an envelope (blended offset): (page 2–914)
To increment an interval of keys without an envelope (nonblended offset): (page 2–914)
To use layers to reposition a biped with freeform animation: (page 2–928)

Props
Example: To animate a biped swinging a prop with one hand: (page 2–899)
Example: To animate the biped switching the prop to the other hand: (page 2–899)
To collapse the transforms of a prop: (page 2–900)

Controllers and Biped
To add a controller to a biped object: (page 2–896)
Chapter 14: character studio

To collapse a controller: (page 2–897)
To add controllers to multiple biped parts at the same time: (page 2–897)
To animate the weights of an added controller: (page 2–897)

Miscellaneous
To load a file created with different system units: (page 2–1099)
To hide the finger, toe, and head dummy objects: (page 2–923)
To change biped display: (page 2–854)
To select from the screen: (page 2–889)
To reposition a freeform animation (with no IK attachment) or a footstep animation: (page 2–927)
To reposition a biped with limbs attached to an Object Space object (IK attachment): (page 2–928)
To reposition a biped with limbs attached to world space (IK attachment): (page 2–928)
To reposition a biped animated with a motion flow script: (page 2–928)
To scale a biped that has a mesh attached to it by using Physique: (page 2–1100)
Facial Animation (page 2–1100)
To isolate lip vertices from influence by inappropriate links: (page 2–1103)

Crowd System
Crowd and Delegate Helpers
To create a Crowd helper object: (page 2–1158)
To create a Delegate helper object: (page 2–1158)
To clone and scatter delegates: (page 2–1158)
To link objects to delegates: (page 2–1169)
To associate bipeds with delegates: (page 2–1169)

To edit multiple delegates: (page 2–1197)
To group delegates into a team: (page 2–1201)

Behaviors
To create a new behavior assignment: (page 2–1201)
To use assign behaviors to delegates: (page 2–1162)
To modify an existing behavior assignment or assignments: (page 2–1202)
To use the Avoid behavior: (page 2–1165)
To use the Orientation behavior: (page 2–1167)
To use the Path Follow behavior: (page 2–1163)
To use the Repel behavior: (page 2–1166)
To use the Seek behavior: (page 2–1163)
To add a Vector Field space warp: (page 2–1166)

Solving a Crowd Simulation
To solve a simulation: (page 2–1168)
To speed up the solution time: (page 2–1168)
To troubleshoot the simulation: (page 2–1168)

Cognitive Controllers
To set up and use a cognitive controller: (page 2–1170)
Testing a Particle System Parameter (page 2–1209)
Testing an Atmospheric Property (page 2–1209)
Testing Another Delegate’s Behavior (page 2–1209)

Motion Synthesis
To use Motion Synthesis with non-bipedal creatures: (page 2–1180)
Procedures: Using Biped in a Crowd Simulation (page 2–1175)

Motion Mixer
General
To access the Motion Mixer from the Motion panel: (page 2–606)
To display the Motion Mixer in a viewport: (page 2–607)
To remove the Motion Mixer from a viewport: (page 2–607)
To add a biped to the Motion Mixer: (page 2–608)
To add a non-biped object to the Motion Mixer: (page 2–608)
To see the motions in the Motion Mixer on the biped in the scene: (page 2–611)

Loading Clips
To import BIP clips from a file: (page 2–610)
To import clips from the Reservoir: (page 2–610)
To import clips from a motion flow script: (page 2–611)
To replace one clip with another: (page 2–612)
To replace a clip with motion from a biped in the scene: (page 2–612)
To clone a clip: (page 2–612)

Clip Timing
To move a clip in time within a track: (page 2–611)

To move all clips horizontally on one track: (page 2–611)
To move a clip to another track: (page 2–611)
To change the length of a clip without changing its speed: (page 2–615)
To change the speed of an entire clip: (page 2–616)
To prepare to warp a clip’s time: (page 2–621)
To warp a clip’s time: (page 2–621)
To add multiple time warps to a clip: (page 2–622)

Trackgroups
To add a new trackgroup for the biped: (page 2–614)
To filter and name a trackgroup: (page 2–614)
To convert a clip track from one type to another: (page 2–608)
To add a Transition or Layer track to a trackgroup: (page 2–608)

Transitions
To create a transition between two clips: (page 2–618)
To change the focus on a foot-based transition with Biped animation: (page 2–619)
To adjust a weight curve: (page 2–620)

Biped Balance
To adjust balance using the balance track: (page 2–623)
To fine-tune balance compensation on the pelvis and spine: (page 2–624)

Saving Mixer Data
To perform a mixdown and copy it to the biped: (page 2–625)
To save Motion Mixer data to a MIX file: (page 2–626)

Reservoir
To access the Reservoir: (page 2–627)
To add clips to the Reservoir: (page 2–627)
To replace a clip in the Reservoir: (page 2–627)
To save an instanced clip to a new clip: (page 2–628)
To save multiple instanced clips from the Reservoir: (page 2–628)
To remove clips not used in the Motion Mixer from the Reservoir: (page 2–628)

Workbench
General
To display a biped body part curve in the Workbench, do one of the following: (page 2–1016)
To hide or unhide the Tab panel: (page 2–1016)

Workbench Panels
To analyze a curve: (page 2–1017)
To fix an individual error: (page 2–1020)
To fix multiple errors: (page 2–1020)
To remove keys from curves automatically: (page 2–1021)
To filter a track: (page 2–1023)
Lights and Cameras

Lights and cameras are scene objects that simulate their real-world counterparts.

Lights provide lighting for the geometry of a scene: they can light the scene from “offstage,” or (with a little extra work), they can appear within the scene itself. Standard lights are simple and easy to use. Photometric lights are more complex, but provide a physically accurate model of real-world lighting. The Daylight and Sunlight systems create outdoor lighting that simulates sunlight based on location and time of day, month and year. You can animate the time of day to create shadow studies.

Cameras frame the scene, providing a controllable point of view. You can animate camera movement. Cameras can simulate some aspects of real-world photography, such as depth-of-field and motion blur.

Create panel > Lights
Create menu > Lights

Nighttime scene with artificial lighting

Lights are objects that simulate real lights such as household or office lamps, the light instruments used in stage and film work, and the sun itself. Different kinds of light objects cast light in different ways, emulating different kinds of real-world light sources.

When there are no lights in a scene, the scene is shaded or rendered with default lighting. You add lights to give the scene a more realistic appearance. Lighting enhances the clarity and three-dimensionality of a scene. In addition to general lighting effects, lights can be used to project images. (See Advanced Effects Rollout (page 2–1341).)

Light objects replace the default lighting. As soon as you create a light, the default lighting is turned off. If you delete all the lights in the scene, default lighting is turned back on. The default lighting consists of two invisible lights: one is above and to the left of the scene, and the other is below and to the right.

Tip: One way to begin your work on lighting a scene is to convert the default lighting into light objects by using the command Add Default Lights To Scene (page 1–49).

Note: A scene's lighting is also affected by the Ambient Light setting on the Environment And Effects dialog > Environment panel (page 3–272).

Types of Lights

3ds Max provides two types of lights: standard and photometric. All types are displayed in viewports as light objects. They share many of the same parameters, including shadow generators.

Standard Lights

Standard lights (page 2–1288) are computer-based objects that simulate lights such as household or office lamps, the light instruments used in stage and film work, and the sun itself. Different kinds of light objects cast light in different ways, emulating different kinds of light sources. Unlike photometric lights, Standard lights do not have physically-based intensity values.

Photometric Lights

Photometric lights (page 2–1301) use photometric (page 3–993) (light energy) values that enable you to more accurately define lights as they would be in the real world. You can set their distribution, intensity, color temperature, and other characteristics of real-world lights. You can also import specific photometric files available from lighting manufacturers to design lighting based on commercially available lights.

Tip: Combine Photometric lights with the radiosity solution (page 3–51) to generate physically accurate renderings or perform lighting analysis.

Tips

• You can animate not only the location of a light, but also its color, intensity and some other
creation parameters. See *Animating Lights* (page 2–1282).

- You can use the *Place Highlight* (page 1–467) command to change a light’s position. See the Procedures in *Working with Lights* (page 2–1274).
- A *Light viewport* (page 3–750) can be a useful way to adjust lights other than omni lights.
- To simulate sunlight, use a *daylight or sunlight system* (page 1–418), which allows you to set the date, time, and geographic location of your model. The daylight system is photometric, while the sunlight system uses a standard directional light.

Note: The standard *Skylight* (page 2–1296) light is distinct from the photometric daylight lights. The Skylight light is for use with *light tracing* (page 3–44).

*Light Include/Exclude Tool* (page 2–1283)

*Light Lister* (page 2–1285)

*Animating Lights* (page 2–1282)

**Procedure**

To change the color of a light’s geometry:

1. Create or select a light in your scene.
2. In the Name and Color rollout, click the color swatch to open a *Color Selector* (page 1–161).
3. Choose a new color and click OK.

To change the name of a light:

1. Create or select a light in your scene.
2. In the Name and Color rollout, click the name field and enter the new name, then press the **Enter** key.

The light’s name has changed.

**Interface**

The Name And Color rollout lets you change the name and geometry color of a light. Changing the color of the light geometry can be useful when working with many lights. For example, in a scene with many different types of lights, you could make all spotlights red, and all omni lights blue to easily distinguish them.

Changing a light’s geometry color has no effect on the color of the light itself. You can set the color the light emits on its *Intensity/Color/Distribution rollout* (page 2–1352) (for photometric lights), or its *Intensity/Color/Attenuation rollout* (page 2–1345) (for standard lights).

Name—The name of the selected light.

Note: When you rename a target-type light, the target object will be renamed to match the light.

Color—The color of the light’s geometry.

(This has no effect on the color the light emits.)
Using Lights

In general, these are the reasons to use light objects (page 2–1272):

- To improve the illumination of a scene.
  The default illumination in viewports might not be bright enough, or it might not illuminate all faces of a complicated object.

- To enhance a scene’s realism through realistic lighting effects.
  Guidelines for Lighting (page 2–1280) has suggestions about making lighting appear realistic.

- To enhance a scene’s realism by having lights cast shadows.
  All kinds of lights can cast shadows. Also, you can selectively control whether an object casts or receives shadows. See Shadow Parameters (page 2–1337).

- To cast projections in a scene.
  All kinds of lights can project still or animated maps. See the Projector Map group in the Advanced Effects rollout (page 2–1341).

- To help model a source of illumination in the scene, such as a flashlight.
  Light objects don’t render, so to model a source of illumination, you also need to create geometry that corresponds to the light source. Use a self-illuminating (page 3–1009) material to make the geometry appear as if it’s emitting light.

- To create lighting scenes using manufacturers’ IES (page 2–1328), CIBSE (page 3–921), or LTI (page 3–964) files.
  You can visualize commercially available lighting in your model by creating photometric lights (page 2–1301) based on manufacturer’s photometric data files. By experimenting with different fixtures, and varying the light intensity and color temperature, you can design a lighting system that produces the results you want. See Photometric Lights: Web Distribution (page 2–1325).

Working with Lights

The procedures in this topic apply to both standard and photometric lights.

Here are some general tips about working with lights:

- One simple way to light a scene is to convert the default lighting into light objects by using the command Add Default Lights To Scene (page 1–49).
  Note: Add Default Lights To Scene works only if you have used the Viewport Configuration dialog (page 3–853) to have the scene use two default lights.

- You can turn the display of light objects on and off with an option in the Display panel (page 3–775). See the “Procedures” section, below.

- You can use the Place Highlight (page 1–467) button to change a light’s position. See the “Procedures” section, below.
A Light viewport (page 2–1338) can be a useful way to adjust spotlights in your scene.

Procedures

To create a light:

1. On the Create panel, click Lights.
2. Choose Standard or Photometric from the drop-down list. Standard is the default.
3. In the Object Type rollout, click the type of light you want to create.
4. Click a viewport to create the light. This step varies slightly depending on the type of light. For example, if the light has a target, you drag and click to set the target’s location.
   Light objects replace the default lighting. As soon as you create a light, the default lighting is turned off. If you delete all lights in the scene, the default lighting is restored.
5. Set the creation parameters.
   Like all objects, lights have a name, a color, and a General Parameters rollout.

To create shadows, do one of the following:

- In the General Parameters rollout, make sure On is checked in the Shadows group. Adjust shadow parameters in the Shadow Parameters rollout and the additional (Shadow Map (page 2–1363), Advanced Ray-traced (page 2–1356), Area Shadows, (page 2–1357) or Ray Traced Shadows (page 2–1363)) shadow rollouts.
- Right-click the light, and turn on Cast Shadows in the Tools 1 (upper-left) quadrant of the quad menu.

Turning on Cast Shadows also turns on the On toggle in the Shadows group of the General Parameters rollout, and vice versa.

Shadows are visible only when rendered, either in a full rendering (page 3–1) or by ActiveShade (page 3–17).

Tip: To turn shadows on or off for multiple lights, select the lights and then use the Light Lister (page 2–1285).

You can set an object to not cast or not receive shadows. By default, objects do both. See Object Properties (page 1–117).

To control the display of light objects:

- On the Display panel, on the Hide By Category rollout, turn on Lights.

All light objects in the scene disappear, but the lighting itself is unchanged.

Light objects can cast light whether or not their display is turned off. The Zoom Extents commands are affected by whether light icons are displayed or not. When lights are displayed, Zoom Extents (page 3–740) and Zoom Extents All (page 3–740) includes the lights in the zoom.

Tip: To control whether a light casts light in the scene, you can use its On toggle, or you can toggle its Renderable property on the light’s Object Properties dialog (page 1–117).

To change a light’s parameters:

1. Select the light.
   Tip: Lights can be hard to select by clicking. Use the keyboard shortcut **H** to select the light by name.

2. Open the Modify panel.

3. Change the light’s parameters in the General Parameters rollout and other rollouts available for that light.
To position a light so it highlights a face:

1. Make sure the viewport you plan to render is active, and that the object you want to highlight is visible in it.
   The result of Place Highlight depends on what is visible in the viewport.
2. Select a light object.
3. On the Main toolbar, choose Place Highlight from the Align flyout (page 1–462).
   You can also choose Tools menu > Place Highlight.
4. Drag over the object to place the highlight.
   When you place an omni light (page 2–1295), free point (page 2–1304), free linear (page 2–1307), free area (page 2–1309) or free direct light (page 2–1293), the program displays a face normal for the face the mouse indicates.
   When you place a target point (page 2–1303), target area (page 2–1307), target linear (page 2–1305) or target direct light (page 2–1292), the program displays the light’s target and the base of its cone.
5. Release the mouse when the normal or target display indicates the face you want to highlight.
   The light now has a new position and orientation. You can see the highlight illumination in shaded viewports that show the face you chose, and when you render those views.

Place Highlight (page 1–467) works with any kind of selected object. You can also use Place Highlight with a selection set of multiple objects. All objects maintain their initial distance from the face.

Note: For materials, highlight rendering depends on the material’s specular properties and the type of rendering you use.

Properties of Light

This topic describes light in the real world. When you light a scene, it can be helpful to know how light naturally behaves.

When light rays strike a surface, the surface reflects them, or at least some of them, enabling us to see the surface. The appearance of a surface depends on the light that strikes it combined with the properties of the surface material, such as color, smoothness, and opacity.

Materials (page 2–1395) let you specify the visual properties of surfaces.

Intensity

The intensity of light at its point of origin affects how brightly the light illuminates an object. A dim light cast on a brightly colored object shows only dim colors.

Left: A room lit by candles, which are a low-intensity source.
Right: The same room lit by a higher-intensity light bulb.

Angle of Incidence

The more a surface inclines away from a light source, the less light it receives and the darker it appears. The angle of the surface normal relative to the light source is known as the angle of incidence.

When the angle of incidence is 0 degrees (that is, the light source strikes the surface perpendicularly), the surface is illuminated with the full intensity of the light source. As the angle of
incidence increases, the intensity of illumination decreases.

Angle of incidence affects intensity.

**Attenuation**

In the real world, light diminishes over distance. Objects far from the light source appear darker; objects near the source appear brighter. This effect is known as *attenuation*.

In nature, light attenuates at an inverse square rate. That is, its intensity diminishes in proportion to the square of the distance from the light source. It is common for attenuation to be even greater when light is dispersed by the atmosphere, especially when there are dust particles in the atmosphere, or fog or clouds.

A. Inverse decay
B. Inverse square decay

The graphs show the decay curves.

**Reflected Light and Ambient Light**

The light an object reflects can illuminate other objects. The more light a surface reflects, the more light it contributes to illuminating other objects in its environment.

Reflected light creates *ambient light*. Ambient light has a uniform intensity and is uniformly diffuse. It has no discernible source and no discernible direction.
Chapter 15: Lights and Cameras

A. Direct light
B. Reflected light
C. Resulting ambient light

Color and Light

The color of light depends partly on the process that generates the light. For example, a tungsten lamp casts orange-yellow light, a mercury vapor lamp casts cold blue-white light, and sunlight is yellow-white. Light color also depends on the medium the light passes through. For example, clouds in the atmosphere tint daylight blue, and stained glass can tint light a highly saturated color.

Light colors are additive colors; the primary light colors are red, green, and blue (RGB). As multiple colored lights mix together, the total light in the scene gets lighter and eventually turns white.

Color Temperature

Color temperature describes a color in terms of degrees Kelvin (K). This is useful for describing the color of light sources and other color values that are close to white. The following table shows color temperatures for some common types of light, with the equivalent hue number (from the HSV color description).

If you use these hue numbers for lights in a scene, set the value to full (255) and then adjust the saturation to meet the needs of your scene. Mentally we tend to correct light color so that objects appear to be lit by white light; usually the effect of color temperature in a scene should be subtle.

Lighting in 3ds Max

Lighting in 3ds Max simulates natural lighting. However, standard lights are simpler than natural lighting. Using photometric lights (page 2–1301) with a radiosity solution (page 3–51) with your lights provides a better model of the real world.

Intensity

The intensity of a standard light is its HSV V alue. At full value (255), the light is at its brightest; at 0, the light is completely dark. Note: See Designing Materials (page 2–1395) for more information about material color and how it interacts with light intensity.

The intensity of a photometric light is set by a real-world intensity value, measured in either lumens, candelas, or lux. See Intensity/Color/Distribution Rollout (page 2–1352).

Angle of Incidence

3ds Max uses a vector from the light object to the face, along with the face normal, to calculate the angle of incidence.

A surface is fully illuminated when the angle of incidence is 0 degrees (that is, the light source strikes the surface perpendicularly). If the angle of incidence increases, attenuation is in effect, or if the light has a color, the surface intensity can be reduced.

In other words, the position and orientation of the light, relative to the object, are what control the angle of incidence in a scene. The Place Highlight command (page 1–467) is one way to fine-tune the location of a light.

Attenuation

For standard lights, attenuation (page 3–912) is turned off by default. To shade or render a scene with attenuation, you turn it on for one or more lights. All types of standard lights support attenuation. You can set explicitly where attenuation begins and where it ends. This is partly so you don’t have to worry about setting up strictly realistic distances between light objects and the objects they illuminate. More importantly, this feature lets you fine-tune the effect of attenuation.

In outdoor scenes, attenuation can enhance the effect of distance. (Another way to model environmental effects is to use the atmospheric settings when you render. See Environment and Atmosphere Effects (page 3–271).) In an indoor setting, attenuation is useful for low-intensity light sources such as candles.

Photometric lights always attenuate, using an inverse-square falloff, as in nature. (In the case of the IES Sun Light, its great intensity makes its attenuation hardly apparent.)

Reflected Light and Ambient Light

Rendering with the default renderer and standard lights does not calculate the effect of lights reflected from objects in the scene. Because of this, lighting a scene with standard lights often requires you to add more light objects than would be needed in real life. You can, however, use radiosity (page 3–51) to show the results of reflected light.

When you do not use a radiosity solution, you can use the Environment panel (page 3–272) to adjust the color and intensity of ambient light. Ambient light affects contrast. The higher the intensity of ambient light, the lower the contrast in the scene. The color of ambient light tints the scene. Sometimes ambient light is bounced light.
that gets its color from other objects in the scene. Most of the time, however, the color of ambient light should be the complement of the color of the principal light source for the scene.

Tip: To better simulate reflected light and variations in it due to the varying reflectivity of objects in the scene, you can add more lights to a scene and set them to exclude the objects you don’t want them to affect. You can also set up lights to affect only the ambient component of surfaces. See General Lighting Parameters (page 2–1331).

**Color**

You can set the color of 3ds Max lights. You can use the RGB values for color temperatures as a guide for the principal lighting of a scene; see Properties of Light (page 2–1276). Be aware, however, that we tend to perceive scenes as always being lit by white light (this is a perceptual phenomenon known as color constancy), so accurately reproducing the color of a light source can make the rendered scene appear to be tinted oddly. Use the light source values as a general guideline only.

**Guidelines for Lighting**

The guidelines for lighting used by photographers, filmmakers, and stage designers can also help you set up the lighting for scenes in 3ds Max.

Your choice of lighting depends on whether your scene simulates natural or artificial illumination. Naturally lit scenes, such as daylight or moonlight, get their most important illumination from a single light source. Artificially lit scenes, on the other hand, often have multiple light sources of similar intensity.

Note: If you use standard instead of photometric lights, both kinds of scenes require multiple secondary light sources for effective illumination.

Whether a scene is indoors or outdoors can also affect your choice of material colors. See Designing Materials (page 2–1395).

**Natural Light**

*Outdoor scene with natural sunlight*

At ground level, for practical purposes, sunlight has parallel rays coming from a single direction. The direction and angle vary depending on the time of day, the latitude, and the season.

In clear weather, the color of sunlight is a pale yellow: for example, RGB values of 250, 255, 175 (HSV 45, 80, 255). Cloudy weather can tint sunlight blue, shading into dark gray for stormy weather. Particles in the air can give sunlight an orange or brownish tint. At sunrise and sunset, the color can be more orange or red than yellow.

3ds Max specifically provides a daylight system to simulate the sun. See Sunlight and Daylight Systems (page 1–418). A single daylight system is appropriate as the main light source for sunlit scenes.

Shadows are more distinct the clearer the day is, and can be essential for bringing out the three-dimensionality of a naturally lit scene.

A directional light can also simulate moonlight, which is white but dim compared to the sun.
Artificial Light

Artificial light, whether used indoors or outdoors at night, uses multiple lights. The following guidelines are for creating normally lit, easily legible scenes. You don’t have to follow the guidelines, of course, but then you call attention to the lighting itself, rather than to the subject of the scene.

The subject of a scene should be lit by a single bright light, known as the key light. Position the key light in front of the subject and slightly above.

In addition to the key light, position one or more other lights to illuminate the background and the side of the subject. These are known as fill lights. Fill lights are less bright than the key light.

When you use only one fill light, the angle at ground level between it, the subject, and the key light should be approximately 90 degrees.

Key-and-fill lighting emphasizes the subject of a scene. It also emphasizes the three-dimensionality of the scene.

In 3ds Max, a spotlight is usually best for the key light, and either spotlights or omni lights are good for creating the fill lighting. See Target Spot (page 2–1289), Free Spot (page 2–1290), and Omni (page 2–1295). Ambient light can be another element of your fill lighting.

You can also add lights to emphasize secondary subjects in a scene. In stage terminology, these lights are known as specials. Special lights are usually brighter than the fill light but less bright than the main key light.

To design using physically based energy values, distributions, and color temperature, you can create photometric lights (page 2–1301).

Ambient Light

Ambient light in 3ds Max simulates the general illumination from light reflecting off diffuse surfaces. Ambient settings determine the illumination level of surfaces in shadow, or those not receiving direct illumination from light sources. The Ambient level on the Environment dialog establishes the scene’s basic illumination level before any light sources are taken into account, and is the dimmest any portion of the scene can ever become.

Ambient light is most often used for exterior scenes, when the sky’s broad lighting produces an even distribution of reflected light to surfaces not in direct sun. A common technique for deepening the shadows is to tint the ambient light color to be the complement of the scene’s key light.

Unlike the outside, interior scenes typically have numerous lights, and a general ambient light level is not ideal for simulating the diffuse reflection of local light sources. For interiors, it’s common to set the scene’s environment ambient level to black,
and use lights that effect ambient only to simulate the regional areas of diffuse reflection.

You set the scene’s ambient light using the Environment And Effects dialog > Environment panel (page 3–272). You set a light to affect only ambient illumination with its Advanced Effects rollout (page 2–1341) > Ambient Only check box.

---

**Positioning Light Objects**

Once you have placed lights in your scene, you can use transforms to change a light’s position or orientation.

**Transforming Lights**

Use transforms on light objects as follows:

- **Move:** Use Move (page 1–439) to change the position of lights. You can also use it to change the position of light targets.

- **Rotate:** Use Rotate (page 1–439) to change the orientation of lights.

  **Note:** You can’t rotate a target light about its local X or Y axes. Instead, use Move to move the light or its target. Rotating the light about its local Z axis can be useful if the light uses a rectangular beam or projects a bitmap.

Rotating a plain omni light or a photometric isotropic light has no effect as these lights cast light uniformly in all directions. However, rotating an omni or isotropic projector light causes the projected image to rotate.

Rotating a photometric isotropic light has no effect as these lights cast light uniformly in all directions. However, rotating an isotropic projector light causes the projected image to rotate.

**Scale:** Scaling Point, Linear, or Area lights has no effect. Using Scale (page 1–441) with spotlights and directional lights changes the size of their light beam and attenuation ranges. Scaling omni lights changes only the attenuation ranges. Scaling photometric lights changes their attenuation rate.

**Light viewports (page 3–750) are another convenient way to transform and change parameters of spotlights and directional lights.**

**Tip:** When you adjust lights, it can be useful to turn on Degradation Override (page 1–34). If Override is off and shaded viewports begin to display in wireframe, you can’t see the result of the changes you make to lights.

---

**Placing Highlights**

You use Place Highlight (page 1–467) to position a light to create a specular highlight at a designated point on an object. Place Highlight is one of the buttons on the Align flyout. Place Highlight moves or rotates the selected light object to aim it at a face on an object you pick. The light maintains its original distance from the face. Place Highlight works with any kind of selected object. You can also use Place Highlight with a selection set that contains more than one object. All objects maintain their initial distance from the face.

---

**Animating Lights**

You animate lights by using transforms or changing creation parameters on different keyframes while the **Auto Key button (page 3–717)** is on. During animation, light transforms and parameter values are interpolated between keyframes.

**Moving and Rotating Light Objects**

You can use the following methods to move and rotate light objects.
• Move an omni light (page 2–1295) when it’s a “practical” light within a scene (a light that appears in the scene itself). Combine the light with a self-illuminating geometric object. If you want to move a target type of light, select both the light and its target to animate them together.

• Use a free spotlight (page 2–1290) when a spotlight is to move within the scene. Free spotlights are especially intended to be animated along a path, using a Path constraint (page 2–398). Unlike target spotlights, free spotlights can bank as they travel. Use target spotlights (page 2–1289) when the light position is fixed.

• If you do need to move a target spotlight, link both the light and its target to a dummy object (page 2–16), then assign the path constraint to the dummy object.

• Use a LookAt Constraint (page 2–406) to have a spotlight track a moving object.

If the spotlight is a target spotlight, its previous target is ignored.

If the spotlight is a free spotlight, it effectively becomes a target spotlight, with the looked-at object the target.

• Change the parameters of a daylight system (page 1–418) or sunlight system to simulate different times of day or year.

**Animating Light Creation Parameters**

The following techniques can be used to animate Modify panel parameters for lights.

• To dim or brighten a light over time, animate its Multiplier parameter.

• To change the color of a light over time, animate its color parameters. Use a smooth tangent (page 2–305) for color change keys unless you want the color to change abruptly.

• To make a standard light flash on and off, set its Multiplier to 0 in repeated keyframes, and assign a step tangent (page 2–305) to this parameter.

---

**Light Include/Exclude Tool**

By default, the Light Include/Exclude tool is unavailable in the 3ds Max user interface. You can add it as a custom keyboard shortcut, quad or menu item, or toolbar button by using the Customize User Interface dialog (page 3–792).

The Light Include/Exclude tool is a modeless dialog that lets you include or exclude objects on a light-by-light basis. When excluded, an object is not illuminated by the selected light and receives no shadows.

This dialog requires at least one light object in your scene. For a selected light, this dialog is a shortcut to the same functionality available on the Exclude/Include dialog (page 2–1335).

Although light exclusion does not occur in nature, this feature is useful when you need exact control over the lighting in your scene. Sometimes, for example, you’ll want to add lights specifically to illuminate a single object but not its surroundings, or you’ll want a light to cast shadows from one object but not from another.

Note: By default, no objects are excluded for a new light. It’s necessary only to include objects that have previously been excluded.

**See also**

*Lights (page 2–1272)*

*Light Lister (page 2–1285)*

**Procedure**

To exclude an object from receiving light:

1. In the scene, select the object or objects to exclude.

2. Open the Light Incl/Excl dialog.
See the path annotation, above. To use the Light Include/Exclude tool, you have to create a custom keyboard shortcut, quad or menu item, or toolbar button.

3. In the Geometry group, choose Exclude.

4. Click the Assign To Light button.

5. In the scene, click a light. If the light is hard to locate, use the Select Objects dialog (page 1–78) (keyboard shortcut [H]) to pick the light.

   The object is now excluded from the light. The Objects list at the bottom of the dialog lists the object.

6. Render to see the effect.

**Interface**

![Light Include/Exclude Interface](image)

**Geometry group**

**Include, Exclude**—Toggles the state of a selected object to receive light from a particular light object. Default=include.

**Assign to Light**—Activates selection so you can choose the light you want to use. You can only choose one light at a time.

**List Light Properties group**

These controls let you view and edit the include/exclude status of objects on a light-by-light basis.
Current displayed light—Names the currently selected light.

Choose Light—Activates selection so you can choose another light.

Clear Light—Empties the Objects list, removing any included or excluded objects assigned to the currently displayed light.

Include, Exclude—Reverses the state of included or excluded objects to receive light from the currently displayed light.

Objects—Lists objects selected for inclusion or exclusion by the currently displayed light.

Help—Provides a quick reminder of procedures.

Procedures

To use global settings:

1. On the Light Lister dialog, on the Configuration rollout, choose General Settings. The General Settings rollout appears.
2. Make changes to the settings. See Interface, below.

To set individual lights:

1. On the Configuration rollout, choose All Lights. The Lights rollout displays settings for all the scene lights (subject to the limit of 150 lights described above). Alternatively, you can select the lights to adjust, and then on the Configuration rollout choose Selected Lights.
   Tip: If you change the light selection, the Light Lister does not update interactively. Click Refresh to update the list.
2. On the Lights rollout, change the settings for any light on the list. See Interface, below.
   Some changes show up immediately in the viewport.

Interface

Configuration rollout

Chooses which lights and controls to affect, and lets you update light settings.

All Lights—The Lights rollout shows all lights in the scene (subject to the 150-light restriction, described above).

Selected Lights—The Lights rollout shows only selected lights.

General Settings—Displays the General Settings rollout.

Light Lister

Tools menu > Light Lister

Light Lister is a modeless dialog that lets you control a number of features for each light. You can also make global settings that affect every light in your scene.

To display information, this dialog requires at least one light object in your scene. For a selected light, this dialog is a shortcut to the same functionality available on the Modify panel > Parameters rollout. Global settings are duplicated on the Environment panel (page 3–272).

Note: The Light Lister cannot control more than 150 unique light objects at a time (instances of a light don’t count). If there are more than 150 unique lights in your scene, the Lister displays controls for the first 150 it finds, and a warning that you should select fewer lights. Select fewer lights and then use the Selected Lights configuration.

See also

Light Include/Exclude Tool (page 2–1283)
**Refresh**—Updates the list of lights to use the current light selection (if Selected Lights is active) and current scene settings.

Note: When the Light Lister needs to be updated, the Refresh button is highlighted in yellow.

**General Settings rollout**

These controls are for general lighting settings.

- **Selected Lights**—When chosen, general settings affect only selected lights.
- **All Lights**—When chosen, general settings affect all lights in the scene (subject to the 150-light restriction, described above).

**On**—When on, affected lights are active in the scene. When off, affected lights go dark in the viewports and renderings.

**Multiplier**—Increases or decreases the light intensity of standard lights. See General Lighting Parameters (page 2–1331) for standard lights.

**Color**—By default, the color of all standard lights is white. Click to display the Color Selector (page 1–161) and change the light color for affected lights.

**Warning:** For photometric lights, this changes the filter color, not the color temperature.

**Shadows**—When on, affected lights cast shadows. When off, they don’t cast shadows.

**Shadow type drop-down list**—Selects the shadow type for affected lights.

**Map Size**—Sets the size (in pixels squared) of the shadow map used by affected lights.

**Bias**—Setting depends on which shadow type is selected. In general, bias moves the shadow toward or away from the shadow-casting object.

For specific effects, see Shadow Map Parameters (page 2–1363) and Ray-Traced Shadow Parameters (page 2–1363).

**Sm. Range (Sample Range)**—For shadow-mapped shadows, sets the Sample Range value. See Shadow Map Parameters (page 2–1363). This value has no effect for ray-traced or area shadows.

**Transp. (Transparency)**—When on, turns on transparency for advanced ray-traced and area shadows. Has no effect on shadow-mapped or standard ray-traced shadows. Default=off.

**Int. (Integrity)**—For advanced ray-traced shadows or area shadows, sets the Shadow Integrity. See Advanced Ray-Traced Parameters Rollout (page 2–1356) or Area Shadows Rollout (page 2–1357).

**Qual. (Quality)**—For advanced ray-traced shadows or area shadows, sets the Shadow Quality. See Advanced Ray-Traced Parameters Rollout (page 2–1356) or Area Shadows Rollout (page 2–1357).

**Decay**—(For standard lights.) Sets the type of decay: None, Inverse, or Inverse Square. See Intensity/Color/Attenuation Parameters (page 2–1345).

**Start**—(For standard lights.) Sets the start range for decay. See Intensity/Color/Attenuation Parameters (page 2–1345).

**Length**—(For photometric lights.) Sets the Length value for Linear and Area lights. See Linear Light Parameters Rollout (page 2–1354) or Area Light Parameters Rollout (page 2–1354).

**Width**—(For photometric lights.) Sets the Width value for Area lights. See Area Light Parameters Rollout (page 2–1354).

**Global Tint**—Adds a color tint to all lights in the scene except ambient light. Click to use the Color Selector (page 1–161). The tint is in addition to the
global light color, or the color of individual lights. The default setting, white, has no tinting effect.

**Global Level**—Increases or decreases the overall lighting level for Standard lights. Default=1.0.

Note: This setting, designed for standard lights, reduces the level of photometric lights to near darkness. If you have photometric lights in your scene, leave this setting at the default.

**Ambient Color**—Changes the ambient color (page 3–908), the color seen in shadows. Click to use the Color Selector (page 1–161).

**Lights rollout**

This rollout is visible while All Lights or Selected Lights is active on the Configuration rollout. Its controls are for individual light objects. This rollout displays two lists: one for standard lights, and another for photometric lights.

**Blank gray button (Select)**—Click to select the named light. This button turns white for selected lights. Selecting a light opens the Modify panel for that light. This button has a gray box in the middle for the light that appears in the Modify panel. The gray box appears whether the light is selected or not.

Clicking Select deselected all other lights. If the entry is for an instanced light, clicking Select selects all instances (see the description of the Name field that follows). If the light is part of a group, the entire group is selected. If you are in Selected Lights mode (on the Configuration rollout), the list of selected lights is not refreshed automatically.

Note: You can set the controls for a light without selecting it.

**Check box**—Turns the light on or off. Default=on.

**Name**—Shows the name of the light object.

If there are multiple instances of a light, only one entry appears in the Light Lister, and the Name field becomes a drop-down list. The list lets you see the names of all instances, but it has no other effect: parameter changes made in the Light Lister affect all instances of the light.

**Multiplier**—(Standard lights only.) Increases or decreases the intensity of the light. Default=1.0.

Note: This control is unavailable if the light has a procedural controller.

**Intensity**—(Photometric lights only.) Sets the light intensity, in candelas. Default=1500.0.

Note: This control is unavailable if the light has a procedural controller.

**Color**—Click to display the Color Selector (page 1–161) and change the light color. Default=white.

**Warning:** For photometric lights, this changes the filter color, not the color temperature.

**Shadows**—Turns shadow casting on or off. Default=on.

**Shadow type drop-down list**—Selects the shadow type for the light.

**Map Size**—Available only when shadow map shadows is on. Sets the size (in pixels squared) of the shadow map used by all lights.

**Bias**—Setting depends on which shadow type is selected. In general, bias moves the shadow toward or away from the shadow-casting object. See Shadow Map Parameters (page 2–1363) and Ray-Traced Shadow Parameters (page 2–1363) for specific effects.

**Sm. Range**—For shadow-mapped shadows, sets the Sample Range value. See Shadow Map Parameters (page 2–1363). This value has no effect for ray-traced shadows. Default=4.0.
Chapter 15: Lights and Cameras

Transp. (Transparency)—When on, turns on transparency for advanced ray-traced and area shadows. Has no effect on shadow-mapped or standard ray-traced shadows. Default=off.

The shadow transparency control is on the Optimizations rollout (page 2–1361).

Int. (Integrity)—For advanced ray-traced shadows or area shadows, sets the Shadow Integrity. See Advanced Ray-Traced Parameters Rollout (page 2–1356) or Area Shadows Rollout (page 2–1357). Default=1.

Qual. (Quality)—For advanced ray-traced shadows or area shadows, sets the Shadow Quality. See Advanced Ray-Traced Parameters Rollout (page 2–1356) or Area Shadows Rollout (page 2–1357). Default=2.

Decay—(Standard Lights only.) Sets the type of decay: None, Inverse, or Inverse Square. See Attenuation Parameters (page 2–1345). Default=None.

Start—(Standard lights only.) Sets the start range for decay. See Attenuation Parameters (page 2–1345). Default=0.0.

Length—(Photometric lights only.) Sets the Length value for Linear and Area photometric lights. See Linear Light Parameters Rollout (page 2–1354) or Area Light Parameters Rollout (page 2–1354).

Width—(Photometric lights only.) Sets the Width value for Area photometric lights. See Area Light Parameters Rollout (page 2–1354).

Standard Lights

Standard lights are computer-based objects that simulate lights such as household or office lamps, the light instruments used in stage and film work, and the sun itself. Different kinds of light objects cast light in different ways, simulating different kinds of real-world light sources. Unlike photometric lights (page 2–1301), standard lights do not have physically-based intensity values.

There are eight types of standard light objects:

- Target Spotlight (page 2–1289)
- Free Spotlight (page 2–1290)
- Target Direct Light (page 2–1292)
- Free Direct Light (page 2–1293)
- Omni Light (page 2–1295)
- Skylight (page 2–1296)
- mr Area Omni Light (page 2–1298)
- mr Area Spotlight (page 2–1299)

Most of the parameters for standard lights are common to all five types. These are described in the following topics:

- General Lighting Parameters (page 2–1331)
- Intensity/Color/Attenuation Parameters (page 2–1345)
- Advanced Effects Rollout (page 2–1341)
- Shadow Parameters (page 2–1337)
- mental ray Indirect Illumination Rollout (for Lights) (page 2–1343)

Spotlights and Directional lights have rollouts specific to them:

- Spotlight Parameters (page 2–1338)
- Directional Parameters (page 2–1348)

For parameters specific to a particular kind of light, see that light’s description.

Shadow Parameters

Different rollouts can appear, depending on which type of shadows you have chosen for a light:
Advanced Ray-Traced Parameters Rollout (page 2–1356)
Area Shadows Rollout (page 2–1357)
Optimizations Rollout (page 2–1361)
mental ray Shadow Map Rollout (page 2–1360)
Ray-Traced Shadow Parameters Rollout (page 2–1363)
Shadow Map Parameters Rollout (page 2–1363)

Target Spotlight

Create panel > Lights > Standard > Target Spot button
Create menu > Standard Lights > Target Spotlight

Top: Top view of a target spotlight
Bottom: Perspective view of the same light

A spotlight casts a focused beam of light like a flashlight, a follow spot in a theater, or a headlight. A target spotlight uses a target object to aim the camera.

Note: When you add a target spotlight, the software automatically assigns a Look At controller (page 2–344) to it, with the light’s target object assigned as the Look At target. You can use the controller settings on the Motion panel to assign any other object in the scene as the Look At target.

Lights (page 2–1272)
Name and Color Rollout (Lights) (page 2–1273)
General Lighting Parameters (page 2–1331)
Intensity/Color/Attenuation Parameters (page 2–1345)
Advanced Effects Rollout (page 2–1341)
Shadow Parameters (page 2–1337)
Spotlight Parameters (page 2–1338)

Procedures
To create a target spotlight:

1. On the Create panel, click Lights. Standard is the default choice of light type.
2. In the Object Type rollout, click Target Spot.
3. Drag in a viewport. The initial point of the drag is the location of the spotlight, and the point where you release the mouse is the location of the target.
   The light is now part of the scene.
4. Set the creation parameters.

To adjust a target spotlight:

1. Select the light.
2. Use Move on the main toolbar to adjust the light. As an alternative, right-click the light and choose Move.
Because the spotlight is always aimed at its target, you can’t rotate it about its local X or Y axis. However, you can select and move the target object as well as the light itself. When you move either the light or the target, the light’s orientation changes so it always points at the target.

Note: The target’s distance from the light does not affect the attenuation or brightness of the light.

To select the target:
The target, displayed as a small square, is often in the same area as objects that you want to illuminate. It can be difficult to select it by clicking.

1. Select the spotlight itself.
2. Right-click the light and choose Select Target from the upper-left (Tools 1) quadrant of the quad menu.
   
   Clicking the line that connects the light and its target selects both objects. However, region selection doesn’t recognize the link line.

   Another way to adjust a spotlight is to use a Light viewport (page 2–1338).

   To change a viewport to a Light view:
   1. Right-click a viewport label.
      The viewport right-click menu is displayed.
   2. Choose Views.
      The name of each spotlight or directional light is displayed in the Views list.
   3. Choose the name of the light you want.
      The viewport now shows the light’s point of view. You can use the Light Viewport Controls (page 3–750) to adjust the light.
      The default keyboard shortcut for switching to a Light viewport is $.

Interface
When you rename a target spotlight, the target is automatically renamed to match. For example, renaming Light01 to Klieg causes Light01.Target to become Klieg.Target. The target’s name must have the extension .Target. Renaming the target object does not rename the light object.

Free Spotlight

Create panel > Lights > Standard > Free Spot button
Create menu > Standard Lights > Free Spotlight

A spotlight casts a focused beam of light like a flashlight, a follow spot in a theater, or a headlight. Unlike a targeted spotlight, a Free Spot has no target object. You can move and rotate the free spot to aim it in any direction.
Free Spotlight

Intensity/Color/Attenuation Parameters (page 2–1345)
Advanced Effects Rollout (page 2–1341)
Shadow Parameters (page 2–1337)
Spotlight Parameters (page 2–1338)

Procedures

To create a free spotlight:

1. On the Create panel, click Lights.
   Standard is the default choice of light type.
2. In the Object Type rollout, click Free Spot.
3. Click the viewport location where you want the light to be.
   The light is now part of the scene. It points away from you in the viewport you clicked.
   You can adjust the light’s direction with Move and Rotate or by using a Light viewport.
4. Set the creation parameters.

To change a viewport to a Light view:

1. Right-click a viewport label.
   The viewport right-click menu is displayed.
2. Choose Views.
   The name of each spotlight or directional light is displayed in the Views list.
3. Choose the name of the light you want.
   The viewport now shows the light’s point of view. You can use the Light Viewport Controls (page 3–750) to adjust the light.

The default keyboard shortcut for switching to a Light viewport is $.

Interface

You aim a free spotlight by adjusting its orientation in a scene using Move and Rotate.

The free spotlight is useful when you want a spotlight to follow a path and either don’t want to bother with linking a spotlight and target to a dummy object (page 3–930), or you need banking along the path.

General Parameters rollout

When you create a Free Spot light, the Targeted parameter is adjustable on the General Parameters rollout (page 2–1331). This is a fixed value for target lights.

Targeted—When on, 3ds Max sets a point to use as an invisible target about which the Free Spot can orbit. The spinner adjusts the distance to the target.

The target distance is animatable.

You aim a free spotlight by adjusting its orientation in a scene using Move and Rotate.

The free spotlight is useful when you want a spotlight to follow a path and either don’t want to bother with linking a spotlight and target to a dummy object (page 3–930), or you need banking along the path.

General Parameters rollout

Targeted—When on, 3ds Max sets a point to use as an invisible target about which the Free Spot can orbit. The spinner adjusts the distance to the target.

The target distance is animatable.
Target Direct Light

Create panel > Lights > Standard > Target Direct button
Create menu > Standard Lights > Target Directional Light

Directional lights cast parallel light rays in a single direction, as the sun does (for all practical purposes) at the surface of the earth. Directional lights are primarily used to simulate sunlight. You can adjust the color of the light and position and rotate the light in 3D space.

A target directional light uses a target object to aim the light.

Because directional rays are parallel, directional lights have a beam in the shape of a circular or rectangular prism instead of a "cone."

Note: When you add a target directional light, the software automatically assigns a Look At controller (page 2–344) to it, with the light’s target object assigned as the Look At target. You can use the controller settings on the Motion panel to assign any other object in the scene as the Look At target.

Note: Direct lights are supported in a radiosity solution (page 3–51) only if they are pointed downwards, outside the boundary box of the scene geometry.

Note: The mental ray renderer assumes that all directional lights come from infinity, so objects that are behind the direct light object in the 3ds Max scene will also be illuminated. In addition, with the mental ray renderer, directional lights cannot generate area shadows, and do not work with the Beam shader (in the lume library).

Intensity/Color/Attenuation Parameters (page 2–1345)
Advanced Effects Rollout (page 2–1341)
Shadow Parameters (page 2–1337)
Directional Parameters (page 2–1348)

Procedures

To create a target direct light:

1. On the Create panel, click Lights. Standard is the default choice of light type.
2. In the Object Type rollout, click Target Direct.
3. Drag in a viewport. The initial point of the drag is the location of the light, and the point where you release the mouse is the location of the target.

The light is now part of the scene.
4. Set the creation parameters.
   To adjust the light’s direction, move the target object.

To change a viewport to a Light view:
1. Right-click the viewport label.
   The viewport right-click menu is displayed.
2. Choose Views.
   The name of each spotlight or directional light is displayed in the Views list.
3. Choose the name of the light you want.
   The viewport now shows the light’s point of view. You can use the Light Viewport Controls (page 3–750) to adjust the light.
   The default keyboard shortcut for switching to a Light viewport is $.

Interface
Clicking the line that connects the light and its target selects both objects. However, region selection doesn’t recognize the link line.

When you rename a target directional light, the target is automatically renamed to match. For example, renaming Light01 to Sol causes Light01.Target to become Sol.Target. The target’s name must have the extension .Target. Renaming the target object does not rename the light object.

Free Direct Light
Create panel > Lights > Standard > Free Direct button
Create menu > Standard Lights > Directional Light

Top: Perspective view of a free directional light
Bottom: Top view of the same light

Directional lights cast parallel light rays in a single direction, as the sun does (for all practical purposes) at the surface of the earth. Directional lights are primarily used to simulate sunlight. You can adjust the color of the light and position and rotate the light in 3D space.

Unlike a targeted directional light, a Free Direct light has no target object. You can move and rotate the light object to aim it in any direction.

A Free Direct light is used when you select a Standard sun in your Daylight system (page 1–418).
Because directional rays are parallel, directional lights have a beam in the shape of a circular or rectangular prism instead of a "cone."

Note: Direct lights are supported in a radiosity solution (page 3–51) only if they are pointed downwards, outside the boundary box of the scene geometry.

Note: The mental ray renderer assumes that all directional lights come from infinity, so objects that are behind the direct light object in the 3ds Max scene will also be illuminated. In addition, with the mental ray renderer, directional lights cannot generate area shadows, and do not work with the Beam shader (in the lume library).

Intensity/Color/Attenuation Parameters (page 2–1345)
Advanced Effects Rollout (page 2–1341)
Shadow Parameters (page 2–1337)
Directional Parameters (page 2–1348)

Procedures

To create a free direct light:

1. On the Create panel, click Lights. Standard is the default choice of light type.
2. In the Object Type rollout, click Free Direct.
3. Click a viewport.
   The light is now part of the scene. It points away from you in the viewport you clicked.
4. Set the creation parameters.
   To adjust the light’s direction, you can rotate it as you would any object.

To change a viewport to a Light view:

1. Right-click the viewport label.
   The viewport right-click menu is displayed.
2. Choose Views.
   The name of each spotlight or directional light appears in the Views list.
3. Choose the name of the light you want.
   The viewport now shows the light’s point of view. You can use the Light Viewport Controls (page 3–750) to adjust the light.
   The default keyboard shortcut for switching to a Light viewport is $.

Interface

Directional Parameters rollout

When you create a Free Direct light, the Targeted parameter is adjustable on the General Parameters rollout (page 2–1331). This is a fixed value for target lights.

Targeted—When on, 3ds Max sets a point to use as an invisible target about which the Free Direct light can orbit. The spinner adjusts the distance to the target.

This parameter also affects the length of the light’s cone display.
Omni Light

Create panel > Lights > Standard > Omni button
Create menu > Standard Lights > Omni Light

Top: Top view of an omni light
Bottom: Perspective view of the same light

An Omni light casts rays in all directions from a single source. Omni lights are useful for adding "fill lighting" to your scene, or simulating point source lights.

Omni lights can cast shadows and projections. A single shadow-casting omni light is the equivalent of six shadow-casting spotlights, pointing outward from the center.

When you set a map projected by an Omni light to be projected using the Spherical, Cylindrical, or Shrink Wrap Environment coordinates, the map is projected in the same way as it would be mapped to the environment. When you use the Screen Environment coordinates or Explicit Map Channel Texture coordinates, six copies of the map are projected radially.

Tip: Omni lights can generate up to six quadtrees (page 3–999), so they generate ray-traced shadows more slowly than spotlights. Avoid using ray-traced shadows with omni lights unless your scene requires this.

See also

Lights (page 2–1272)
Name and Color Rollout (Lights) (page 2–1273)
General Lighting Parameters (page 2–1331)
Intensity/Color/Attenuation Parameters (page 2–1345)
Advanced Effects Rollout (page 2–1341)
Shadow Parameters (page 2–1337)

Procedure

To create an omni light:

1. On the Create panel, click Lights. Standard is the default choice of light type.
2. In the Object Type rollout, click Omni.
3. Click the viewport location where you want the light to be. If you drag the mouse, you can move the light around before releasing the mouse to fix its position.
4. Set the creation parameters.

To adjust the light’s effect, you can move it as you would any object.
Skylight

Create panel > Lights > Standard > Skylight button

Create menu > Lights > Skylight

The Skylight light models daylight. It is meant for use with the Light Tracer (page 3–44). You can set the color of the sky or assign it a map. The sky is modeled as a dome above the scene.

Tip: There are several ways to model daylight in 3ds Max, but if you use the Light Tracer, a Skylight often gives the best results.

Warning: When you render with the mental ray renderer (page 3–78), objects illuminated by a Skylight appear dark unless you turn on Final Gathering (page 3–940). The toggle for Final Gathering is on the Final Gather rollout (page 3–111) of the Render Scene dialog.

Tip: If you encounter visual anomalies when rendering a bump-mapped material with a Skylight, convert the material to an Advanced Lighting Override material (page 2–1601) and then reduce the Indirect Light Bump Scale value.

Using a Map with the Skylight

If you use a map with a Skylight, the following guidelines can improve its effect:

- Make sure that the mapping coordinates are spherical or cylindrical.
- For light tracing, make sure you use sufficient samples. A good rule of thumb is to use at least 1,000 samples: set Initial Sample Spacing to 8x8 or 4x4, and increase the value of Filter Size to 2.0.
- Use an image-processing application to blur the map before you use it. With a blurred map, you can use fewer samples to obtain good results. When used with Skylight, a blurred map will still render well.

Be aware that using sufficient samples with a mapped Skylight will take longer to render than if the light were not mapped.
Using Render Elements with a Skylight

If you use Render Elements (page 3–130) to output the lighting element (page 3–141) of a skylight in a scene using either radiosity or the light tracer, you cannot separate the direct, indirect, and shadow channels of the light. All three elements of the skylight lighting are output to the Indirect Light channel.

Procedures

To create a Skylight:

1. On the Create panel, click Lights. Standard is the default choice of light type.
2. In the Object Type rollout, click Skylight.
3. Click a viewport. The light is now part of the scene.
   Note: The position of the Skylight, and its distance from objects, has no effect. The Skylight object is simply a helper. Skylight always comes from “overhead.”
4. Set the creation parameters.

Interface

On—Turns the light on and off. When On is on, shading and rendering use the light to illuminate the scene. When off, the light is not used in shading or rendering. Default=on.

Multiplier—Amplifies the power of the light by a positive or negative amount. For example, if you set the multiplier (page 3–977) to 2, the light will be twice as bright. Default=1.0.

Using this parameter to increase intensity can cause colors to appear "burned out." It can also generate colors not usable in videos. In general, leave Multiplier set to its default of 1.0 except for special effects and special cases.

Sky Color group

Use Scene Environment—Colors the light using the environment set up on the Environment panel (page 3–272).

This setting has no effect unless light tracing is active.

Sky Color—Click the color swatch to display a Color Selector (page 1–161) and choose a tint for the Skylight.

Map controls—These let you use a map to affect Skylight color. The button assigns a map, the toggle sets whether the map is active, and the spinner sets the percentage of the map to use (when the value is less than 100%, map colors are mixed with the Sky Color).

Tip: For best results, use an HDR File (page 3–613) for illumination.

The map has no effect unless light tracing is active.
Render group

Note: If the renderer is not set to Default Scanline, or if the Light Tracer is active, these controls are disabled.

**Cast Shadows**—Causes the skylight to cast shadows. Default=off.

Note: The Cast Shadows toggle has no effect when using radiosity or the light tracer.

Note: Skylight objects will not cast shadows in an *Active Shading* rendering (page 3–17).

**Rays per Sample**—The number of rays used to calculate skylight falling on a given point in the scene. For animation, you should set this to a high value to eliminate flickering. A value of around 30 should eliminate flickering.

Increasing the number of rays increases the quality of your image. However, it also increases rendering time.

**Ray Bias**—The closest distance at which objects can cast shadows on a given point in the scene. Setting this value to 0 can cause the point to cast shadows upon itself, and setting it to a large value can prevent objects close to a point from casting shadows on the point.

---

**mr Area Omni Light**

Create panel > Lights > mr Area Omni button > Area Light Parameters rollout

When you render a scene using the *mental ray renderer* (page 3–78), an area omni light emits light from a spherical or cylindrical volume, rather than from a point source. With the default scanline renderer, the area omni light behaves like any other standard omni light.

Note: In 3ds Max, area omni lights are created and supported by a MAXScript script. Only the mental ray renderer uses the parameters on the Area Light Parameters rollout. See *Enhancements to Standard Features* (page 3–84) for more details.

Tip: Area lights take longer to render than point lights. To create a quick test (or draft) rendering, you can use the Area/Linear Lights as Point Lights toggle in the *Common Parameters rollout* (page 3–27) of the Render Scene dialog to speed up your rendering.

See also

*mr Area Spotlight* (page 2–1299)

**Procedures**

**To create an area omni light:**

1. ![Lights Icon](image)

   On the Create panel, click Lights.

2. ![Object Type Rollout](image)

   On the Object Type rollout, click mr Area Omni.

3. Click in a viewport.

4. Set the shape and size of the area light in the Area Light Parameters rollout.

   While you use the spinners to adjust the size of the area light, a gizmo (yellow by default) appears in viewports to show the adjusted size. This gizmo disappears once you finish adjusting the value.

   Tip: You can use Rotate to adjust the orientation of a cylindrical area omni light. However, no gizmo appears while you rotate the light.

**To convert a standard 3ds Max light to an area light:**

1. Select one or more lights.

2. Go to the Utilities panel.
3. On the Utilities rollout, click MAXScript. The MAXScript rollout is displayed.

4. On the MAXScript rollout, choose “Convert To mr Area Lights” from the Utilities drop-down list.
   The “Convert To mr Area Lights” rollout is displayed.

5. On the “Convert To mr Area Lights” rollout, click Convert Selected Lights. A MAXScript alert is displayed, that says "Delete Old Lights?" Click Yes to delete the original light and replace it with the area light. Click No to leave the original light in place. If you click No there are now two lights in the scene: the original light, and the area light based on it.

6. Click Close to dismiss the “Convert To mr Area Lights” and MAXScript rollouts.

**Interface**

- **On**—Turns the area light on and off. When On is on, the mental ray renderer uses the light to illuminate the scene. When On is off, the mental ray renderer doesn’t use the light. Default=on.

- **Show Icon in Renderer**—When on, the mental ray renderer renders a dark shape at the light’s location. When off, the area light doesn’t render. Default=off.

- **Type**—Changes the shape of the area light. The choices are Sphere, for a spherical volume, and Cylinder, for a cylindrical volume. Default=Sphere.

  **Tip:** You can use Rotate to adjust the orientation of a cylindrical area omni light. However, no gizmo appears while you rotate the light.

- **Radius**—Sets the radius of the sphere or cylinder, in 3ds Max units. Default=20.0.

- **Height**—Available only when Cylinder is the active type of area light. Sets the height of the cylinder, in 3ds Max units. Default=20.0.

  As you use these spinners to adjust the size of the area light, a gizmo appears in viewports to show the adjusted size. This gizmo disappears once you finish adjusting the value.

**Samples group**

- **U and V**—Adjust the quality of shadows cast by the area light. These values specify how many samples to take within the light’s area. Higher values can improve rendering quality at a cost of rendering time. For a spherical light, U specifies the number of subdivisions along the radius, and V specifies the number of angular subdivisions. For a cylindrical light, U specifies the number of sampled subdivisions along the height, and V specifies the number of angular subdivisions. Default=5 for both U and V.

**mr Area Spotlight**

When you render a scene using the mental ray renderer (page 3–78), an area spotlight emits light from a rectangular or disc-shaped area, rather than from a point source. With the default scanline renderer, the area spotlight behaves like any other standard spotlight.
Note: In 3ds Max, area spotlights are created and supported by a MAXScript script. Only the mental ray renderer uses the parameters in the Area Light Parameters rollout. See Enhancements to Standard Features (page 3–84) for more details.

Tip: Area lights take longer to render than point lights. To create a quick test (or draft) rendering, you can use the Area/Linear Lights as Point Lights toggle on the Common Parameters rollout (page 3–27) of the Render Scene dialog to speed up your rendering.

See also
mr Area Omni Light (page 2–1298)

Procedures
To create an area spotlight:

1. Go to the Create panel and click Lights.
2. On the Object Type rollout, click mr Area Spot.
3. Drag in a viewport. The initial point of the drag is the location of the light, and the point where you release the mouse is the location of the target.
The mental ray renderer will ignore the spotlight cone, but the location of the spotlight target determines the orientation of the plane of the area light, and the direction in which it’s projected.
4. Set the shape and size of the area light in the Area Light Parameters rollout.
While you use the spinners to adjust the size of the area light, a gizmo (yellow by default) appears in viewports to show the adjusted size. This gizmo disappears once you finish adjusting the value.

To convert a standard 3ds Max light to an area light:
1. Select one or more lights.
2. Go to the Utilities panel.
3. On the Utilities rollout, click MAXScript.
The MAXScript rollout is displayed.
4. On the MAXScript rollout, choose Convert To Area Lights from the Utilities drop-down list.
The Convert To Area Lights rollout is displayed.
5. On the Convert To Area Lights rollout, click Convert Selected Lights. A MAXScript alert is displayed, that says "Delete Converted Lights?" Click Yes to delete the original light and replace it with the area light. Click No to leave the original light in place. If you click No there are now two lights in the scene: the original light, and the area light based on it.
6. Click Close to dismiss the Convert To Area Lights and MAXScript rollouts.

Interface

On—Turns the area light on and off. When On is on, the mental ray renderer uses the light to illuminate the scene. When On is off, the mental ray renderer doesn’t use the light. Default=on.

Show Icon in Renderer—When on, the mental ray renderer renders a dark shape where the area light is. When off, the area light is invisible. Default=off.
**Photometric Lights**

Photometric lights use photometric (page 3–993) (light energy) values that enable you to more accurately define lights as they would be in the real world. You can create lights with various distribution and color characteristics, or import specific photometric files available from lighting manufacturers.

**Type**—Changes the shape of the area light. Can be either Rectangle, for a rectangular area, or Disc, for a circular area. Default=Rectangle.

**Radius**—Available only when Disc is the active type of area light. Sets the radius of the circular light area, in 3ds Max units. Default=20.0.

**Height and Width**—Available only when Rectangle is the active type of area light. Set the height and width of the rectangular light area, in 3ds Max units. Default=20.0 for both Height and Width.

While you use these spinners to adjust the size of the area light, a gizmo (yellow by default) appears in viewports to show the adjusted size. This gizmo disappears once you finish adjusting the value.

**Samples group**

**U and V**—Adjust the quality of shadows cast by the area light. These values specify how many samples to take within the light’s area. Higher values can improve rendering quality at a cost of rendering time. For a rectangular light, U specifies the number of sampled subdivisions in one local dimension, and V the number of subdivisions in the other local dimension. For a circular (disc) light, U specifies the number of subdivisions along the radius, and V specifies the number of angular subdivisions. Default=5 for both U and V.

Note: Photometric lights always attenuate using an inverse-square falloff, and rely on your scene using realistic units.

3ds Max includes the following types of photometric light objects:

- Target Point Light (Photometric) (page 2–1303)
- Free Point Light (Photometric) (page 2–1304)
- Target Linear Light (Photometric) (page 2–1305)
- Free Linear Light (Photometric) (page 2–1307)
- Target Area Light (Photometric) (page 2–1307)
- Free Area Light (Photometric) (page 2–1309)
- IES Sun Light (Photometric) (page 2–1309)
- IES Sky Light (Photometric) (page 2–1312)
- mr Sky (page 2–1318)
- mr Sun (page 2–1319)

Note: The remainder of this topic discusses photometric lights with the exception of mr Sky and mr Sun. For information about these light types, see mental ray Sun & Sky (page 2–1313).

**Distribution Capabilities of Photometric Lights**

Each type of photometric light supports two or three different light distribution options.

The point light sources (target and free) support these distributions:

- **Isotropic** (page 2–1323)
- **Spotlight** (page 2–1324)
- **Web** (page 2–1325)

The linear and area light sources (target and free) support these distributions:

- **Diffuse** (page 2–1323)
- **Web** (page 2–1325)
Parameters for Photometric Lights

Most of the photometric light parameters are common to all photometric light types, and are described in the following topics:

* Intensity/Color/Distribution Rollout (page 2–1352)

Photometric Linear and Area Lights have rollouts specific to them:

* Linear Light Parameters Rollout (page 2–1354)
* Area Light Parameters Rollout (page 2–1354)
* Area Light Sampling Rollout (page 2–1354)

The remaining photometric light parameters are shared with standard lights, and are described in the following topics:

* Name and Color Rollout (Lights) (page 2–1273)
* General Lighting Parameters (page 2–1331)
* Shadow Parameters (page 2–1337)
* Advanced Effects Rollout (page 2–1341)

Other photometric-specific topics include:

* IES Standard File Format (page 2–1328)
* Example of Photometric Data File (page 2–1329)
* Common Lamp Values for Photometric Lights (page 2–1329)

Notes

* A scene’s lighting can also be affected by the Ambient Light setting on the Environment panel (page 3–272).
* You can use the Place Highlight (page 1–467) command to change a light’s position.

Photometric Lights: Preset Lights

Create menu > Lights > Photometric Lights > Presets

Preset Lights are photometric lights that have a preset configuration in 3ds Max. Preset Lights load up correct values based on their equivalent commercial product. For example, a 60W light setting loads up the correct intensity, lighting, and distribution settings corresponding to a real 60W bulb. Using Preset Lights, you’re able to quickly create lights that are correct simulations of real-world objects.

The Preset Lights available are:

* Generic 60W Bulb
* Generic 75W Bulb
* Generic 100W Bulb
* Generic Halogen Spotlight
* Generic Recessed 75W Lamp (web)
* Generic Recessed 75W Wallwash (web)
* Generic Recessed 250W Wallwash (web)
* Generic 4ft Pendant Fluorescent (web)
* Generic 4ft Cove Fluorescent (web)
* Generic Street 400W Lamp (web)
* Generic Stadium 100W Lamp (web)

See also

* Photometric Lights (page 2–1301)
* Target Point Light (Photometric) (page 2–1303)
* Target Linear Light (Photometric) (page 2–1305)
* Target Area Light (Photometric) (page 2–1307)
* Free Point Light (Photometric) (page 2–1304)
* Free Linear Light (Photometric) (page 2–1307)
* Free Area Light (Photometric) (page 2–1309)
**Procedure**

The procedures for adding any of the 11 Preset Lights are identical. Follow the same procedure for any of the other Preset Lights as shown for the following:

**To add a photometric preset generic 60W bulb to a scene:**

1. From the Create menu, choose Photometric Lights > Preset Lights > Generic 60W Bulb.
2. Position your cursor where you want and click to place the light.

**Interface**

For each of the Preset Lights 3ds Max displays the appropriate parameters in the Command Panel. See the following interface descriptions for each Photometric Light object type:

- **Target Point Light (Photometric)** (page 2–1303)
- **Target Linear Light (Photometric)** (page 2–1305)
- **Target Area Light (Photometric)** (page 2–1307)
- **Free Point Light (Photometric)** (page 2–1304)
- **Free Linear Light (Photometric)** (page 2–1307)
- **Free Area Light (Photometric)** (page 2–1309)

**Target Point Light (Photometric)**

- Create panel > Lights > Photometric Lights > Target Point button
- Create menu > Lights > Target Point Light

A Target Point light, like a standard omni light, emits light from a geometric point. You can set the light distribution; this light has three types of distribution, with corresponding icons. You use a target object to aim the light.

Note: When you add a Target Point light, 3ds Max automatically assigns a *Look At controller* (page 2–344) to it, with the light’s target object assigned as the Look At target. You can use the controller settings on the Motion panel to assign any other object in the scene as the Look At target.

Note: When you rename a Target Point light, the target is automatically renamed to match. For example, renaming *Point01* to *Klieg* causes *Point01.Target* to become *Klieg.Target*. The target’s name must have the extension .Target. Renaming the target object does not rename the light object.

- *Name and Color Rollout (Lights)* (page 2–1273)
- *General Lighting Parameters* (page 2–1331)
- *Intensity/Color/Distribution Rollout* (page 2–1352)
- *Shadow Parameters* (page 2–1337)
- *Advanced Effects Rollout* (page 2–1341)

**Procedures**

To create a Target Point light:

1. On the Create panel, click Lights.
2. Choose Photometric from the drop-down list. (The default is Standard.)

3. In the Object Type rollout, click Target Point.

4. Drag in a viewport. The initial point of the drag is the location of the light, and the point where you release the mouse is the location of the target.

The light is now part of the scene.

5. Set the creation parameters.

You can use the Move transform to adjust the light.

To select the target:
The target, displayed as a small square, is often in the same area as objects that you want to illuminate. It can be difficult to select it by clicking.

1. First select the target point light.

2. Right-click the light and choose Select Target from the quad menu (page 3–694).

You can also choose Lights from the Selection Filters list on the toolbar, and then click the target. Clicking the line that connects the light and its target selects both objects.

To adjust the light and target:

1. Select the light or target or both.

2. On the Main toolbar, click Move. Drag the selection to adjust the light.

Because the light is always aimed at its target, you can’t rotate it about its local X or Y axes. However, you can select and move the target object as well as the light itself. When you move either the light or the target, the light’s orientation changes so it always points at the target.

You can use the Place Highlight (page 1–467) command to change a light’s position.

For target point lights with spotlight distributions, you can also adjust the light using a Light viewport (page 3–750).

To change a viewport to a light view:

Note: The viewport can only be set to a light view when the target point light’s distribution is spotlight.

1. Right-click the viewport label.

The viewport right-click menu is displayed.

2. Choose Views.

The name of each light is displayed in the Views list. By default, Target Point lights are named Point01, Point02, and so on.

3. Choose the name of the light you want.

The viewport now shows the light’s point of view. You can use the Light viewport (page 3–750) controls to adjust the light.

Tip: The default keyboard shortcut for Light viewports is $.

---

**Free Point Light (Photometric)**

Create panel > Lights > Photometric Lights > Free Point button

Create menu > Lights > Free Point Light

A Free Point light, like a standard omni light, emits light from a geometric point. You can set the light distribution; this light has three types of distribution, with corresponding icons. A free point light has no target object. You use transforms to aim the light.

For target point lights with spotlight distributions, you can also adjust the light using a Light viewport (page 3–750).

To change a viewport to a light view:

Note: The viewport can only be set to a light view when the target point light’s distribution is spotlight.

1. Right-click the viewport label.

The viewport right-click menu is displayed.

2. Choose Views.

The name of each light is displayed in the Views list. By default, Target Point lights are named Point01, Point02, and so on.

3. Choose the name of the light you want.

The viewport now shows the light’s point of view. You can use the Light viewport (page 3–750) controls to adjust the light.

Tip: The default keyboard shortcut for Light viewports is $.

---

**Free Point Light (Photometric)**

Create panel > Lights > Photometric Lights > Free Point button

Create menu > Lights > Free Point Light

A Free Point light, like a standard omni light, emits light from a geometric point. You can set the light distribution; this light has three types of distribution, with corresponding icons. A free point light has no target object. You use transforms to aim the light.

For target point lights with spotlight distributions, you can also adjust the light using a Light viewport (page 3–750).

To change a viewport to a light view:

Note: The viewport can only be set to a light view when the target point light’s distribution is spotlight.

1. Right-click the viewport label.

The viewport right-click menu is displayed.

2. Choose Views.

The name of each light is displayed in the Views list. By default, Target Point lights are named Point01, Point02, and so on.

3. Choose the name of the light you want.

The viewport now shows the light’s point of view. You can use the Light viewport (page 3–750) controls to adjust the light.

Tip: The default keyboard shortcut for Light viewports is $.

Intensity/Color/Distribution Rollout (page 2–1352)
Shadow Parameters (page 2–1337)
Advanced Effects Rollout (page 2–1341)

Procedures

To create a Free Point light:

1. On the Create panel, click Lights.
2. Choose Photometric from the drop-down list. (Standard is the default.)
3. In the Object Type rollout, click Free Point.
4. Click the viewport location where you want the light to be.

   The light is now part of the scene. It points away from you in the viewport you clicked.
5. Set the creation parameters.

   You can position the light (page 2–1282) and adjust its direction with the transform tools or by using a Light viewport. You can also adjust the light's position with the Place Highlights (page 1–467) command.

To adjust the light:

1. Select the light.
assigned as the Look At target. You can use the controller settings on the Motion panel to assign any other object in the scene as the Look At target.

Note: When you rename a Target Linear light, the target is automatically renamed to match. For example, renaming Linear01 to Klieg causes Linear01.Target to become Klieg.Target. The target’s name must have the extension .Target. Renaming the target object does not rename the light object.

Procedures

To create a Target Linear light:

1. On the Create panel, click Lights.
2. Choose Photometric from the drop-down list. (The default is Standard.)
3. In the Object Type rollout, click Target Linear.
4. Drag in a viewport. The initial point of the drag is the location of the light, and the point where you release the mouse is the location of the target.
   The light is now part of the scene.
5. Set the creation parameters.
   You can use the Move transform to adjust the light.

To select the target:

The target, displayed as a small square, is often in the same area as objects that you want to illuminate. It can be difficult to select it by clicking.

1. First select the light itself.
2. Right-click the light to open the quad menu (page 3–694). From the tools quadrant, choose Select Target.

You can also choose Lights from the Selection Filters list on the toolbar, and then click the target. Clicking the line that connects the light and its target selects both objects.

To adjust the light and target:

1. Select the light or target or both.
2. On the Main toolbar, click Move. Drag the selection to adjust the light.

Because the light is always aimed at its target, you can't rotate it about its local X or Y axes. However, you can select and move the target object as well as the light itself. When you move either the light or the target, the light’s orientation changes so it always points at the target.

You can use the Place Highlight (page 1–467) command to change a light's position.
Free Linear Light (Photometric)

Create panel > Lights > Photometric Lights > Free Linear button
Create menu > Photometric Lights > Free Linear Light

A Free Linear light emits light from a line, like a fluorescent tube. You can set the light distribution; this light has two types of distribution, with corresponding icons. A free linear light has no target object. You use transforms to aim the light.

Shadow Parameters (page 2–1337)
Advanced Effects Rollout (page 2–1341)

Procedures

To create a Free Linear light:

1. On the Create panel, click Lights.
2. Choose Photometric from the drop-down list. (Standard is the default.)
3. In the Object Type rollout, click Free Linear.
4. Click the viewport location where you want the light to be.
   The light is now part of the scene. It points away from you in the viewport you clicked.
5. Set the creation parameters.
   You can position the light (page 2–1282) and adjust its direction with the transform tools.
   You can also adjust the light’s position with the Place Highlight (page 1–467) command.

To adjust the light:

1. Select the light.
2. On the Main toolbar, click Move. Drag the selection to position the light.
3. On the Main toolbar, click Rotate. Drag the selection to adjust the light.
   Tip: You can also adjust the light’s position with the Place Highlight (page 1–467) command.

Target Area Light (Photometric)

Create panel > Lights > Photometric Lights > Target Area button
Create menu > Photometric Lights > Target Area Light

A Target Area light emits light from a rectangular area, like a skylight. You can set the light distribution; this light has two types of distribution, with corresponding icons. A target area light uses a target object to aim the light.

Note: When you add a Target Area light, the software automatically assigns a Look At controller (page 2–344) to it, with the light’s target object assigned as the Look At target. You can use the controller settings on the Motion panel to assign any other object in the scene as the Look At target.
Note: When you rename a Target Area light, the target is automatically renamed to match. For example, renaming Area01 to Klieg causes Area01.Target to become Klieg.TARGET. The target’s name must have the extension .TARGET. Renaming the target object does not rename the light object.

To select the target:
The target, displayed as a small square, is often in the same area as objects that you want to illuminate. It can be difficult to select it by clicking.
1. First select the light itself.
2. Right-click the light to open the quad menu (page 3–694). In the Tools quadrant, choose Select Target from the pop-up menu.

To adjust the light and target:
1. Select the light or target or both.
2. On the Main toolbar, click Move. Drag the selection to adjust the light.

Because the light is always aimed at its target, you can’t rotate it about its local X or Y axes. However, you can select and move the target object as well as the light itself. When you move either the light or the target, the light’s orientation changes so it always points at the target.

You can also choose Lights from the Selection Filters list on the toolbar, and then click the target. Clicking the line that connects the light and its target selects both objects.

To create a Target Area light:
1. On the Create panel, click Lights.
2. Choose Photometric from the drop-down list. (The default is Standard.)
3. In the Object Type rollout, click Target Area.
4. Drag in a viewport. The initial point of the drag is the location of the light, and the point where you release the mouse is the location of the target.
The light is now part of the scene.
5. Set the creation parameters.

You can use the Move transform to adjust the light.
Free Area Light (Photometric)

A Free Area light emits light from a rectangular area, like a skylight. You can set the light distribution; this light has two types of distribution, with corresponding icons. A free area light has no target object. You use transforms to aim the light.

General Lighting Parameters (page 2–1331)
Intensity/Color/Distribution Rollout (page 2–1352)
Shadow Parameters (page 2–1337)
Advanced Effects Rollout (page 2–1341)

Procedures

To create a Free Area light:

1. On the Create panel, click Lights.
2. Choose Photometric from the drop-down list. (Standard is the default.)
3. In the Object Type rollout, click Free Area.
4. Click the viewport location where you want the light to be.
   The light is now part of the scene. It points away from you in the viewport you clicked.
5. Set the creation parameters.
   You can position the light (page 2–1282) and adjust its direction with the transform tools.
   You can also adjust the light’s position with the Place Highlight (page 1–467) command.

To adjust the light:

1. Select the light.
2. On the Main toolbar, click Rotate. Drag the selection to adjust the light.
   Tip: You can also adjust the light’s position with the Place Highlight (page 1–467) command.

IES Sun Light (Photometric)

IES Sun is a physically-based light object that simulates sunlight (page 3–1018). When used in conjunction with a daylight system (page 1–418), its values are set automatically based on geographic location, time, and date. (IES stands
for Illuminating Engineering Society; see IES Standard File Format (page 2–1328).)

Outdoor scene illuminated by the IES Sun light

The mental ray renderer gives physically accurate results for IES Sun, and renderings that use it will appear similar to renderings done with the default scanline renderer. You do not need to turn on Final Gather for light from IES Sun to render.

Note: While you can create daylight lights manually, you should use them in conjunction with the Daylight system to get the best results. The Daylight system combines the two daylight components of sun and sky in a unified interface.

Tip: If you use the IES sun or sky with the Logarithmic Exposure Control (page 3–297), turn on both the Daylight and Exterior options. This will provide greater control for properly mapping the higher energy levels to RGB colors. In addition, it is important to set the Physical Scale to the brightest light source in your scene. If the IES Sun is used, set the Physical Scale to 90000 cd.

Note: When you add an IES Sun light, 3ds Max automatically assigns a Look At controller (page 2–344) to it, with the light’s target object assigned as the Look At target. You can use the controller settings on the Motion panel to assign any other object in the scene as the Look At target.

**Interface**

<table>
<thead>
<tr>
<th>Sun Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>![Check box] On</td>
</tr>
<tr>
<td>![Check box] Targeted</td>

</tr>
<tr>
<td>Shadows</td>
</tr>
<tr>
<td>![Check box] On</td>
</tr>
<tr>
<td>Shadow Map</td>
</tr>
<tr>
<td>Use Global Settings</td>
</tr>
</tbody>
</table>

On—Turns sunlight on and off in the viewport.

Targeted—Applicable only when you add the IES Sun light directly, rather than as part of a Daylight system (page 1–418). When on, the light is targeted and you can change the target distance by moving the target. The distance between the light and its target is displayed to the right of the check box. When off, you can set this value directly.

Cast Shadows—Sets whether the sunlight casts shadows or not.

Intensity—The intensity of the sunlight. The color swatch to the right of the spinner opens the Color Selector (page 1–161) to set the color of the light. Typical intensities in a clear sky are around 90,000 lux.

Note: Intensity is set automatically and cannot be set manually if the sun is under the control of a daylight system.

Shadows group

On—Determines whether the sunlight casts shadows or not.

Shadow Method drop-down list—Determines whether the renderer uses shadow maps (page...
IES Sun Light (Photometric)

3–1010), ray-traced shadows (page 3–1000), advanced ray-traced shadows (page 3–1000), mental ray shadow maps (page 2–1360), or area shadows (page 3–911) to generate shadows for this light.

Each shadow type has a rollout with its associated controls.

Tip: When you use the mental ray renderer and mental ray shadow maps, you can set up soft-edged shadows.

Use Global Settings—Turn on to use global settings for shadows cast by this light. Turn off to enable individual control of the shadows. If you choose not to use the global settings, you must choose which method the renderer will use to generate shadows for this particular light.

When Use Global Settings is on, the shadow parameters switch over to show you what the current global setting is. This data is shared by every other light of this class. When Use Global Settings is off, the shadow parameters are specific to that particular light.

Exclude—Excludes selected objects from the effects of the light. Click this button to display the Exclude/Include dialog (page 2–1335).

Excluded objects still appear lit in shaded viewports. Exclusion takes effect only when you render the scene.

Advanced Effects Rollout

- Advanced Effects:
  - Affect Surfaces:
    - Contrast: 0.0
    - Soften Diff. Edge: 50.0
    - Diffuse
    - Specular

Contrast—Adjusts the contrast between the diffuse and ambient areas of the surface. Leave this set to 0 for normal contrast. Increase the value to increase the contrast for special effects: for example, the harsh light of outer space. Default=0.0.

Soften Diffuse Edge—Increasing the value of Soften Diffuse Edge softens the edge between the diffuse and ambient portions of a surface. This helps eliminate edges that can appear on a surface under certain circumstances. Default=50.

Note: Soften Diffuse Edge slightly reduces the intensity of the light. You can counter this, to some extent, by increasing the Multiplier value.

Diffuse—When on, the light affects the diffuse properties of an object’s surface. When off, the light has no effect on the diffuse surface. Default=on.

Specular—When on, the light affects the specular properties of an object’s surface. When off, the light has no effect on the specular properties. Default=on.

For example, by using the Diffuse and Specular check boxes you can have one light color the specular highlights of an object, while not coloring its diffuse component, and then have a second light color the diffuse component of the surface while not creating specular highlights.

Optimizations rollout

This rollout is identical to the Optimizations rollout (page 2–1361) for advanced ray-traced and area shadows.
IES Sky Light (Photometric)

Create panel > Systems > Create a Daylight system in your scene. > Modify panel > Daylight Parameters rollout > Skylight > IES Sky

Create panel > Lights > Photometric > IES Sky

Create menu > Lights > Photometric > IES Sky

IES Sky is a physically-based light object that simulates atmospheric effects on skylight (page 3–1012).

IES Sky works correctly only when the sky object is pointing down from the Z axis, meaning that it points down when looking from the Top view.

When using the default scanline renderer, IES Sky produces the best results when used in conjunction with one of the advanced lighting options (page 3–44): radiosity or light tracing.

Warning: When you render with the mental ray renderer (page 3–78), objects illuminated by IES Sky appear dark unless you turn on Final Gathering (page 3–940). The toggle for Final Gathering is on the Final Gather rollout (page 3–111) of the Render Scene dialog.

When you add an IES Sky light, 3ds Max automatically assigns a Look At controller (page 2–344) to it, with the light’s target object assigned as the Look At target. You can use the controller settings on the Motion panel to assign any other object in the scene as the Look At target.

Using Render Elements with an IES Sky Light

If you use Render Elements (page 3–130) to output the lighting element (page 3–141) of an IES Sky light in a scene using either radiosity or the light tracer, you cannot separate the direct, indirect, and shadow channels of the light. All three elements of the IES Sky lighting are output to the Indirect Light channel.

See also

IES Sun Light (Photometric) (page 2–1309)
Interface

On—Turns the sky light on and off in the viewport.

Multiplier—Adjusts the intensity of the skylight.

When this is set to 1.0, the intensity will be physically accurate based on angle. You can, however, override this by changing the value. This is useful for doing night shots with artificial lighting.

Sky Color—The color swatch opens the Color Selector (page 1–161), which lets you set the color of the sky.

Coverage group

Clear, Partly Cloudy, Cloudy—This choice determines the extent to which light is scattered through the sky. Use the slider to set the control to one of the named settings or anywhere in between.

Render group

Note: These controls are unavailable when the mental ray renderer is active.

Cast Shadows—Causes the sky light to cast shadows.

A great deal of processing is dedicated to the calculation of the subtle shadows cast by skylight (page 3–1012). If shadows are not important in your model, you can disable them and save substantial amounts of processing time. However, the results will not be as realistic.

Note: The Cast Shadows toggle has no effect when using radiosity or the light tracer.

Note: IES Sky objects will not cast shadows in an ActiveShade rendering (page 3–17).

Rays per Sample—The number of rays used to calculate skylight falling on a given point in the scene. For animation you should set this to a high value to eliminate flickering. A value of around 30 should eliminate flickering.

Increasing the number of rays increases the quality of your image. However, it also increases rendering time.

Ray Bias—The closest distance at which objects can cast shadows on a given point in the scene. Setting this value to 0 can cause the point to cast shadows upon itself, and setting it to a large value can prevent objects close to a point from casting shadows on the point.

mental ray Sun & Sky

The mental ray Sun & Sky solution is designed to enable physically plausible daylight simulations and accurate renderings of daylight scenarios. In 3ds Max, this is achieved through the use of two
special photometric lights and an environment shader that all work together:

- The *mr Sun* photometric light is responsible for the sunlight; the direct light from the sun.

  ![The scene is lit by *mr Sun* only.](image)

- The *mr Sky* photometric light is responsible for the skylight; it simulates the real-world phenomenon of indirect light created by the scattering of sunlight in the atmosphere.

  ![The scene is lit by *mr Sky* only.](image)

- The *mr Physical Sky* environment shader is responsible for the visible representation of the sun disk and the sky, both to the camera and in reflections and refraction, as well as for the *virtual ground plane* (gray in the following illustration).

  ![mr Physical Sky is visible, but no lighting is present in the scene.](image)

While you can use these separately, their intended functionality is unleashed only when used together. *mr Sun* and *mr Sky* are meant primarily for use within the *3ds Max Daylight system* (page 1–418). When used in combination, this solution is called *Sun & Sky*.

Note: *Sun & Sky* is a true high-dynamic range photometric lighting system that requires the Logarithmic Exposure Control to be enabled. In some of the mental ray rendering presets (page 3–23), such as those starting with “mental.ray.daylight,” this is done automatically. Also, when you add a Daylight System from the Create menu, you have the option to activate Logarithmic Exposure Control automatically.

**Using Sun & Sky with SSS Materials**

To use a mental ray fast SSS material (page 2–1583) together with the high-dynamic range Sun & Sky solution, be sure to turn on Scatter Indirect Illumination on the material’s Advanced Options rollout so that the material can scatter the skylight, which is considered indirect.

Also, turn off Screen (Soft) Compositing Of Layers, also on the Advanced Options rollout; otherwise the output of the SSS shaders is clamped to a low dynamic range and will appear to render black.
Procedure

To use mental ray Sun & Sky:

1. Make sure mental ray (page 3–78) is the active renderer.

2. From the Create menu, choose Lights > Daylight System.
   You can also find Daylight System on the Create menu under Systems.
   Note: The Daylight System is also available from Create panel > Systems, but if you go that route you’re not prompted to turn on Logarithmic Exposure control (see next step), so when using Sun & Sky it’s best to make a habit of choosing Daylight System from the Create menu.

3. You’re prompted to activate Logarithmic Exposure Control with the Exterior Daylight Flag, if both are not already active. Click Yes to do so automatically.

4. Create a Daylight system in the Perspective (or a Camera) viewport: Drag and release to create the compass rose, move the mouse to position the light, and then click to place the light and finish creating the system.

5. Go to the Modify panel, and on the Daylight Parameters rollout, set Sunlight to mr Sun and Skylight to mr Sky.

6. When you choose mr Sky, you’re prompted to add a mr Physical Sky environment map. Click Yes to do so.
   The parameters rollouts for mr Sun and mr Sky now appear on the Modify panel.

7. Open the Environment dialog (page 3–272) (press 8) and make sure Common Parameters > Environment Map is set to mr Physical Sky, Exposure Control (page 3–293) is set to Logarithmic Exposure Control, and Logarithmic Exposure Control Parameters has Exterior Daylight on.
Tip: Should you wish to edit the mr Physical Sky parameters, an easy way to access them is to open the Material Editor (press \[M\]) and then drag the Environment Map button from the Environment panel > Common Parameters rollout to a material slot (sample sphere) in the Material Editor. When prompted for the copy method, choose Instance.

8. Open the Render Scene dialog (page 3–2) \([F10]\) to the Indirect Illumination panel and turn on Enable Final Gather. Choose the Draft preset as a starting point.

9. Render with Sun & Sky. To specify different times, dates, and locations in the Daylight system for different effects, use the Motion panel > Control Parameters settings or turn on Manual Override to place the sun by hand.

Tip: Adjust the Brightness and Contrast of the Logarithmic Exposure Control for a pleasing image.

**Common Parameters**

Certain parameters do the same things in mr Sun, mr Sky, and mr Physical Sky. For physical correctness, it is necessary to keep these parameters in sync with each other in all three elements. For example, a sun with a different Haze value than the sky cannot be guaranteed to be physically plausible.

For this reason the concept of parameter inheritance is included. Both the mr Sun light and the mr Physical Sky shader have check boxes labeled “Inherit from mr Sky” that are on by default. When these are on, the common

**Important:** Don't forget to turn on Enable Final Gather when using Sun & Sky, since the skylight is a form of indirect light, which can be rendered only with the help of Final Gather. If this is not done, Sun shadows will be unnaturally dark or black rather than bluish, as they should be.
parameters are all guided by the mr Sky light, which is the central point of control.

With parameter inheritance, you can concentrate on tweaking the parameters in one spot (mr Sky) and, as long as Inherit From mr Sky is on for both mr Sun and mr Physical Sky, you’re sure to obtain consistent results.

Interface (common parameters)
The most important common parameters are those that drive the entire shading and colorization model.

Note: mr Sun and mr Physical Sky can inherit parameters from mr Sky even if the latter is off.

</tbody>
</table>

**Haze**—The amount of water vapor or other particulate matter in the air. Possible values range from 0.0 (a completely clear day) to 15.0 (extremely overcast, or a sandstorm in the Sahara). The Haze value influences the intensity and color of the sky and horizon, the intensity and color of sunlight, the softness of the sun’s shadows, the softness of the glow around the sun, and the strength of the aerial perspective.

**Horizon Height**—The vertical position of the horizon.

The default value, 0.0, places the horizon at a standard height. However, because the horizon is infinitely far away, this can cause trouble joining up with any finite geometry that is supposed to represent the ground. It can also cause issues rendering locations that are supposed to be at a high altitude, like mountain tops or the top of New York skyscrapers where the horizon really is visibly “below” the viewer.

This parameter allows tuning the position of the horizon. Note that this horizon doesn’t actually exist at a specific height in 3D space; it is a shading effect for rays that go below a certain angle. This parameter tweaks that angle. The total range available range is somewhat extreme, reaching from -10.0 (the horizon is “straight down”) to 10.0 (the horizon is at the zenith). In practice, only much smaller values are actually useful. For example, to push the horizon down just below the edge of a finite visible ground plane, use ~0.2.

Note: The Horizon height affects not only the visual representation of the horizon in the mr Sky light, but also the color of the mr Sun itself. In other words, the point where the sun “sets” will change for a Horizon height settings other than 0.0.

**Horizon Blur**—The “blurriness” with which the horizon is rendered.

At 0.0 the horizon is completely sharp. Generally only values lower than 0.5 are useful, but the full range is up to 10.0 for a horizon that consists of blur only, with no actual horizon at all.

**Ground Color**—The color of the virtual ground plane. Note that this is a diffuse reflectance value (that is, albedo). The ground appears as a Lambertian reflector with this diffuse color, lit by
the sun and sky only, and does not receive any shadows. Tip: Some sky models neglect the influence of bounce light from the ground, assuming only the sky is illuminating the scene. To compare the output of mr Sky with, for example, the IES Sky light, set Ground Color to black.

**Night Color**—The minimum color of the sky: The sky will never become darker than this value. It can be useful for adding things like moon, stars, high-altitude cirrus clouds that remain lit long after sunset, etc. As the sun sets and the sky darkens, the contribution from Night Color is unaffected and remains as the base light level.

**Red/Blue Tint**—Gives artistic control over the redness of the light. The default value of 0.0 is the physically correct value (calculated for a 6500K whitepoint), but can be changed with this parameter, which ranges from -1.0 (extremely blue) to 1.0 (extremely red).

**Saturation**—Also an artistic control, where 1.0 is the physically calculated saturation level. The parameter ranges from 0.0 (black and white) to 2.0 (extremely boosted saturation).

---

### mr Sky

The mr Sky light is intended primarily for use in the mental ray Sun & Sky combination. This topic mainly provides information on parameters unique to this component. A number of mr Sky parameters are common to all three Sun & Sky components. For some of those parameters, this topic provides a brief explanation plus a link to the main topic with additional details.

---

**See also**

- mental ray Sun & Sky (page 2–1313)
- mr Sun (page 2–1319)
- mr Physical Sky (page 2–1321)

**Interface**

- **On**—Turns the light on and off.
- **Multiplier**—A scalar multiplier for the light output. Default=1.0.
- **Haze**—The amount of particulate matter in the air. Possible values range from 0.0 (a completely clear day) to 15.0 (extremely overcast, or a sandstorm in the Sahara). Default=0.0.
  
  For details, see Haze.

**Horizon group**

- **Height**—The vertical position of the horizon. Default=0.0.
For details, see *Horizon Height*.

**Blur**—The “blurriness” with which the horizon is rendered. Default=0.1.

At 0.0 the horizon is completely sharp. Generally only values lower than 0.5 are useful, but the full range is up to 10.0 for a horizon that consists of blur only, with no actual horizon at all.

**Ground Color**—The color of the virtual ground plane. Note that this is a diffuse reflectance value (that is, albedo). The ground appears as a Lambertian reflector with this diffuse color, lit by the sun and sky only, and does not receive any shadows.

Tip: Some sky models neglect the influence of bounce light from the ground, assuming only the sky is illuminating the scene. To compare the output of mr Sky with, for example, the IES Sky model, one must therefore set Ground Color to black.

**Night Color**—The minimum color of the sky: The sky will never become darker than this value. It can be useful for adding things like moon, stars, high-altitude cirrus clouds that remain lit long after sunset, etc. As the sun sets and the sky darkens, the contribution from Night Color is unaffected and remains as the base light level.

**Non-Physical Tuning group**

**Red/Blue Tint**—Provides artistic control over the redness of the sky light. The default value of 0.0 is the physically correct value (calculated for a 6500K whitepoint), but can be changed with this parameter, which ranges from -1.0 (extremely blue) to 1.0 (extremely red).

**Saturation**—Provides artistic control over saturation of the sky light. The default value of 1.0 is the physically calculated saturation level. Possible values range from 0.0 (black and white) to 2.0 (extremely high saturation).

**Aerial Perspective group**

**Visibility Distance**—Aerial Perspective is a term used by painters to convey how distant objects are perceived as hazier and tinted towards the blue end of the spectrum. mr Sky emulates this with the Visibility Distance parameter. When nonzero, it defines the “10% distance”, that is, the distance at which approximately 10% of haze is visible at a Haze level of 0.0.

---

**mr Sun**

| Daylight system > Modify panel > Daylight Parameters rollout > Sunlight drop-down list > mr Sun |
| Create panel > Lights > Photometric > mr Sun |
| Create menu > Lights > Photometric Lights > mr Sun |

The mr Sun light is intended primarily for use in the mental ray Sun & Sky combination. This topic mainly provides information on parameters unique to this component. A number of mr Sky parameters are common to all three Sun & Sky components. For some of those parameters, this topic provides a brief explanation plus a link to the main topic with additional details.

**See also**

*mental ray Sun & Sky (page 2–1313)*

*mr Sky (page 2–1318)*

*mr Physical Sky (page 2–1321)*
Interface

mr Sun Basic Parameters rollout

On—Turns the mr Sun light on and off. Default=on.

Targeted—Applicable only when you add an mr Sun light directly to the scene via Create panel > Lights > Photometric, rather than as part of a Daylight system (page 1–418). When on, the light is targeted and you can change the target distance by moving the target. The distance between the light and its target is displayed to the right of the check box. When off, you can set this value directly. Default=on.

Shadows group

On—Toggles shadowing for the light. Default=on.

Softness—The softness of shadow edges. The default value of 1.0 accurately matches the softness of real solar shadows. Lower values make the shadows sharper and higher values make them softer.

Softness—The number of shadow samples for the soft shadows. If it is set to 0, no soft shadows are generated. Default=8.

mr Sun Parameters rollout

Multiplier—A scalar multiplier for the light output. Default=1.0.

Inherit from mr Sky—Uses the equivalent settings from the mr Sky Parameters rollout for the remaining mr Sun Parameters rollout settings. Default=on.

For further information, see Common Parameters (page 2–1316)

Haze—The amount of particulate matter in the air. Possible values range from 0.0 (a completely clear day) to 15.0 (extremely overcast, or a sandstorm in the Sahara). Default=0.0.

For details, see Haze.

Height—The vertical position of the horizon. Default=0.0.

For details, see Horizon Height.

Non-Physical Tuning group

Red/Blue Tint—Provides artistic control over the redness of the sky light. The default value of 0.0 is the physically correct value (calculated for a 6500K whitepoint), but can be changed with this parameter, which ranges from -1.0 (extremely blue) to 1.0 (extremely red).

Saturation—Provides artistic control over saturation of the sky light. The default value of
1.0 is the physically calculated saturation level. Possible values range from 0.0 (black and white) to 2.0 (extremely high saturation).

**mr Sun Photons rollout**

Use these settings to focus global-illumination photons on an area of interest. For example, if you’ve modeled a huge city as a backdrop, but are rendering only a room interior, you probably don’t want mental ray to shoot photons over the entire city, with the result that only a few will find their way into the room.

**Use Photon Target**—When on, uses the Radius setting with respect to the light target.

**Radius**—Sets the radial distance from the target in which the mr Sun casts GI photons.

**mr Physical Sky**

The mr Physical Sky shader is intended primarily for use in the mental ray Sun & Sky combination. This topic mainly provides information on parameters unique to this component. A number of mr Physical Sky parameters are common to all three Sun & Sky components. For some of those parameters, this topic provides a brief explanation plus a link to the main topic with additional details.

**See also**

*mental ray Sun & Sky (page 2–1313)*

*mr Sky (page 2–1318)*
either case the mr Physical Sky will still be visible in reflections and refraction.

To apply a map or shader to this parameter, click the None button.

Note: The background area in the rendered image’s alpha channel is always fully transparent, as is the case in general in 3ds Max.

**Inherit from mr Sky**—Uses the equivalent settings from the mr Sky Parameters rollout for the remaining mr Physical Sky Parameters rollout settings, except for Aerial Perspective. Default=on.

For further information, see Common Parameters (page 2–1316)

**Haze**—The amount of particulate matter in the air. Possible values range from 0.0 (a completely clear day) to 15.0 (extremely overcast, or a sandstorm in the Sahara). Default=0.0.

For details, see Haze.

To apply a map or shader to this parameter, click the None button.

**Horizon and Ground group**

**Horizon Height**—The vertical position of the horizon. Default=0.0.

For details, see Horizon Height.

**Blur**—The “blurriness” with which the horizon is rendered. Default=0.1.

At 0.0 the horizon is completely sharp. Generally only values lower than 0.5 are useful, but the full range is up to 10.0 for a horizon that consists of blur only, with no actual horizon at all.

**Ground Color**—The color of the virtual ground plane. Note that this is a diffuse reflectance value (that is, albedo). The ground appears as a Lambertian reflector with this diffuse color, lit by the sun and sky only, and does not receive any shadows.

To apply a map or shader to this parameter, click the None button.

Tip: Some sky models neglect the influence of bounce light from the ground, assuming only the sky is illuminating the scene. To compare the output of mr Sky with, for example, the IES Sky model, one must therefore set Ground Color to black.

**After Dark group**

**Night Color**—The minimum color of the sky: The sky will never become darker than this value. It can be useful for adding things like moon, stars, high-altitude cirrus clouds that remain lit long after sunset, etc. As the sun sets and the sky darkens, the contribution from Night Color is unaffected and remains as the base light level.

To apply a map or shader to this parameter, click the None button.

**Non-Physical Tuning group**

**Red/Blue Tint**—Provides artistic control over the redness of the sky light. The default value of 0.0 is the physically correct value (calculated for a 6500K whitepoint), but can be changed with this parameter, which ranges from -1.0 (extremely blue) to 1.0 (extremely red).

To apply a map or shader to this parameter, click the None button.

**Saturation**—Provides artistic control over saturation of the sky light. The default value of 1.0 is the physically calculated saturation level. Possible values range from 0.0 (black and white) to 2.0 (extremely high saturation).

To apply a map or shader to this parameter, click the None button.

**Aerial Perspective group**

Note: This parameter is for advanced users, and functions only when you use mr Physical Sky is
Isotropic Light Distribution (Photometric Lights)

An Isotropic light distributes the light equally in all directions.

Used as a lens shader or volume shader. When used as a lens shader, the aerial perspective “mist” applies to primary rays only; it doesn’t appear in reflections. When used as a volume shader, it applies to the entire scene and every ray in it, including reflections and refraction.

Visibility Distance—Aerial Perspective is a term used by painters to convey how distant objects are perceived as hazier and tinted towards the blue end of the spectrum. mr Sky emulates this with the Visibility Distance parameter. When nonzero, it defines the “10% distance”, that is, the distance at which approximately 10% of haze is visible at a Haze level of 0.0.

Lights (page 2–1272)
Target Point Light (Photometric) (page 2–1303)
Free Point Light (Photometric) (page 2–1304)
Intensity/Color/Distribution Rollout (page 2–1352)

Procedure

To create a light with an Isotropic distribution:

1. On the Create panel, click Lights.
2. Choose Photometric from the drop-down list. (The default is Standard.)
3. In the Object Type rollout, select Free Point.
4. In the Intensity/Color/Distribution rollout, select Isotropic from the Distribution list.
5. Click in a viewport to position the light.
   The light is now part of the scene.
6. Set the creation parameters.
   You can use the Move transform to adjust the light.
   You can also use the Place Highlight (page 1–467) command to change a light’s position.

Diffuse Distribution (Photometric Lights)

Diffuse distribution emits light from a surface. Light that leaves the surface at a right angle is
at the light’s greatest intensity. At increasingly oblique angles, the intensity of the emitted light diminishes.

**Spotlight Distribution (Photometric Lights)**

Create panel > Lights > Photometric Lights > Click Target Point or Free Point. > Intensity/Color/Distribution rollout > Choose Spotlight in Distribution list. > Click in viewport to create light.

A spotlight distribution casts a focused beam of light like a flashlight, a follow spot in a theater or a headlight. At the light’s **beam angle**, intensity has fallen to 50 per cent. At its **field angle**, intensity has fallen to zero. (The beam angle is similar to the hotspot angle for standard lights, but all of a hotspot is at 100 per cent intensity. The field angle is comparable to the falloff angle for standard lights.)

**See also**

*Lights (page 2–1272)*

*Target Point Light (Photometric) (page 2–1303)*

*Free Point Light (Photometric) (page 2–1304)*

*Spotlight Parameters (page 2–1338)*

*Intensity/Color/Distribution Rollout (page 2–1352)*

**Procedures**

To create a light with a spotlight distribution:

1. On the Create panel, click Lights.
2. Choose Photometric from the drop-down list. (Standard is the default.)
3. In the Object Type rollout, click Target Point or Free Point.
4. In the Intensity/Color/Distribution rollout, select Spotlight from the Distribution list.
5. If you are creating a Target Point light, drag in a viewport. The initial point of the drag is the location of the light, and the point where you release the mouse is the location of the target. If you are creating a Free Point light, click in a Viewport to position the light.
   The light is now part of the scene.
6. Set the creation parameters.
   You can use the Move transform to adjust the light.
   You can also use the *Place Highlight (page 1–467)* command to change a light’s position.

To adjust a target point spotlight:

1. Select the light.
2. Use Move on the main toolbar to adjust the light.

Because the spotlight is always aimed at its target, you can’t rotate it about its local X or Y
axis. However, you can select and move the target object as well as the light itself. When you move either the light or the target, the light’s orientation changes so it always points at the target.

You can use the Place Highlight (page 1–467) command to change a light’s position. Another way to adjust a spotlight is to use a Light viewport (page 3–750).

To select the target:
If the spotlight distribution is on a target point light, you can move the target to adjust the direction of the spotlight. The target, displayed as a small square, is often in the same area as objects that you want to illuminate. It can be difficult to select it by clicking.

1. First select the spotlight itself.
2. Right-click the light and choose Select Target from the pop-up menu. Clicking the line that connects the light and its target selects both objects.

To change a viewport to a light view:
1. Right-click the viewport label.
   The Viewport Right-Click menu is displayed.
2. Choose Views.
   The name of each light is displayed in the Views list. By default, photometric lights are named Point01, Point02, and so on.
3. Choose the name of the light you want.
   The viewport now shows the light’s point of view. You can use the Light Viewport Controls (page 3–750) to adjust the light.

The default keyboard shortcut for Light viewports is $.

Web Distribution (Photometric Lights)
A Web distribution uses a photometric web definition (page 2–1326) to distribute the light. A photometric web is a 3D representation of the light intensity distribution of a light source. Web definitions are stored in files. Many lighting manufacturers provide web files that model their products; these are often available on the Internet. A web file can be in the IES (page 2–1328), LTLD (page 3–964), or CIBSE (page 3–921) format. Controls for assigning the web file are on the Web Parameters rollout.

Example of web distribution

Various web distributions

Free Point Light (Photometric) (page 2–1304)
Target Linear Light (Photometric) (page 2–1305)
Free Linear Light (Photometric) (page 2–1307)
Target Area Light (Photometric) (page 2–1307)
Free Area Light (Photometric) (page 2–1309)
Intensity/Color/Distribution Rollout (page 2–1352)
Web Parameters Rollout (page 2–1355)
IES Standard File Format (page 2–1328)

Procedure
To create a light from a manufacturer’s IES file:

1. On the Create panel, click Lights.
2. Choose Photometric from the drop-down list. (The default is Standard.)
3. In the Object Type rollout, select any photometric light type.
4. In the Intensity/Color/Distribution rollout, select Web from the Distribution list.
5. If you are creating a Target Point, Linear, or Area light, drag in a viewport. The initial point of the drag is the location of the light, and the point where you release the mouse is the location of the target. If you are creating a Free Point, Linear or Area light, click in a viewport to position the light.

A light is created using the default photometric web which is a diffuse distribution shining from one edge.
6. Go to the Web Parameters rollout, and select the IES file that you want to use. See Web Parameters (page 2–1355).
7. Set the creation parameters.

You can use the Move transform to position the light (page 2–1282). You can also use the Place Highlight (page 1–467) command to change a light’s position.

Photometric Webs

A photometric web is a 3D representation of the light intensity distribution of a light source. This directional light distribution information is stored in a photometric data file in the IES format using the *IES LM-63-1991 standard file format* (page 2–1328), or in the LTII or CIBSE formats for photometric data. You can load photometric data files provided by various manufacturers as web parameters (page 2–1355). The light icon represents the photometric web you select.

To describe the directional distribution of the light emitted by a source, 3ds Max approximates the source by a point light placed at its photometric center. With this approximation, the distribution is characterized as a function of the outgoing direction only. The luminous intensity of the source for a predetermined set of horizontal and vertical angles is provided, and the system can compute the luminous intensity along an arbitrary direction by interpolation.
**Goniometric Diagrams**

Photometric data is often depicted using a goniometric diagram.

![Goniometric diagram of a web distribution](image1)

This type of diagram visually represents how the luminous intensity of a source varies with the vertical angle. However, the horizontal angle is fixed and, unless the distribution is axially symmetric, more than one goniometric diagram may be needed to describe the complete distribution.

**Photometric Web**

The photometric web is a three-dimensional representation of the light distribution. It extends the goniometric diagram to three dimensions, so that the dependencies of the luminous intensity on both the vertical and horizontal angles can be examined simultaneously. The center of the photometric web represents the center of the light object.

The luminous intensity in any given direction is proportional to the distance between this web and the photometric center, measured along a line leaving the center in the specified direction.

**Example 1: Isotropic Distribution**

![Example of isotropic distribution](image2)

A sphere centered around the origin is a representation of an isotropic distribution. All the points in the diagram are equidistant from the center and therefore light is emitted equally in all directions.

**Example 2: Ellipsoidal Distribution**

![Example of ellipsoidal distribution](image3)
In this example, the points in the negative Z direction are the same distance from the origin as the corresponding points in the positive Z direction, so the same amount of light shines upward and downward. No point has a very large X or Y component, either positive or negative, so less light is cast laterally from the light source.

IES Standard File Format

You can create a photometric data file in the IES format using the IES LM-63-1991 standard file format for photometric data. (IES stands for Illuminating Engineering Society.) However, only the information relevant to 3ds Max is described here. For a complete description of the IES standard file format, see IES Standard File Format for Electronic Transfer of Photometric Data and Related Information, prepared by the IES Computer Committee (http://www.iesna.org).

The luminous intensity distribution (LID) of a luminaire is measured at the nodes of a photometric web for a fixed set of horizontal and vertical angles. The poles of the web lie along the vertical axis, with the nadir corresponding to a vertical angle of zero degrees. The horizontal axis corresponds to a horizontal angle of zero degrees and is oriented parallel to the length of the luminaire. This type of photometric web is generated by a Type C goniometer and is the most popular in North America; other types of goniometry are supported by the IES standard file format but are not discussed here.

The photometric data is stored in an ASCII file. Each line in the file must be less than 132 characters long and must be terminated by a carriage return/line-feed character sequence. Longer lines can be continued by inserting a carriage return/line-feed character sequence. Each field in the file must begin on a new line and must appear exactly in the following sequence:

1. IESNA91
2. [TEST] the test report number of your data
3. [MANUFAC] the manufacturer of the luminaire
4. TILT=NONE
5. 1
6. The initial rated lumens for the lamp used in the test or -1 if absolute photometry is used and the intensity values do not depend on different lamp ratings.
7. A multiplying factor for all the candela values in the file. This makes it possible to easily scale all the candela values in the file when the measuring device operates in unusual units—for example, when you obtain the photometric values from a catalog using a ruler on a goniometric diagram. Normally the multiplying factor is 1.
8. The number of vertical angles in the photometric web.
9. The number of horizontal angles in the photometric web.
10. The type of unit used to measure the dimensions of the luminous opening. Use 1 for feet or 2 for meters.
11. The width, length, and height of the luminous opening. Currently, Lightscape ignores these dimensions because you can associate a given luminous intensity distribution with any of the luminaire geometric entities supported by Lightscape. It is normally given as 0 0 0.
12. The set of vertical angles, listed in increasing order. If the distribution lies completely in the bottom hemisphere, the first and last angles must be 0° and 90°, respectively. If the distribution lies completely in the top hemisphere, the first and last angles must be 90° and 0°.
and 180°, respectively. Otherwise, they must be 0° and 180°, respectively.

15. The set of horizontal angles, listed in increasing order. The first angle must be 0°. The last angle determines the degree of lateral symmetry displayed by the intensity distribution. If it is 0°, the distribution is axially symmetric. If it is 90°, the distribution is symmetric in each quadrant. If it is 180°, the distribution is symmetric about a vertical plane. If it is greater than 180° and less than or equal to 360°, the distribution exhibits no lateral symmetries. All other values are invalid.

16. The set of candela values. First all the candela values corresponding to the first horizontal angle are listed, starting with the value corresponding to the smallest vertical angle and moving up the associated vertical plane. Then the candela values corresponding to the vertical plane through the second horizontal angle are listed, and so on until the last horizontal angle. Each vertical slice of values must start on a new line. Long lines may be broken between values as needed by following the instructions given earlier.

Here is an example of a photometric data file (page 2–1329).

**Example of Photometric Data File**

The following is an example of a photometric data file:

```
[TEST] Simple demo intensity distribution
[TEST] Lightscap Technologies, Inc.

Common Lighting Rollouts

General Lighting Parameters

Create panel > Lights > Create a light. > General Parameters rollout

Create menu > Photometric Lights > Create a light. > Modify panel > General Parameters rollout.

The General Parameters rollout is displayed for all types of lights. These controls turn a light on and off, and exclude or include objects in the scene.

On the Modify panel, the General Parameters rollout also lets you control the light’s target object and change the light from one type to another.

Shadow Types

The General Parameters rollout also lets you turn shadow-casting on or off for the light, and choose which type of shadow the light uses.

The following table describes the advantages and disadvantages of each shadow type:

<table>
<thead>
<tr>
<th>Shadow Type</th>
<th>Advantages</th>
<th>Disadvantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Area Shadows</td>
<td>Supports transparency and opacity mapping.</td>
<td>Slower than shadow maps.</td>
</tr>
<tr>
<td></td>
<td>Uses very little RAM.</td>
<td>Processes at every frame.</td>
</tr>
<tr>
<td></td>
<td>Recommended for complex scenes with many lights or faces.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Supports different formats for area shadows.</td>
<td></td>
</tr>
<tr>
<td>mental ray</td>
<td>Can be quicker than ray-traced shadows with the mental ray renderer.</td>
<td></td>
</tr>
<tr>
<td>Shadow Maps</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Raytrace Shadows</td>
<td>Supports transparency and opacity mapping.</td>
<td>Can be slower than shadow maps.</td>
</tr>
<tr>
<td></td>
<td>Processes only once if there are no animated objects.</td>
<td>Does not support soft shadows.</td>
</tr>
<tr>
<td>Shadow Maps</td>
<td>Produces soft shadows.</td>
<td>Uses a lot of RAM. Does not support objects with transparency or opacity maps.</td>
</tr>
<tr>
<td></td>
<td>Processes only once if there are no animated objects.</td>
<td></td>
</tr>
</tbody>
</table>

Procedures

To turn a light on and off:

- Turn the On toggle on or off. Default=on.

  Tip: To make a standard light flash on and off, set its Multiplier parameter to 0 in repeated keyframes, and assign a step tangent (page 2–305) to this parameter.

To have a light cast shadows:

- In the General Parameters rollout > Shadows group, make sure On is selected.
The light will now cast shadows when you render the scene.

Note: With Overshoot turned on, standard spotlights cast light in all directions but cast shadows only within the falloff cone; standard directional lights cast light throughout the scene, but cast shadows only within the falloff area.

Left: A spotlight's projection cone truncates shadows. Right: An omni light casts complete shadows.

**To have a light use the global settings for shadows:**
- On the General Parameters rollout, turn on Use Global Settings.

  When Use Global Settings is on, the other shadow controls are set to the values used by all other shadow-casting lights in the scene that have Use Global Settings set.

  Changing the affected parameters for one light with Use Global Settings set, changes them for all lights with Use Global Settings set.

**To set a light’s shadow parameters individually:**
- On the General Parameters rollout, turn off Use Global Settings.

  The settings revert to the individual settings for the light.

  By default, Shadow Map is the active shadow type. In the Shadow Map Params rollout (page 2–1363), the default settings are: Map Bias=1; Size=512; Sample Range=4.0; Absolute Map Bias=Off.

Note: When you render a scene, you can turn rendering of shadows on or off.

**To cast area shadows:**
- On the General Parameters rollout, choose Area Shadows from the drop-down list.

  Use controls on the Area Shadows rollout (page 2–1357) to adjust the shadow properties.

**To cast advanced ray-traced shadows:**
Advanced ray-traced shadows are similar to ray-traced shadows, however they provide control over antialiasing (page 3–907), letting you fine-tune how shadows are generated.
- On the General Parameters rollout, choose Advanced Ray-traced Shadows from the drop-down list.

  Use controls on the Advanced Ray-traced Params rollout (page 2–1356) to adjust the shadow properties.

**To cast shadow-mapped shadows:**
1. On the General Parameters rollout, choose Shadow Maps from the drop-down list.

2. Go to the Shadow Map Params rollout (page 2–1363).
• Use the Size spinner to set the size of the shadow map.
• Use the Bias spinner to adjust the shadow offset, if necessary.
• Use the Sample Range spinner to create a soft-edged shadow.

To cast ray-traced shadows:
Ray-traced shadows (page 3–1000) are generated by tracing the path of rays sampled from a light source. Ray-traced shadows are more accurate than shadow-mapped shadows.
1. On the General Parameters rollout, choose Ray-Traced Shadows from the drop-down list.
2. Use controls on the Ray Traced Shadow Params rollout (page 2–1363) to adjust the shadow offset, if necessary.

To keep an object from casting shadows:
1. Select the object.
2. Right-click the object to display the quad menu and choose Properties from the Transform quadrant.
   The Object Properties dialog (page 1–117) is displayed.
3. Turn off Cast Shadows, and then click OK.
   Now when you render the scene, the object casts no shadows.

To make an object not receive shadows:
1. Select the object.
2. Right-click the object to display the quad menu and choose Properties from the lower-right (Transform) quadrant.
   The Object Properties dialog (page 1–117) is displayed.
3. Turn off Receive Shadows, and then click OK.
   Now when you render the scene, the object receives no shadows.

Note: You can also prevent objects from casting shadows by excluding them from a light.

Light Type group (Modify panel)

On—(Both Create panel and Modify panel) Turns the light on and off. When On is on, shading and rendering use the light to illuminate the scene. When On is off, the light is not used in shading or rendering. Default=on.

In viewports, the interactive renderer shows the effect of turning lights on or off.

Light Type List—Changes the type of the light.
If you have selected a standard light type (page 2–1288), the light can be changed to an omni, spot, or directional light. If you have selected a photometric light type (page 2–1301), you can change the light to a point, linear, or area light.

This parameter is available only in the Modify panel.

Targeted—When on, the light is targeted. The distance between the light and its target is displayed to the right of the check box. For a free light, you can set this value. For target lights, you can change it by turning off the check box, or by moving the light or the light’s target object.
Shadows group

**On**—Determines whether the current light casts shadows or not. Default=on.

**Shadow Method drop-down list**—Determines whether the renderer uses shadow maps (page 3–1010), ray-traced shadows (page 3–1000), advanced ray-traced shadows (page 3–1000), or area shadows (page 3–911), to generate shadows for this light.

The “mental ray Shadow Map” type is provided for use with the mental ray renderer (page 3–78). When you choose this shadow type and enable shadow maps (on the Shadows & Displacement rollout (page 3–114) of the Render Scene dialog), shadows use the mental ray shadow-map algorithm. If this type is chosen but you render with the default scanline renderer, no shadows appear in the rendering.

Note: When shadow maps are enabled and the shadow map type is Shadow Map, the mental ray renderer attempts to translate the shadow map settings into comparable settings for mental ray shadow maps. (The results might not be what you expected.) In all other cases, the mental ray renderer generates ray-traced shadows.

Each shadow type has its particular controls:

- **Advanced ray-traced shadows**—See Advanced Ray-Traced Parameters Rollout (page 2–1356) and Optimizations Rollout (page 2–1361).
- **Area shadows**—See Area Shadows Rollout (page 2–1357) and Optimizations Rollout (page 2–1361).
- **mental ray shadow maps**—See mental ray Shadow Map Rollout (page 2–1360).
- **Shadow maps**—See Shadow Map Parameters Rollout (page 2–1363).

**Tip:** Use ray-traced or advanced ray-traced shadows when you want shadows cast by opacity-mapped objects. Shadow-mapped shadows don’t recognize the transparent portions of the mapping, and as a result they don’t look convincing.

**Use Global Settings**—Turn on to use global settings for shadows cast by this light. Turn off to enable individual control of the shadows. If you choose not to use the global settings, you must choose which method the renderer will use to generate shadows for this particular light.

When Use Global Settings is on, the shadow parameters switch over to show you what the global settings are. This data is shared by every other light of this class. When Use Global Settings is off, the shadow parameters are specific to that particular light.

**Exclude button**

Excludes selected objects from the effects of the light. Click this button to display the Exclude/Include dialog (page 2–1335).

Excluded objects still appear lit in shaded viewports. Exclusion takes effect only when you render the scene.

**Roll Angle Manipulator**

To change the roll angle of a target light, you can use a manipulator. This can be useful if the light does not cast a round beam, or if it is a projector light (see Advanced Effects Rollout (page 2–1341)). To display the manipulator, select the light, right-click it, and then click Roll Angle Manipulator Toggle in the Tools 1 (upper left) quadrant of the quad menu.
Drag the circular portion of the manipulator to rotate the light by an arbitrary number of degrees. Click one of the red or green “clock hands” of the manipulator to rotate the light in 90-degree increments.

Note: You can also access the roll angle manipulator by selecting the light object and then turning on Select And Manipulate (page 2–15) on the main toolbar.

The Exclude/Include dialog determines which objects are not illuminated by a selected light, or which objects are considered in a Matte render element (page 3–130).

Although light exclusion does not occur in nature, this feature is useful when you need exact control over the lighting in your scene. Sometimes, for example, you’ll want to add lights specifically to illuminate a single object but not its surroundings, or you’ll want a light to cast shadows from one object but not from another.

**Procedures**

**To exclude objects from a light:**

1. In the General Parameters rollout, click Exclude.
   The Exclude/Include dialog is displayed.

2. Make sure Exclude is on.

3. Choose to exclude objects from Illumination, Shadow Casting, or Both.

4. In the list of object names on the left, highlight the objects you want to exclude.

5. Click the arrow pointing to the right to move the selected object names into the right-hand list.
   Objects in the right-hand list will be excluded.
   To remove an object from this list, highlight its name and click the arrow pointing to the left.
   To remove all objects from this list, click Clear.

6. Click OK.
   Now when you shade or render the scene, the light will have no effect on the objects you chose.
   The object still appears lit in shaded viewports. Exclusion takes effect only when you render the scene.

**To include objects that were excluded:**

1. Click Exclude.
   The Exclude/Include dialog is displayed.

2. Select the names of objects in the right-hand list, and then click the arrow pointing to the left.

3. Click OK.

**To include all excluded objects at once:**

1. Click Exclude or Include.
   The Exclude/Include dialog is displayed.
2. Click Clear.
3. Click OK.

Interface

The Exclude/Include dialog contains the following controls:

Exclude/Include—Determines whether the light (or Matte render element) will exclude or include the objects named in the list on the right.

Illumination—Excludes or includes illumination of the object’s surface.

Note: This control has no effect on the matte render element.

Shadow Casting—Excludes or includes creation of the object’s shadow.

Note: This control is not available with the matte render element.

Both—Excludes or includes both of the above.

Note: This control is not available with the matte render element.

Scene Objects—Select objects from the Scene Objects list on the left, then use the arrow buttons to add them to the exclusion list on the right.

The Exclude/Include dialog treats a group as an object. You can exclude or include all objects in a group by selecting the group’s name in the Scene Objects list. If a group is nested within another group, it isn’t visible in the Scene Objects list. To exclude a nested group or individual objects within the group, you have to ungroup them before you use this dialog.

Search field—The edit box below the Scene Objects list searches for objects by name. You can enter names that use wildcards.

Display Subtree—Indents the Scene Objects list according to the object hierarchy.

Case Sensitive—Uses case sensitivity when searching object names.

Selection Sets—Displays a list of named selection sets (page 1–83). Choosing a selection set from this list selects those objects in the Scene Objects list.

Clear—Clears all entries from the Exclude/Include list on the right.
Shadow Parameters

Create panel > Lights > Create a light. > Shadow Parameters rollout

A bridge’s shadow cast by sunlight

The Shadow Parameters rollout is displayed for all light types except Skylight and IES Sky, and for all shadow types. It lets you set shadow colors and other general shadow properties.

The controls also let atmospheric effects cast shadows.

See also

Advanced Ray-Traced Parameters Rollout (page 2–1356)
Area Shadows Rollout (page 2–1357)
mental ray Shadow Map Rollout (page 2–1360)
Optimizations Rollout (page 2–1361)
Ray-Traced Shadow Parameters Rollout (page 2–1363)
Shadow Map Parameters Rollout (page 2–1363)

Interface

Color—Displays a Color Selector (page 1–161) to choose a color for the shadows cast by this light. Default=black.

You can animate the shadow color.

Dens. (density)—Adjusts the density of shadows.

The shadow density increases from right to left.

Increasing the Density value increases the density (darkness) of shadows. Decreasing Density makes shadows less dense. Default=1.0.

Density can have a negative value, which can help simulate the effect of reflected light. A white shadow color and negative Density render dark shadows, though the quality of these is not as good as a dark shadow color and positive Density.
You can animate the Density value.

**Map check box**—Turn on to use the map assigned with the Map button. Default=off.

**Map**—Assigns a map to the shadows. The map’s colors are blended with the shadow color. Default=None.

**Light Affects Shadow Color**—When on, blends the light’s color with the shadow color (or shadow colors, if the shadow is mapped). Default=off.

---

**A checker map is used to alter the shadow cast by the piano.**

### Atmosphere Shadows group

These controls let atmospheric effects cast shadows.

**On**—When on, atmospheric effects cast shadows as the light passes through them. Default=off.

**Opacity**—Adjusts the opacity of the shadows. This value is a percentage. Default=100.0.

**Color Amount**—Adjusts the amount that the atmosphere's color is blended with the shadow color. This value is a percentage. Default=100.0.

---

A cloud casts a colored shadow on the city.

### Spotlight Parameters

Create a standard Target Spotlight or Free Spotlight, or a photometric light with Spotlight distribution. > Spotlight Parameters rollout

The Spotlight Parameters rollout appears when you create or select a Target Spot (page 2–1289) or Free Spot (page 2–1290), or a photometric light with spotlight distribution (page 2–1324).

### Procedures

**To see the spotlight cone in viewports:**

The cone is always visible while the light is selected. This setting keeps the cone visible when the light is unselected.

1. Select the spotlight.
2. In the Spotlight Parameters rollout > Light Cone group, turn on Show Cone.
3. Select another object, deseleting the light.

A wireframe outline of the light’s cone appears. The hotspot region is outlined in light blue, and the falloff region is outlined in dark gray.

**Note:** The cone is always visible while the light is selected.
Tip: The hotspot and falloff borders are not visible in shaded viewports. Use controls in the Light Cone group to adjust hotspot and falloff in the viewport. Render the scene to see the full effect of the light’s border.

To adjust the hotspot and falloff, do one of the following:

- Use the Hotspot and Falloff spinners to increase or decrease the size of the hotspot and falloff regions. For spotlights, Hotspot and Falloff are expressed in degrees.
- Use manipulators to adjust hotspot and falloff by dragging in a viewport, as described in the procedure that follows.

By default, falloff value is always constrained to be at least two degrees or two units greater than the hotspot value. The size of this constraint is a preference that you can change in the Rendering panel (page 3–826) of the Preferences dialog. The falloff value can range from 0 to 10,000 units.

When the hotspot and falloff values are close in value, the light casts a hard-edged beam.

To use manipulators to control hotspot and falloff:

1. Select the spotlight.
   
   Tip: When you select multiple spotlights, all their manipulators are accessible.

2. On the default main toolbar, click to turn on Select And Manipulate.
   
   Now when you move the mouse over the hotspot or falloff circle, the circle turns red to show you can adjust it by dragging. Also, a tooltip displays the spotlight name, the parameter, and its value.

3. Drag the hotspot or falloff circle to adjust the value.
   
   The hotspot and falloff constrain each other, as their spinner controls do.
   
   Spotlight manipulators are described at the end of this topic.

To set the shape of the light beam:

1. Choose either Rectangle or Circle.
   
   The shape of the light’s cone changes to reflect the shape you chose.

2. If you chose Circle, you are done. If you chose Rectangle, you can now adjust the aspect ratio (page 3–911) of the rectangular light in the Aspect field.

To change a rectangular light’s aspect ratio:

1. Choose Rectangle, as described above.

2. Change the Aspect value to the aspect ratio that you want.
   
   The Bitmap Fit button is another way to set the aspect ratio. It is mainly used with projections.
### Interface

#### Light Cone group

These parameters control hotspots and falloff (page 3–954) for spotlights.

- **Show Cone**—Turns display of the cone on or off.
  
  **Note:** The cone is always visible when a light is selected, so turning off this check box has no apparent effect until you deselect the light.

- **Overshoot**—When Overshoot (page 3–988) is set, the light casts light in all directions. However, projections and shadows occur only within its falloff cone.

- **Hotspot/Beam**—Adjusts the angle of a light’s cone. The Hotspot value is measured in degrees. Default=43.0.

  For photometric lights, the Beam angle is the angle at which the light’s intensity has fallen to 50 per cent of its full intensity. (As opposed to the Hotspot, where intensity is still 100 per cent.)

- **Falloff/Field**—Adjusts the angle of a light’s falloff. The Falloff value is measured in degrees. Default=45.0.

  For photometric lights, the Field angle is comparable to the Falloff angle. It is the angle at which the light’s intensity has fallen to zero.

  You can manipulate the hotspot and falloff by dragging manipulators in viewports, as described in the previous procedures, and the later section "Manipulators for Spotlights."

  You can also adjust hotspot and falloff angles in a Light viewport (looking at the scene from the point of view of the spotlight).

- **Circle/Rectangle**—Determine the shape of the falloff and hotspot areas. Set Circle when you want a standard, circular light. Set Rectangle when you want a rectangular beam of light, such as light cast through a window or doorway.

- **Aspect**—Sets the aspect ratio (page 3–911) for the rectangular light beam. The Bitmap Fit button lets you make the aspect ratio match a specified bitmap. Default=1.0.

- **Bitmap Fit**—If the light’s projection aspect is rectangular, sets the aspect ratio to match a particular bitmap. This is useful when you are using the light as a projector light (page 3–998).

#### Manipulators for Spotlights

- **Manipulators are visible and usable while the Select And Manipulate button (page 2–15) is turned on. This button is on the default main toolbar (page 3–685).** When you move the mouse over a manipulator, the manipulator turns red to show that dragging or clicking it will have an effect. Also, a tooltip appears, showing the name of the object, the parameter, and its value.

- **Tip:** When you select multiple spotlights, all their manipulators are accessible.

  For more information on using the spotlight manipulators, see the Procedures section at the top of this topic.

- **Hotspot manipulator:** In a viewport, drag the hotspot circle to adjust the hotspot value.

- **Falloff manipulator:** In a viewport, drag the falloff to adjust the falloff value.
The hotspot and falloff constrain each other, as their spinner controls do.

Advanced Effects Rollout

Create panel > Lights > Create a light. > Advanced Effects rollout

The Advanced Effects rollout provides controls that affect how lights affect surfaces, and also includes a number of fine adjustments and setting for projector lights.

You can make a light object (page 2–1272) into a projector by choosing a map for the light to project. A projected map can be a still image or an animation.

Casting a projection with a light

Note: If your scene includes animated bitmaps, including materials, projector lights, environments, and so on, the animation file is reloaded once per frame. If your scene uses multiple animations, or if the animations are large files, this can slow down rendering performance.

Procedures

To make a light a projector:

1. Open the Material Editor (page 2–1409). The Material Editor is where you adjust the map’s parameters.

2. Use an unused sample slot to display a map.

3. Drag the map from the Material Editor to the light’s Map button in the Advanced Effects rollout. A dialog asks if the projection map should be a copy or an instance. Choose Instance. If you choose Copy, adjusting the map in the Material Editor has no effect on the projected map.

You can also drag from any other used map button, as in the Environment dialog.

Assigning the map displays the map name in the button, and turns on the Projector toggle. After you have set up the map, you can turn off Projector to test rendering the scene without the projected image.

An alternative is to click the Map button. This displays the Material/Map Browser (page 2–1412), which lets you choose the map type. At this point, the light behaves as a projector. To assign a map or adjust its parameters, you need to use the Material Editor.

Note: Lights project maps only within their cone, even if Overshoot is turned on.

To put the map in the Material Editor:

- Drag from the light’s Map button to an unused sample slot in the Material Editor.

Note: Sample slots with white triangles in the corners indicate materials that are used in the current scene.

You can adjust the map in the Material Editor by changing the map’s parameters.

To blur a projection map:

- Increase the value of Blur Offset in the map’s Coordinates rollout in the Material Editor.

You can animate Blur Offset to have a projected map go in or out of focus.
To make the shape of the light fit the projected bitmap:

Note: This procedure only applies to standard spot and direct lights.

1. Choose a bitmap to project, as described in the preceding procedures.
2. Make sure the light’s shape is set to Rectangular, and then click Bitmap Fit.
   A file selection dialog is displayed.
3. Choose the same bitmap you chose for the standalone map, and then click OK.
   You can also choose a bitmap other than the one the light projects.

Interface

Affect Surfaces group

Contrast—Adjusts the contrast between the diffuse and ambient areas of the surface. Leave this set to 0 for normal contrast. Increase the value to increase the contrast for special effects: for example, the harsh light of outer space. Default=0.0.

Soften Diffuse Edge—Increasing the value of Soften Diffuse Edge softens the edge between the diffuse and ambient portions of a surface. This helps eliminate edges that can appear on a surface under certain circumstances. Default=50.

Note: Soften Diffuse Edge reduces the amount of light, slightly. You can counter this, to some extent, by increasing the Multiplier value.

Diffuse—When on, the light affects the diffuse properties of an object’s surface. When off, the light has no effect on the diffuse surface. Default=on.

Specular—When on, the light affects the specular properties of an object’s surface. When off, the light has no effect on the specular properties. Default=on.

For example, by using the Diffuse and Specular check boxes you can have one light color the specular highlights of an object, while not coloring its diffuse area, and then have a second light color the diffuse portion of the surface while not creating specular highlights.

Ambient Only—When on, the light affects only the ambient component of the illumination. This gives you more detailed control over the ambient illumination in your scene. When Ambient Only is on, Contrast, Soften Diffuse Edge, Diffuse, and Specular are unavailable. Default=off.

The effect of Ambient Only isn’t visible in viewports. It appears only when you render the scene.
mental ray Indirect Illumination Rollout (for Lights)

Projector Map group
These controls make the photometric light a projector.

**Check box**—Turn on to project the map selected by the Map button. Turn off to turn off projection.

**Map**—Names the map used for the projection. You can drag from any map specified in the Material Editor, or any other map button (as on the Environment panel), and drop that map on the light’s Map button. Clicking Map displays the Material/Map Browser. You can choose the map type using the Browser, then drag the button to the Material Editor, and use the Material Editor to select and adjust the map.

### mental ray Indirect Illumination Rollout (for Lights)

Create panel > Lights > Create a light. > Modify panel > mental ray Indirect Illumination rollout

Note: This rollout does not appear on the Create panel.

The mental Indirect Illumination rollout provides controls for light behavior with the *mental ray* renderer (page 3–78). The settings in this rollout have no effect on rendering with the default scanline renderer, or on advanced lighting (the light tracer or a radiosity solution). These settings control how the light behaves when it generates indirect illumination; that is, caustics (page 3–92) and *global illumination* (page 3–93).

Tip: By default, each light uses the global settings that are found in the Global Light Properties group on Render Scene Dialog > Indirect Illumination panel > Indirect Illumination rollout (page 2–1343). It is more convenient to adjust all lights in the scene at once. If you need to adjust a specific light, you can use the multiplier controls for energy and photons. In general, you should rarely if ever need to turn off Use Global Settings and specify local light settings for indirect illumination.

**Important:** In addition to the values specified here, the light must also be set to generate caustics, *global illumination*, or both. These controls are on the mental ray panel (page 1–126) of the Object Properties dialog. You also need to turn on Caustics, Global, or both, on the Render Scene dialog’s *Indirect Illumination rollout* (page 2–1343).

### Interface

![mental ray Indirect Illumination Rollout](image)

- **Automatically Calculate Energy and Photons**—When on, the light uses the global light settings for indirect illumination, rather than local settings. Default=on.

  When this toggle is on, only the controls in the Global Multipliers group are available.

**Global Multipliers group**

- **Energy**—Multiplies the global Energy value to increase or decrease the energy of this particular light. Default=1.0.

  **Caustic Photons**—Multiplies the global Caustic Photons value to increase or decrease the count of...
photons used to generate caustics by this particular light. Default=1.0.

**GI Photons**—Multiplies the global GI Photons value to increase or decrease the count of photons used to generate global illumination by this particular light. Default=1.0.

**Manual Settings group**

When Automatically Calculate is off, the Global Multipliers group becomes unavailable, and the manual settings for indirect illumination become available.

<table>
<thead>
<tr>
<th>Manual Settings:</th>
</tr>
</thead>
<tbody>
<tr>
<td>On</td>
</tr>
<tr>
<td>Energy:</td>
</tr>
<tr>
<td>Decay:</td>
</tr>
<tr>
<td>Caustic Photons:</td>
</tr>
<tr>
<td>GI Photons:</td>
</tr>
</tbody>
</table>

**On**—When on, the light can generate indirect illumination effects. Default=off.

**Filter color**—Click to display a Color Selector (page 1–161) and choose a color that filters the light energy. Default=white.

**Energy**—Sets the energy of the light. Energy, or "flux," is the amount of light used in indirect illumination. Each photon carries a fraction of the light’s energy. This value is independent of the light intensity determined by the light’s color and Multiplier, so you can use the Energy value to fine-tune indirect illumination effects without changing the light’s other effects in a scene (such as providing diffuse illumination). Default=50000.0.

**Decay**—Specifies how photon energy decays as it moves away from the light source. Range=0.0 to 100.0. Default=2.0 (inverse square; physically correct falloff).

This value is applied as an exponent to the distance \( r \) between the light source and each indirectly illuminated point to determine the energy at that point, in the formula \( 1/r^{\text{Decay}} \), and is intended for tweaking the GI solution. The most commonly used values are:

- **0.0 (no decay)**—The energy doesn’t decay, and photons provide equal indirect illumination throughout the scene.
- **1.0 (inverse)**—The energy decays proportionally to its distance from the light, with linear falloff. That is, a photon’s energy is \( 1/r \), where \( r \) is the distance from the light source.
- **2.0 (inverse square)**—The energy decays at an inverse square rate. That is, a photon’s energy is the inverse of the square of the distance \( r \) from the light source \( (1/r^2) \).

In the real world, light decays at the inverse square rate, but this gives strictly realistic results only if you provide a realistic value for the energy of the light. You can use other values to help adjust indirect illumination without worrying about physical accuracy.

**Caustic Photons**—Sets the number of photons emitted by the light for use in caustics. This is the number of photons in the photon map (page 3–994) used for caustics. Increasing this value increases the accuracy of caustics, but also increases the amount of memory used and the length of render time. Decreasing this value improves memory usage and render time, and can be useful for previewing caustic effects. Default=10000.

**GI Photons**—Sets the number of photons emitted by the light for use in global illumination. This is the number of photons in the photon map used for global illumination. Increasing this value increases the accuracy of global illumination, but also increases the amount of memory used and the length of render time. Decreasing this value improves memory usage and render time, and can be useful for previewing global-illumination effects. Default=10000.
mental ray Light Shader Rollout

Select a light. > Modify panel > mental ray Light Shader rollout

Note: This rollout appears only if you have enabled the mental ray extensions by using the mental ray Preferences panel.

Note: This rollout does not appear on the Create panel; only on the Modify panel.

The mental ray Light Shader rollout lets you add mental ray shaders (page 2–1710) to lights. When you render with the mental ray renderer (page 3–78), light shaders can alter or adjust the light's effect.

To adjust the settings for a light shader, drag the shader's button to an unused Material Editor sample slot. If the software prompts you to choose Instance or Copy, be sure to choose Instance. (If you edit a copy of the shader, you will have to drag the sample slot back to the shader button on the Light Shader rollout before any changes take effect.)

Interface

Enable—When on, rendering uses the light shaders you have assigned to this light. When off, the shaders have no effect on rendering. Default=off.

Light Shader—Click the button to display a Material/Map Browser (page 2–1412) and choose a shader. Once you have chosen a shader, its name appears on the button.

Photon Emitter Shader—Click the button to display a Material/Map Browser and choose a shader. Once you have chosen a shader, its name appears on the button.

Note: No photon emitter shaders are provided with 3ds Max. This option is for users who have access to light map shaders via other shader libraries or custom shader code.

Additional Rollouts for Standard Lights

Intensity/Color/Attenuation Parameters

Create panel > Lights > Create a Standard light. > Attenuation Parameters rollout

Enable—When on, rendering uses the light shaders you have assigned to this light. When off, the shaders have no effect on rendering. Default=off.

Light Shader—Click the button to display a Material/Map Browser and choose a light shader. Once you have chosen a shader, its name appears on the button.

Photon Emitter Shader—Click the button to display a Material/Map Browser and choose a shader. Once you have chosen a shader, its name appears on the button.

Intenstiy/Color/Attenuation Parameters allow you to set the color and intensity of your light. You can also define the attenuation of your light.
Attenuation (page 3–912) is the effect of light diminishing over distance. In 3ds Max, you can set attenuation values explicitly. The effects can vary from real-world lights, giving you more direct control over how lights fade in or fade out.

Note: With no attenuation, an object can paradoxically appear to grow brighter as it moves away from the light source. This is because the angle of incidence more closely approaches 0 degrees for more of the object's faces.

Two sets of values control attenuation for objects. The Far attenuation value sets the distance at which the light drops off to zero. The Near attenuation value sets the distance at which the light "fades in." Both these controls are turned on and off by a toggle called Use.

When Use is set for far attenuation, the light at its source uses the value specified by its color and multiplier controls. It remains at this value from the source to the distance specified by Start, then its value drops off to zero at the distance specified by End.

The Decay controls are an additional way to make a light fade out.

Tip: When lights are attenuated, the light might be too bright on near surfaces or too dim on far surfaces. If you see this in renderings, exposure control can help correct the problem. It adjusts the larger dynamic range of the (simulated) physical scene, into the smaller dynamic range of the display. See Environment Panel (page 3–272) for additional information on exposure control.

Procedures

To choose the color of a light using the color selector:

1. Click the color swatch next to the On check box. A modal Color Selector (page 1–161) is displayed.
2. Use the Color Selector to choose a new color, and then click OK.

Shaded viewports update to show the new light color, which also appears in renderings.

To change a light's intensity:

• Increase the light's Multiplier value.

To use attenuation:

1. Set the Start and End values.
2. Turn on Use.

Attenuation is now in effect for this light when the scene is shaded or rendered.

Note: You can also change the decay type (and values) to reduce the light’s intensity over distance.

To see the attenuation range in viewports:

• Set Show for far or near attenuation.

You can preview the effect of attenuation in shaded viewports only if you turn this on as an option in viewport preferences (page 3–821).
Interface

Multiplier—Amplifies the power of the light by a positive or negative amount. For example, if you set the multiplier (page 3–977) to 2, the light will be twice as bright. Multipliers are also useful for subtracting light and selectively placing dark areas in the scene. Default=1.0.

Using this parameter to increase intensity can cause colors to appear "burned out." It can also generate colors not usable in videos. In general, leave Multiplier set to its default of 1.0 except for special effects and special cases.

High Multiplier values wash out colors. For example, if you set a spotlight to be red but then increase its Multiplier to 10, the light is white in the hotspot and red only in the falloff area, where the Multiplier isn’t applied.

Negative Multiplier values result in "dark light." That is, the light darkens objects instead of illuminating them.

Color Swatch—Shows the color of the light. Clicking the color swatch displays the Color Selector (page 1–161) so you can choose a color for the light.

Decay group

Decay is an additional way to make a light’s intensity reduce over distance.

Type—Sets the type of decay to use. There are three types to choose from.

- **None**—(The default.) Applies no decay. The light maintains full strength from its source to infinity, unless you turn on far attenuation.

- **Inverse**—Applies inverse decay. The formula is luminance=\(R_0 / R\), where \(R_0\) is the radial source of the light if no attenuation is used, or the Near End value of the light if attenuation is used. \(R\) is the radial distance of the illuminated surface from \(R_0\).

- **Inverse Square**—Applies inverse-square decay. The formula for this is \((R_0 / R)^2\). This is actually the "real-world" decay of light, but you might find it too dim in the world of computer graphics.

Tip: If Inverse Square decay makes the scene too dim, you can try using the Environment Panel (page 3–272) to increase the Global Lighting Level value.

The point at which decay begins depends on whether or not you use attenuation:

- With no attenuation, decay begins at the source of the light.

- With near attenuation, the decay begins at the Near End position.

Once the beginning point is established, the decay follows its formula to infinity, or until the light itself is cut off by the Far End distance. In other words, the distance between Near End and Far End does not scale, or otherwise affect, the apparent ramp of decaying light.
Tip: Because decay continues to calculate dimmer and dimmer values as the distance of the light throw increases, it’s a good idea to set at least the Far End of attenuation to eliminate unnecessary calculations.

Near Attenuation group
Start—Sets the distance at which the light begins to fade in.
End—Sets the distance at which the light reaches its full value.
Use—Enables near attenuation for the light.
Show—Displays the near attenuation range settings in viewports. For spotlights, attenuation ranges appear as lens-shaped sections of the cone. For directional lights, the ranges appear as circular sections of the cone. For omni lights and spot or directional lights with Overshoot turned on, the ranges appear as spheres. By default, Near Start is dark blue and Near End is light blue.

Far Attenuation group
Start—Sets the distance at which the light begins to fade out.
End—Sets the distance at which the light has faded to zero.
Use—Enables far attenuation for the light.
Show—Displays the far attenuation range settings in viewports. For spotlights, attenuation ranges appear as lens-shaped sections of the cone. For directional lights, the ranges appear as circular sections of the cone. For omni lights and spot or directional lights with Overshoot turned on, the ranges appear as spheres. By default, Far Start is light brown and Far End is dark brown.

Directional Parameters
Create a standard Target Direct or Free Direct light. > Directional Parameters rollout

The Directional Parameters rollout appears when you create or select a target direct (page 2–1292) or free direct (page 2–1293) light. These parameters control hotspots (page 3–954) and falloff (page 3–954).

Procedures
To see the directional cone in viewports:
The cone is always visible while the light is selected. This setting keeps the cone visible when the light is unselected.
1. Select the spotlight.
2. In the Directional Parameters rollout > Light Cone group, turn on Show Cone.
3. Select another object, deselecting the light.

A wireframe outline of the light’s cone appears. The hotspot region is outlined in light blue, and the falloff region is outlined in dark gray.
The cone is always visible while the light is selected.
Tip: The hotspot and falloff borders are not visible in shaded viewports. Use the cone values to adjust hotspot and falloff in the viewport. Render the scene to see the full effect of the light’s border.

To adjust the hotspot and falloff:
• Use the Hotspot and Falloff spinners to increase or decrease the size of the hotspot and falloff regions. For directional lights, Hotspot and Falloff are expressed in units.

By default, the falloff value is always constrained to be at least two degrees or two units greater than the hotspot value. The size of this constraint is a preference that you can change.
in the Rendering panel (page 3–826) of the Preferences dialog. The falloff value can range from 0 to 10,000 units.

When the hotspot and falloff values are equal, the light casts a hard-edged beam.

To set the shape of the light beam:
1. Choose either Rectangle or Circle.
   The shape of the light’s cone changes to reflect the shape you chose.
2. If you chose Circle, you are done. If you chose Rectangle, you can now adjust the aspect ratio (page 3–911) of the rectangular light using the spinner labeled Aspect.

To change a rectangular light’s aspect ratio:
1. Choose Rectangle, as described above.
2. Change the Aspect value to the aspect ratio that you want.
   The Bitmap Fit button is another way to set the aspect ratio. It is mainly used with projections.

Interface

Light Cone group
These parameters control hotspots (page 3–954) and falloff (page 3–954) for spotlights.

Show Cone—Turns display of the cone on or off.

Note: The cone is always visible when a light is selected, so clearing this check box has no apparent effect until you deselect the light.

Overshoot—When Overshoot (page 3–988) is set, the light casts light in all directions. However, projections and shadows occur only within its falloff cone.

Hotspot/Beam—Adjusts the size of a light’s cone. The Hotspot value is measured in 3ds Max units. Default=43.0.

Falloff/Field—Adjusts the size of a light’s falloff. The Falloff value is measured in 3ds Max units. Default=45.0.

You can also adjust hotspot and falloff angles in a Light viewport (page 2–1338) (looking at the scene from the point of view of the spotlight).

Circle/Rectangle—Determine the shape of the falloff and hotspot areas. Set Circle when you want a standard, circular light. Set Rectangle when you want a rectangular beam of light, such as light cast through a window or doorway.

Aspect—Sets the aspect ratio (page 3–911) for the rectangular light beam. The Bitmap Fit button lets you make the aspect ratio match a specified bitmap. Default=1.0.

Bitmap Fit—If the light’s projection aspect is rectangular, sets the aspect ratio to match a particular bitmap. This is useful when you are using the light as a projector light (page 3–998).

Atmospheres and Effects for Lights

The Atmospheres & Effects rollout lets you assign, delete, and set up parameters for atmospheres and rendering effects associated with the light. This
rollout appears only in the Modify panel; it doesn't appear at creation time.

Adding an atmosphere or effect associates that atmosphere or effect with the light object. This rollout is a shortcut to either the Environment panel (page 3–272) or the Effects panel (page 3–219) on the Environment And Effects dialog.

**Procedures**

**To add a new atmosphere or rendering effect:**
1. In the Atmospheres & Effects rollout, click Add. This displays the Add Atmosphere or Effect dialog (page 2–1351).
2. In the dialog, choose Atmosphere, Effect, or All. Choose New.
3. Choose an atmosphere or effect in the list, then click OK.
   This associates a new atmosphere or rendering effect with the light.

**To add an existing atmosphere or rendering effect:**
1. In the Atmospheres & Effects rollout, click Add. This displays the Add Atmosphere or Effect dialog (page 2–1351).
2. In the dialog, choose Existing.
3. Choose an atmosphere or effect in the list, then click OK.
   This creates a duplicate atmosphere or rendering effect for the light. Its settings are initially identical to the atmosphere or effect you chose. You can adjust them using Setup.

**To delete an atmosphere or rendering effect:**
- In the Atmospheres & Effects rollout, choose the name of an atmosphere or effect in the list, then click Delete.

**To set up the parameters for an atmosphere or rendering effect:**
- In the Atmospheres & Effects rollout, choose the name of an atmosphere or effect in the list, then click Setup.

If you chose an atmosphere, clicking Setup displays the Environment panel (page 3–272). If you chose an effect, clicking Setup displays the Effects panel (page 3–219).

**Interface**

These controls are displayed for all light types.

<table>
<thead>
<tr>
<th>Atmospheres &amp; Effects</th>
<th>Add</th>
<th>Delete</th>
</tr>
</thead>
</table>

Add—Displays the Add Atmosphere or Effect dialog (page 2–1351), which lets you add an atmosphere or a rendering effect to the light.

Delete—Deletes the atmosphere or effect you have selected in the list.

List of atmospheres and effects—Displays the names of all atmospheres or effects you have assigned to this light.

Setup—Lets you set up the atmosphere or rendering effect you have selected in the list. If the item is an atmosphere, clicking Setup displays the Environment panel (page 3–272). If the item is an effect, clicking Setup displays the Effects panel (page 3–219).
Add Atmosphere or Effect Dialog

Modify panel > Select light object. > Atmospheres & Effects rollout > Add button

The Add Atmosphere or Effect dialog lets you associate an atmosphere or a rendering effect with the light. The list shows either atmospheres, rendering effects, or both. It shows only atmospheres and effects that can be associated with light objects, or that use light objects as their apparatus.

Interface

List of atmospheres and effects—Displays the atmospheres or effects that you can associate with the light.

List filter group

These radio buttons choose what to show in the list.

Atmosphere—Lists only atmospheres.

Effect—Lists only rendering effects.

All—Lists both atmospheres and rendering effects.

New or existing group

These radio buttons choose between new or existing effects.

New—Lists only new atmospheres or effects.

Existing—Lists only atmospheres or effects that have been already assigned to the light.

Adding an existing atmosphere or effect creates a new atmosphere or effect whose settings are initially identical to the previous one.

Hair Light Attributes Rollout

Add a supported light. > Select an object with the Hair And Fur modifier applied. > Render Settings > Effects panel > Select the light (in a viewport). > Hair And Fur rollout > Lighting group > Click Add Hair Properties. > Modify panel > Hair Light Attr rollout

The Hair Light Attributes rollout lets you adjust properties for the hair shadow map generated by the light. This rollout appears for supported lights at render time. If you want to adjust a light’s hair settings before render time, you can display it explicitly by following the steps shown in the path annotations at the beginning of this topic.

You specify which lights to use in the Hair And Fur render effect (page 3–220). By default, Use All Lights At Render Time is on, so all supported lights in the scene can illuminate hair. Use this rollout to set hair-specific shadow-map values. Hair shadows ignore the light’s ordinary shadow-map settings (for other 3ds Max objects).

Important: The settings on this rollout apply only to “buffer”-rendered hair (the default rendering method, set in the Hair And Fur render effect). The “geometry” and “mr prim” methods use the light’s ordinary shadow settings.
Interface

- Light hair Attr
  - Light hair
  - Resolution: 512
  - Fuzz: 4.0

**Light hair**—When on, the light can illuminate and cast shadows from the hair.

*Note:* The light must also be set to cast shadows (General Parameters rollout > Shadows > On).

**Resolution**—Sets the size (in pixels squared) of the shadow map that’s computed for the light.

The shadow map size specifies the amount of subdivisions for the map. The higher the value, the more detailed the map will be, but the more memory is required.

**Fuzz**—Sets the softness of the shadow edges. See *Sample Range* (page 3–1004).

Left: Fuzz=0.0  
Center: Fuzz=5.0  
Right: Fuzz=10.0

The arrow points to the shadow cast by the hair on the underlying surface.

---

**Additional Rollouts for Photometric Lights**

**Intensity/Color/Distribution Rollout**

Create panel > Lights > Create a Photometric light. > Intensity/Color/Distribution rollout

The Intensity/Color/Distribution rollout lets you set the type of distribution for photometric lights (page 2–1301). You can also define the color and intensity of lights.

**See also**

- *Lights* (page 2–1272)
- *Photometric Lights* (page 2–1301)
- *Isotropic Light Distribution (Photometric Lights)* (page 2–1323)
- *Spotlight Distribution (Photometric Lights)* (page 2–1324)
- *Diffuse Distribution (Photometric Lights)* (page 2–1323)
- *Web Distribution (Photometric Lights)* (page 2–1325)

**Procedure**

To change the distribution type of a photometric light:

1. Select the light.
2. In the Modify panel > Intensity/Color/Distribution rollout, choose a type from the Distribution list.
Interface

Distribution—Describes the directional distribution of the light emitted by a source. There are several different distributions:

- Isotropic (page 2–1323)
- Spotlight (page 2–1324)
- Web (page 2–1325)
- Diffuse (page 2–1323)

Note: Target Point and Free Point lights can have either Isotropic, Spotlight, or Web distribution. All other photometric lights use either Web or Diffuse distribution.

Color group

Light—Pick a common lamp specification to approximate the spectral character of your light. The color swatch next to the Kelvin parameter is updated to reflect the light you select.

Kelvin—Set the color of the light by adjusting the color temperature spinners. The color temperature is displayed in degrees Kelvin. The corresponding color is visible in the color swatch next to the temperature spinners.

Filter—Use a color filter to simulate the effect of a color filter placed over the light source. For example, a red filter over a white light source casts red light. Set the filter color by clicking the color swatch to display the Color Selector (page 1–161). Default=white (RGB=255,255,255; HSV=0,0,255).

Intensity group

These controls specify the strength or brightness of photometric lights in physically based quantities.

You set the intensity of a light source using one of the following units:

- **lm (lumen)**—Measures the overall output power of the light (luminous flux (page 3–955)). A 100-watt general purpose light bulb has a luminous flux of about 1750 lm.
- **cd (candela)**—Measures the maximum luminous intensity (page 3–965) of the light, usually along the direction of aim. A 100-watt general purpose light bulb has a luminous intensity of about 139 cd.
- **lx at (lux)**—Measures illuminance (page 3–955) caused by the light shining on a surface at a certain distance and facing in the direction of the source. The lux is the International Scene unit, which is equivalent to 1 lumen per square meter. The SI unit for illuminance is the footcandle (fc) which is equivalent to 1 lumen per square foot. To convert from footcandles to lux, multiply by 10.76. For example, to specify an illuminance of 35 fc, set illuminance to 376.6 lx.

To specify the illuminance of a light, you must set the lx value, and enter the distance at which that illuminance is measured.

Note: You can obtain these values directly from lighting manufacturers. A table of some common

### Linear Light Parameters Rollout

Create panel > Lights > Create a photometric linear light. > Linear Light Parameters rollout

Select a linear light. > Modify panel > Linear Light Parameters rollout

The Linear Light parameters rollout lets you set the length of your photometric linear light.

**See also**

Photometric Lights (page 2–1301)
Target Linear Light (Photometric) (page 2–1305)
Free Linear Light (Photometric) (page 2–1307)

**Interface**

Length—Sets the length of your linear light.

### Area Light Parameters Rollout

Create panel > Lights > Create a photometric area light. > Area Light Parameters rollout

The Area Light parameters rollout lets you set the dimensions of your photometric area light.

**See also**

Photometric Lights (page 2–1301)
Target Area Light (Photometric) (page 2–1307)
Free Area Light (Photometric) (page 2–1309)

**Interface**

Length—Sets the length of your area light.
Width—Sets the width of your area light.

### Area Light Sampling Rollout

Select a linear or photometric area light. > Modify panel > Area Light Sampling rollout

The Area Light Sampling rollout lets you control the number of samples to use for the minimum subdivision size conversion. The values in this rollout affect rendering performed by the default scanline renderer (page 3–38) and the mental ray renderer (page 3–78). It’s also used for Radiosity in order to compute Shoot Direct Lights (page 3–69) for area and linear lights. The number of samples are divided into the area of an area light or into the length of a linear light.

Note: This rollout appears only on the Modify panel.

**See also**

Photometric Lights (page 2–1301)
Target Linear Light (Photometric) (page 2–1305)
Free Linear Light (Photometric) (page 2–1307)
Target Area Light (Photometric) (page 2–1307)
Free Area Light (Photometric) (page 2–1309)
Interface

Enable Area Sampling—Toggles area sampling. Default=on.

Num. Samples—The number of samples to use for subdivision conversion. Default=16.

Web Parameters Rollout

Create panel > Lights > Photometric Lights > Create a photometric light. > Intensity/Color/Distribution Parameters rollout > Choose Web distribution type.

The Web Parameters rollout is displayed on the Modify panel when you create or select a photometric light with a web distribution (page 2–1325). Use these parameters to select a photometric web file and to adjust the orientation of the web.

3ds Max can use the IES (page 2–1328), CIBSE (page 3–921), or LTLI (page 3–964) photometric web formatting.

See also

Target Point Light (Photometric) (page 2–1303)
Free Point Light (Photometric) (page 2–1304)
Target Linear Light (Photometric) (page 2–1305)
Free Linear Light (Photometric) (page 2–1307)
Target Area Light (Photometric) (page 2–1307)
Free Area Light (Photometric) (page 2–1309)

Procedures

To select a photometric web file:

1. On the Web Parameters rollout for a selected light, click the Web File button. The Open A Photometric Web dialog is displayed.

2. Navigate to the location of the file you want to import. Select the file and click Open.

If you are modifying a light, the light’s icon is replaced by a wireframe outline of the photometric web. If you are creating a light, the photometric web icon appears when you drag your cursor in the viewport to create the light.

Note: You can obtain photometric web files from various lighting manufacturers. You can use the Content Browser to download IES files or use IES files available in the Lightscape Libraries provided with Lightscape software.

To change the orientation of the photometric web:

- Use the rotation spinners to change the X, Y, or Z rotation or the photometric web.

Note: These parameters cannot be animated.

To change the direction of a light, you can also use the Rotation transform or for target point lights, move the light’s target point.

Tip: To see the shape of the photometric web, you can make the light icon larger by increasing the Non Scaling Object size in Tools menu > Options dialog > Viewports panel > Viewport Parameters.

Interface
**Web File**—Selects an IES file to use as a photometric web. The default web is a diffuse distribution shining from one edge.

**X Rotation**—Rotates the photometric web about the X axis. The center of rotation is the photometric center of the web. Range=-180 degrees to 180 degrees.

**Y Rotation**—Rotates the photometric web about the Y axis. The center of rotation is the photometric center of the web. Range=-180 degrees to 180 degrees.

**Z Rotation**—Rotates the photometric web about the Z axis. The center of rotation is the photometric center of the web. Range=-180 degrees to 180 degrees.

**Photometric web icon**—Shows a three-dimensional representation of the light distribution. See Web Distribution (page 2–1326).

---

### Rollouts for Specific Shadow Types

#### Advanced Ray-Traced Parameters Rollout

Create panel > Lights > Create or select a light. > General Parameters rollout > Shadow type > Advanced Ray-traced Shadows

Advanced Ray-traced shadows are similar to ray-traced shadows (page 3–1000), however they give you more control over shadow behavior. Additional controls are available in the Optimizations rollout (page 2–1361).

---

**Mode**—Selects the type of raytracing for generating shadows:

- **Simple**—Casts a single ray of light toward the surface. No antialiasing (page 3–907) is performed.
- **Antialias 1-Pass**—Casts a bundle of rays. The same number of rays is cast from each illuminated surface. The number of rays is set using the Pass 1 Quality spinner.
- **Antialias 2-Pass**—Casts two bundles of rays. The first batch of rays determines if the point in question is fully illuminated, shadowed, or in the penumbra (soft area) of the shadow. If the point is in the penumbra, a secondary
The number of initial rays is specified using the Pass 1 Quality spinner. The number of secondary rays is specified using the Pass 2 Quality spinner.

2-Sided Shadows—When on, backfaces are not ignored when calculating shadows. Objects seen from the inside are not lit by lights from the outside. This costs a bit more render time. When off, backfaces are ignored. Rendering is quicker, but outside lights illuminate object interiors.

Increasing the Shadow Spread value softens shadow edges.

Shadow Bias—The minimum distance from the point being shaded that an object must be to cast a shadow. This prevents blurred shadows from affecting surfaces they shouldn’t.

Note: As you increase the blur value, you should also increase the bias.

Jitter Amount—Adds randomness to the ray positions. The rays are initially in a very regular pattern, which can show up in the blurry part of the shadow as regular artifacts. Jittering will convert these artifacts to noise, which is generally less noticeable to the eye. Recommended values are 0.25 to 1.0. However, very blurry shadows will require more jitter.

The Area Shadow generator can be applied to any light type to achieve the effect of an area shadow effect. In order to create an area shadow, the user needs to specify the dimensions of a virtual light created to "fake" an area shadow.

Note: When using area lights, the user should try to make the properties of the light match the...
properties in the Area Light Dimensions group of the Area Shadows rollout.

Tip: Area shadows can take a fair amount of time to render. If you want to create a quick test (or draft) rendering, you can use the Area/Linear Lights as Point Lights toggle in the Common Parameters rollout (page 3–27) of the Render Scene dialog to speed up your rendering. When this toggle is on, the shadows are processed as if the light object is a point source.

Area shadows create a soft edge that becomes more noticeable as the distance between the object and the shadow increases.
A: Penumbra (soft area)
B: Shadow

Area shadow cast by a point light

Interface

Basic Options group

Mode—Selects the way the area shadows are generated:

- **Simple**—Casts a single ray from the light toward the surface. No antialiasing (page 3–907) or area light calculation is performed.
- **Rectangle Light**—Casts rays from the light in a rectangular array.
- **Disc Light**—Casts rays from the light in a circular array.
- **Box Light**—Casts rays from the light as if it were a box.
- **Sphere Light**—Casts rays from the light as if it were a sphere.
The shape of the area shadow array affects how shadows are cast.

Left: Rectangle
Right: Box

2-Sided Shadows—When on, backfaces are not ignored when calculating shadows. Objects seen from the inside are not lit by lights from the outside. This costs a bit more render time. When off, backfaces are ignored. Rendering is quicker, but outside lights illuminate object interiors.

The faces inside the sliced sphere do not cast shadows if 2-Sided Shadows is off.

Antialiasing Options group

Shadow Integrity—Sets the number of rays in the initial bundle of rays cast. These rays are projected from every surface that receives light from the light source.

The number of rays is as follows:
1 = 4 rays
2 = 5 rays
3 to N = N x N rays.

For example, setting Shadow Integrity to 5 generates 25 rays.

This is the primary control for “finding” small objects and thin spaces between objects. If the shadows are missing a small object in your scene, try increasing Shadow Integrity one step at a time. Also, if the penumbra (soft area) is blotchy, try increasing this setting.

Increasing the Shadow Integrity value creates more accurate shadow contour and detail.

Shadow Quality—Sets the total number of rays cast in the penumbra (soft area) region, including the rays fired in the first pass.

These rays are projected from every point that is in the penumbra, or antialiased edge of the shadow, to smooth it out.

The number of rays is as follows:
• 2 = 5 rays
• 3 to N = N x N

For example, setting Shadow Quality to 5 generates 25 rays.

The Shadow Quality value should always be greater than the Shadow Integrity value. This is because the software overlays the secondary rays atop the first pass’s rays using the same algorithm.
Increase Shadow Quality to fix banding in the penumbra, and eliminate the noise pattern from jittering.

Increasing the Shadow Quality value produces a more accurate penumbra (soft area) within the contour defined by the Shadow Integrity value.

**Sample Spread**—The radius, in pixels, to blur the antialiased edge.

Note: As this value increases, so does the quality of the blur. However, increasing this value also increases the likelihood of missing small objects. To avoid this problem, increase the value of Shadow Integrity.

**Shadow Bias**—The minimum distance that an object must be from the point being shaded in order to cast a shadow. This prevents blurred shadows from affecting surfaces they shouldn’t.

Note: As you increase the blur value, you should also increase the bias.

**Jitter Amount**—Adds randomness to the ray positions. The rays are initially in a very regular pattern, which can show up in the blurry part of the shadow as regular artifacts. Jittering will convert these artifacts to noise, which is generally less noticeable to the eye. Recommended values are 0.25 to 1.0. However, very blurry shadows require more jitter.

**Increasing jitter blends the individual shadow samples.**

**Area Light Dimensions group**

The software uses these dimensions to compute the area shadowing. They do not affect the actual light object.

**Length**—Sets the length of the area shadow.

**Width**—Sets the width of the area shadow.

**Height**—Sets the height of the area shadow.

**mental ray Shadow Map Rollout**

Choosing “mental ray Shadow Map” as the shadow type tells the mental ray renderer (page 3–78) to generate shadows using the mental ray shadow-map algorithm. If you render with the default scanline renderer (page 3–38) instead, no shadows appear in the rendering.
Interface

Map Size—Sets the resolution of the shadow map. The size of the map is the square of this value. Greater resolutions require more time to process, but produce more accurate shadows. Default=512.

Sample Range—When greater than zero, generates soft-edged shadows. This value specifies the area of the map to soften, by removing portions of the map as specified by Samples. Default=0.0.

If you set Sample Range to be greater than zero, you must also set Samples to be greater than zero, to obtain a soft shadow effect.

Samples—Sets the number of samples to remove from a shadow map when generating soft shadows. Default=1.

Use Bias—When on, changes the map bias (page 3–966). Increasing the value moves the shadow farther away from the shadow casting object. Default=10.

Transparent Shadows group

Enable—When on, shadow maps are saved with multiple Z-layers, and can have transparency. Default=off.

Color—When on, surface color affects the color of the shadow. Default=on.

Turning off Color saves memory at rendering time.

Merge Dist.—The minimum distance between two surfaces for them to be considered “distinct.” If two surfaces are closer than this value, the shadow map treats them as a single surface. When set to 0.0, the mental ray renderer automatically calculates a distance value to use. Default=0.0 (automatic).

Larger Merge Distance values reduce memory consumption, but can reduce shadow quality. Low Merge Distance values increase memory consumption and slow down rendering speed.

Samp./Pixel—The number of samples used to generate a pixel in the shadow map. Higher values increase the quality and detail of the shadow, at a cost of render time. Default=5.

If a mapped shadow appears to be aliased (page 3–907), increase the value of Samples/Pixel. This setting is especially useful when shadows are cast by finely detailed geometry.

Optimizations Rollout

The Optimizations rollout provides additional controls for Advanced Ray-traced Shadow (page 3–1000) and Area Shadow (page 3–911) generation.

See also

General Lighting Parameters (page 2–1331)

Shadow Parameters (page 2–1337)

Area Shadows Rollout (page 2–1357)

Advanced Ray-Traced Parameters Rollout (page 2–1356)
Interface

Transparent Shadows group

On—When checked, transparent surfaces will cast a colored shadow. Otherwise, all shadows are black.

Note: Shadows will generate faster with this value turned off.

Antialiasing Threshold—The maximum color difference allowed between transparent object samples before antialiasing (page 3–907) is triggered. Increasing the value of this color will make the shadow less sensitive to aliasing artifacts and improve speed, decreasing the value will increase the sensitivity, improving quality.

Antialias Suppression group

Supersampled Material—When on, only pass 1 is used during 2-pass antialiasing when shading a supersampled (page 3–1018) material.

Note: When off, rendering time can increase without resulting in a better image.

Reflect/Refract—When on only pass 1 is used during 2-pass antialiasing when shading reflections or refractions.

Note: When off, rendering time can increase without resulting in a better image.

Coplanar Face Culling group

Skip Coplanar Faces—Prevents adjacent faces from shadowing each other. This is of particular concern at the terminator on curved surfaces such as spheres.

Threshold—The angle between adjacent faces.

Range = 0.0 (perpendicular) to 1.0 (parallel).

A stained glass appears solid with the transparency optimization turned off.

Antialiasing Threshold—The maximum color difference allowed between transparent object samples before antialiasing (page 3–907) is triggered. Increasing the value of this color will make the shadow less sensitive to aliasing artifacts.
Ray-Traced Shadow Parameters Rollout

Create a light. > General Parameters rollout > Ray Traced Shadows chosen > Ray Traced Shadow Params rollout

Ray-traced shadows

The Ray-Traced Shadow Parameters rollout appears when you have chosen raytracing as the shadow-generation technique for a light. You select this in the General Parameters rollout (page 2–1331).

For greater control of ray-traced shadows, use Advanced Ray-Traced Shadows (page 2–1356).

Interface

Bias—Ray-Trace Bias (page 3–1000) moves the shadow toward or away from the shadow-casting object (or objects).

If the Bias value is too low, shadows can "leak" through places they shouldn't, producing moiré patterns or making out-of-place dark areas on meshes. If Bias is too high, shadows can "detach" from an object. If the Bias value is too extreme in either direction, shadows might not be rendered at all.

2-Sided Shadows—When on, backfaces are not ignored when calculating shadows. Objects seen from the inside are not lit by lights from the outside. This costs a bit more render time. When off, backfaces are ignored. Rendering is quicker, but outside lights illuminate object interiors. Default=on.

The faces inside the sliced sphere do not cast shadows if 2-Sided Shadows is not selected.

Max Quadtree Depth—Adjusts the depth of the quadtree (page 3–999) used by the ray-tracer. Greater quadtree depth values can improve ray-tracing time at the cost of memory use.

However, there is a depth value where the performance improvement is offset by the time it takes to generate the quadtree itself. This depends on the geometry of the scene. Default=7.

Tip: Omni lights can generate up to six quadtrees, so they generate ray-traced shadows more slowly than spotlights. Avoid using ray-traced shadows with omni lights unless your scene requires this.

Shadow Map Parameters Rollout

Create a light. > General Parameters rollout > Shadow Map chosen > Shadow Map Params rollout

The Shadow Map Parameters rollout is displayed when you have chosen shadow mapping as the
shadow-generation technique for a light. You select this in the General Parameters rollout (page 2–1331).

**Interface**

<table>
<thead>
<tr>
<th>Shadow Map Params</th>

<th>Size: 512</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Sample Range: 4.0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Absolute Map Bias</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2 Sided Shadows</td>
<td></td>
</tr>
</tbody>
</table>

**Bias**—Map Bias (page 3–966) moves the shadow toward or away from the shadow-casting object (or objects).

If the Bias value is too low, shadows can “leak” through places they shouldn’t, produce moiré patterns or making out-of-place dark areas on meshes. If Bias is too high, shadows can “detach” from an object. If the Bias value is too extreme in either direction, shadows might not be rendered at all.

This value depends on whether Absolute Map Bias is on or off:

- When Absolute is off (the default), Bias is calculated based on the scene extents, and then normalized to one. This provides similar default shadow results, regardless of scene size. User adjustments to Bias are typically low decimal values near 1.0 (for example, 1.2).
- When Absolute is on, Bias is a value in 3ds Max units. User adjustments to Bias depend on the size of the scene, and can range from values close to zero to values in the hundreds (see the Tip at the end of this topic).

**Size**—Sets the size (in pixels squared) of the shadow map that’s computed for the light.

*Left: Too small a Bias value causes shadow “leaks.” Right: Increasing the Bias value fixes the problem.*

The shadow map size specifies the amount of subdivisions for the map. The greater the value, the more detailed the map will be.

*Left: Size set to 32. Right: Size set to 256.*
Sample Range—The sample range (page 3–1004) determines how much area within the shadow is averaged. This affects how soft the edge of the shadow is. Range=0.01 to 50.0.

Increasing the Sample Range blends the shadow edges and creates a smooth effect, hiding the granularity of the map.

Absolute Map Bias—When on, the bias for the shadow map is not normalized, but is instead based on a fixed scale expressed in 3ds Max units. This value does not change during an animation. You must choose the value, based on the size of the scene extents.

When off, the bias is computed relative to the rest of the scene, and then normalized to 1.0. This provides a common starting bias value in scenes of any size. If the scene extents change, this internal normalization can vary from frame to frame. Default=off.

Tip: Leaving Absolute Map Bias off gives good results in most situations, because the bias is internally balanced to match the scene size. In animations, however, if moving objects cause a large change in the scene extents (or if objects are hidden, and so on), the normalized bias value might become inappropriate, causing shadows to flicker or disappear. If this happens, turn on Absolute Map Bias. You will have to set the Bias control to a value appropriate for the scene. As a rule of thumb, try a Bias value that is the distance between the light and the target object, divided by 100.

2-Sided Shadows—When on, backfaces are not ignored when calculating shadows. Objects seen from the inside are not lit by lights from the outside. When off, backfaces are ignored, which can cause outside lights to illuminate object interiors. Default=on.

The faces inside the sliced sphere do not cast shadows if 2-Sided Shadows is not selected.

Cameras

Cameras present a scene from a particular point of view. Camera objects simulate still-image, motion picture, or video cameras in the real world.

With a Camera viewport (page 3–745) you can adjust the camera as if you were looking through its lens. Camera viewports can be useful for editing geometry as well as setting up a scene for rendering. Multiple cameras can give different views of the same scene.

The Camera Correction modifier (page 2–1392) lets you correct a camera view to 2-point perspective, in which vertical lines remain vertical.

If you want to animate the point of view, you can create a camera and animate its position. For example, you might want to fly over a landscape or walk through a building. You can animate other
camera parameters as well. For example, you can animate the camera's field of view to give the effect of zooming in on a scene.

The Display panel's *Hide By Category* (page 1–52) rollout has a toggle that lets you turn the display of camera objects on and off.

A convenient way to control the display of camera objects is to create them on a separate layer (page 3–655). You can hide them quickly by turning off the layer.

Tip: The *Camera Match utility* (page 2–1387) allows you to start with a background photograph and create a camera object that has the same point of view. This is useful for site-specific scenes.

There are two kinds of camera objects:

- **Target cameras** (page 2–1371) view the area around a target object. When you create a target camera, you see a two-part icon representing the camera and its target (a white box). The camera and the camera target can be animated independently, so target cameras are easier to use when the camera does not move along a path.

- **Free cameras** (page 2–1370) view the area in the direction the camera is aimed. When you create a free camera, you see a single icon representing the camera and its field of view. The camera icon appears the same as a target camera icon, but there is no separate target icon to animate. Free cameras are easier to use when the camera's position is animated along a path.

You can create cameras from the Create menu > Cameras submenu, or by clicking the Cameras button on the Create panel. You can also create a camera by activating a Perspective viewport, and then choosing Views menu > Create Camera From View.

After you have created a camera, you can change viewports to display the camera's point of view. While a camera viewport is active, the navigation buttons change to *camera navigation buttons* (page 3–745). You use the Modify panel in conjunction with a camera viewport to change the camera's settings.

While you use the navigation controls for a camera viewport, you can constrain Truck, Pan, and Orbit...
Cameras

movement to be vertical or horizontal only with the Shift key.

You can move a selected camera so its view matches that of a Perspective, Spotlight, or another Camera view.

Choosing a Camera for Vertical Views

If you need an animated camera to look vertically upward or downward, use a free camera. If you use a target camera you might run into a problem of unexpected movement. The program constrains a target camera’s up-vector (its local positive Y axis) to be as close as possible to the world positive Z axis. This is no problem when you are working with a static camera. However, if you animate the camera and put it in a nearly vertical position, either up or down, the program flips the Camera view to prevent the up-vector from becoming undefined. This creates sudden changes of view.

Camera Object Icons

Camera objects are visible in viewports unless you choose not to display them. However, the geometry that appears in the viewport is only an icon meant to show you where the camera is located and how it is oriented.

Target cameras (page 2–1371) create a double icon, representing the camera (a blue box intersecting a blue triangle) and the camera target (a blue box). Free cameras (page 2–1370) create a single icon, representing the camera and its field of view.

mental ray Camera Shaders

When you use the mental ray renderer (page 3–78), you can apply shaders to the camera used to render the scene. Specifically, you can assign shaders to modify the camera’s lens, its output, or
its volume (effectively making a volume out of the entire scene).

A dimly lit scene

The scene's colors desaturated using the Night shader

Lens shader: lume Night shader with Multiplier set to 0.5

You assign camera shaders using the Render Scene dialog's Camera Effects rollout (page 3–101) while the mental ray renderer is active.

Note: No camera output shaders are provided with 3ds Max. You might have access to light map shaders if you have obtained them from other shader libraries or custom shader code.

See also

Common Camera Parameters (page 2–1373)
Characteristics of Cameras (page 2–1372)

Using Transforms to Aim a Camera (page 2–1379)
Using Clipping Planes to Exclude Geometry (page 2–1379)
Using the Horizon to Match Perspective (page 2–1380)
Animating Cameras (page 2–1381)

Procedures

To render a scene using a camera:

1. Create the camera and aim it at the geometry you want to be the subject of your scene. To aim a target camera, drag the target in the direction you want the camera to look. To aim a free camera, rotate and move the camera icon.

2. With one camera selected, or if only one exists in the scene, set a Camera viewport for that camera by activating the viewport, then press [C]. If multiple cameras exist and none or more than one are selected, the software prompts you to choose which camera to use.

You can also change to a Camera viewport by right-clicking the viewport label and then selecting Views and the camera of choice.

3. Adjust the camera's position, rotation, and parameters using the Camera viewport's navigation controls. Simply activate the viewport, then use the Truck, Orbit, and Dolly Camera buttons. Alternately you can select the camera components in another viewport and use the move or rotate icons.

If you do this while the Auto Key button (page 3–717) is on, you animate the camera.

4. Render the camera viewport.

To change a viewport to a Camera view:

1. Right-click the viewport label.

   The Viewport Properties menu is displayed.

2. Choose Views.
The name of each camera is displayed at the top of the Views submenu.

3. Choose the name of the camera you want.

   The viewport now shows the camera’s point of view.

   The default keyboard shortcut for camera viewports is **C**.

   Making a camera viewport active does not automatically select the camera. To adjust a camera by using its viewport and the Modify panel at the same time, select the camera and then make the Camera viewport active.

As in other viewports, in Camera viewports you can opt to see a display of safe frame areas to help you compose the final rendered output.

**To control the display of camera objects, do one of the following:**

- **Go to the Display panel and in the Hide By Category rollout, turn Cameras on or off.**
  Choose Views > Hide > Hide By Category, and toggle the menu item Hide Cameras.

- **Choose Tools menu > Display Floater, and on the Object Level tab turn Cameras on or off.**
  Cameras appear in viewports if Cameras is off; if Cameras is on, they don’t appear.

   When camera icons are displayed, the *Zoom Extents commands (page 3–737)* include them in views. When camera icons are not displayed, the Zoom Extents commands ignore them.

**To change the display size of camera icons:**

- **Choose Customize > Preferences > Viewports, and set Non-Scaling Object Size (default=1.0 in current units).**

   Note: This also changes the size of light icons, helper objects, and other non-scaling objects in the scene.

**To use the Modify panel in conjunction with a Camera viewport:**

1. Select the camera in any viewport.

2. Right-click the Camera viewport to activate the viewport without deselecting the camera.

   The Camera viewport becomes active, but the camera is still selected in the other viewports.

3. Adjust the camera using its Parameters rollout in the Modify panel and the navigation buttons.

   The Camera viewport updates as the parameters are changed.

**To constrain Pan and Orbit to be vertical or horizontal:**

- **Hold down **Shift** as you drag in the viewport.**

   The initial direction of the drag sets the constraint. If you drag vertically at first, the pan or orbit is constrained to be vertical; if you drag horizontally at first, the constraint is horizontal.

   The Zoom Extents All flyout and the Min/Max toggles remain visible. These controls aren’t specific to camera views. Clicking Zoom Extents All affects other kinds of viewports, but does not affect Camera viewports.

**To see the safe frame:**

- **Right-click the viewport label and choose Show Safe Frame.**

   The *safe frames (page 3–1030)* are displayed in three concentric boxes. The outermost safe frame matches the render output resolution.

   The *safe frame (page 3–1030)* matches the render output resolution.
Chapter 15: Lights and Cameras

Boxes in the viewport indicate safe frames.

To match a camera to a viewport:
1. (Optional) Select a camera.
2. Activate a Perspective viewport.
3. If no camera was selected, 3ds Max creates a new target camera whose field of view matches the viewport. If you first selected a camera, the camera is moved to match the Perspective view. 3ds Max also changes the viewport to a camera viewport for the camera object, and makes the camera the currently selected object.

Free Camera

Create panel > Cameras > Free
Create menu > Cameras > Free Camera

Free cameras view the area in the direction where the camera is aimed. Unlike target cameras, which have two independent icons for the target and the camera, free cameras are represented by a single icon, making them easier to animate. Free cameras can be used when the camera’s position is animated along a trajectory (page 3–1025), as in a walkthrough of a building or when the camera is attached to a moving vehicle. The free camera can bank as it travels along the path. If the camera needs to be directly overhead in a scene, use a free camera to prevent it from spinning.

A free camera can move and be oriented without restrictions.

Initial Direction of a Free Camera

A free camera’s initial direction is along the negative Z axis of the active construction grid of the viewport you click.

In other words, if you click in an orthogonal viewport, the initial camera direction is directly away from you. Clicking the Top viewport aims the camera downward, clicking the Front viewport aims the camera at the scene from the front, and so on.

Clicking in a Perspective, User, Light, or Camera viewport aims the free camera downward, along the negative Z axis of the World Coordinate System.

Because the camera is created on the active construction plane, where you also create geometry, you might have to move the camera before you can see objects in its Camera viewport. Check the camera’s position from several viewports to correct.
**Procedure**

To create a free camera:

1. From the Create menu, choose Cameras > Free Camera, or click Cameras on the Create panel, then click Free on the Object Type rollout.
2. Click the viewport location where you want the camera to be.
   - The kind of viewport you click determines the free camera’s initial direction.
   - The camera is now part of the scene.
3. Set the creation parameters.
4. Rotate and move the camera to adjust the point of view.

**Interface**

See *Common Camera Parameters (page 2–1373)*.

---

**Target Camera**

Create panel > Cameras > Target

Create menu > Cameras > Target Camera

A target camera “views” the area around the target icon that you place when you create the camera. A target camera is easier to aim than a free camera because you simply position the target object at the center of interest.

You can animate both the target camera and its target to create interesting effects. To animate both the target and camera along a path, it is best to link them both to a dummy object, then animate the dummy.

Note: When you add a target camera, 3ds Max automatically assigns a Look At controller (page 2–344) to it, with the camera’s target object assigned as the Look At target. You can use the controller settings on the Motion panel to assign any other object in the scene as the Look At target.

---

**Procedure**

To create a target camera:

1. Do one of the following:
   - Click Cameras on the Create panel, then click Target in the Object Type rollout.
   - Choose Create menu > Cameras > Target Camera.
2. Drag in a Top or Perspective viewport. The initial point of the drag is the location of the camera, and the point where you release the mouse is the location of the target.
   - The camera is now part of the scene. It is aimed at the target, which is a separate object.
3. Set the creation parameters.

**Interface**

See *Common Camera Parameters (page 2–1373)* for a description of the common camera parameters.

The distance from the camera to the target is displayed at the bottom of the Parameters rollout.

You can animate this parameter, or directly animate the target object’s location.
When you rename a target camera, the target is automatically renamed to match. For example, renaming *Camera01* to *Rolli* causes *Camera01.Target* to become *Rolli.Target*. The target’s name must have the extension .Target. Renaming the target object does not rename the camera object.

Clicking the line that connects the camera and its target selects both objects. However, region selection doesn’t recognize the link line.

If a target camera is already selected, you add its target to the selection by right-clicking the camera, and then choosing Select Target from the quad menu > Tools1 quadrant. Or you can hold down the Ctrl key and click the target to add it to the selection set.

---

**Using Cameras**

**Characteristics of Cameras**

Real-world cameras use lenses to focus the light reflected by a scene onto a focal plane that has a light-sensitive surface.

---

**Real-world camera measurements.**

A: Focal length

B: Field of view (FOV)

---

**Focal Length**

The distance between the lens and the light-sensitive surface, whether film or video electronics, is called the focal length of the lens. Focal length affects how much of the subject appears in the picture. Lower focal lengths include more of the scene in the picture. Higher focal lengths include less of the scene but show greater detail of more distant objects.

Focal length is always measured in millimeters. A 50mm lens is a common standard for photography. A lens with a focal length less than 50mm is called a short or wide-angle lens. A lens with a focal length longer than 50mm is called a long or telephoto lens.

---

**Field of View (FOV)**

The field of view (FOV) controls how much of the scene is visible. The FOV is measured in degrees of the horizon. It is directly related to the focal length of the lens. For example, a 50mm lens shows 46 degrees of the horizon. The longer the lens, the narrower the FOV. The shorter the lens, the wider the FOV.
Relationship Between FOV and Perspective

Short focal lengths (wide FOV) emphasize the distortions of perspective, making objects seem in-depth, looming toward the viewer.

Long focal lengths (narrow FOV) reduce perspective distortion, making objects appear flattened and parallel to the viewer.

Upper left: Long focal length, narrow FOV
Lower right: Short focal length, wide FOV

The perspective associated with 50 mm lenses appears normal, partly because it is close to what the eye sees, and partly because such lenses are so widely used for snapshots, news photos, cinema, and so on.

Differences Between Camera Objects and Real-World Cameras

Many other controls on real-world cameras (such as those for focusing a lens, and advancing film) aren’t needed for computer rendering and have no counterpart in the camera objects.

The program does have counterparts for the camera movements used in movie making, such as truck, dolly, and pan. See Camera Viewport Controls (page 3–745).

Procedure

To match a real-world camera frame proportion:

1. Choose Rendering > Render.
   
   The Render Scene dialog is displayed.
2. In the Output Size group, click the arrow to display the list of real world output sizes.
3. Select the type you want (both film and video output sizes are available).
4. Right-click the Camera viewport label, and turn on Show Safe Frame.
   
   The Safe Frame proportions will match those of the selected output size.

Common Camera Parameters

Create panel > Cameras > Target button or Free button > Parameters rollout

Most of the camera controls are common to both kinds of cameras. This topic describes those controls.

Procedures

To view a wider area, do either of the following:

• Use the FOV spinner to increase the camera’s field of view.

• Click a button with a shorter focal length. Use the Lens spinner to give the focal length a value other than the preset "stock" values on the buttons.

To view a narrower area, do either of the following:

• Change the FOV parameter to decrease the camera’s field of view.

• Click a button with a longer focal length. Use the Lens parameter to give the focal length a value other than the preset "stock" values on the buttons.
In a camera viewport, the FOV button lets you adjust the field of view interactively.

The camera viewport Perspective button also changes the FOV in conjunction with dollying the camera.

Note: Only the FOV value is saved with the camera. The focal length value is merely an alternative way to express and select the FOV.

To set the camera lens size:
1. In the Stock Lenses group, click a button to choose a stock focal length.
2. Set the Lens spinner to a custom focal length.
   Tip: If you want to maintain the same lens, avoid using the FOV or Perspective controls among the navigation icon buttons, and don’t change the FOV spinner.

   Important: When a camera viewport is active, changing the Output Size or (custom) Aperture Width in the Render Scene dialog (page 3–2) will change the camera’s Lens setting.

To match a camera to a film or video format:
1. In the Render Scene dialog (page 3–2), choose the type of output you want.
   • If it’s a preset, choose the preset from the Output Size drop-down list. The Aperture Width will be locked to the preset’s values.
   • If it’s Custom, you can set your own Aperture Width, and should do so at this point. (You can adjust the other output values at any later time. They have no affect on the camera lens settings, although they do affect the cropping of the scene.)
2. Once the Aperture Width is set, set the Lens spinner to the type of camera lens you want to emulate (for example, 50mm).

   If you want to maintain the same lens, avoid using the FOV or Perspective controls among the navigation icon buttons.

To find a lens’s focal length:
• To find the focal length of a lens based on changes in aperture width, display the Render Scene dialog (page 3–2), choose Custom from the Output Size drop-down list, and specify a value in the Aperture Width spinner. The new value of the camera’s Lens spinner is based on the new Aperture Width value.

To display a camera’s cone:
• Turn on Show Cone.
   The camera’s field-of-view cone appears outlined in light blue.

   Note: A camera’s cone is always visible while the camera object is selected, regardless of the Show Cone setting.

To display a camera’s horizon line:
• Turn on Show Horizon.
   A dark gray line appears at the level of the horizon in the camera’s viewport.
The horizon line shown in the viewport.

The horizon line might not be visible if the horizon is beyond the camera’s field of view, or if the camera is tilted very high or low.

**To change the environment range:**
- Adjust the value of Near Range or Far Range.
  By default, the Near Range=0.0 and the Far Range equals the Far clipping plane value.
  Environment ranges determine the near and far range limits for atmospheric effects you set in the Environment dialog.

**To see the environment ranges in viewports:**
- Turn on Show.
  The environment range displays as two planes. The plane closest to the camera is the near range and the one farthest from the camera is the far range.

**To set clipping planes:**
1. Turn on Clip Manually.
   When Clip Manually is off, the camera ignores the location of the Near and Far clipping planes, and their controls are unavailable. The camera renders all geometry within its field of view.
2. Set the Near Clip value to position the near clipping plane.

Objects closer to the camera than the Near distance are not visible to the camera and aren’t rendered.

3. Set the Far Clip value to position the far clipping plane.

Objects farther from the camera than the Far distance are not visible to the camera and aren’t rendered.

You can set the Near clipping plane close to the camera so that it doesn’t exclude any geometry, and still use the Far plane to exclude objects. Similarly, you can set the Far clipping plane far enough from the camera that it doesn’t exclude any geometry, and still use the Near plane to exclude objects.

The Near value is constrained to be less than the Far value.

If the clipping plane intersects an object, it cuts through that object, creating a cutaway view.

**To apply a multi-pass rendering effect to a scene:**
1. In the Multi-Pass Effect group, turn on Enable and choose either Depth Of Field or Motion Blur.
2. Use the Depth Of Field Parameters rollout (page 2–1383) or the Motion Blur Parameters rollout (page 2–1386) to set the values for the effect you chose.
3. Activate a camera viewport.

4. In the Multi-Pass Effect group, click Preview to preview the effect in the camera viewport. The Preview button has no effect if a camera viewport isn’t active.

5. Render the scene or animation.

**Interface**

- **Lens**—Sets the camera’s focal length in millimeters. Use the Lens spinner to give the focal length a value other than the preset “stock” values on the buttons in the Stock Lenses group box.
When you change the Aperture Width value in the Render Scene dialog, you also change the value in the Lens spinner field. This doesn’t change the view through the camera, but it does change the relationship between the Lens value and the FOV value, as well as the aspect ratio of the camera’s cone.

**FOV Direction flyout**—Lets you choose how to apply the field of view (FOV) value:

- **Horizontal**—(The default.) Applies the FOV horizontally. This is the standard way to set and measure the FOV.
- **Vertical**—Applies the FOV vertically.
- **Diagonal**—Applies the FOV diagonally, from one corner of the viewport to the other.

**FOV**—Determines how wide an area the camera views (field of view (page 3–937)). When FOV Direction is horizontal (the default), the FOV parameter directly sets the arc of the camera’s horizon (page 3–953), measured in degrees. You can also set the FOV Direction to measure FOV vertically or diagonally.

You can also adjust the field of view interactively in a camera viewport (page 3–745) by using the FOV button.

**Orthographic Projection**—When on, the camera view looks just like a User view. When off, the camera view is the standard perspective-like view. While Orthographic Projection is in effect, the viewport navigation buttons behave as they ordinarily do, except for Perspective. Perspective function still moves the camera and changes the FOV, but the Orthographic Projection cancels the two out, so you don’t see any change until you turn off Orthographic Projection.

### Stock Lenses group

15mm, 20mm, 24mm, 28mm, 35mm, 50mm, 85mm, 135mm, 200mm—These preset values set the camera’s focal length in millimeters.

**Type**—Changes the camera’s type from a Target camera (page 2–1371) to a Free camera (page 2–1370), and vice versa.

Note: When you switch from a target camera to a free camera, any animation applied to the camera’s target is lost, because the target object goes away.

**Show Cone**—Displays the cone (actually a pyramid) defined by a camera’s field of view. The cone appears in the other viewports but does not appear in a camera viewport.

**Show Horizon**—Displays the horizon line. A dark gray line appears at the level of the horizon in the camera’s viewport.

### Environment Ranges group

**Near Range and Far Range**—Determine the near and far range limits for the atmospheric effects set on the Environment panel (page 3–272). Objects between the two limits fade between the Far % and Near % values.

**Show**—Displays rectangles within the camera’s cone to show the Near and Far range settings.
Clipping Planes group

Sets options to define clipping planes (page 3–921). In viewports, clipping planes are displayed as red rectangles (with diagonals) within the camera's cone.

Clip Manually—Turn on to define clipping planes. When Clip Manually is off, geometry closer to the camera than 3 units is not displayed. To override this, use Clip Manually.

Near Clip and Far Clip—Sets near and far planes. Objects closer than the near clipping plane or farther than the far clipping plane are invisible to the camera. The limit of the Far Clip value is 10 to the power of 32.

With manual clipping on, the near clipping plane can be as close to the camera as 0.1 unit.

**Warning:** Extremely large Far Clip values can produce floating-point error, which can cause Z-buffer problems in the viewport, such as objects appearing in front of other objects when they shouldn't.

**Multi-Pass Effect group**

These controls let you assign a depth-of-field or motion blur effect to the camera. When generated by a camera, these effects generate blurring by rendering the scene in multiple passes, with offsets. They increase rendering time.

**Tip:** The depth-of-field and motion blur effects are mutually exclusive. Because they rely on multiple rendering passes, applying both to the same camera could be prohibitively slow. If you want to use both depth-of-field and motion blurring in the same scene, use multi-pass depth-of-field (using these camera parameters) and combine it with object motion blur (page 3–981).

**Enable**—When on, previewing or rendering uses the effect. When off, the effect is not rendered.

**Preview**—Click to preview the effect in an active camera viewport. This button has no effect if the active viewport is not a camera view.
Effect drop-down list—Lets you choose which multi-pass effect to generate, *Depth Of Field* (page 2–1383) or *Motion Blur* (page 2–1386). These effects are mutually exclusive. Default=Depth Of Field.

This list also lets you choose *Depth of Field (mental ray)* (page 2–1383), which lets you use the mental ray renderer’s depth of field effect.

Note: The rollout for the chosen effect appears, by default, after the Parameters rollout.

Render Effects Per Pass—When on, applies rendering effects (page 3–218), if any are assigned, to each pass of the multi-pass effect (depth of field or motion blur). When off, applies rendering effects only after the passes that generate the multi-pass effect. Default=off.

Turning off Render Effects Per Pass can improve the render time for multi-pass effects.

Target Distance—With a free camera, sets a point to use as an invisible target so that you can orbit a camera around that point. With a target camera, indicates the distance between the camera and its target.

You can also choose Cameras from the Selection Filters list on the toolbar, and then click the target.

*Rotate* (page 1–439) adjusts the orientation of the camera object. This transform is most useful with free cameras (page 2–1370).

You can’t rotate a Target camera about its local X and Y axes, because it is constrained to aim at its target. Use Move to move the camera or its target.

Also, if you rotate a Target camera to a nearly vertical position, either up or down, the program must flip the Camera view to prevent the up-vector from becoming undefined. If you need a camera to look vertically upward or downward, use a Free camera.

In a Camera viewport, you can also use the navigation buttons (page 3–745) to adjust the camera interactively. Some navigation buttons, such as Dolly and Orbit actually move the camera or its target.

**Using Transforms to Aim a Camera**

You can use transforms to aim a camera and change its orientation in the scene.

*Move* (page 1–439) adjusts the position of the camera object or the position of a target camera’s target (page 2–1371).

Because the target is displayed as a small square, and because it is often in the same area as objects that are the subject of the camera, it can be hard to select by clicking. Select the camera object, right-click, then choose Select Target from the Tools 1 (upper-left) quadrant of the quad menu.

**Using Clipping Planes to Exclude Geometry**

Clipping planes let you exclude some of a scene’s geometry and view or render only certain portions of the scene. Each camera object has a near and a far clipping plane. Objects closer than the near clipping plane or farther than the far clipping plane are invisible to the camera.

Clipping planes are useful for rendering selected portions of a scene that has a lot of complex geometry. They can also help you create cutaway views.
Using the Horizon to Match Perspective

The horizon of a scene is the edge of vision at the height of the camera, parallel with the world coordinate plane. You can view the horizon in camera viewports.

A camera is level when it and its target are the same height from the world coordinate plane. In other words, the camera’s local Z axis is parallel to the world plane. When the camera is level, the horizon line is centered in the viewport. As the camera tilts up, the horizon line lowers; as it tilts down, the horizon line raises.

The horizon line control is in the camera’s Parameters rollout (page 2–1373).

The horizon line can help you match the perspective of your scene to the perspective of a still image. In general, matching perspective involves the following steps:

1. Display the horizon line. Use it to help you adjust the camera and target so they are level.
2. Display the image in the camera viewport. Use Views > Viewport Background and choose Files in the Background Source group.

Clipping plane settings are part of the camera’s parameters (page 2–1373). The location of each clipping plane is measured along the camera’s line of sight (its local Z axis) in the current units for the scene.

You can set the near clipping plane close to the camera so that it doesn’t exclude any geometry, and still use the far plane to exclude objects. Similarly, you can set the far clipping plane far enough from the camera that it doesn’t exclude any geometry, and still use the near plane to exclude objects.

The near value is constrained to be less than the far value.

If the clipping plane intersects an object, it cuts through that object, creating a cutaway view. (How much of the cutaway object is visible depends on whether the object’s material is two-sided or not.)

You can also use clipping planes in non-camera viewports. Simply right-click the viewport label and choose Viewport Clipping (page 3–731).

Warning: If you use the mental ray renderer (page 3–78), geometry outside the clipping planes might still appear in renderings.
If the image's horizon and the camera horizon don't match, you have to offset the image, perhaps by using a paint program.

3. Use Orbit (page 3–749) to move the camera until the perspective of the scene roughly matches that of the still image.

4. Adjust the camera's perspective (page 3–747) to fine-tune the perspective match.

5. Use Move (page 1–439) with the camera or target to position the scene against the background.
   If you raise or lower the camera, raise or lower the target by an equal amount, in order to keep them level and maintain the horizon.
   You can also use the Camera Match utility (page 2–1387) to match the perspective of a camera to a photograph. You will need accurate scene measurements to do so.

**Animating Cameras**

You animate a camera by using transforms or changing its creation parameters in different keyframes while the Set Key or Auto Key button is on. The program interpolates camera transforms and parameter values between keyframes, as it does for object geometry.

See Auto Key Animation Mode (page 3–717) and Track View (page 2–501) for further descriptions of animation. This topic summarizes some possibilities and suggests some techniques.

In general, it’s best to use a free camera (page 2–1370) when the camera is to move within the scene; use a target camera (page 2–1371) when camera position is fixed.

**Moving a Camera Along a Path**

Having a camera follow a path is a common way to create architectural walkthroughs, roller coaster rides, and so on.

- If the camera must bank or tilt close to the vertical (as on a roller coaster), use a free camera. Assign the Path constraint (page 2–398) directly to the camera object. The camera follows the path, and you can adjust its point of view by adding pans or rotate transforms. This is comparable to filming with a hand-held camera.
  - For a target camera, link both the camera and its target to a dummy object (page 2–16), then assign the path constraint to the dummy object. This is comparable to mounting the camera on a tripod on a dolly. It is easier to manage than having, for example, separate paths for the camera and its target.

**Following a Moving Object**

You can use a LookAt constraint (page 2–406) to have the camera automatically follow a moving object.

- The LookAt constraint makes the object replace the camera's target.
  - If the camera is a target camera, its previous target is ignored.
  - If the camera is a free camera, it effectively becomes a target camera. While the LookAt constraint assignment is in effect, the free camera cannot rotate around its local X and Y axes, and can't be aimed vertically because of the up-vector constraint.
  - An alternative is to link (page 2–422) a target camera's target to the object.

**Panning**

You can animate the pan of any camera very easily by following these steps:
1. Select the camera.
2. Activate the Camera viewport.
3. Turn on the Auto Key button and advance the time slider to any frame.
4. Use the Pan button (in the viewport navigation tools) and pan.

**Orbiting**

You can animate the orbiting of any camera very easily by following these steps:

1. Select the camera.
2. Activate the Camera viewport.
3. Turn on the Auto Key button and advance the time slider to any frame.
4. Use the Orbit button (in the viewport navigation tools) and orbit.

The target camera revolves around its target; the Free camera revolves around its target distance.

**Zooming**

Zooming moves toward or away from the camera’s subject matter by changing the focal length of the lens. It differs from dollying, which physically moves the camera but leaves the focal length unchanged. You can zoom by animating the value of the camera’s FOV parameter (page 2–1373).

**Creating Animated Cutaway Views**

You can animate the creation of a cutaway view by animating the location of the near or far clipping planes (page 2–1379), or both.

---

**Multi-Pass Rendering Effects**

Create panel > Cameras > Target or Free > Parameters rollout > Multi-Pass Effect group

Motion blur applied to wings of the flying dragon

Cameras can create two kinds of rendering effects:

- Depth of field (page 2–1383)
- Motion blur (page 2–1386)

Multi-pass rendering effects use multiple renderings of the same frame, with slight camera movement between each rendering. The multiple passes simulate the blurring that film in a camera would register under certain conditions.

Although it is not a multi-pass effect, the choices in the drop-down list also let you specify the depth-of-field value for the mental ray renderer (page 3–78). See Depth of Field Parameter (mental ray Renderer) (page 2–1383).
Depth of Field Parameter (mental ray Renderer)

Create panel > Cameras > Target button or Free button > Parameters rollout > Multi-Pass Effect group. > Turn on Enable and choose Depth Of Field (mental ray). > Depth of Field Parameters rollout

On the Parameters rollout (page 2–1373), a “Depth Of Field (mental ray)” choice has been added to the Multi-Pass Effect drop-down list to support the mental ray renderer’s depth-of-field effects. To use this, turn on both Enable in the camera’s Multi-Pass Effect group, and Depth Of Field on the Camera Effects rollout of the Render Scene dialog (page 3–2).

The mental ray depth-of-field is exclusive of the multi-pass version of the depth-of-field effect. The mental ray renderer also supports motion blur for cameras, but the controls are not on the camera’s Parameters rollout: use the Motion Blur toggle on the Object Properties dialog for camera objects. This setting has no effect on the default 3ds Max scanline renderer.

Note: When you use the mental ray renderer, reflected or refracted light rays do not always respect a camera’s clipping planes (set in the Clipping Planes group of the Parameters rollout). Also, large clipping-plane values can cause poor quality in the rendering of shadow maps. To fix this, narrow the clipping range or use ray-traced shadows.

Interface

| Depth of Field Parameters | f-Stop: 2.0 |

f-Stop—Sets the camera’s f-Stop. Increasing the f-Stop value narrows the depth of field, and decreasing the f-Stop value broadens the depth of field. Default=2.0.

The f-Stop can have a value less than 1.0. This is not realistic in terms of an actual camera, but it can help you adjust the depth of field for scenes whose scale does not use realistic units.

Multi-Pass Depth of Field Parameters for Cameras

Create panel > Cameras > Target button or Free button > Parameters rollout > Multi-Pass Effect group > Choose Depth Of Field effect. > Depth of Field Parameters rollout

Multi-pass depth of field

Top: Focus is in the middle distance, near and far objects are blurred.
Bottom left: Focus on near objects, far objects are blurred.
Bottom right: Focus on far objects, near objects are blurred.

Cameras can generate depth-of-field effects. Depth of field is a multi-pass effect (page 3–77). You turn it on in the Parameters rollout (page 2–1373) for cameras. Depth of field simulates a camera’s depth of field by blurring areas of the frame at a distance from the camera’s focal point (that is, its target or target distance).

You can preview depth of field in viewports.
Chapter 15: Lights and Cameras

Previewing multi-pass depth of field in a shaded and a wireframe viewport

Important: This effect is for the default scanline renderer. The mental ray renderer (page 3–78) has its own depth-of-field effect. See Depth of Field Parameter (mental ray Renderer) (page 2–1383).

Tip: To reduce the visible effect of multiple camera passes, try setting the antialiasing filter to Blend, with a Width value in the range 4.0 to 5.0, and a Blend value in the neighborhood of 0.1. (You choose the antialiasing filter and adjust its settings in the Default Scanline Renderer rollout (page 3–38).) Also, try reducing the Dither Strength value, in the effect’s Pass Blending group, to the neighborhood of 0.2.

Note: There is also a depth-of-field rendering effect (page 3–269).

See also
Multi-Pass Motion Blur Parameters for Cameras (page 2–1386)

Interface

- Depth of Field Parameters

  Focal Depth
  - Use Target Distance
  - Focal Depth: 100

  Sampling
  - Display Passes
  - Use Original Location
  - Total Passes: 12
  - Sample Radius: 1.0
  - Sample Bias: 0.5

  Pass Blending
  - Normalize Weights
  - Dither Strength: 0.4
  - Tile Size: 32

  Scanline Renderer Params
  - Disable Filtering
  - Disable Antialiasing

Note: The multi-pass depth-of-field parameters are animatable.

Focal Depth group

Use Target Distance—When on, uses the camera’s target distance as the point about which to offset the camera for each pass. When off, uses the Focal Depth value to offset the camera. Default=on.

Focal Depth—When Use Target Distance is off, sets the depth from which the camera is offset. Can range from 0.0 to 100.0, where 0.0 is at the camera’s location and 100.0 is in the extreme distance (effectively, infinity). Default=100.0.

Low values of the Focal Depth give wildly blurry results. High Focal Depth values blur the distant portions of the scene. In general, using Focal
Depth instead of the camera’s Target Distance tends to blur the entire scene.

**Sampling group**

**Display Passes**—When on, the rendered frame window displays the multiple rendering passes. When off, the frame window displays only the final result. This control has no effect on previewing depth of field in camera viewports. Default=on.

**Use Original Location**—When on, the first rendering pass is in the camera’s original location. When off, the first rendering pass is offset like all subsequent passes. Default=on.

**Total Passes**—The number of passes used to generate the effect. Increasing this value can increase the effect’s accuracy, but at a cost of rendering time. Default=12.

**Sample Radius**—The radius by which the scene is shifted to generate blurriness. Increasing this value increases the overall blurriness of the effect. Decreasing it reduces the blurriness. Default=1.0.

**Sample Bias**—Weights the blurring toward or away from the Sample Radius. Increasing this value increases the magnitude of depth-of-field blurring, giving a more even effect. Decreasing it decreases the magnitude, giving a more random effect. Can range from 0.0 to 1.0. Default=0.5.

**Pass Blending group**

The multiple depth-of-field passes are blended by dithering, which you can control by the parameters in this group.

These controls apply only to renderings of the depth-of-field effect, not to previews in viewports.

**Normalize Weights**—Passes are blended with random weighting to avoid artifacts such as streaking. When Normalize Weights is on, the weights are normalized, giving a smoother result.

When off, the effect is a bit sharper but usually grainier. Default=on.

**Dither Strength**—Controls how much dithering is applied to the rendered passes. Increasing this value increases the amount of dithering, and can make the effect grainier, especially at the edges of objects. Default=0.4.

**Tile Size**—Sets the size of the pattern used in dithering. This value is a percentage, where 0 is the smallest tile, and 100 is the largest. Default=32.

**Scanline Renderer Params group**

These controls let you disable antialiasing or antialias filtering when you render the multi-pass scene. Disabling these rendering passes can improve render time.

These controls apply only to renderings of the depth-of-field effect, not to previews in viewports.

**Disable Filtering**—When on, disables the filtering pass. Default=off.

**Disable Antialiasing**—When on, disables antialiasing. Default=off.
Multi-Pass Motion Blur Parameters for Cameras

Create panel > Cameras > Target button or Free button > Parameters rollout > Multi-Pass Effect group > Choose Motion Blur effect. > Motion Blur Parameters rollout

Important: This effect is for the default scanline renderer. The mental ray renderer (page 3–78) has its own depth-of-field effect. See Motion Blur with the mental ray Renderer (page 3–89).

Tip: To reduce the visible effect of multiple camera passes, try setting the antialiasing filter to Blend, with a Width value in the range 4.0 to 5.0, and a Blend value in the neighborhood of 0.1. (You choose the antialiasing filter and adjust its settings on the Default Scanline Renderer rollout (page 3–38).) Also, try reducing the Dither Strength value, in the effect’s Pass Blending group, to the neighborhood of 0.2.

Interface

Sampling group

Display Passes—When on, the rendered frame window displays the multiple rendering passes. When off, the frame window displays only the final result. This control has no effect on previewing motion blur in camera viewports. Default=on.

Important: This effect is for the default scanline renderer. The mental ray renderer (page 3–78) has its own depth-of-field effect. See Motion Blur with the mental ray Renderer (page 3–89).

Tip: To reduce the visible effect of multiple camera passes, try setting the antialiasing filter to Blend, with a Width value in the range 4.0 to 5.0, and a Blend value in the neighborhood of 0.1. (You choose the antialiasing filter and adjust its settings on the Default Scanline Renderer rollout (page 3–38).) Also, try reducing the Dither Strength value, in the effect’s Pass Blending group, to the neighborhood of 0.2.

Interface

Sampling group

Display Passes—When on, the rendered frame window displays the multiple rendering passes. When off, the frame window displays only the final result. This control has no effect on previewing motion blur in camera viewports. Default=on.

Important: This effect is for the default scanline renderer. The mental ray renderer (page 3–78) has its own depth-of-field effect. See Motion Blur with the mental ray Renderer (page 3–89).

Tip: To reduce the visible effect of multiple camera passes, try setting the antialiasing filter to Blend, with a Width value in the range 4.0 to 5.0, and a Blend value in the neighborhood of 0.1. (You choose the antialiasing filter and adjust its settings on the Default Scanline Renderer rollout (page 3–38).) Also, try reducing the Dither Strength value, in the effect’s Pass Blending group, to the neighborhood of 0.2.

Interface

Sampling group

Display Passes—When on, the rendered frame window displays the multiple rendering passes. When off, the frame window displays only the final result. This control has no effect on previewing motion blur in camera viewports. Default=on.
**Total Passes**—The number of passes used to generate the effect. Increasing this value can increase the effect’s accuracy, but at a cost of rendering time. Default=12.

**Duration (frames)**—The number of frames in the animation to which the motion blur effect will be applied. Default=1.0.

**Bias**—Changes the blurring so that it appears to derive more from frames before or after the current frame. Range=0.01 to 0.99. Default=0.5.

By default, the blurring comes equally from frames before and after the current frame; that is, a blurred object appears at the center of the blurred area. This is the closest to what an actual camera would capture. Increasing the Bias value moves the blurring behind the blurred object, in relation to its direction of motion. Decreasing it moves the blurring in front of the blurred object.

Extreme values move most of the blurring very close to the blurred object, which makes it difficult to see. For best results, use intermediate Bias values in the range 0.25 to 0.75.

**Pass Blending group**

The multiple motion blur passes are blended by dithering, which you can control by the parameters in this group.

These controls apply only to renderings of the motion blur effect, not to previews in viewports.

**Normalize Weights**—Passes are blended with random weighting to avoid artifacts such as streaking. When Normalize Weights is on, the weights are normalized, giving a smoother result. When off, the effect is a bit sharper but usually grainier. Default=on.

**Dither Strength**—Controls how much dithering is applied to the rendered passes. Increasing this value increases the amount of dithering, and can make the effect grainier, especially at the edges of objects. Default=0.4.

**Tile Size**—Sets the size of the pattern used in dithering. This value is a percentage, where 0 is the smallest tile, and 100 is the largest. Default=32.

**Scanline Renderer Params group**

These controls let you disable antialiasing or antialias filtering when you render the multi-pass scene. Disabling these rendering passes can improve render time.

These controls apply only to renderings of the motion blur effect, not to previews in viewports.

**Disable Filtering**—When on, disables the filtering pass. Default=off.

**Disable Antialiasing**—When on, disables antialiasing. Default=off.

---

**Camera Match Utility**

The Camera Match utility uses a bitmap background photo and five or more special “CamPoint” objects to create or modify a camera so that its position, orientation, and field-of-view matches that of the camera that originally created the photo.

**Procedures**

The general process to follow in using Camera Match is described in the following procedures.

**To use camera matching:**

1. Load a bitmap as a background for the renderer.
2. Load a bitmap as a background for the viewport.

3. Identify on the bitmap at least five features that will be used for the match. These should be objects or corners of objects in the scene that can be identified and tracked. They should remain visually throughout the scene, and should not change their shape too much or they won't work.

4. Create CameraPoints, which are helper objects found in these locations: Create panel > Helpers > Camera Match > Object Type rollout > CamPoint, and Create menu > Helpers > Camera Point.

You must have accurate measurements of distances between at least five features in your scene, which can't all be on a single plane. Try to use points that are distributed throughout the scene rather than features that are all clustered in the front or back. This will give the most accurate results.

5. Position these CameraPoints to correspond to points in your photo. You can use the Transform Type-In (page 1–431) to position the points in the correct locations in 3D space.

6. Use the Camera Match utility to assign the CameraPoints to pixel locations on the bitmap.

7. Choose Create Camera and a camera is created to match the one that took the picture.

   If there are errors and the camera cannot be created, readjust the point positions in 3D space, and reassign them to the bitmap. It’s easy to make a mistake doing either, but once you get it right the match should work.

To establish the bitmap background for the render:

1. Reset the software and enlarge the Perspective viewport to full screen.

2. From the Rendering menu choose Environment.

3. In the Common Parameters rollout, under Environment Map, click the gray box marked None. This launches the Material/Map Browser.

4. Be sure to set Browse From to New; if it isn't set already, then choose Bitmap from the list and click OK. The Select Bitmap Image File dialog appears.

5. Navigate and select the appropriate bitmap and then choose Open. Use Map is turned on automatically.

6. Render the viewport to verify that the background appears in the rendering. Press [Shift+Q] to render.

To establish the bitmap background to display in the viewport:

1. Choose Views menu > Viewport Background (page 1–38).

   This opens the Viewport Background dialog

2. In the Background Source group, click Files. This launches the Select Background Image dialog.

3. Navigate and select the appropriate bitmap and then choose Open.

4. Set Aspect Ratio to Match Bitmap.

5. Make sure Display Background is turned on, and then choose OK.

   The background appears in the viewport.

   Note: You can click the Use Environment Background button, but then you don't have the Aspect Ratio controls.

To create CamPoint objects:

1. In the Helpers group of the Create panel, open the list and select Camera Match.

2. On the Object Type rollout, click the CamPoint button.

3. Open the Keyboard Entry rollout.
4. Enter the coordinates of the first CamPoint object (0,0,0), click the Create button, and then enter the name in the name field.

Tip: To use the keyboard, first click in the X field, enter its value, and then press [Tab] to move to the next field and enter its value. Continue this until you tab to the Create button, and then press [Enter] to create the CamPoint, followed by [Tab] to move back to the X field, where you can start again. You can create all the CamPoint objects with default names, and then use the Select By Name floater (Tools > Selection Floater) to select and rename the six pointers.

5. Repeat the above steps for the remaining CamPoint objects.

Note: An alternative method is to create the CamPoint objects anywhere in the scene, and then reselect each of them and enter their absolute coordinates using the Transform Type-In.

You now have the CamPoint objects occupying real-world coordinate positions that correspond to the structure in the bitmap image. The last sequence of steps involves using the Camera Match utility to specify the screen coordinate points, one for each CamPoint object, and generating a camera position based on the data.

To use the Camera Match utility:
1. On the Utilities panel, click the Camera Match button.

   The Camera Match utility appears, listing the CamPoint objects.

2. Select the first CamPoint object and click the Assign Position button.

3. Place the cursor over the corresponding feature in the bitmap and click.

   A small, red cross appears.

4. If the dot is not in the right position, you can either click again with the mouse or adjust the Input Screen Coordinates to tweak its position.

5. Select the second object in the list, and repeat steps 3 and 4.

6. Repeat for all the points. By setting the red crosses, you’ve indicated the X and Y pixel position on the bitmap and correlated it with each CamPoint as it exists in 3D space.

7. Once you have all of the points set, click the Create Camera button.

   A camera is created in the scene based on the location of the CamPoint objects and the specifications of the screen coordinates points.

   Note: If the Current Camera Error reading is greater than five, at least one of your screen coordinate points is placed wrong. Check each of them, and review the description following step 5. After reassigning the points, select the existing camera and click the Modify Camera button to recalculate the camera position.

8. Press [C] to switch the Perspective view to that of the new camera.

Interface

CamPoint Info rollout

**List window**—Displays a list of the CamPoint helper objects in the scene. You select the CamPoint
objects from this list to assign screen coordinate points. Note that if you select a CamPoint object in the viewport, it’s highlighted in this list as well.

**Input Screen Coordinates**—

* X/Y—Fine-tunes the position of the screen coordinate points in 2D space.

* Use This Point—Turns off a specific coordinate point without deleting it. Select the corresponding CamPoint in the list, and then turn off Use This Point. This feature is typically used for troubleshooting when the Current Camera Error is too high (greater than five, for example).

* Assign Position—Click a location on the viewport bitmap to place a screen coordinate point visually against the background image. The point you place corresponds to the currently selected CamPoint object. After activating the Assign Position button, select a CamPoint object from the list, and then click in the viewport at a position on the bitmap background that corresponds with where the associate CamPoint object should be in the 3D scene. After repeating this process with each CamPoint object in the list, you can click the Create Camera button to create a camera that matches the placed coordinates with their associate CamPoint objects.

**Camera Match rollout**

- **Create Camera**—Creates a camera in the scene whose position, orientation, and field of view is based on the current location of the CamPoint helpers and the assigned screen coordinate points.

- **Modify Camera**—Modifies the position, orientation and FOV of an existing, selected camera based on the CamPoint helpers and assigned screen coordinate points.

- **Iterations**—Maximum number of iterations used to calculate the camera position. Default is 500, though a stable solution is usually found in less than 100 iterations.

- **Freeze FOV**—Prevents the FOV (field of view) of the camera from being changed when using the Create Camera or Modify Camera buttons. Use if the FOV of the camera that took the photograph is known and you want to preserve it.

- **Current Camera Error**—Displays the total error that remains between the placed screen coordinate points, the CamPoint helpers, and the camera position after the final computation. The calculations involved in the camera match are seldom perfect. A good error range is about 0 to 1.5.

- **Close**—Exits the Camera Match utility.
Camera Match Helper

Objects

**Camera Match Helper**

| Create panel > Helpers > Camera Match (from drop-down list) |
| Create menu > Helpers > Camera Point |

Camera Match helper objects (CamPoints) are used by the Camera Match utility to reproduce in a camera the same settings (position, roll, and FOV) that were used by a real-world camera to shoot a background image. This allows you to view your scene from the same perspective as the background image, which is a key step to mixing computer-generated and photographically-generated images in a single composited shot.

Camera point objects are placed in the scene at locations that will be visible in the background photograph. By comparing the X/Y/Z position of several camera point objects to their analogous positions in a background image, the Camera Match utility is able to determine the real-world camera's settings, and use these settings to either create a new camera or move/reset an existing camera to match them.

To see the CamPoint (page 2–1391) object type, choose CameraMatch from the Object set list.

**See also**

CamPoint Helper (page 2–1391)

Camera Match Utility (page 2–1387)

**CamPoint Helper**

| Create panel > Helpers > Camera Match > CamPoint |
| Create menu > Helpers > Camera Point |

The CamPoint helper lets you create camera points in your scene. These points are used by the Camera Match (page 2–1387) utility to match the camera with a photographic background. The virtual camera is positioned to mimic the position of the actual camera that was used to take the photograph.

Clicking CamPoint displays the Keyboard Entry and Camera Match Point rollouts, which you use to create and name the camera points.

**Procedures**

**To create a camera match point:**

1. On the Create panel, click the Helpers tab.
2. Choose Camera Match from the list and click the CamPoint button in the Object Type rollout. The button turns yellow when it is active. You are now ready to create a camera point.
3. Choose Create menu > Helpers > Camera Point.
4. Click in the viewport to create a CamPoint helper object. Alternatively, you can use the keyboard to create a CamPoint object by expanding the Keyboard Entry rollout, entering values in the fields, and then clicking Create.

**To position camera match points in your scene, do one of the following:**

- Create your camera match points using keyboard entry. Use this if you have accurate actual measurements of the locations of the points.
- Build geometry that matches your scene geometry, and then snap the points to the
geometry using snaps. Use this technique when you don’t have measurements and can approximate the geometry.

- Create your camera match points interactively, and then use Transform Type-In to move them to the correct locations.

### Interface

**Camera Match Point rollout**

**Show Axis Tripod**—Controls whether an axis tripod is displayed with the Camera point object. Default=on.

**Axis Length**—Controls the length of the axis tripod. When Show Axis Tripod is on you can watch the tripod change length in the viewport while you adjust the spinner arrows. When Show Axis Tripod is off, you can still make adjustments the Axis Length value, but the axis tripod won’t be displayed.

### Two-Point Perspective

**Camera Correction Modifier**

Select a camera. > Right-click. > Tools 1 (upper-left) quadrant of the quad menu > Apply Camera Correction Modifier

The Camera Correction modifier applies two-point perspective to a camera view. By default, camera views use three-point perspective, in which vertical lines appear to converge with height. In two-point perspective, vertical lines remain vertical.

The amount of correction you need to use depends on how steeply the camera tilts. For example, a camera that looks up from ground level to the top of a high building will need more correction than a camera that looks toward the horizon.

**Note:** This modifier doesn’t appear on the Modify panel’s Modifier List.
Procedure

To apply two-point perspective to a camera:

1. Select a camera.
   
   Tip: For best results, set a viewport to this camera's view. The change in perspective appears both in the viewport and when you render this view.

2. Apply the Camera Correction modifier.

3. On the 2-Point Perspective Correction rollout, click Guess.

   The Camera Correction modifier creates a first-guess Amount value for the two-point perspective.

4. Adjust the Amount and Direction to get the effect you want.

   In the viewports, the camera's field-of-view "cone" distorts or moves to show the perspective adjustments.

5. Render the view.

Interface

Materials describe how an object reflects or transmits light. Within a material, maps can simulate textures, applied designs, reflections, refractions, and other effects. (Maps can also be used as environments and projections from lights.) The Material Editor is the dialog you use to create, alter, and apply the materials in your scene.

See also
Designing Materials (page 2–1395)
Types of Materials (page 2–1457)
Material Editor (page 2–1409)
Types of Maps (page 2–1617)

Designing Materials

These topics give you an overview of using the Material Editor to design materials (page 3–971). The Material Editor (page 2–1427) gives you a huge number of options in material design. It also has a large number of controls. If you aren’t already familiar with using it, read this topic for a general idea of working with materials, and what the most important options are.

For more details, follow the links in the workflow outline.
Workflow Outline

In general, when you create a new material and apply it to an object, you follow these steps:

1. Make a sample slot (page 2–1396) active, and enter a name for the material you are about to design.

2. Choose the material type (page 2–1397).
   Tip: 3ds Max provides two renderers, the default scanline renderer (page 3–38) and the mental ray renderer (page 3–78). Each has its own capabilities. In general, for each scene, you will decide which renderer you want to use. It is a good idea to design materials with a particular renderer in mind. The mental ray Connection rollout (page 2–1461) lets you add features unique to the mental ray renderer to basic 3ds Max materials.

3. For a Standard or Raytrace material, choose the shading type (page 2–1398).

4. Enter settings for the various material components (page 2–1399): diffuse color, glossiness, opacity, and so on.
   Note: Lights and Shading (page 2–1399) describes how lights affect the appearance of a material. Choosing Colors for Realism (page 2–1400) gives guidelines on getting good results from unmapped materials.

5. Assign maps (page 2–1403) to the components you want to map, and adjust their parameters.

6. Apply (page 2–1405) the material to the object.

7. If necessary, adjust the UV mapping coordinates (page 2–1405) in order to orient maps with objects correctly.

8. Save (page 2–1406) the material.

Sample Slots and Material Name

The sample slots (page 2–1420) display previews of materials. They are the most prominent feature of the Material Editor interface. Below and to the right of the sample slots are various tool buttons (page 2–1427) for the Material Editor. Below the tool buttons is a name field that shows the name of the material.

Tip: Always give a material a unique, intelligible name as soon as you begin to work on it.

By default, six sample slots are visible at once. The Material Editor actually holds 24 materials at one time. You can use the scroll bars to move among the sample slots, or you can change the number of sample slots visible at once to 15 or 24 slots. Seeing more slots at once can be helpful if you are working with a complex scene.

Important: While the Material Editor can edit no more than 24 materials at a time, a scene can contain an unlimited number of materials. When you are through editing one material, and have applied it to objects in the scene, you can use that sample slot to get a different material from the scene (or create a new one) and then edit it.

To increase the number of sample slots visible at once, right-click a slot and then choose 5 X 3
Sample Windows or 6 X 4 Sample Windows from the pop-up menu.

Note: The right-click menu also has an Options choice (page 2–1436). This displays a dialog with various options for sample display. Exploring these options can help you learn to preview materials effectively. However, keep in mind that these settings affect the sample display only. They change nothing in the 3ds Max scene.

When more sample slots are visible, the images are smaller, but you can display a larger, floating, and resizable material sample by double-clicking the slot you want to see better.

Click a sample slot to make it active. Now you can design a new material from scratch, or you can load a previously stored material by clicking Get Material (page 2–1439), which displays the Material/Map Browser. The Browser is a dialog that lets you choose materials and maps from a material library, from the scene, and so on.

You can also copy a material from one sample slot to another. Drag the slot with the material to another slot. To avoid confusion, rename the copy in the new sample slot before you begin to make changes to it.

If the \matlibs subdirectory contains a material library called medit.mat, the sample slots show the first 24 materials in this library file. If the library contains fewer than 24 materials, the remaining slots contain Standard materials of various colors, as they do if no medit.mat library is found.

Material Type

Every material has a type. The default is Standard (page 2–1465), which is the material type you will probably use most often. In general, other material types are for special purposes. The other material types are:

- Advanced Lighting Override (page 2–1601)
  Used to fine-tune the effects of a material on Advanced Lighting (page 3–44), including light tracing (page 3–44) and radiosity solutions (page 3–51). Radiosity Override is not required for calculating advanced lighting, but it can enhance the result.

- Blend (page 2–1588)
  Mixes two other materials together. Can use a mask or a simple amount control.

- Composite (page 2–1589)
  Mixes up to 10 materials.

- Double-Sided (page 2–1591)
  Contains two materials, one for the front and one for the back faces of an object.

- Ink 'n Paint (page 2–1605)
  Creates cartoon effects with flat shading and “inked” borders.

- Lightscape (page 2–1604)
  Supports import (page 3–573) and export (page 3–572) of data from the Lightscape product.

- Matte/Shadow (page 2–1584)
  Displays the environment but receives shadows. This is a special-purpose material. The effect is similar to using a matte in filmmaking.

- Morpher (page 2–1592)
Chapter 16: Material Editor, Materials, and Maps

Lets you morph between materials using the *Morpher modifier (page 1–729).*

- **Multi/Sub-Object (page 2–1594)**
  Lets you apply multiple sub-materials to a single object’s sub-objects.

- **Raytrace (page 2–1512)**
  Supports the same kind of diffuse mapping as Standard material, but also provides fully raytraced reflections and refractions, along with other effects such as fluorescence.

- **Shell (page 2–1600)**
  Contains a material that has been rendered to a texture (page 3–144), as well as the original material upon which the texture is based.

- **Shellac (page 2–1597)**
  Mixes two materials by applying a "shellac" material to another.

- **Top/Bottom (page 2–1599)**
  Contains two materials, one for faces that point upward, the other for faces that point downward.

Standard materials let you set values for components such as color, glossiness, and opacity. They also let you apply maps to the components, which can produce an enormous variety of effects. Some other material types have these features as well. Some materials, such as Multi/Sub-Object or Multiplied, have controls only for combining other materials.

**mental ray Materials**

A group of materials is provided for use with the *mental ray renderer (page 3–78).* See *mental ray Materials (page 2–1543).*

---

**Shading Type**

The Standard and Raytrace materials let you specify a shading type. Shading types are handled by a "shader," which describes how the surface responds to light.

**Warning:** When you change the shading type of a material, you lose the settings (including map assignments) for any parameters that the new shader does not support. If you want to experiment with different shaders for a material with the same general parameters, copy the material to a different sample slot (page 2–1420) before you change its shading type. That way, you can still use the original material if the new shader doesn't give you the effect you want.

![Samples of different shading for a standard material](image)

1. Anisotropic
2. Blinn
3. Metal
4. Multi-layer
5. Oren-Nayar-Blinn
6. Phong
7. Strauss
8. Translucent
Several different shaders are available. Some of these are not available for the Raytrace material, as indicated below. Blinn is the most general-purpose of these shaders. The others have special purposes, especially regarding how the material creates highlights.

- **Anisotropic (page 2–1480)**
  Creates surfaces with noncircular, "anisotropic" highlights; good for modeling hair, glass, or metal.

- **Blinn (page 2–1480)**
  Creates smooth surfaces with some shininess; a general-purpose shader.

- **Metal (page 2–1481)**
  Creates a lustrous metallic effect.

- **Multi-Layer (page 2–1481)**
  Creates more complex highlights than Anisotropic by layering two anisotropic highlights.
  Not available for Raytrace material.

- **Oren-Nayar-Blinn (page 2–1482)**
  Creates good matte surfaces such as fabric or terra-cotta; similar to Blinn.

- **Phong (page 2–1480)**
  Creates smooth surfaces with some shininess; similar to Blinn, but doesn't handle highlights (especially glancing highlights) as well.

- **Strauss (page 2–1483)**
  Creates both nonmetallic and metallic surfaces; has a simple set of controls.
  Not available for Raytrace material.

- **Translucent (page 2–1484)**
  Translucent shading is similar to Blinn shading, but it also lets you specify translucency, where light is scattered as it passes through the material. You can use translucency to simulate frosted and etched glass.

Not available for the Raytrace material.

---

**Material Components**

A material's components describe its visual and optical properties. The components in the [Architectural material](page 2–1535) are based on physical qualities; for example, diffuse color, shininess, transparency, and so on. The components in a [Standard material](page 2–1465) include color components, highlight controls, self-illumination, and opacity. Like the Standard material, the [Raytrace material](page 2–1512) uses a nonphysical model to describe surfaces.

Standard and Raytrace material components vary depending on which shader (page 2–1398) you use.

You can assign maps to most components, including color components such as Diffuse, and value components such as Transparency or Opacity. Maps can increase the complexity and realism of the material’s appearance.

---

**Lights and Shading**

Materials work in combination with [lights](page 2–1272). The intensity of light that falls on a surface determines the intensity of color to display. Three factors contribute to the intensity of light where it falls on an object:

- **Light intensity**: A light’s original intensity at its point of origin.

- **Angle of incidence**: The more a surface inclines away from the light source, the less light it receives and the darker it appears. The angle between a ray of light and the [face normal](page 3–980) of a surface is the angle of incidence for that face.

  When the angle of incidence is 0 degrees (that is, the light strikes the face perpendicularly), the face is illuminated at full intensity unless
the light is attenuated. Full intensity is the light’s Multiplier value times the value of the face’s surface color. The Multiplier value is 1.0 by default; the surface value is the Value component of the surface color’s HSV description (page 3–1001). As the angle of incidence increases, the intensity of the face illumination decreases.

Angle of incidence affects intensity.

- **Distance**: Light diminishes over distance. This effect is known as attenuation (page 3–912). By default, attenuation is turned off, but you can turn it on and specify the distance over which it operates.

**Lights and the Component Colors of a Standard Material**

As the names of a standard material’s color components (page 2–1399) imply, the kind of light that strikes a surface with a material determines how the surface appears when it is shaded.

- **Ambient color** appears where the surface is lit by ambient light alone (where the surface is in shadow).
- **Diffuse color** appears where light falls directly on the surface. It is called ”diffuse” because light striking it is reflected in various directions. Highlights, on the other hand, are reflections of light sources.
- **Specular highlights** appear where the viewing angle is equal to the angle of incidence. Glancing highlights appear where the angle of incidence is high, relative to the observer or camera (that is, the light ray is nearly parallel to the surface). Shiny surfaces usually have specular highlights. Glancing highlights are characteristic of metallic surfaces.

Some surfaces are completely reflective, or nearly so. These reflect their environment as well as the light sources that illuminate them. To model such surfaces, you need to use reflection mapping (page 2–1699) or ray tracing (see Raytrace Material (page 2–1512)).

The three color components blend at the edges of their regions. Between ambient and diffuse, the blending is calculated by the shader. Between diffuse and specular, you set the amount of blending by using the standard material’s highlight controls.

---

**Choosing Colors for Realism**

Materials add greater realism to a scene only if you choose their colors and other properties to appear like real-world objects. This topic presents some general guidelines for choosing standard material colors. When possible, you should also observe colors in the objects you are modeling, especially under different lighting conditions.

For objects on which you want the viewer to focus attention, an unmapped standard material doesn’t often provide the level of realistic detail you probably want. However, for distant and peripherally visible objects, as well as some kinds of real-world materials, such as molded plastic, an unmapped standard material can work well. Keeping the number of maps to a minimum can help keep down the file size.
Choosing Colors for Realism

Indoor and Outdoor Lighting

Whether a scene is indoors or outdoors affects your choice of material colors, just as it affects the way you set up lights (page 2–1272). Full sunlight is bright and unidirectional. Most indoor lighting is less intense and more even (that is, multidirectional) than daylight. However, some special indoor lighting (and nighttime outdoor lighting), as for the stage, also features intense, directional light.

Direct sunlight has a yellow tint. Materials for objects to appear in daylight should have a specular color of a pale, unsaturated yellow (for example, RGB values of 240, 240, 188). The ambient color should be the complement of the specular: a deep, dark purple with a hint of the diffuse color.

Materials for objects to appear under normal interior lighting should have a specular color that is close to white. (Our perception compensates for the yellow or green tint that is often present in artificial light.) The ambient color can often have the same hue as the diffuse color, but with a darker value.

Materials for objects to appear under spotlights should follow the general guidelines for daylight materials. The specular color should match the spotlight’s color, and the ambient color should be a very dark value of the spotlight color’s complementary hue, mixed with a bit of the material’s diffuse color.

If you want to render an object under changing lighting conditions, you can choose colors that are a compromise between the optimal colors for each kind of lighting, or you can animate (page 2–1449) the material so that its colors change to suit the changing light.

Representing Natural Materials

Outdoor scene with natural materials

Most natural materials have a matte surface with little or no specular color. For natural materials such as these, use the following guidelines:

- **Ambient color**: The ambient color depends on whether the scene is indoors or outdoors, as previously described.
- **Diffuse color**: Choose a color found in nature. It is best to use the observed color of the object itself, or a similar object.
- **Specular color**: Make the specular color the same hue as the diffuse, but with a higher value and a lower saturation.
- **Glossiness**: Set the Glossiness to a low value.

Some foliage, bird feathers, fish scales, and so on, are shiny. For materials such as these, set the Glossiness to higher values. You might also want to change the specular color so it’s closer to the lighting color than the surface’s diffuse color.

Water is reflective, and is best modeled by a color component in combination with a reflection map (page 2–1699) or a water map (page 2–1683).

While metal is a natural material, its special visual characteristics are most apparent when it has been polished. Standard material represents this by
Representing Manufactured Materials

Manufactured materials often have a synthetic color rather than an "earth tone." Also, many manufactured materials, such as plastics and porcelain glazes, are very shiny. For manufactured materials, use the following guidelines:

- **Ambient color:** The ambient color depends on whether the scene is indoors or outdoors, as previously described.
- **Diffuse color:** Although the diffuse color doesn’t have to be an "earth tone," as with natural materials you should use the observed color of the object or a similar object.
- **Specular color:** Make the specular color close to white, or to the color of the light source. White is especially characteristic of plastic materials.
- **Glossiness:** Set the glossiness to a high value.

Representing Metallic Objects

Polished metal has a characteristic "glancing" highlight that appears where the light is at a high angle of incidence. To generate this effect, Metal shading uses the Cook/Torrance illumination model.

For metallic materials, you can use the Metal shading type. This disables the specular color and highlight controls. The Metal shader calculates its own specular color, which can vary between the diffuse color and the color of the light.

In the diffuse region of a metal material, the ambient component is greater than it is for other kinds of materials.

The Anisotropic, Multi-Layer, and Strauss shaders give you further options for modeling polished metal.

If the metallic object is the focus of the scene, you can improve realism by using a Blend material (page 2–1588) to combine metallic shading with a reflection map (page 2–1699).

Tip: When you preview metallic surfaces, it is useful to turn on a backlight. This displays the metal’s glancing highlight. The Backlight button is to the right of the sample slots.
Using Maps to Enhance a Material

Maps provide images, patterns, color adjustments, and other effects you can apply to the visual/optical components of a material. Without maps, material design in 3ds Max is limited. Maps give the Material Editor its full flexibility, and can give you dramatic results.

![Spheres with various maps applied to them (as well as a reflection map applied to the surface beneath them)](image)

The simplest use of a map is to assign a pattern to a material's Diffuse color. Diffuse mapping (page 2–1498) is also known as "texture mapping." It applies an image or pattern to geometry the material is applied to.

Example of designing a mapped material:
1. Choose a sample slot.
2. Increase the highlight.
3. Apply a checker map to the material's diffuse component.
4. Apply a bump map to give the material ridges.
5. The checker map displays in viewports, but the bump map does not.
6. Rendering the material shows the full effect of mapping.

Warning: When you change the shading type (page 2–1398) of a standard material, you lose the settings (including map assignments) for any parameters that the new shader does not support. If you want to experiment with different shaders for a material with the same general parameters, copy the material to a different sample slot (page 2–1420) before you change its shading type. That way, you can still use the original material if the new shader doesn't give you the effect you want.
Map Terminology

The term "material map" is sometimes used to describe a map assigned in the material editor. A material map applies a color or pattern to a surface. This is different from maps used for displacement mapping with the Displace modifier (page 1–629), environment mapping for backgrounds, or projection mapping from lights.

The term "texture map" is sometimes used as well. It is interchangeable with "diffuse map"; that is, with a map that applies colors to geometry, as opposed to a map that create reflections, bumps, and so on.

In the Material/Map Browser (page 2–1412), maps are categorized according to how the map software functions. The categories are:

- **2D maps**
  A bitmap (page 2–1631) is the prototypical 2D map. 2D maps apply pictures and patterns to the surface of objects.

- **3D maps**
  3D maps are generated procedurally. 3D maps apply patterns throughout an object's geometry.

- **Compositors**
  Compositors combine other maps.

- **Color Modifiers**
  Color modifiers are usually composited with another map to adjust its color. The Vertex Color map is a special case that displays the colors you assign to vertices in a mesh.

- **Other**
  "Other" maps include maps that simulate reflection or refraction.

The names of individual map types describe the pattern or effect they create, such as Checker map, Bitmap, Gradient, Flat Reflection, and so on.

Note: In some cases the user interface also uses "map" to describe not the map type, but the visual component being mapped. For example, a "diffuse map" means a map of any type applied to a material’s diffuse component. This is an ambiguity in the use of "map" that can be a bit confusing when you first encounter it.

Assigning Maps

For a standard material (page 2–1465), you assign maps using the Maps rollout. Click the Map button in line with the name of the visual component you want to map. The Material/Map Browser (page 2–1412) is displayed. Select the map type (for example, Bitmap) from the list of maps, and then click OK. Double-clicking the map’s name in the Browser also assigns the map type.

The Browse From group box in the Browser creates new maps by default. You can also use it to obtain maps from a library (see Saving A Material), from the current scene, from objects selected in the scene, or from elsewhere in the material editor.

In the Browser, you can turn on icons of differing sizes to preview maps before you assign them.

A Standard material’s Basic Parameters rollout has shortcut buttons for assigning a map to some of the material’s visual components. These small buttons are equivalent to the buttons in the Maps rollout. Assigning a map to a button in one rollout changes the corresponding button in the other.

Each type of map has its own set of parameters and controls. If the map is a Checker map, for example, you can choose the colors of the checkers, and whether a checker color has a map of its own. You can change tiling values to affect the scale of the checkers, adjust noise parameters to make the checkers irregular, and so on.

Note: To save loading time, if a map with the same name is in two different locations (in two different paths), it is loaded only once. This poses a problem only if your scene includes two maps that have different content but the same name.
In this case, only the first map encountered will appear in the scene.

**Navigating the Material/Map Tree**

When you build a material of any complexity, you are building a material/map tree. The root of the tree is the material itself. The branches are the maps you have assigned to the material’s components. Some maps can themselves contain maps, as in a map applied to one color of a Checker material (page 2–1638), so the tree can be more than two levels deep, and can actually be as deep as you need it to be.

The Material/Map Navigator (page 2–1447) is a dialog that displays the tree for the current material. It is useful for finding a map and displaying its parameters. Click the map to display its rollouts in the Material Editor. To copy a map to a different component of the same material, you can also drag the map’s name from the Navigator to a map button in the Material Editor.

The Go Forward To Sibling and Go To Parent buttons also navigate the map tree. Go Forward To Sibling moves laterally in the map tree, while Go To Parent moves up the tree. (To move down the tree, click a map button that has a map assigned to it.) Another way to move between parents and children in the tree is to drop down the material name field (page 2–1448) and click the name of a map or material.

---

**Applying a Material to an Object**

There are two ways to apply a material to an object:

- If the sample slot is active and the object is already selected, click Assign Material To Selection (page 2–1441).
- Drag from the sample slot to the object.

As you drag, a tooltip appears over each object beneath the mouse, showing the object’s name. You can apply the material whether the object is selected or not. Release the mouse to apply the material.

Applying a material overrides any previous material assignment the object might have had. Once the material is applied, while the sample slot is active, the material is "hot" and changes you make to it affect the object automatically. See Sample Slots (page 2–1420) for more about hot and cold materials.

The Undo command (page 1–94) works for material assignment.

You can apply only one material to an object. To overcome this restriction, use a Multi/Sub-Object material (page 2–1594). This is a container for various sub-materials that correspond to specified sub-objects such as different faces in a mesh, NURBS surfaces in a NURBS model, and so on.

You can apply the same material to multiple objects in the scene.

**See also**

Dragging and Dropping Maps and Materials (page 2–1423)

Drag and Drop Sub-Object Material Assignment (page 2–1424)

---

**Mapping Coordinates**

An object assigned a 2D mapped material (or a material that contains 2D maps) must have mapping coordinates. These coordinates specify how the map is projected onto the material, and whether it is projected as a "decal," or is tiled or mirrored. Mapping coordinates are also known as UV or UVW coordinates (page 3–1028). These letters refer to coordinates in the object’s own
space, as opposed to the XYZ coordinates that describe the scene as a whole.

Most renderable objects have a Generate Mapping Coordinates parameter. If you don’t turn this on, but apply a mapped material to the object, you get a warning when you try to render.

Some objects, such as editable meshes, don’t have automatic mapping coordinates. For these types of objects, you can assign coordinates by applying a UVW Map Modifier (page 1–922).

If the material appears the way you want it with the default mapping, you don’t need to adjust the mapping. If you need to adjust it, use the map’s Coordinates rollout. There are two typical sets of coordinates parameters: one for 2D maps such as Bitmaps (page 2–1631), and another for 3D maps such as Noise (page 2–1674). See Coordinates Rollout (2D) (page 2–1625) and Coordinates Rollout (3D) (page 2–1663).

Note: The UVW Remove utility (page 2–1408) provides a way to remove mapping coordinates or an entire material from selected objects.

### Saving a Material

While a material is in the Material Editor or applied to an object, it is part of the scene, and is saved with the scene. However, for complicated scenes it is inconvenient to have all materials active in the Material Editor. You can also save a material by putting it into a material library. Some libraries are provided in the \matlibs subdirectory. The file 3dsmax.mat is the default library. You can add your material to this library, or create your own libraries.

### Procedure

**To save a material in a library:**

This stores a material in the current material library. To use a different library, first open it using the Material/Map Browser (page 2–1412).

1. In the Material Editor, click the sample sphere for the material to save.
2. On the Material Editor toolbar, click Put to Library (page 2–1443). A Put to Library dialog (page 2–1455) is displayed. Either change the material name or leave it as is, and then click OK.
3. Choose Rendering > Material/Map Browser, or, on the Material Editor toolbar, click Get Material (page 2–1439). The Material/Map Browser (page 2–1412) opens.
4. In the Browser > Browse From group, choose Mtl Library, if necessary. The stored material appears in the list.
5. In the Browser > File group, click Save to save the library with the current name (if any) or Save As to save it as a different file.
Tip: You can use the Merge function in the File group to add materials from the current library to another library.

Material XML Exporter Utility

Utilities panel > Utilities rollout > More button > Utilities dialog > Material XML Export

You can export materials you create in 3ds Max to XML files, which can then be shared with other 3ds Max users or used in AutoCAD Architecture (formerly Autodesk Architectural Desktop) to modify material definitions.

Note: You can add an exported XML material to your 3ds Max scene by dragging and dropping from a Web site or Windows Explorer onto an object in your scene, or by importing it directly onto objects.

Interface

Selection Method group
The Selection Method group lets you set the method for selecting the materials you wish to export.

Material/Map Browser—Lets you select a material to export from the Material/Map browser (page 2–1412).

Object List—Lets you select objects from a Select Objects dialog (page 1–78). All materials assigned to the selected objects are exported.

Pick Object in Scene—Lets you select an object from your scene. Any materials assigned to the selected object are exported.

All Objects in Scene—Exports all of the assigned materials in your scene.
Output Format group
The Output Format group defines the format of the XML Material output.

Native XML (vizML)—Materials are exported as raw XML.
Tip: Use this format for sharing XML material files within 3ds Max.

Tool Catalog—Materials are exported to the ATC (Autodesk Tool Catalog) format.
This file type is suitable for display in the AutoCAD Content Browser and the Autodesk VIZ Content Browser.
Note: This file type cannot be imported to 3ds Max unless you also have Autodesk VIZ Render installed on the same system.

Specify XSLT—This option lets you apply your own XSL transform to the XML output.

Export group
The Export group lets you define the parts of the material assignments to export.

Material—Exports the material definitions.
Create Thumbnails—Exports thumbnails for each material.
Note: Thumbnail images are referenced by the ATC and displayed in the AutoCAD Content Browser and Autodesk VIZ Content Browser.

Mapping Modifiers—Exports the mapping modifiers applied to specific objects.
Export—This button begins the XML export process, using the defined selection method, output format, and export parameters.

Upon clicking Export, you are prompted to set the path or URL to store in the XML file as the path to any referenced bitmap files. The default is an empty string, which means no path will be prepended to the bitmap filenames when written to XML. When the material is later imported, it will be assumed that the referenced bitmap file can be found in the bitmap search path.

If you have elected to export thumbnails or to apply your own XSL transform, you are then prompted to set a path to store the thumbnail files and to locate your XSLT file, respectively.

UVW Remove Utility
Utilities panel > Utilities rollout > More button > Utilities dialog > UVW Remove

The UVW Remove utility removes mapping coordinates or materials from the currently selected objects.

Interface

UVW—Click to remove UVW mapping from this object.
Materials—Click to remove material assignment from the selected objects.
Set Gray—If this is on when you click the Materials button, the object color is set to a neutral gray. Default=off.
Material Editor

Main toolbar > Material Editor
Rendering menu > Material Editor
Keyboard > M

The Material Editor provides functions to create and edit materials (page 3–971) and maps (page 3–968).

Materials create greater realism in a scene. A material describes how an object reflects or transmits light. Material properties work hand-in-hand with light properties; shading or rendering combine the two, simulating how the object would look in a real-world setting.

You apply materials to individual objects or selection sets; a single scene can contain many different materials.

Note: Creating a new material clears the Undo/Redo lists.

Procedures

To view the Material Editor:

- Click the Material Editor button on the main toolbar.

  The Material Editor dialog has sample slots (page 2–1420) for viewing previews of materials. When you first view the Material Editor, the material previews have a uniform default color.

To give a material a different name:

- Edit the name field that appears below the Material Editor toolbar.

  The name of the active material appears in the title bar of the Material Editor dialog. The name of the material is not a file name: it can contain spaces, numbers, and special characters.

  The name field displays only 16 characters, but a material name can be longer than that.

To make a copy of a preview material:

- On the Material Editor toolbar, click Make Material Copy (page 2–1442).

To get a material from a scene:

If a material that you want to change has been saved in the scene, but not in the Material Editor, you can load the material by getting it from the scene.

1. Click a sample slot to make it active.
   Be careful not to click the sample slot of a material you want to use later.

   A modeless Material/Map Browser (page 2–1412) is displayed.

3. In the Browse From group box at the upper left, make sure that either Selected or Scene is chosen.
   The Selected option lists only materials in the current selection. If no objects are selected, the list of materials is blank.
   The Scene option lists all the materials currently in the scene.

4. In the list of materials, double-click the name of the material you want.
   You can also drag the material name to the sample slot.
   The material you chose replaces the previous material in the active sample slot.

Warning: When you get a material from a scene, it is initially a hot material (page 3–953).
To apply a material to objects in a scene:
1. Select the sample slot that contains the material you want to apply.
2. Select the object you want to apply the material to.
3. Drag from the sample slot to the object. If you selected more than one object, you are asked if you want to apply to the single object only, or to the whole selection.

You can also apply materials by clicking Assign Material To Selection (page 2–1441) on the Material Editor toolbar.

Warning: When you apply a material to an object or selection, that material becomes a hot material (page 3–953) (its sample slot is displayed with white corner brackets). When you change the properties of a hot material, the scene immediately updates to reflect those changes. Any object with that material will change its appearance, not just the objects in the current selection.

To remove a material from an object:
1. On the Material Editor toolbar, click Get Material.
The Material/Map Browser appears.
2. Drag the entry NONE from the top of the list in the Browser to the object.
The object now has no material applied to it.

To make a material no longer hot so it doesn’t change the current scene, click Make Material Copy (page 2–1442).

To put a material back into a scene:
- On the Material Editor toolbar, click Put Material To Scene (page 2–1440).
The material in the active sample slot is now a hot material (page 3–953).

The Put Material button is available only when (1) the material in the active sample slot has the same name as a material in a scene, and (2) the material in the active sample slot is not hot. In other words, this command is meant to fit into the following overall sequence of handling materials:

- You create a hot material either by applying it to objects in the scene or by getting it from the scene.
- You make a copy of the material.
- You make changes to the copy of the material.
- You update the scene by putting the changed material back into the scene.

These steps are not as immediate as changing a material while it is hot, but they help you avoid changing the scene’s materials unintentionally or in unexpected ways.

When a material in the Material Editor is applied to objects in the scene, you can select the objects from the Material Editor.

To select objects that have the same material applied:
When a material in the Material Editor is applied to objects in the scene, you can select the objects from the Material Editor.

1. Click a sample slot that contains a material in the scene.
   White corner brackets indicate materials that are in the scene.

2. Click Select By Material (page 2–1439).
   This button is unavailable unless the active sample slot contains a material in the scene.

   A Select Objects dialog (page 1–78) is displayed. The names of objects with the active material applied are highlighted when the dialog appears.
3. Click Select to select objects that have the active material applied to them.

You can also change the selection by choosing other objects. If you change the selection, you must then click Assign Material To Selection (page 2–1441) to apply the active material to newly selected objects.

**To get a material from a library:**

A modeless Material/Map Browser (page 2–1412) is displayed.

2. In the Browse From group box at the upper left, make sure that Material Library is chosen.

If you have opened a library, the list of materials shows the contents of the library.

If you haven't opened a library, click Open in the file area of the Browser. In the file dialog that is displayed, you can choose a material library to open. After you open the library, the list of materials updates to show the library’s contents.

3. In the list of materials, double-click the name of the material you want.

You can also drag the name of the material to the sample slot.

The material you chose replaces the previous material in the active sample slot.

**To save a material in a library:**

1. Click to select the sample slot that has the material you want to save.

2. On the Material Editor toolbar, click Put To Library (page 2–1443).

3. A Put To Library dialog (page 2–1455) appears.

4. Either change the material name or leave it as is, and then click OK.
For choosing materials, see Material/Map Browser (page 2–1412). For applying materials using drag and drop techniques, see Dragging and Dropping Maps and Materials (page 2–1423).

For an overview of how to use the Material Editor, see Designing Materials (page 2–1395).

For the user interface elements in Material Editor and the different materials and map types, see the following topics:

- Material Editor Menu Bar (page 2–1428)
- Sample Slots (page 2–1420)
- Material Editor Tools (page 2–1427)
- Types of Materials (page 2–1457)
- Types of Maps (page 2–1617)

For information about how to animate materials, see Animating Materials (page 2–1449).

Material/Map Browser

| Main toolbar > Material Editor > Get Material > Material/Map Browser |
| Rendering menu > Material/Map Browser |
| Material Editor > Click Material Type button or Map Type button > Material/Map Browser |

Procedure (page 2–1413) Interface (page 2–1414)

The Material/Map Browser lets you choose a material (page 3–971), map (page 3–968), or mental ray shader (page 2–1710).

When you click Get Material (page 2–1439), the Browser that is displayed is modeless (you can leave it displayed while you do other work). However, when you display the Browser by clicking the Type (page 2–1449) button, a map assignment button in the Environment dialog (page 3–272), or from a projector light (see Advanced Effects Rollout (page 2–1341)), it appears as a modal dialog with OK and Cancel buttons.

You can leave the modeless Browser displayed, and drag materials from its listings to material or map sample slots and buttons in the user interface. When the Browser displays a Material Library, you can also add materials to the library by dragging them from the Material Editor sample slots (page 2–1420).

When you double-click a material, map, or shader in the Browser, it places that material, map, or shader in the Material Editor’s active sample slot. It automatically chooses between an instance or a copy, as follows:

- Browsing New Materials: Creates a new material.
- Browsing a Library: Makes a copy.
- Browsing the Material Editor, Scene, or Selected: Depends on the status of the map or material.

When you browse the Material Editor, the Scene, or Selected objects, the choice between making a copy or an instance depends on the status of the material, as follows:

- If the material or map is already in the active slot, the Browser does nothing.
- If the material or map is in some other sample slot, the Browser puts a copy in the active slot.
- In all other cases, the Browser makes an instance of the material or map.

Browsing mental ray Materials and Maps

When you use the mental ray renderer (page 3–78), you might want to use the materials and shaders that provide effects for this renderer only. (The default scanline renderer renders these materials and shaders only as black or white, or it simply ignores their effects.) The Material/Map Browser lists mental ray maps and materials only if you
assign the mental ray renderer as the currently active renderer.

Once you have enabled the renderer, when you use the Browser, it shows mental ray materials and shaders. Materials are displayed with a yellow sphere, rather than blue for standard materials, and shaders are displayed with a yellow parallelogram, rather than green as for standard maps.

mental ray maps in the browser’s list are shown with yellow icons.

When you use the mental ray Connection rollout (page 2–1461), or other shader buttons specific to mental ray materials and shaders, the shaders that appear in the Browser’s list are restricted to those that the mental ray renderer allows for that particular shader component. By default, only shaders that ship with 3ds Max are listed. If you have acquired other shader libraries, you might see the names of shaders that are not mentioned in this reference.

Note: You can see the listing of materials, maps, or shaders that are incompatible with the current renderer, if you turn on the Incompatible toggle in the Show group, as described under “Interface,” below.

See also

Material/Map Navigator (page 2–1447)

Procedures

To navigate materials with the Browser:
Tip: Use the Browser primarily in Root Only mode, to see only the top levels of the materials. This provides a simpler view of your materials, and speeds redraws when you’re using any of the icon display modes. (You can also create thumbnails to speed up redraws, as described below.)

1. In the Material Editor, choose any sample slot you want that contains a complex, multilevel material.

2. In the Browser > Browse From group, choose Active Slot mode to display all levels of the active sample slot.

3. Click any of the items in the Browser’s material/map list to move to that level of the current material.

4. When you want to switch to a different material, select its sample slot in the Material Editor, and its hierarchy will appear in the Browser.

5. Again, click the items in the Browser to change levels.

To delete an assigned map:

1. While viewing the map parameters, click the Map Type button.

2. In the Material/Map Browser, choose NONE as the new map type.

Tip: You can also remove a material or map by dragging the NONE item from the Browser over to the object or map button.

To merge material libraries:

1. In the Browse From group, choose Mtl Library, and then click the Merge button.
2. In the Merge Material Library dialog (page 2–1454), select a material library other than the current library, or select a 3ds Max or VIZ Render (DRF (page 3–527)) scene. A Merge dialog (page 2–1453) is displayed, listing all materials in the specified library, or all materials assigned to the 3ds Max or VIZ Render file. Below the list are All and None buttons to help in the selection.

3. Select the materials in the list that you want to merge, and then click OK. The selected materials are merged into the current material library.

4. Save the library to save your changes.

To save the sample spheres as thumbnail images:

1. Open the Browser. In the Browse From group, choose Mtl Library.

2. Choose View Small Icons.

3. Display all of the icons in the library by either scrolling through all of them, or by enlarging the Browser so that all of the icons have been displayed at least once.

The action of displaying the icons automatically creates thumbnails in memory.

**Important:** If you want to include thumbnails of the sub-materials and maps, be sure to turn off Root Only.

4. Save the library.

When you save the library, you save the thumbnail images of the samples as they appeared in the Browser at that time. If you change any of the materials or maps later, you must re-save the library in order to update the thumbnails. If you do not re-save the library after altering or adding a materials, the icon of the material will still appear correctly, but it will be rerendered when it first appears in the Browser, while all the other icons will appear immediately.

### Interface

The Material/Map Browser contains the following controls:

**Material/Map list**—The main part of the Material/Map Browser dialog is a scrollable list of materials and maps. The list indicates a material with a blue sphere, and indicates a map with a green parallelogram. When you list both materials and maps, the materials are listed first.

Note: Icons of materials and maps for which Show Map in Viewport (page 2–1445) is on are red.
Also, the names of instanced (page 3-957) materials and maps appear in boldface.

Both of these effects are shown in the following illustration:

Text entry—As you enter a material name in this field, the first matching text item is selected in the list. Press Enter to select the next matching name, and so on.

For example, if you enter ch when the list includes the material names Cherry Red, Chrome Blue, and Chrome Zinc, Cherry Red is selected first. Press Enter and the Chrome Blue is selected. Press Enter again, and Chrome Zinc is selected.

The search is not case-sensitive.

Sample slot—Below the text-entry field is a single sample slot. This displays a sample of the current selection. You can drag the sample to any other sample slot or material button. The sample slot display is interruptible, so you can quickly click from one list item to the next without waiting. In addition, if you complete the display of one sample, then move on to another sample, when you return to the first sample, it displays instantly.

Tool buttons

The first part of this row of buttons controls how you view the list. The second part is for managing material libraries.

To speed up the display of the sample spheres in the Browser, the smaller of the sample spheres (those displayed when you choose View Small Icons or View List + Icons) can be saved as thumbnail images in the material library file. (See the Procedures for this topic, above.)

Keep in mind that the saved thumbnails increase the size of the material library file.

View List—Displays the materials and maps in list format. Blue spheres are materials. Green parallelograms are maps. The green parallelograms turn red if Show Map in Viewport is on for a material.

View List + Icons—Displays the materials and maps in a list with small icons.

View Small Icons—Displays the materials and maps as small icons. As you move the mouse over the icons, tooltip labels pop up, showing you the name of the material or map.

View Large Icons—Displays the materials and maps as large icons.

The large icons are labeled with the name of the material or map and are displayed using progressive refinement—samples are rendered quickly, with large pixels, then rendered a second time in greater detail.

Update Scene Materials from Library—Updates materials in the scene with the materials of the same name stored in the library.

When you click Update Scene Materials from Library, the Update Scene Materials dialog (page 2–1457) is displayed. This dialog lists materials in the library that have the same name as materials in the scene. In the list, select the materials you want to update in the scene, and then click OK.

If no materials exist in the scene that match the names in the library, an alert informs you of this.
This button is available only when the Browser is viewing a library.

Delete from Library—Removes the selected material or map from the library display. The library on disk is not affected until you save it. Use Open to reload the original library from disk. This button is only active when you select a named material that exists in the current library.

This button is available only when the Browser is viewing a library.

Clear Material Library—Removes all materials from the library display. The library on disk is not affected until you save it. Use Open to reload the original library from disk.

This button is available only when the Browser is viewing a library.

Browse From group

The controls in this group choose the source of the materials displayed in the material/map list.

Material Library—Displays the contents of a material library file from disk. When you set this option, the buttons under File become active (see below).

You can also load a library from a MAX file. When browsing from the Material Library in the Material/Map Browser, choose Open, and then choose 3ds Max (*.max) from Files of type. Select and load a .max file. All materials assigned in that scene are listed in the Browser. To convert the collection of materials to a library file, click Save, and save it as a MAT (.mat) file.

Material Editor—Displays the contents of the sample slots.

Active Slot—Displays the contents of the currently active sample slot.

This option is unavailable in the modal version of the Browser.

When you choose this mode, all check boxes in the Show group box are made available. The entire material and map tree of the active material is displayed, regardless of the state of these check boxes in other Browse From modes.

You can also use Active Slot mode to navigate the hierarchy of the active material. When Active Slot is chosen, clicking an item in the material/map list moves Material Editor controls to that level of the material.

Selected—Displays the material applied to the selected objects.

Scene—Displays all materials applied to objects in the scene.

All maps assigned to the scene, including Environment Background or spotlight projector maps, are displayed in the Browser list.

New—Displays the set of material/map types for you to create a new material.

Show group

These options filter what is displayed in the list. Either Materials or Maps is always on, and both can be on at the same time. The first two options can be unavailable, depending on the active Browse From and View settings.

Materials—Turns display of materials and sub-materials on or off.
This is always unavailable in the modal version of the Browser.

**Maps**—Turns display of maps on or off.

This is always unavailable in the modal version of the Browser.

**Incompatible**—When on, displays materials or maps and shaders that are incompatible with the currently active renderer. The incompatible materials are displayed in gray. You can still assign incompatible materials, maps, or shaders to buttons where they would be legal, but if you use the current renderer, the results might not be correct. Default=off.

**Root/Object group**

**Root Only**—When on, the material/map list displays only the root of the material hierarchy. When off, the list displays the full hierarchy.

The default state of Root Only depends on how you display the Browser. Generally, when you display the modeless Browser, you’re selecting materials rather than maps (to begin with), so Root Only is on. However, when you display the modal Browser (by clicking a map button anywhere in the user interface), Root Only is off so you can see all the maps.

**By Object**—This is available only when you’re browsing from either Scene or Selected. When on, the list displays materials by their object assignment in the scene. At the left are the names of the objects arranged alphabetically, with a yellow cube icons as in *Track View* (page 2–501). Applied materials are shown as children of the objects. When off, the list displays only material names.

**File group**

This button group is displayed when you’ve chosen Material Library, Material Editor, Selected, or Scene in the Browse From group. All four buttons are displayed only when browsing from the Material Library; otherwise, only the Save As button appears.

**Open**—Opens a material library.

**Merge**—Merges materials from another material library or scene. When you click Merge, the *Merge Material Library dialog* (page 2–1454) is displayed. This file dialog lets you choose a material library or a scene. When you choose a library or scene to merge, the *Merge dialog* (page 2–1453) is displayed. This lets you select which materials to merge. If there are duplicate names among the materials you’re merging, the *Duplicate Name dialog* (page 2–1453) is displayed so you can resolve the name conflicts.

**Save**—Saves the open material library.

**Save As**—Saves the open material library under another name.

**Display group**
This group of radio buttons is displayed only when you’ve chosen New under Browse From. It controls what types of maps the Browser displays in the material/map list. (The Browser displays materials regardless of this setting.)

2D Maps—Lists only 2D map types.

3D Maps—Lists only 3D (procedural) (page 3–997) map types.

Compositors—Lists only compositor map types.

Color Mods—Lists only color modifier map types.

Other—Lists reflection and refraction map types.

All—(The default.) Lists all map types.

Copying and Pasting: Right-Click Menu for Materials, Maps, Bitmaps, and Colors

Material Editor > Right-click a Type button, sub-materials button, map button, bitmap button, or color swatch.

Elsewhere in the user interface > Right-click a map button or color swatch.

A set of right-click pop-up menus in the Material Editor (and elsewhere in the program’s user interface) lets you copy and paste, and otherwise manage materials, maps, bitmaps, and colors.

You see these menus only if copy and paste actions are appropriate. For example, if you copy a material and then right-click a map button, nothing happens.

Material Right-Click Menu

When you right-click a button that represents a material, this menu appears. This includes the Type button (page 2–1449) for a material, and sub-material buttons such as you find in the Multi/Sub-Object material (page 2–1594), the Blend material (page 2–1588), and others.

Cut—Makes a copy of the material. If you right-click a sub-material button, this also removes the material from that sub-material component. If you right-click the Type button, Cut is equivalent to Copy.

Copy—Makes a copy of the material.

Paste (Copy)—Pastes a copy from the copy buffer. This item doesn’t appear if you haven’t yet copied a material.

Paste (Instance)—Pastes an instance from the copy buffer. This item doesn’t appear if you haven’t yet copied a material.

Clear—If you right-click a sub-material button, Clear removes the material from that sub-material component without making a copy of it. If you right-click the Type button, Clear has no effect.

Map Right-Click Menu

When you right-click the button for a map component (a “map slot”), the menu you see depends on whether a map has been assigned yet.

When a Map Has Been Assigned

The following menu appears if a map has been assigned:
**Copying and Pasting: Right-Click Menu for Materials, Maps, Bitmaps, and Colors**

<table>
<thead>
<tr>
<th>Cut</th>
<th>Removes the assigned map, and puts a copy of it in the copy buffer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Copy</td>
<td>Copies the map without removing it.</td>
</tr>
<tr>
<td>Paste (Copy)</td>
<td>Pastes a copy from the copy buffer.</td>
</tr>
<tr>
<td>Clear</td>
<td>Removes the assigned map without copying it.</td>
</tr>
<tr>
<td>Open</td>
<td>Launches whichever application is associated with the currently assigned 2D map.</td>
</tr>
<tr>
<td>Reveal Location in Explorer</td>
<td>Launches a copy of Windows Explorer to display the folder where the map is saved.</td>
</tr>
</tbody>
</table>

**When No Map Has Been Assigned**

If no map has been assigned, all you can do is paste another:

<table>
<thead>
<tr>
<th>Paste (Copy)</th>
<th>Pastes a copy from the copy buffer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paste (Instance)</td>
<td>Pastes an instance from the copy buffer.</td>
</tr>
</tbody>
</table>

**When No Map Has Been Either Assigned or Copied**

If no map has been assigned and you haven’t copied a map yet, then no right-click menu appears at all.

**Bitmap Right-Click Menu**

This menu appears when you click a button that specifies an external bitmap (page 3–917). See Bitmap 2D Map (page 2–1631).

<table>
<thead>
<tr>
<th>Copy</th>
<th>Copies the bitmap.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paste</td>
<td>Pastes the bitmap from the copy buffer.</td>
</tr>
<tr>
<td>Open</td>
<td>Launches whichever application is associated with the bitmap.</td>
</tr>
<tr>
<td>Reveal Location in Explorer</td>
<td>Launches a copy of Windows Explorer to display the folder where the bitmap is saved.</td>
</tr>
</tbody>
</table>

**Color Swatch Right-Click Menu**

This menu appears when you right-click a color swatch.

Note: This menu does not apply to the VertexPaint modifier’s Color Palette (page 1–950), which has its own right-click menu.

<table>
<thead>
<tr>
<th>Copy</th>
<th>Copies the color.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paste</td>
<td>Pastes a color from the copy buffer.</td>
</tr>
</tbody>
</table>
Sample Slots

The sample slots let you maintain and preview materials (page 3–971) and maps. (page 3–968) Each slot previews a single material or map. You can change the material by using the Material Editor controls, and you can apply the material to objects in the scene. The easiest way to do this is to drag the material from the sample slot to objects in viewports. See Dragging and Dropping Maps and Materials (page 2–1423).

Important: While the Material Editor can edit no more than 24 materials at a time, a scene can contain an unlimited number of materials. When you are through editing one material, and have applied it to objects in the scene, you can use that sample slot to get a different material from the scene (or create a new one) and then edit it.

You can display a sample slot in a window of its own. This magnifies the sample slot, which can make it easier to preview the material. You can resize the magnified window to make it even larger. To magnify a sample slot, double-click it, or right-click and choose Magnify from the pop-up menu. See Sample Slot Right-Click Menu (page 2–1422).

The Material Editor has 24 sample slots. You can view them all at once, six at a time (the default), or 15 at a time. When you view fewer than 24 slots at once, scroll bars let you move among them. See Material Editor Options (page 2–1436) and Sample Slot Right-Click Menu (page 2–1422).

A material in a slot is shown on a sample object. By default, the object is a sphere. Use the Sample Type flyout (page 2–1432) to change the sample object.

By default, a standalone map in a slot fills the whole slot. This is when the slot shows only a standalone map at the top of a tree; when the map is assigned to a material, the slot shows it as part of the material, mapped to the sample object. See Get Material (page 2–1439) and Material Editor Options (page 2–1436).

The Material Editor renders only the active sample sphere for the current frame.

If the \matlibs subdirectory contains a material library called medit.mat, the sample slots show the first 24 materials in this library file. If the library contains fewer than 24 materials, the remaining slots contain Standard materials of various colors, as they do if an medit.mat library is not found.
**Hot and Cool Materials**

A sample slot is *"hot"* (page 3–953) when the material in the slot is assigned to one or more surfaces in the scene. When you use the Material Editor to adjust a hot sample slot, the material in the scene changes at the same time.

The corners of a sample slot indicate whether the material is a hot material:

- **No triangle:** The material is not used in the scene.
- **Outlined white triangle:** The material is hot. In other words, it’s instanced in the scene. Changes you make to the material in the sample slot will change the material displayed in the scene.
- **Solid white triangle:** The material is not only hot, but is applied to the currently selected object.

If you drag to copy a material from a hot slot to another slot, the destination slot is cool, and the original slot remains hot.

**See also**

- Sample Slot Right-Click Menu (page 2–1422)
- Dragging and Dropping Maps and Materials (page 2–1423)
- Creating a Custom Sample Object (page 2–1425)

**Procedures**

**To use a sample slot:**

- Click the sample slot to make it active. The active sample slot is displayed with a white border around it.

  The sample slot shows a sample object shaded with a material. (By default, the sample object is a sphere.) The sample object is lit by a light source above it and slightly toward the viewer. For the sphere, the highlight is in the upper-left quadrant. The diffuse color shows most clearly above and to the left of the highlight, shading toward the ambient color at the sphere’s lower right.

**To change the preview shape:**

1. Make sure the sample slot of the material you want to view is active.

2. Use the *Sample Type* flyout (page 2–1432) to choose the shape you want to view. The flyout gives you three options: sphere (the default), cylinder, or box.

   The new shape is displayed in the sample slot, with the material mapped to it.

**To render the current mapping level:**

1. Move to the level of the map hierarchy that you want to render.
2. Right-click in the sample slot, and choose Render Map from the pop-up menu.

   The Render Map dialog (page 2–1455) is displayed.

3. Choose Single or the range of frames you want to render.

4. In the Dimensions group box, specify the pixel resolution of the map.

5. Click the Files button, and specify a path and file name for the file. Make sure Save To File is on unless you want to see the image only in a rendered frame window (page 3–5).

6. Click Render.

   A rendered frame window appears displaying the map. If Save To File is on, the image is also saved to disk.

---

**Sample Slot Right-Click Menu**

When you right-click the active sample slot, a pop-up menu is displayed. For other sample slots, click or right-click once to select them, then right-click to use the pop-up menu.

The pop-up menu is available in magnified sample slot windows. See the "Magnify" option, below.

**Interface**

- Drag/Copy
- Drag/Flatten
- Reset Rotation
- Render Map
- Options
- Magnify

- 3 X 2 Sample Windows
- 5 X 3 Sample Windows
- 6 X 4 Sample Windows

---

The pop-up menu has these options:

**Drag/Copy**—Sets dragging a sample slot to copy mode. When on, dragging a sample slot copies the material from one sample slot to another, or from the sample slot to an object in the scene or a material button.

**Drag/Rotate**—Sets dragging a sample slot to rotate mode. When on, dragging in the sample slot rotates the sample object. This helps you preview the material. Drag over the object to rotate it about its X or Y axis; drag in the corners of the sample slot to rotate the object about its Z axis. In addition, if you press [Shift] before dragging in the center, the rotation is constrained to the vertical or horizontal axis, depending on your initial drag direction.

If you have a three-button mouse and are using Windows NT, the middle mouse button rotates the sample object while Drag/Copy mode is active.

**Reset Rotation**—Resets the sample object to its default orientation.

**Render Map**—Renders the current map, creating a bitmap or an AVI file (if the map is animated). Only the current map level renders. That is, the rendering shows the image displayed when Show End Result is turned off.

If you’re at a material level instead of a map level, this menu item is disabled.

**Options**—Displays the Material Editor Options dialog (page 2–1436). This is an alternative to clicking the Options button.

**Magnify**—Generates a magnified view of the current sample slot. The magnified sample is displayed in its own, floating (modeless) window. You can display up to 24 magnified windows, but you can’t display the same sample slot in more than one magnified window at a time. You can resize magnify windows. Clicking a magnify window activates the sample slot, and vice versa.
Dragging and Dropping Maps and Materials

**Shortcut**—Double-click a sample slot to display the magnified window.

The magnify window’s title bar displays the contents of the editable *material name field* (page 2–1448). It varies depending on which level of the material is active.

**Auto**—Turn off to prevent the magnified window from updating automatically. This can save rendering time, especially when you have resized the magnified window to make it larger. Default=on.

**Update**—Click to update the magnified window. This button is unavailable unless Auto is turned off.

Dragging a different sample slot to the magnify window changes the contents of the magnify window.

**Sample Windows options**

The Material Editor always has 24 sample slots available. You can choose to display fewer sample slots at a larger size. When you do, scroll bars let you move around among the sample slots.

**3 X 2 Sample Windows**—Displays a 3 x 2 array of sample slots. (The default: 6 windows.)

**5 X 3 Sample Windows**—Displays a 5 X 3 array of sample slots. (15 windows.)

**6 X 4 Sample Windows**—Displays a 6 X 4 array of sample slots. (24 windows.)

---

**Dragging and Dropping Maps and Materials**

You can move materials from sample slots to objects using a drag-and-drop operation. You can also drag to and from map and material buttons. See the following lists to determine where in the interface you can drag from and drag to.

When dragging materials, use the *Undo command* (page 1–94) to cancel material assignments.

**Where You Can Drag From**

- **Sample Slots** (page 2–1420)
  The content you drag from a sample slot is always at the top level of the sample slot, regardless of which level is currently displayed. If the sample slot contains a material, you can’t drag from the sample slot to a map button, even if you’re at the map level of the material.
- **The Material Editor Type button** (page 2–1449)
- **Material/Map Browser** (page 2–1412) lists (text or icon lists)
  You can’t drag from the modal version of the Browser (when OK and Cancel buttons are present).
- **The sample slot in the Browser**
- **Material map buttons**
- **A projector light map button** (see *Advanced Effects Rollout* (page 2–1341))
- **The Environment Background** (page 3–272) map button
- **Fog** (page 3–282) Color and Opacity map buttons
- **Displace modifier** (page 1–629) map buttons
Material Map Buttons

The material map buttons you can drag from include:

- The buttons in the Maps rollout (page 2–1474)
- The small shortcut map buttons on the Basic Parameters rollouts (page 2–1470).
- Any map buttons at any level.
- Sub-material buttons, such as those found in the Multi/Sub-Object material (page 2–1594).

Where You Can Drag To

- Objects in viewports.
  Drag from a material button, sample slot, or Browser listing into the viewport and over an object. When you release the mouse, the material is applied.
  If you drag a material over two or more selected objects, an alert message asks if you want to apply the material to the object or to the selection. Choose the option you want, and click OK.
- The Material Editor Type button (page 2–1449).
  You can drag to the Type button only from the Browser. If the Type button shows a standalone map, you can drag only a map to it. If it shows a material type, you can drag only a material to it.
- All of the items in the previous list, except that you can drag to the Browser only when it displays a material library.
  When the Browser is set to browse from a Material Library, dragging materials and maps into the Browser adds them to the library.
- A Face, Polygon, Patch, or Element sub-object selection of an editable surfacemesh object (mesh, patch, or poly).
- A Face, Polygon, Patch, or Element sub-object selection created by the Edit Mesh modifier (page 1–634) or Edit Patch (page 1–638); or by one of these selection modifiers: Mesh Select (page 1–719), Patch Select (page 1–751), or Poly Select (page 1–762).

See also

Applying a Material to an Object (page 2–1405)
Drag and Drop Sub-Object Material Assignment (page 2–1424)

Drag and Drop Sub-Object Material Assignment

You can apply a material to a selection of renderable sub-objects, such as faces in a mesh. In the Material Editor, you can use Assign Material to Selection (page 2–1441). You can also drag the material from the Material Editor or the Material/Map Browser (page 2–1412) to the selected faces. This can create a new Multi/Sub-Object material (page 2–1594) on the fly.

You can disable drag-and-drop of materials to sub-objects. To do so, go to the General tab (page 3–815) of the Preferences dialog (page 3–815), and in the Sub-Materials group, turn off Assign Automatically. This check box is on by default.

Procedure

To drag materials onto sub-object selections:

1. In the Modify panel > Modifier Stack rollout, choose Face as the sub-object level.
2. Select faces of an editable mesh object.
3. Drag a material from a Material Editor sample slot to the selected faces.
4. In the Modifier Stack rollout, click to turn off Sub-Object and return to the object level.
5. On the Material Editor, click Pick Material From Object, then use the eyedropper to get the material from the sphere.
The new Multi/Sub-Object material appears in the active sample slot.

**How the Multi/Sub-Object Material Is Created**

The Multi/Sub-Object material is created in one of three ways, depending on what material is already applied to the selected sub-objects:

- **No material applied**
  If the selected faces have no material applied, a new Multi/Sub-Object material is created. The dragged material becomes a sub-material in the new material. If material IDs already exist, they are preserved.

- **Existing material applied (other than Multi/Sub-Object material)**
  A new Multi/Sub-Object material is created and applied to the selected faces. The existing material is moved into the Multi/Sub-Object material and becomes the first sub-material. Unselected faces get material ID #1, the selected faces get material ID #2, and the dragged material becomes part of the Multi/Sub-Object material. Existing material IDs are not preserved.

- **Multi/sub-object material applied**
  If the existing Multi/Sub-Object material is already applied more than once in the scene, the material is copied and the new copy is applied to the selected faces.
  If the Multi/Sub-Object material is only applied once in the scene, then the existing material is used. The dragged material is added to the existing Multi/Sub-Object material.
  If the dragged material already is a part of the Multi/Sub-Object material, then the selected faces receive the corresponding material ID number. If the selected faces all have the same material ID number, and no unselected faces are already using this number, then this number is used and the new material replaces the old sub-material at this ID. Otherwise, a new material ID number is assigned to the faces, and used for the dragged material. In this case, any existing material IDs are preserved.

**Creating a Custom Sample Object**

Material Editor > Right-click the active sample slot. > Right-click menu > Options > Material Editor Options dialog

Material Editor > Material Editor Options > Material Editor Options dialog

Custom sample object fits within a 100-unit cube

By default, the sample object in a sample slot is a sphere. You can use the Sample Type flyout (page 2–1432) to change this to a cube or a cylinder. You can also create a custom sample object by creating a 3ds Max scene that shows the object.

**Overview of Using a Custom Sample Object**

See Procedures for more details.

The scene you create should contain a single object that fits into an imaginary cube that is 100 units on each side. The object must be at the root level of the scene: it can’t be linked to other objects. If more than one object is in the scene, only the first...
object listed in the Track View hierarchy is used as the sample object.

If the object is of a type that doesn’t have a Generate Mapping Coords check box, apply a UVW Map modifier (page 1–922) to it.

After you have saved the single-object scene as a .max file, use the Custom Sample Object group in the Material Editor Options dialog (page 2–1436) to specify the file. When you specify the file, a new button is displayed at the right of the Sample Type flyout. This button, which shows an object with a question mark, displays the sample object file you chose.

If the sample object scene contains only the object, sample slots display it with default lighting. If the scene also contains a camera and lights, you can use the camera to specify the view, and the lights to light the object as you choose. Turn on Load Camera and/or Lights in the Custom Sample Object group.

Procedures

To set up a custom sample object:

1. Create a scene with a single object, such as a pyramid.

   The object should fit into an imaginary cube that is 100 units on each side. Also, the object must be at the root level of the scene: it can’t be linked to other objects.

   If more than one object is in the scene, the Material Editor uses the first object listed in the Track View hierarchy.

2. If the object does not have built-in mapping coordinates (via a Generate Mapping Coords check box), then assign a UVW Map modifier to it to provide mapping coordinates.

   If the object has a Generate Mapping Coords check box, it’s on by default, and the Material Editor uses those coordinates. If you want to use coordinates other than those built into the object, assign a UVW Map modifier (page 1–922) and set up your own coordinates.

3. Save the .max file.

4. In the Material Editor Options dialog, click the File Name button in the Custom Sample Object group box, and choose the .max file that contains your object.

5. Activate the sample slot in which you want to see the custom object, then choose the button at the far right of the Sample Type flyout.

   Your custom object is displayed in the sample slot.

   If the size of your object is not quite right for the sample slot, adjust its size and save the scene again. To update the sample slot so it uses the newly saved .max file, open the Material Editor Options dialog, and then click OK.

To use a camera and lights with the custom sample object:

1. Create a camera in the scene that contains your sample object, and then adjust the camera to show the object as you want it seen in sample slots.

   Tip: Viewports have a different aspect ratio than sample slots, so using Zoom Extents (page 3–740) on the sample object usually results in the object appearing smaller in a sample slot. Do Zoom Extents on the object, and then before you save the file, zoom in a little farther so the object more than fills the viewport. The sample slot projection is based on the width of the sample object’s geometry, not on the image in the viewport.

   If more than one camera is in the scene, the Material Editor uses the first camera listed in the Track View hierarchy.

2. If you want to use your own lighting rather than the default sample-slot lighting, set up as many lights as you need. If you want to use the
sample-slot lighting, do not add any lights to the scene.

3. Save the .max file.

4. In the Material Editor Options dialog, specify the file as the Custom Sample Object file.

5. Turn on Load Camera and/or Lights.
   Sample Slots set to use the custom object now display the object as seen through the camera. If lights are in the scene, those lights are used in the sample slot instead of the default lights.

---

**Material Editor Tools**

Main toolbar > Material Editor

---

Note: These fields are not displayed unless you change a toggle in Preferences > Advanced Lighting.

**Buttons below the sample slots (the "toolbar")**

- Get Material (page 2–1439)
- Put Material to Scene (page 2–1440)
- Assign Material to Selection (page 2–1441)
- Reset Map/Mtl to Default Settings (page 2–1442)
- Make Material Copy (page 2–1442)
- Make Unique (page 2–1442)
- Put to Library (page 2–1443)
- Material Effects Channel (page 2–1443)
- Show Map in Viewport (page 2–1445)
- Show End Result (page 2–1446)
- Go to Parent (page 2–1446)
- Go Forward to Sibling (page 2–1447)

**Buttons to the right of the sample slots**

- Sample Type (page 2–1432)
- Backlight (page 2–1432)
- Pattern Background (page 2–1433)
- Sample UV Tiling (page 2–1433)

---

Above the sample slots (page 2–1420) is the menu bar. Below and to the right of the Material Editor sample slots are buttons and other controls that you use to manage and change maps and materials.

*Material Editor Menu Bar (page 2–1428)*

*Reflectance and Transmittance Display (page 2–1430)*
Video Color Check (page 2–1434)

Make Preview, Play Preview, Save Preview (page 2–1434)

Material Editor Options (page 2–1436)

Select By Material (page 2–1439)

Material/Map Navigator (page 2–1447)

Controls below the toolbar

Pick Material from Object (page 2–1448)

Material name field (page 2–1448)

Material Type button (page 2–1449)

Procedures

To use the Material Editor Options dialog:

1. Click Options (page 2–1436) to the right of the sample slots.
2. Set the options as you want, and then click OK.

To change the preview shape:

1. Activate the sample slot of the material you want to view.
2. Use the Sample Type flyout (page 2–1432) to choose the shape you want to view.
   The new shape is displayed in the sample slot, with the material mapped to it.
   The flyout gives you three options: sphere (the default), cylinder, or box. An additional custom object option is available if you define a custom object as described in Creating a Custom Sample Object (page 2–1425).

Material Editor Menu Bar

Material Editor > Menu bar

The Material Editor menu bar appears at the top of the Material Editor window. It provides another way to invoke the various Material Editor tools.

Material Menu

The Material menu provides the most commonly used Material Editor tools.

- Get Material (page 2–1439)
- Pick from Object (page 2–1448)
- Assign to Selection (page 2–1441)
- Put to Scene (page 2–1440)
- Put to Library (page 2–1443)
- Change Material/Map Type—Equivalent to clicking the Material Type Button (page 2–1449).
- Make Material Copy (page 2–1442)
- Launch Magnify Window—Equivalent to double-clicking the active sample slot (page 2–1420), or choosing Magnify on its right-click menu (page 2–1422).
- Make Preview (page 2–1434)
- View Preview (page 2–1434)
- Save Preview (page 2–1434)
- Show End Result (page 2–1446)
- Show Map in Viewport (page 2–1445)
- Activate All Maps—Turns on Show Map in Viewport (page 2–1445) for every material used in the scene.
- Deactivate All Maps—Turns off Show Map in Viewport (page 2–1445) for every material used in the scene.
- Reset Sample Slot Rotation—Returns the active sample slot’s object to its default orientation;
equivalent to choosing Reset Rotation on the sample slot right-click menu (page 2–1422).

- **Update Active Material**—If Material Editor Options dialog (page 2–1436) > Update Active Only is on, choosing this updates the active material in its sample slot.

**Navigation Menu**
The Navigation menu provides tools that navigate a material’s hierarchy.
- **Go to Parent** (page 2–1446)
- **Go Forward to Sibling** (page 2–1447)
- **Go Backward to Sibling**—Like Go Forward To Sibling, but navigates to the preceding sibling map in the tree, instead of the succeeding one.

**Options Menu**
The Options menu provides some additional tools and display choices.
- **Propagate Materials to Instances** (page 2–1432)
- **Manual Update Toggle**—Equivalent to the Manual Update toggle in the Material Editor Options dialog (page 2–1436).
- **Copy/Rotate Drag Mode Toggle**—Equivalent to choosing either Drag/Copy or Drag/Rotate on the sample slot right-click menu (page 2–1422).
- **Background** (page 2–1433)
- **Custom Background Toggle**—If you have used the Material Editor Options dialog (page 2–1436) to assign a custom background, this toggles its display.
- **Backlight** (page 2–1432)
- **Cycle 3X2, 5X3, 6X4 Sample Slots**—Cycles through the equivalent choices on the sample slot right-click menu (page 2–1422).
- **Options**—Opens the Material Editor Options dialog (page 2–1436).

**Utilities Menu**
The Utilities menu provides map rendering and selecting objects by material.
- **Render Map**—Equivalent to choosing Render Map on the sample slot right-click menu (page 2–1422).
- **Select Objects by Material** (page 2–1439)
- **Clean MultiMaterial** (page 2–1742)
- **Instance Duplicate Map** (page 2–1744)
- **Reset Material Editor Slots**—Replaces all materials in the Material Editor with the default material type. This action is not undoable, but you can restore the previous state of the Material Editor with the Restore Material Editor Slots command (see below).
- **Condense Material Editor Slots**—Sets all unused materials in the Material Editor to the default type, retaining only materials in the scene and moving those materials to the first slots in the editor. This action is not undoable, but you can restore the previous state of the Material Editor with the Restore Material Editor Slots command (see below).
- **Restore Material Editor Slots**—When you use either of the two previous commands, 3ds Max saves the current state of the Material Editor in a buffer; using this command restores the state of the editor using the buffer contents.

**Tip:** The buffer that holds the material definitions survives the File menu > Reset command. Thus, if you use either the Reset Material Editor Slots or the Condense Material Editor Slots function, and then reset 3ds Max, you can then use Restore Material Editor Slots to bring all materials back into the Material Editor. This makes it easy to use the same materials in different projects.

For best results, follow this procedure:
1. Save your scene.
2. Use the Reset Material Editor Slots or Condense Material Editor Slots function.

3. Reset 3ds Max. When prompted to save the scene, click No. Otherwise, you might lose material definitions in the Material Editor that were saved with the scene.

4. Open the Material Editor and choose Utilities menu > Restore Material Editor Slots.
   The Material Editor status before step 2 is restored.

Reflectance and Transmittance Display

Material Editor > Reflectance and Transmittance fields (below the sample slots)

These fields show the reflectance and transmittance of the active material. Both the average value and the maximum value are shown.

Note: These fields are not displayed unless you turn on Display Reflectance & Transmittance Information in the Advanced Lighting panel (page 3–836) of the Preferences dialog.

<table>
<thead>
<tr>
<th>Reflectance</th>
<th></th>
<th>Transmittance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Avg: 67%</td>
<td>Max: 67%</td>
<td>Avg: 0%</td>
</tr>
</tbody>
</table>

These fields can change according to the current Show End Result setting (page 2–1446). When Show End Result is off, the reflectance and transmittance show the properties of the current element in the material hierarchy, not the properties of the material overall.

The reflectance and transmittance values of a material are particularly important when you are preparing a radiosity solution (page 3–51) to obtain a physically accurate lighting simulation. If a material’s reflectance or transmittance values are not what your scene needs, you need to adjust these values.

Note:

Materials and Radiosity

Upper left: Washed-out walls due to high reflectance.
Right: Better radiosity achieved by reducing the HSV Value (V) of materials in the scene.

To get good radiosity results, keep these points in mind as you design materials:

• Before you generate a radiosity solution, check the reflectance value of all materials in the scene, to make sure it is not too high. The reflectance of a material determines how much of the light energy it receives is subsequently used in the radiosity calculation. Keep this value within the range of the physical materials you are simulating. (See the table in the description of “Reflectance,” below.)

• Don’t be concerned if a material preview seems too dark. For example, a white wall with the maximum recommended reflectance of 80% appears gray. The color balance will be adjusted correctly by the exposure control (page 3–293) in the final rendering.

• Bitmaps used as diffuse textures have already been illuminated by the scanner, digital camera, or paint program in which you created them. To bring them into the proper reflectance range, you might have to dim them by reducing the
RGB Level value in the bitmap’s Output rollout (page 2–1621).

Left: Wood grain bitmap as originally photographed has too high a reflectance.
Right: Reducing the RGB Level value reduces the map’s reflectance.

**Interface**

**Reflectance**—Reflectance is the percentage of diffuse light energy that is reflected from a material. When you increase a material’s HSV value (V), the material reflects more diffuse light. Decreasing a material’s Opacity also decreases its reflectance.

Typically, the reflectance of a material should never be greater than 85%. This is an unusually high value that will lead to poor-quality renderings. In the real world, even the whitest wall reflects no more than 80% of the light it receives.

One source of high reflectance can be a map assigned to the material’s diffuse component. For example, a white tile bitmap might create high reflectance. In this case, you can reduce reflectance by reducing the RGB Level in the bitmap’s Output rollout.

An alternate way to reduce a bitmapped material’s reflectance is to set the diffuse color of the material to black, and then reduce the diffuse map’s Amount (in the parent material’s Maps rollout (page 2–1474)). You can use this method to reduce the reflectance of 3D procedural maps (page 2–1662) as well.

Here are some typical reflectance ranges for common materials:

<table>
<thead>
<tr>
<th>Material</th>
<th>Minimum</th>
<th>Maximum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ceramic</td>
<td>20%</td>
<td>70%</td>
</tr>
<tr>
<td>Fabric</td>
<td>20%</td>
<td>70%</td>
</tr>
<tr>
<td>Masonry</td>
<td>20%</td>
<td>50%</td>
</tr>
<tr>
<td>Metal</td>
<td>30%</td>
<td>90%</td>
</tr>
<tr>
<td>Paint</td>
<td>30%</td>
<td>80%</td>
</tr>
<tr>
<td>Paper</td>
<td>30%</td>
<td>70%</td>
</tr>
<tr>
<td>Plastic</td>
<td>20%</td>
<td>80%</td>
</tr>
<tr>
<td>Stone</td>
<td>20%</td>
<td>70%</td>
</tr>
<tr>
<td>Wood</td>
<td>20%</td>
<td>50%</td>
</tr>
</tbody>
</table>

**Transmittance**—Transmittance is the amount of light energy transmitted through a material. A completely opaque material has 0% transmittance.

When the material is transparent (like clear glass), the energy transmitted is specular, and light passes directly through the material (subject to refraction). The value of specular transmittance is an interaction between the material’s Opacity value (page 2–1488) and its filter color (page 3–939). When the filter color is pure white, specular transmittance is the inverse of Opacity.

When the material is translucent (like frosted glass), the energy transmitted is diffuse, and scattered in all directions. The value of diffuse transmittance is based on the HSV value (V) of the translucent color (page 2–1491). Diffuse transmittance happens only for materials that use the Translucent shader (page 2–1484), or Raytrace materials (page 2–1512), that specify translucency.

Usually, when a material has high transmittance, it has low reflectance, and the other way around.
Chapter 16: Material Editor, Materials, and Maps

Sample Type

Material Editor > Sample Type

The Sample Type flyout lets you choose which geometry to display in the active sample slot (page 2–1420). This flyout has three buttons:

- **Sphere (the default)**—Displays the material on a sphere.
- **Cylinder**—Displays the material on a cylinder.
- **Cube**—Displays the material on a cube.
- **Custom**—Displays the material on a custom object. This button appears only if you have used the Material Editor Options dialog (page 2–1436) to specify a custom object for sample slots.

See also

Creating a Custom Sample Object (page 2–1425)

Propagate Materials to Instances

Material Editor > Options menu > Propagate Materials to Instances

When Propagate Materials To Instances is on, any material assignment you make will be propagated to all instances (page 3–957) of the object in your scene, including imported AutoCAD blocks and ADT style-based objects; these object types are common in DRF files (page 3–527). Assignments are also propagated to instances of Revit objects and of other instances that you’ve made in the current scene.

When Propagate Materials To Instances is off, materials are assigned in traditional 3ds Max fashion; each object has a unique material assignment.

Backlight

Material Editor > Backlight

Material Editor menu > Options menu > Backlight

Turning on Backlight adds a backlight to the active sample slot. This button is on by default.

The effect is most easily seen with the sample spheres, where the backlight highlights the lower-right edge of the sphere.

Backlight is especially useful whenever you’re creating metal (page 2–1481) and Strauss (page 2–1483) materials. Backlight lets you see and adjust the specular highlight created by glancing light, which is much brighter on metals.
Sample Slot Background

Turning on Background adds a multicolored checkered background to the active sample slot. The pattern background is helpful when you want to see effects of opacity and transparency.

The Material Editor Options dialog (page 2–1436) also lets you assign a bitmap to use as a custom background.

Sample UV Tiling

The buttons on the Sample UV Tiling flyout adjust the repetition of the map (page 3–968) pattern on the sample object in the active sample slot. The tiling pattern you set with this option affects only the sample slot. It has no effect on the tiling on the geometry in the scene, which you control with parameters in the map’s own coordinates rollout.

- **1 x 1 (the default)**—Tile once in the U dimension and once in V. This is equivalent to no tiling at all.
- **2 x 2**—Tile twice in U and twice in V.
- **3 x 3**—Tile three times in U and three times in V.
- **4 x 4**—Tile four times in U and four times in V.

The buttons specify the number of times the pattern repeats over the surface of the sample object. Because maps are mapped spherically around the sample sphere, the tiling (page 3–1022) repetition covers the entire surface of the sphere. The sample cylinder maps cylindrically. The sample cube uses box mapping: the tiling appears on each side of the cube. Custom sample objects use the default mapping coordinates for that kind of object, unless the object has a UVW Map modifier (page 1–922) applied to it, in which case the modifier controls the mapping.

This flyout is unavailable when the sample slot displays a standalone (top-level) map.

Creating a Custom Sample Object (page 2–1425)
Chapter 16: Material Editor, Materials, and Maps

Video Color Check

Material Editor > Video Color Check

1. Material with oversaturated colors
2. Video color check shows black areas that are beyond the video threshold

Video Color Check checks the material on the sample object for colors that are beyond the safe NTSC (page 3–980) or PAL (page 3–988) threshold.

Such colors tend to blur or fuzz when transferred from computer to video. Pixels containing these "illegal" or "hot" colors are flagged on the sample object.

You can have 3ds Max correct illegal colors automatically when you render, depending on the settings in the Rendering tab (page 3–826) of the Customize/Preferences dialog (page 3–815).

Use this option as a guide only. The colors in a rendered scene depend not only on the material color but also on the intensity and color of the lighting. A material that shows as safe in the sample slot might become illegal if rendered under several bright lights. A safe practice for video is to use colors whose saturation is less than 80 to 85 percent.

Procedures

To check for illegal video colors:

1. On the Material Editor, turn on Video Color Check (page 2–1434).
   
   The active sample slot now renders "illegal" pixels as black. Illegal pixels have a color that is beyond the safe video threshold.
   
   If Video Color Check detects illegal colors, try reducing the saturation of the material colors in question.

2. You can also check for legal video colors when you render a scene.

To change the video system:

NTSC (page 3–980) is the default video system to check. You can change the video checking to PAL (page 3–988).

- In the Tools menu > Options > Options dialog > Rendering panel (page 3–826) > Video Color Check group, change the setting to PAL.

   The sample slot does not automatically update when you change the video system preference. Turn video checking off and back on to see the change.

   Note: The Rendering panel also shows options for choosing alternate ways to display illegal pixels. These apply to renderings only, not to the sample slots in the Material Editor.

Make Preview, Play Preview, Save Preview

Material Editor > Make/Play/Save Preview flyout

Material Editor menu > Material menu > Make Preview, View Preview, or Save Preview

You can use animated maps to add movement to a scene. For example, to simulate a sky view,
you could map an animation of moving clouds to a clerestory window. The Make Preview options let you experiment with the effect in the Material Editor before you apply it to your scene.

The buttons on the Make Preview, Play Preview, Save Preview flyout let you preview the effect of an animated map on the object in a sample slot (see Sample Type (page 2–1432) for alternatives to the default sphere.) You can use an AVI file (page 3–609), or IFL file (page 3–616) as a source for the animation. The finished preview is saved as a new AVI file and automatically played back. You can also view the preview in a sample slot by dragging the time slider.

This flyout has three options:

- **Make Preview**—Displays a Create Material Preview dialog (page 2–1452) to create an AVI file of the animated material.

  When the preview is complete, it is saved as _medit.avi_ in the \previews subdirectory. The file is then opened in the Windows Media Player and played back.

  Without this option, the only other way to preview a complex animated material in real time is to use the renderer (page 3–27) to render an animated sequence and save it to an AVI file, a digital disk recorder, or a video tape recorder.

- **Play Preview**—Uses the Windows Media Player to play the current _medit.avi_ preview file in the \previews subdirectory.

- **Save Preview**—Saves the _medit.avi_ preview to an AVI file of a different name in the \previews subdirectory.

**Procedures**

**To create a preview of an animated material:**

1. Choose Make Preview from the flyout.

2. In the Create Material Preview dialog, set the preview conditions you want, and then click OK.

   The preview is created, and then plays.

**To play back a preview of an animated material:**

- Choose Play Preview from the flyout.

   The Material Editor starts the Windows Media Player. The Player then loads the current _medit.avi_ preview file in the \previews subdirectory and plays it in a separate window.

**To view an animated material in a sample slot:**

- Drag the time slider through the range of frames.

   By default, all sample slots with animated maps update at the same time. To change this, see Material Editor Options Dialog (page 2–1436).

**To save a preview under a different name:**

1. Choose Save Preview from the flyout.

   The Material Editor displays a File Save dialog.

2. Enter a new name for the preview, and then click OK to save the file in the \previews subdirectory.

**To play a renamed preview:**

1. Choose Tools menu > Display Image.

2. In the View File dialog, change to the \previews subdirectory.

3. Select the renamed preview file and click Open.

   The preview is played in a separate window.
Material Editor Options

This button displays the Material Editor Options dialog to let you control how materials and maps are displayed in the sample slots (page 2–1420).

These settings are “sticky”; they survive a reset, and even quitting and restarting 3ds Max.

Note: The controls to assign a renderer for the sample slots are on the Assign Renderer rollout (page 3–35).

Interface

<table>
<thead>
<tr>
<th>Manual Update</th>
<th>Don’t Animate</th>
<th>Animate Active Only</th>
<th>Update Active Only</th>
<th>Anti-alias</th>
<th>Progressive refinement</th>
<th>Simple Multi Display Below Top Level</th>
<th>Display Maps as 2D</th>
<th>Custom Background</th>
<th>Display Multi/Sub-object Material Propagation Warning</th>
<th>Auto-Select Texture Map Size</th>
<th>Use Real-World Map Scale for Geometry Sampling</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **Manual Update**—When on, the sample slots don’t update their contents until you click them. This option affects only the updating of the sample slots; it doesn’t affect the icon displays in the Browser. Default=off.

- **Don’t Animate**—When on, animated maps are not updated in the sample slots while you play an animation or drag the time slider. However, the animation is updated to the current frame when you stop the animation or release the time slider. An animated map can use an AVI file (page 3–609) or IFL file (page 3–616) as a source. Default=off.

- **Animate Active Only**—When on, only the active sample slot is animated when you play an animation or drag the time slider. This option is good for situations where you have multiple animated materials in the Material Editor, but you only need to see one at a time. This check box is unavailable when Don’t Animate is on. Default=off.

- **Update Active Only**—When on, sample slots do not load or generate maps until you make one sample slot active. This can save time while you use the Material Editor, especially when your scene uses a lot of materials with maps. Default=off.

- **Anti-alias**—Turns on antialiasing (page 3–907) in the sample slots. Default=off.

  If the mental ray renderer is used to render sample slots, this setting is disregarded. The mental ray renderer’s sampling values control antialiasing.

- **Progressive Refinement**—Turns on progressive refinement in the sample slots. When on, samples are rendered quickly, with large pixels, then rendered a second time in greater detail. Default=off.

- **Simple Multi Display Below Top Level**—When on, the sample sphere for a Multi/Sub-Object material displays the multiple patches only at the top level of the material. The sub-materials are displayed over the entire sphere. When you use nested
Multi/Sub-Object materials, the multiple patches again appear at the top level of the nested material, but the sample sphere is again whole when displaying any of the sub-materials. Default=on.

Display Maps as 2D—When on, sample slots display maps, including standalone maps, in 2D. The map fills the entire slot. When off, maps are displayed on the sample object, as materials are. Default=on.

Custom Background—Lets you specify a custom background for the sample slots, instead of the default checkers background. Click the file-assignment button to display a file dialog from which you can select the custom background. This can be any bitmap format supported by 3ds Max. Turn on Custom Background to use the new background instead of the checkered background. The custom background is stored in the 3dsmax.ini (page 1–18) file, so it is available from session to session. Default=off.

Display Multi/Sub-Object Material Propagation Warning—Toggles display of warning dialog when you apply a Multi/Sub-Object material (page 2–1594) to an instanced ADT style-based object.

Auto-Select Texture Map Size—When on, and you have a material that uses a texture map set to Use Real-World Scale, ensures that the map will be displayed correctly on the sample sphere. Turn off to be able to enable Use Real-World Map Size For Geometry Samples (see following).

Note: If a material uses several texture maps at different levels, and only one is set to Use Real-World Scale, the sample sphere will render with real-world size coordinates.

Use Real-World Map Size For Geometry Samples—This is a global setting that allows you to manually choose which style of texture coordinates are used. When on, real-world coordinates are used for the sample slot display. Otherwise, the old style of 3ds Max mapping coordinates is active. When off, you must turn on Use Real-World Scale on the map’s Coordinates rollout to see the sample sphere as you’d expect. Available only when Auto-Select Texture Map Size (above) is off. Default=off.

Top Light color/Back Light color—Specify the two lights used in the sample slots. Click the color swatch to alter the color of either light. Adjust the Multiplier spinners to multiply the values (intensity) of the lights.

Use the Default buttons to return to the initial settings.

Ambient Light—Shows the color of ambient light (page 3–908) used in the sample slots. Click the color swatch to change the color. When the lock button is on, changing the Ambient Light color here or on the Environment panel (page 3–272) changes both; when off, changing one setting does not affect the other.

Use the Default button to return to the initial setting.

Background Intensity—Sets the background intensity in the sample slots. The range is from 0 (black) to 1 (white). Default=0.2.

Use the Default button to return to the initial setting.

Render Sample Size—Sets the scale of the sample sphere to any size, making it consistent with the object or objects in the scene that have the texture on them. This setting affects how 2D and 3D maps are displayed providing that the sample spheres are set to display real-world scale.

Note: The size is scaled to use the current units.

This is a global option that affects all the sample slots. Default=100.0 (Imperial units) and 2.54m (Metric units).
Use the Default button to return to the initial setting.

Default Texture Size—Controls the initial size (both height and width) of a newly created real-world texture. You see the result of changing this option only when you create a new texture in a material; the change appears in the Coordinates rollout (page 2–1625). Default=48.0 (Imperial units) and 1.219m (Metric units).

Note: This setting applies to real-world textures only. For the default size to be applied to newly created textures, the Preferences dialog > General panel > Use Real-World Texture Coordinates check box must be on.

Use the Default button to return to the initial setting.

DirectX Shader group
These options affect the viewport behavior of the DirectX 9 Shader material (page 2–1613).

Force Software Rendering—When on, forces DirectX 9 Shader materials to use the selected software render style for viewports. When off, the FX file specified in the DirectX 9 Shader is used unless the material’s local Force Software Rendering toggle is on. Default=off.

Shade Selected—When Force Software Rendering is on, selected objects, and only selected objects, are shaded by the DirectX 9 Shader material. This toggle is unavailable unless Force Software Rendering is on. Default=off.

Custom Sample Object group
Controls in this group let you specify a custom sample object (page 2–1425) to use in the sample slots (page 2–1420).

File Name—Selects the MAX scene file. The scene should contain a single unlinked object that fits in an imaginary cube 100 units on a side. The object must be either a primitive with a Generate Mapping Coords. check box, or have a UVW Map modifier (page 1–922) applied to it. The scene can contain a camera and lights.

Load Camera and/or Lights—Turn on to have sample slots use the camera and lights in the scene, instead of the default sample slot lighting.

Slots group
These options let you choose how many sample slots to display at a time.

The Material Editor always has 24 sample slots available. You can choose to display fewer sample slots at a larger size. When you do, scroll bars let you move around among the sample slots.

3 X 2—Specifies a 3 x 2 array of sample slots. (The default: 6 windows.)

5 X 3—Specifies a 5 X 3 array of sample slots. (15 windows.)

6 X 4—Specifies a 6 X 4 array of sample slots. (24 windows.)

Apply—Applies the current settings, except for changes to the Slots group, without leaving the Material Editor Options dialog. This is useful when you adjust lighting values for the sample slots.

OK—Closes the dialog and applies any changes you made.

Cancel—Closes the dialog and cancels any changes you made, including changes you applied with the Apply button.
Select By Material

Select By Material allows you to select objects in the scene, based on the active material in the Material Editor. This button is unavailable unless the active sample slot contains a material used in the scene.

Clicking this button displays a Select Objects dialog (page 1–78). All objects that have the selected material applied to them are highlighted in the list.

Note: Hidden objects don’t appear in this list, even if the material is applied to them. However, in the Material/Map Browser (page 2–1412), you can choose Browse From: Scene, turn on By Object, and then browse from the scene. This lists all objects in the scene, hidden or unhidden, along with their assigned materials.

Procedure

To select objects that have the same material applied:

1. Click a sample slot that contains a material in the scene.
   White corner brackets indicate materials that are in the scene.

2. Click Select By Material (page 2–1439) in the Material Editor.
   A Select Objects dialog (page 1–78) is displayed.
   The names of objects with the active material applied are highlighted.

3. Click Select to select objects with the active material applied.

You can also change the selection by choosing other objects. If you change the selection, you must then click Assign Material To Selection (page 2–1441) to apply the active material to newly selected objects.

Get Material

Get Material displays the Material/Map Browser (page 2–1412) to allow you to choose a material (page 3–971) or map (page 3–968).

Procedures

To get a material from a scene:

1. Click a sample slot to make it active.
   Be careful not to click the sample slot of a material you want to use later.

   A modeless Material/Map Browser (page 2–1412) is displayed.

3. In the Browse From group box at the upper left, make sure that either Selected or Scene is chosen.
   The Selected option lists only materials in the current selection. If no objects are selected, the list of materials is blank.
   The Scene option lists all the materials currently in the scene.

4. In the list of materials, double-click the name of the material you want to get.
   You can also drag the material name to the sample slot.
The material you chose replaces the previous material in the active sample slot.

**Warning:** When you get a material from a scene, initially it is a **hot** material.

**To get a material from a library:**

1. On the Material Editor toolbar, click **Get Material**.
   A modeless **Material/Map Browser** is displayed.

2. In the Browse From group box at the upper left, make sure that Material Library is chosen.
   If you have opened a library, the list of materials shows the contents of the library.
   If you haven’t opened a library, click **Open** in the file area of the Browser. A file dialog is displayed. Choose a library. After you open the library, the list of materials updates to show the library contents.
   **Note:** **Open** also lets you get materials from a 3ds Max scene (a **.max** file).

3. In the list of materials, double-click the name of the material you want to get.
   You can also drag the name of the material to the sample slot.
   The material you chose replaces the previous material in the active sample slot.

**To create a standalone map tree:**

1. Activate a sample slot.

2. On the Material Editor toolbar, click **Get Material**.

3. In the **Material/Map Browser** (page 2–1412), make sure **Browse From** is set to **New**.

4. In the Show group box, turn off Materials so only maps are displayed in the list.

5. Double-click the name of the map type (not a material type) you want to use, or drag the map to a sample slot.
   The sample slot now contains a standalone map not associated with material parameters.

6. Use the Material Editor to modify the map as you would any other map.
   By default, the sample slots distinguish maps from materials by displaying maps as 2D surfaces without lighting or shading.

**To remove a material from an object:**

1. On the Material Editor toolbar, click **Get Material**.

2. Drag the entry **NONE** from the top of the list in the Browser to the object.
   The object now has no material applied to it.

---

**Put Material to Scene**

**Material Editor > Put Material to Scene**

**Material Editor menu > Material menu > Put to Scene**

Put Material To Scene updates a material in the scene after you edit the material. Put Material To Scene is available only when:

- The material in the active sample slot has the same name as a material in a scene.
- The material in the active sample slot is not hot.

In other words, this command is intended to fit into the overall sequence of handling materials:

- You create a hot material either by applying it to objects in the scene or by getting it from the scene.
- You make a copy of the material.
- You make changes to the copy of the material.
You update the scene by putting the changed material back into the scene.

Notes

- If you apply a mapped material to a parametric object whose Generate Mapping Coords option is off, the software automatically turns on mapping coordinates at render time. In addition, if you apply a mapped material with Show Map In Viewport active to an object, that object’s Generate Mapping Coords option is turned on if necessary.
- The Show Map In Viewport flag is now saved with individual materials, so when you drag mapped materials from the modeless Browser onto objects in your scene, the mapping appears in the viewports.

Procedure

To put a material back into a scene:

- On the Material Editor toolbar, click Put Material To Scene (page 2–1440).

The material in the active sample slot is now a hot material (page 3–953).

Assign Material to Selection applies the material in the active sample slot to the currently selected object or objects in the scene. At the same time, the sample slot becomes hot (page 3–953).

If you apply a mapped material with Show Map In Viewport active to a parametric object, that object’s Generate Mapping Coords option is turned on if necessary.

The Show Map In Viewport flag is saved with individual materials, so when you drag mapped materials from the modeless Browser onto objects in your scene, the mapping appears in the viewports.

The Undo command works for material assignment.

Procedure

To apply a material to objects in a scene:

1. Select the sample slot that contains the material you want to apply.
2. Select the objects you want to apply the material to.
3. Drag from the sample slot to the objects. If more than one object is selected, you are asked whether you want to apply to the single object or to the whole selection.

You can also apply materials by clicking Assign Material To Selection (page 2–1441) on the Material Editor toolbar.

Warning: When you apply a material to an object or selection, that material becomes a hot material (page 3–953). When you change the material’s properties, the scene immediately updates to reflect those changes. Any object with that material will change its appearance, not just the objects in the current selection. When a material is hot, its sample slot is displayed with white corner brackets.

To make a material no longer hot so it doesn’t change the current scene, click Make Material Copy (page 2–1442).
Reset Map/Mtl to Default Settings

Material Editor > Reset Map/Mtl to Default Settings

Reset Map/Mtl to Default Settings resets the values for the map or material in the active sample slot.

The material colors are removed and set to shades of gray. Glossiness, opacity, and so on are reset to their default values. Maps assigned to the material are removed.

If you are at a map level, this button resets the map to default values.

Reset changes the name (page 2–1448) only when this field names a material used in the scene.

Make Material Copy

Material Editor menu > Material menu > Make Material Copy

Make Material Copy "cools" (page 3–924) the current hot (page 3–953) sample slot by copying the material to itself.

The sample slot is no longer hot, but the material retains its properties and name. You can adjust the material without affecting it in the scene. Once you’ve got what you want, you can click Put Material to Scene (page 2–1440) to update the material in the scene and change the sample slot to hot again.

Make Unique (Material Editor)

Material Editor > Make Unique

Make Unique makes a map instance (page 3–957) into a unique copy. It also makes an instanced sub-material into a unique, standalone sub-material. It gives the sub-material a new material name. A sub-material is a material within a Multi/Sub-Object material (page 2–1594).

Using Make Unique prevents changes to the top-level material instance from affecting the sub-material instance within the Multi/Sub-Object material.

You can also use Make Unique at the map level, when a map is instanced to different components of the same material.

Note: If you drag an instanced map to a Material Editor sample slot, the Make Unique button will not be available, because it is not clear from the context what it would be unique relative to. Instead, you need to bring one of the parent maps or materials into the Material Editor, browse down into the map, and then make the map unique relative to that parent.

Procedure

Example: Create an instanced sub-material:

1. Create a box and a sphere.
2. Open the Material Editor.
3. Choose a sample slot, click the Material Type button, choose Multi/Sub-Object in the Material/Map Browser, and then click OK.
4. Select the box, and then apply the new Multi/Sub-Object material to it.
5. Drag one of the Sub-Material buttons from the Material Editor to the sphere.

6. Choose a different sample slot, and use the Pick Material From Object button to get the sub-material applied to the sphere.

At this point, the material applied to the sphere and the sub-material are instances of each other.

7. Go to the parameters for the instanced sub-material by clicking its Sub-Material button.

8. The Make Unique button is now available. Click it to make the sub-material unique again, and assign it a new material name.

Make Unique is not available for the top-level instance of the sub-material.

---

**Put to Library**

Material Editor > Put to Library

Material Editor menu > Material menu > Put to Library

Put to Library adds the selected material to the current library.

A *Put to Library dialog* (page 2–1455) is displayed, which lets you enter a name for the material that’s different from the one you used in the Material Editor.

The material becomes visible in the material library display in the *Material/Map Browser* (page 2–1412). The material is saved to the library file on disk. (You can also save a library by using the Save button in the Material/Map Browser.)

---

**Procedure**

**To save a material in a library:**

1. Click to select the sample slot that has the material you want to save.

2. On the Material Editor toolbar, click *Put To Library* (page 2–1443).

3. A *Put To Library dialog* (page 2–1455) is displayed.

4. Either change the material name or leave it as is, and then click OK.

The material is saved in the currently open library. If no library is open, a new library is created. You can save the new library as a file using the *Material/Map Browser* (page 2–1412) file controls.

---

**Material ID Channel**

Material Editor > Material ID Channel

The buttons on the Material ID Channel flyout tag a material as a target for a *Video Post* (page 3–311) effect or a *rendering effect* (page 3–218), or for storing with a rendered image saved in *RLA* (page 3–630) or *RPF* (page 3–631) file format (so that the channel value can be used in a post-processing application). The material ID value is the counterpart of a *G-buffer value* (page 3–946) for objects.

Zero (0), the default, indicates that no material ID channel is assigned.
A value from 1 to 15 means to apply a Video Post or rendering effect that uses this channel ID to this material.

For example, you might want a material to glow wherever it appears in the scene. The material is in the Material Editor and the glow comes from a rendering effect. First, you add a Glow rendering effect (page 3–226) and set it up so that it operates on ID 1. Use Material ID Channel to give the material an ID number of 1, then apply the material to objects in the scene in the usual way.

To save the channel data with the rendering, use the RLA or RPF format.

**Warning:** The mental ray renderer (page 3–78) does not recognize Z-depth with G-buffers. G-buffer data is saved on a single layer. Also, the mental ray renderer does not support the following effects:

- Glow lens effect (page 3–226) (rendering effect)
- Ring lens effect (page 3–230) (rendering effect)
- Lens effects Focus filter (page 3–362) (Video Post)

**Procedure**

**To assign a material ID channel to a material:**

- Choose a channel number from the Material ID Channel flyout (page 2–1444).

  Note: Giving a material a nonzero ID channel number tells the renderer to generate a material ID channel containing that value. This information is stored in images only if you save the rendered scene in RLA or RPF format. However, the ID channel data is available to rendering effects at render time.
Show Map In Viewport displays mapped materials on the surfaces of objects in viewports with the interactive renderer (page 3–1030).

The following conditions must be met for mapped materials to display in the viewport:

- **Mapping coordinates** (page 3–967) must be applied to the object. This is already the case with most primitive objects, which by default have Generate Mapping Coords on at creation. If an object doesn’t have mapping coordinates, you can turn this on, or apply a mapped material to the object (if it has a Generate Mapping Coords check box), or apply a UVW Map modifier (page 1–922) or an Unwrap UVW modifier (page 1–878).

- A mapped material must be applied to the object.

- Show Map In Viewport must be on, either at the level of the material that contains the map (page 3–968), or at the top level of the material.

**Tip:** Displaying mapped materials in a viewport can slow performance. If you don’t need to view the map, turn off its viewport display.

**Note:** With the software display driver (page 3–840), viewports don’t accurately display a map with transparency that has UV tiling or mirroring. Also, this driver cannot display a map on a faceted material.

The state of this button is saved with the material in the library. When you apply a mapped material while Show Map In Viewport is active, the object’s Generate Mapping Coords check box is turned on. This means that you can drag mapped materials from the Material Library in the Browser over objects in your scene, and have the mapped material appear in the viewports.

**Tip:** You can turn Show Map In Viewport on or off for all materials by choosing Views menu > Activate/Deactivate All Maps.

**Note:** In the Material/Map Browser (page 2–1412) and Material/Map Navigator (page 2–1447), icons of materials and maps for which Show Map in Viewport is on are red, as shown in the following example:

```
07 - Default ( Multi/Sub-Object )
  (1) : Material #25 ( Standard )
       - Diffuse Color: Map #5 ( FLOWER3.TGA )
  (2) : Material #26 ( Standard )
       - Diffuse Color: Map #5 ( JAGLEAF.TGA )
  (3) : Material #27 ( Standard )
       - Diffuse Color: Map #5 ( JAGLEAF.TGA )
  (4) : Material #29 ( Standard )
  (5) : Material #29 ( Standard )
```

**3D Maps in Viewports**

Show Map In Viewport works for 3D procedural maps as well as 2D maps.

3D map display in viewports is not necessarily accurate. To improve the 3D preview, you can use the Material Editor Options dialog (page 2–1436) to set the 3D Map Sample Scale to equal a main dimension of the object you are applying the map to. For example, if you want to use the planet map
Chapter 16: Material Editor, Materials, and Maps

on a sphere with a radius of 20, change the map scale from 100 (the default) to 20.

Particle Age and Particle MBlur maps do not preview in viewports.

Multiple Maps in Viewports

Viewports can display multiple maps. For multiple map display, the display driver must be OpenGL (page 3–841) or Direct3D (page 3–844). The software display driver (page 3–840) does not support multiple map display.

The composite map (page 2–1688) and mix map (page 2–1689) support multiple map display.

In addition, turning on Show Map In Viewport at the top level of a standard material (page 2–1465) lets you view maps on both the diffuse and opacity components (though not on other mapped components).

Procedures

To view maps interactively:

1. Select an object.
2. In the object’s creation parameters, make sure that Generate Mapping Coords. is on. (If this option isn’t enabled, the object can’t be mapped.)
   
   If the object type does not have a mapping coordinates check box, apply a UVW Map (page 1–922) modifier.
3. In the Material Editor, apply the mapped material to the object.
4. Turn on Show Map In Viewport.
   
   The map appears on objects assigned the material in all shaded viewports. Now when you adjust a map, the viewports update to display the adjustments.

To turn off interactive texture display:

- Turn off Show Map In Viewport.
   
   The object is shaded but the map no longer appears.

Show End Result

Material Editor > Show End Result

Material Editor menu > Material menu > Show End Result

Show End Result lets you look at the material at the level you’re on instead of looking at the end result of all the other maps (page 3–968) and settings.

When this button is off, the sample slot shows only the current level of the material. This tool is useful when you are working with compound materials (page 3–922). It would be difficult to see exactly what effect you’re creating on a particular level if you didn’t have the ability to turn off the display of the other levels.

Go to Parent

Material Editor > Go to Parent

Material Editor menu > Navigation menu > Go to Parent

Go To Parent moves up one level in the current material.

This button is available only when you are not at the top level of a compound material (page 3–922). You can tell you’re at the top level when this button is unavailable and the name in the edit field matches the name in the Material Editor title bar.

A typical situation is one in which you have a material with a Diffuse map. The Material level is the parent and the Diffuse map is the child. The Go To Parent button becomes available at the level of the Diffuse map.
Tip: You can also navigate through the levels of a material with the Material/Map Navigator (page 2–1447).

Go Forward to Sibling

Material Editor > Go Forward to Sibling

Material Editor menu > Navigation menu > Go Forward to Sibling

Go Forward To Sibling moves to the next map or material at the same level in the current material.

This button is available only when you are not at the top level of a compound material (page 3–922), and there is more than one map or material at the current level.

A typical situation is one in which you have a material with a Diffuse map, a Bump map, and a Glossiness map. The Material level is the parent and the Diffuse map, Bump map, and Glossiness map are its children. Go Forward To Sibling becomes available at the level of the children and allows you to go from one to another.

You can also navigate through the levels of a material with the Material/Map Navigator (page 2–1447).

Material/Map Navigator

Material Editor > Material/Map Navigator

The Material/Map Navigator is a modeless dialog that provides quick navigation through the hierarchy of maps (page 3–968) in a material (page 3–971), or of sub-materials in a compound material (page 3–922).

The Navigator displays the material and maps in the currently active sample slot. You can navigate the hierarchy of the current material by clicking the material or map listed in the Navigator. Conversely, as you navigate the material in the Material Editor, the current level is highlighted in the Navigator. The selected material or map becomes active in the sample slot, while the rollouts for the selected material or map are displayed below.

You can also drag from the Navigator to any valid sample slot or button in the user interface.

Use the view buttons at the top to change the display. The list displayed in the Navigator is similar to the one displayed in the Track View hierarchy.

See also

Material/Map Browser (page 2–1412)

Interface

Note: Icons of materials and maps for which Show Map in Viewport (page 2–1445) is on are red.

Also, the names of instanced (page 3–957) materials and maps appear in boldface.

Both of these effects are shown in the following illustration:
The view buttons are as follows:

- **View List**—Displays the materials and maps in list format. Blue spheres are materials. Green parallelograms are maps. The green parallelograms turn red if Show Map in Viewport is on for a material.

- **View List + Icons**—Displays the materials and maps as small icons in a list.

- **View Small Icons**—Displays the materials and maps as small icons. As you move the mouse over the icons, tooltip labels show you the name of the material or map.

- **View Large Icons**—Displays the materials and maps as large icons. As you move the mouse over the icons, tooltip labels show you the name of the material or map.

The large icons are labeled with the name of the material or map and are displayed using progressive refinement. That is, samples are rendered quickly, with large pixels, then rendered a second time in greater detail.

---

**Pick Material From Object**

*(Eyedropper)*

Pick Material From Object lets you select a material from an object in the scene. Click the eyedropper button, and then move the eyedropper cursor over the objects in the scene. When the eyedropper cursor is over an object containing a material, it fills with "ink" and a tooltip with the name of the object pops up. Click the object. The material is placed in the active sample slot.

If the material is already in the active sample slot, the eyedropper has no effect.

If the eyedropper cursor is over an editable mesh (page 1–996) with faces selected at the sub-object level, and the mesh has a Multi/Sub-Object material (page 2–1594) applied to it, then the eyedropper picks up the sub-material. However, if the selected faces have more than one sub-material assigned to them, then the eyedropper picks up the entire Multi/Sub-Object material.

---

**Name Field (Materials and Maps)**

The Name field displays the name of the material or map. Default material names are "01 – Default," and so on, the number changing to reflect the material’s sample slot. Maps are named "Map #1," and so on.

You can edit this field to change the name of the material in the active sample slot. You can also edit
the names of maps and sub-materials assigned at lower levels of the map or material hierarchy.

The name of the material is not a file name: it can contain spaces, numbers, and special characters. It can be of any length.

Note: In releases prior to 3ds Max 4, material names were limited to 16 characters. As of 3ds Max 4, you can assign material names of arbitrary length.

This field also functions as a drop-down list. At the top level, it shows only the material or map name. At lower levels of the hierarchy, drop the list down to see the names of ancestors to the map or material. The top level is at the top of the list, the current level is at the bottom, and intermediate levels appear between them.

Procedure

To give a material a different name:

- Edit the name field that appears below the Material Editor toolbar.

  The name of the active material appears in the title bar of the Material Editor dialog.

Type Button (Materials and Maps)

Material Editor > Type button

Material Editor menu > Material menu > Change Material/Map Type

Click the Type button to display the Material/Map Browser (page 2–1412) and choose which material type or map type to use.

When changing a material’s type, the original material type is replaced unless you choose a compound material (page 3–922), in which case a Replace Material dialog (page 2–1456) is displayed. The Replace Material dialog lets you choose between discarding the original material or using it as a sub-material within the new material.

For a standalone map (a map at the top level), clicking the Type button lets you change the map type instead of the material type. However, you can’t use this button to make a map standalone. To make a standalone map, you have to click Get Material (page 2–1439) and choose a map from the Browser it displays.

When you change the type of a standalone map, a Replace Map dialog (page 2–1456) is displayed. The Replace Map dialog lets you choose between discarding the original map or using it as a sub-map within the new map.

---

### Animating Materials

This topic provides some suggestions about how to animate materials.

#### Animating Basic Materials

In general, you animate a basic material by changing its parameters in different keyframes while Auto Key is active. 3ds Max interpolates values between keyframes, as it does when you animate transforms and modifiers.

Be aware that the tracks for a material assigned to an object are distinct from the material tracks that belong to the Material Editor: animating a material in the Material Editor affects the scene only if the material is hot (page 3–953).

#### Animating Mapped Materials

As with basic materials, you can create animation keys for map parameters.

The noise parameters and the Noise map (page 2–1674) itself provide the Phase parameter specifically for animating the noise function.

You can also produce an animated material by applying an animated bitmap as a map. This
automated bitmap can be an AVI (page 3–609) or MOV (page 3–621) file, or an image sequence in the form of an IFL (page 3–616) file.

**Changing One Material into Another**
Probably the easiest way to animate the change of one material into another is to create a Blend material (page 2–1588), make the two other materials its sub-materials, and then animate its Mix Amount parameter.

**Preview and Playback**
When you animate a material, or use an animated bitmap in a material, you can create and view a preview of this material before you decide to use it in a fully rendered animation.

*Creating and Playing Animated Material Previews* (page 2–1450)
*Synchronizing an Animated Bitmap with the Scene* (page 2–1450)

---

### Creating and Playing Animated Material Previews

You can create a preview movie of an animated material. Use Make Preview (page 2–1434) in the Material Editor. Clicking this button displays the Create Material Preview dialog (page 2–1452), which like the Renderer has controls for which frames to render, playback speed, and output size.

The preview movie is saved in the \previews subdirectory in a file called _medit.avi. Each time you create a new preview, the Material Editor overwrites this file. To keep a preview movie on hand, save it under a different name by using the Save Preview button on the same flyout as Make Preview.

### Procedures

**To create a preview of an animated material:**

1. Choose Make Preview from the flyout.
2. In the Create Material Preview dialog, set the preview conditions you want, and then click OK.

   The Material Editor creates the preview.

**To play back a preview of an animated material:**

1. Choose Play Preview from the flyout.

   The Material Editor starts the Windows Media Player with the active preview movie loaded.
2. Click Play to view the preview movie.

**To save a preview movie under a different name:**

1. Choose Save Preview from the flyout.

   The Material Editor displays a file save dialog.
2. Enter a new name for the preview, and then click OK.

---

### Synchronizing an Animated Bitmap with the Scene

Material editor > Bitmap map > Time rollout

Bitmaps (page 2–1631) have a Time rollout with controls that let you synchronize an animated bitmap with scene animation.

### Interface

![Interface Diagram](image)
**Start Frame**—The frame number of the 3ds Max scene at which the bitmap animation begins to play.

**Playback Rate**—Sets the bitmap's playback rate. This value is a multiplier: 1.0 is one bitmap frame per scene frame, 2.0 is twice as fast, 3.33 is 1/3 as fast, and so on. Default=1.0.

**Sync Frames to Particle Age**—When on, the software synchronizes the frames of a bitmap sequence to the age of particles to which the map is applied. With this effect, each particle displays the sequence from the start when it is born, rather than being assigned whichever frame is current. Default=off.

When using Particle Flow, assign the material containing the Bitmap map to a Material Dynamic operator. For more details and a procedure, see Material Dynamic Operator (page 2–191).

Note: This functionality is not supported by the mental ray renderer.

**End Condition group**

Determines what happens after the last frame of the bitmap animation if the animation is shorter than the scene.

**Loop**—Causes the animation to repeat over and over again from the beginning.

**Ping-Pong**—Causes the animation to be played forward and then backward repeatedly, making every animated sequence "loop smoothly."

**Hold**—Freezes on the last frame of the bitmap animation.

---

**Material Editor Subdialogs**

### Copy (Instance) Map Dialog

The Copy (Instance) Map dialog is displayed when you copy a map by dragging and dropping a map button. It gives you the choice of copying the map, making the newly assigned map an instance of the one you dragged, or swapping maps.

You can drag map buttons in the Maps rollout, in the Basic Parameters rollout, or from one rollout to the other.

Tip: Usually when you use the same map for multiple parameters, such as both self-illumination and opacity, it is easier to work with an instance rather than a copy.

**Interface**

![Copy (Instance) Map Dialog](image)

- **Instance**—Makes an instance of the map you dragged. The newly assigned map is not independent. Adjusting the parameters of one map or the other changes both of them.

- **Copy**—Copies the map you dragged. The newly assigned map is a copy whose parameters you can adjust independently.
Swap—Swaps the maps. This option isn’t displayed when you drag from one rollout to another.

Copy or Swap Colors Dialog

The Copy or Swap Colors dialog is displayed when you copy a color by dragging and dropping a color swatch. It gives you the choice of copying the color or swapping the colors, trading one for the other.

Interface

Create Material Preview Dialog

The Create Material Preview dialog is displayed when you click Make Preview (page 2–1434) to preview an animated material. By default, the preview is saved in the \previews subdirectory with the name _medit.avi. You can use Save Preview to give the preview a different name so it won’t be overwritten the next time you use Make Preview.

Preview Range group

Active Time Segment—Renders the active time segment (page 3–904).

Custom Range—Renders a custom range from the start to the end frame you specify in the spinners below.

Frame Rate group

These controls specify the playback rate.

Every Nth Frame—Renders a regular sampling of the animation. For example, a value of 8 includes only every eighth frame in the preview. Default=1 (every frame).

Playback FPS—Specifies the playback rate in frames per second. Default=30 (full speed).
Duplicate Name Dialog (Material Library)

Material Editor > Get Material or Type button > Browse From group > Select Mtl Library. > File group > Open material library. > File group > Merge > Merge Material Library dialog > Open another material library or a 3ds Max scene. > Merge dialog > Select materials to merge > OK

File > XRef Objects > XRef Objects dialog > Create XRef Record from File > Choose a file. > Select objects to XRef. > Duplicate Name dialog

The Duplicate Name dialog is displayed if, after you click OK in the Merge dialog (page 2–1453), one or more materials to merge have the same name as materials in the open library.

If this dialog appears while you are using XRef Objects (page 3–394), in the XRef Objects dialog you can see the updated material name in the “Scene Name” column, while the original name in the source scene appears in the “Source Name” column.

Interface

![Duplicate Name Dialog](image)

Material name—At the right, the dialog displays a duplicate material name. You can edit the name to make it unique before you merge it with the open (current) library by clicking the Merge button.

Apply to All Duplicates—If you turn this on before you use the buttons, all subsequent incoming materials with duplicate names are treated the same way as the current one, and no further alert messages are displayed.

Use this option when you know that you’ve got several duplicate materials, and don’t need constant reminders.

This check box is unavailable if you edit the material name.

Merge—Merges the material with the open, current library. This button is unavailable unless you edit the duplicate name to be a different, unique name.

Skip—Skips this material and doesn’t merge it with the open, current library.

Delete Old—Deletes the "old" material in the open, current library and replaces it with the material to merge.

Auto-Rename—Click to have 3ds Max automatically rename the material by appending a sequence number to the duplicate material name.

Cancel—Cancels further merging of materials with duplicate names. If you have already merged some materials, they appear in the open, current library.

Merge Dialog (Material Library)

Material Editor > Get Material or Type button > Browse From group > Select Mtl Library. > File group > Open material library. > File group > Merge > Merge Material Library dialog > Open another material library or a 3ds Max scene.

The Merge dialog displays a list of materials to merge with the open library. The materials are from a different material library or from a 3ds Max or VIZ Render (DRF (page 3–527)) scene.
Procedures

To merge all materials:
- Click All.

To select a single material to merge:
- Click the material’s name.

To select materials to merge one by one:
1. Click a material’s name.
2. Hold down [Ctrl], and click other material names.

To select a group of contiguous materials to merge:
1. Click a material’s name.
2. Hold down [Shift] and click another material’s name.

The dialog selects the two materials you clicked, and all materials whose names lie between the two.

Material list—Shows the names of all materials in the library or scene.

All—Selects all materials in the list.

None—Deselects all materials in the list.

Merge Material Library Dialog

Material Editor > Get Material or Type button >
Material/Map Browser > Browse From group > Select Mtl Library. > File group > Open material library. > File group > Merge

The Merge Material Library dialog lets you merge materials in the open material library with materials in another material library or another 3ds Max or VIZ Render (DRF (page 3–527)) scene.

Interface

This is a standard Windows file dialog. It lets you select either material library (.mat) files, 3ds Max (.max), or VIZ Render (DRF (page 3–527)) scene files.

When you click OK, a further Merge dialog (page 2–1453) is displayed. This lets you select by name the materials you want to merge with the open library.
Put to Library Dialog

Material Editor > Put To Library

The Put To Library dialog is displayed when you want to save the material in an active sample slot (page 2–1420) into a material library file. It lets you change the material’s name before you save it.

Interface

Name—Shows the name of the material to save. You can edit this name to save it under a different name.

Render Map Dialog

Material Editor > Right-click a sample slot. > Render Map > Render Map dialog

The Render Map dialog is displayed when you use Render Map on the Sample Slots Right-Click Menu (page 2–1422) to render the map displayed in a sample slot

Time Output group
These controls specify how many frames to render.

Single—Renders a single frame.

Every Nth Frame—Renders a regular sampling of the animation. For example, a value of 8 includes only every eighth frame in the preview. Default=1 (every frame).

Active Time Segment—Renders the active time segment (page 3–904).

Range—Renders a custom range from the start to the end frame you specify in the spinners below.

Dimensions group
These controls specify the size of the rendered frames, in pixels.

Width—Specifies the frame width, in pixels.

Height—Specifies the frame height, in pixels.

Output group
These controls let you save the rendered map to a file.
Files—Click to display a file dialog that lets you specify where to save the rendered map.

When you click Save in the file dialog, you might see an additional dialog that gives you options specific to the file type you chose. These are the file formats available for a rendered map:

- AVI (page 3–609)
- BMP (page 3–610)
- Kodak Cineon (page 3–610)
- Encapsulated Postscript (page 3–612)
- JPEG (page 3–620)
- PNG (page 3–628)
- MOV (QuickTime) (page 3–621)
- SGI (page 3–633)
- RLA (page 3–630)
- RPF (page 3–631)
- Targa (page 3–633)
- TIFF (page 3–634)

Save to File—When on, the rendered map is saved to a file. When off, the map is rendered only to a rendered frame window (page 3–5). This check box is unavailable unless you use Files to specify a file name, when it defaults to on.

File name field—Displays the name of the file you chose.

Render—Renders the map to a rendered frame window (page 3–5), and to a file if you chose one.

Replace Map Dialog

Material Editor > Go to a map level or a standalone map. > Type button > Material/Map Browser > Choose a compound map.

The Replace Map dialog is displayed when you change a map type to any type of map that can have sub-maps. It gives you the choice of replacing the original ("old") map completely, or using the original map as a sub-map of the new map.

Interface

Discard old map—Discards the old map.

Keep old map as sub-map—Retains the old map as a sub-map.

Replace Material Dialog

Material Editor > Type button > Material/Map Browser > Choose a compound material.

The Replace Material dialog is displayed when you change a material type to one of the compound material types (page 2–1587). It gives you the choice of replacing the original ("old") material completely, or using the original material as a sub-material of the new material.
The Update Scene Materials dialog lets you use a library to update materials in the scene. It appears only when you click Update Scene Materials from Library in the Material/Map Browser (page 2–1412), and the scene contains materials that have the same name as materials in the library.

Procedures

To update a material in the scene and replace it with a material from the library:

- In the Update Scene Materials dialog, select the name of the material, and then click OK.

To leave a material in the scene unchanged, do one of the following:

- In the Update Scene Materials dialog, make sure the name of the material is not selected, and then click OK.
- Click Cancel.

Materials

Materials create greater realism in a scene. A material describes how an object reflects or transmits light. You assign materials to individual objects or selection sets; a single scene can contain many different materials.

Different materials have different uses.
Standard material (page 2–1465) is the default material. This is a versatile surface model with a large number of options.

Raytrace material (page 2–1512) can create fully raytraced reflections and refractions. It also supports fog, color density, translucency, fluorescence, and other special effects.

Architectural material (page 2–1535) provides a physically accurate material. It is especially intended for use with the default scanline renderer and radiosity (page 3–51).

mental ray materials (page 2–1543) are provided for use with the mental ray renderer (page 3–78).

Matte/Shadow material (page 2–1584) is specifically for making an object into a matte object (page 3–971) that reveals the current environment map (page 3–934). A matte object is effectively invisible in the scene, but it can receive shadows cast onto it from other objects.

Shell material (page 2–1600) is for storing and viewing rendered textures (page 3–144).

Advanced Lighting Override material (page 2–1601) is used to fine-tune the effects of a material on radiosity solutions (page 3–51) or the Light Tracer (page 3–44). This material is not required for calculating advanced lighting, but it can help improve the result.

Note: The Architectural material has its own controls for adjusting advanced lighting.

Lightscape material (page 2–1604) helps support import and export of data from the Lightscape product.

Ink ’n Paint material (page 2–1605) gives a cartoon appearance to objects.

The DirectX 9 Shader material (page 2–1613) enables you to shade objects in viewports using DirectX 9 (DX9) shaders. To use this material, you must have a display driver that supports DirectX 9, and you must be using the Direct3D display driver.

The XRef material (page 2–1616) lets you externally reference a material in a different scene file.

Other material types fall into the category of Compound materials (page 2–1587).

Compound Materials

Compound materials combine other materials in some way.

Blend (page 2–1588) material mixes two materials on a single side of a surface.

Composite (page 2–1589) material mixes up to 10 materials, using additive colors, subtractive colors, or opacity mixing.

Double-Sided (page 2–1591) material lets you assign different materials to the front and back faces of an object.

Morpher (page 2–1592) material uses the Morpher modifier (page 1–729) to manage multiple materials over time.

Multi/Sub-Object (page 2–1594) material uses the sub-object level to assign multiple materials to a single object, based on material ID values.

Shellac (page 2–1597) material superimposes one material on another using additive composition.

Top/Bottom (page 2–1599) material lets you assign different materials to the top and bottom of faces of an object.

Procedures

To get a material:

1. Click Get Material on the Material Editor toolbar.
   
   The Material/Map Browser (page 2–1412) is displayed.

2. Double-click a material type (not a map type) in the list, or drag the material to a sample slot.
The Material Editor replaces the original material.

To change a material type:

1. At the level of a material, click the Type button below the Material Editor toolbar.

   A modal Material/Map Browser (page 2–1412) is displayed. If you were at a material when you clicked Type, the Browser lists only materials (if you were at a map, it lists only maps).

2. Choose a material from the list, and then click OK.

   If you choose a compound material, a Replace Material (page 2–1456) dialog is displayed.

   This dialog lets you choose whether to keep or discard the original material.

   The Material Editor now displays controls for the new material.

---

**SuperSampling Rollout**

<table>
<thead>
<tr>
<th>Material Editor</th>
<th>Architectural material</th>
<th>SuperSampling rollout</th>
</tr>
</thead>
<tbody>
<tr>
<td>Material Editor</td>
<td>Raytrace material</td>
<td>SuperSampling rollout</td>
</tr>
<tr>
<td>Material Editor</td>
<td>Standard material</td>
<td>SuperSampling rollout</td>
</tr>
</tbody>
</table>

The SuperSampling rollout is used by Architectural, Raytrace, and Standard. It lets you choose a supersampling method (page 3–1018). Supersampling performs an additional antialiasing (page 3–907) pass on the material. This requires more time but can improve image quality.

Supersampling is especially helpful when you need to render very smooth specular highlights, subtle bump mapping, or high resolutions.

In 3ds Max the default is to apply a single supersampling method to all materials in the scene. This feature gives you more control over your scenes, especially larger models that make use of many materials, by letting you control the supersampling at a global level from the Rendering dialog. You can override this locally by turning off Use Global Settings. It also gives you file compatibility and workflow replication with DRF files imported from VIZ Render.

Note: SuperSampling settings are ignored by the mental ray Renderer (page 3–78), which has its own sampling method.

Use supersampling when you notice artifacts in your final renderings. For example, a thin bump map might produce scintillating, jagged bumps that supersampling can correct. Supersampling requires considerably more time to render, although it does not necessarily require any additional RAM.

Note: Supersampling is not processed when you turn off Antialiasing in the production renderer (page 3–27). You can also globally disable supersampling for all materials using the parameters for the default scanline renderer (page 3–38). Globally disabling supersampling can speed up test renderings.

---

Supersampling uses smaller sampling points, and returns averaged values to increase the antialiasing effect.

## Supersampling and Antialiasing

Supersampling is one of several antialiasing techniques. Textures, shadows, highlights, and
raytraced reflections and refractions all have their own preliminary antialiasing strategies. Supersampling is an additional step that provides a "best guess" color for each rendered pixel. The supersampler’s output is then passed on to the renderer, which performs a final antialiasing pass.

A single rendered pixel represents an area of the scene’s geometry. The pixel can stand in for multiple colors, especially when it appears at the edge of an object or a region of color. This is where aliasing effects occur.

When supersampling is turned off, 3ds Max simply looks at the center of the geometry covered by the pixel, and uses that for the pixel color.

When you turn on supersampling, a supersampler performs an additional antialiasing pass on the material. You can choose one of four supersamplers. As the name implies, a supersampler takes additional samples of geometry color in or near each pixel, in order to obtain a more accurate pixel color that is less prone to aliasing error.

These are the supersampling methods:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adaptive Halton</td>
<td>Spaces samples along both X and Y axes according to a scattered, &quot;quasi random&quot; pattern. Depending on Quality, the number of samples can range from 4 to 40. This method is adaptive, as described below.</td>
</tr>
<tr>
<td>Adaptive Uniform</td>
<td>Spaces samples regularly, from a minimum quality of 4 samples to a maximum of 36. The pattern is not square, but skewed slightly to improve accuracy in the vertical and horizontal axes. This method is adaptive, as described below.</td>
</tr>
<tr>
<td>Hammersley</td>
<td>Spaces samples regularly along the X axis, but along the Y axis it spaces them according to a scattered, &quot;quasi random&quot; pattern. Depending on Quality, the number of samples can range from 4 to 40. This method is not adaptive.</td>
</tr>
<tr>
<td>MAX 2.5 Star</td>
<td>The sample at the center of the pixel is averaged with four samples surrounding it. The pattern is like the fives on dice. This is the supersampling method that was available in 3ds Max 2.5.</td>
</tr>
</tbody>
</table>

Regular sampling, as performed by the Adaptive Uniform and MAX 2.5 Star methods, is more prone to aliasing than the irregular patterns performed by the Adaptive Halton and Hammersley methods.

You can set a variable Quality value for the Adaptive Halton, Adaptive Uniform, and Hammersley methods. Quality can range from 0.0 to 1.0. A quality of 0.0 is minimal, with about four samples per pixel. A quality of 1.0 is the highest possible, with between 36 and 40 samples per pixel. High-quality supersampling is very time consuming.

Another setting for the Adaptive Halton and Adaptive Uniform supersamplers is the Adaptive toggle, which works in conjunction with the Threshold spinner. When Adaptive is on, these methods take fewer samples unless a change in color is greater than the Threshold value. In that case, they take the full number of samples specified by the Quality. To reduce the amount of time the supersampler spends, leave the Adaptive check box on.
Interface

Use Global Settings—When on, the material uses the supersampling options set in the Default Scanline Renderer rollout (page 3–38). Default=on.

Enable Local Supersampling—When on, applies supersampling to the material. Default=off.

Sampler drop-down list—Lets you choose which supersampling method to apply. The list is not active unless Use Global Settings is turned off. Default=Max 2.5 Star.

Supersample Maps—When on, the maps applied to the material are supersampled as well. When off, the supersampler uses pixel averages for maps. This switch is active only when Use Global Settings is turned off. Default=on.

Quality—Adjusts the quality of supersampling by controlling the number of samples used for each pixel. At the minimum value, 0.0, four samples are taken per pixel. At the maximum value, 1.0, about 40 samples are taken per pixel (the value varies depending on which shader is active). Range=0.0 to 1.0. Default=0.5.

This spinner is unavailable for the Max 2.5 Star method.

Adaptive—Visible only for the Adaptive Halton and Adaptive Uniform methods. When on, these methods take fewer samples than the Quality specifies unless samples show a change in color greater than the Threshold value. In that case, they take all the samples specified by the Quality.

Turning on Adaptive On can reduce the amount of time required to supersample. Default=on.

Threshold—Controls the Adaptive methods. Visible only for the Adaptive Halton and Adaptive Uniform methods. A change in color greater than the Threshold value causes the adaptive methods to take the full number of samples specified by the Quality. If the color does not change as much, the adaptive method takes fewer samples and does not require as much processing time. Can range from 0.0 to 1.0. Setting Threshold to 0.0 has the same effect as turning off Adaptive On. Default=0.1.

mental ray Connection Rollout

Material Editor > Click a sample slot that contains a material other than a Multi/Sub-Object or a mental ray material. > mental ray Connection rollout

The mental ray Connection rollout is available for all types of materials except the Multi/Sub-Object material and the mental ray materials themselves (for which it would be redundant). With this rollout you can add mental ray shading to conventional 3ds Max materials. These effects are visible only when you use the mental ray renderer (page 3–78).

Important: The mental ray Connection rollout does not appear unless you have enabled the mental ray extensions by using the mental ray Preferences panel (page 3–837). In addition, you can't assign shaders to the options in this rollout unless the mental ray renderer is the currently active renderer.
Interface

For each kind of shader on this rollout, there is a toggle and a button.

- The toggle controls whether the assigned shader is active or not.
  
  If no shader is assigned, the toggle has no effect.

- The button lets you assign a shader to the component type. Clicking it displays the Material/Map Browser (page 2–1412): assigning a shader is just like assigning a map to a component of a standard material.

  While a shader is assigned, its name appears on the button.

- In addition to the toggle and button, some of the shader types have a lock button to the right. When button is on, the component is inherited from the base material, and you can’t assign a shader. For example, by default the Surface component is locked, and the surface is shaded using the settings of the 3ds Max material (basic parameters, maps, and so on). Turn off this button to replace the base material’s settings with a mental ray shader.

Note: Using a shader for the Surface component can result in a material whose appearance in mental ray renderings is completely different from the appearance it has in the sample slot, viewports, and scanline renderings.

Basic Shaders group

Surface—Shades the surface of objects that have this material. Default=locked to parent material.

In addition to any of the usual 3ds Max materials, the surface component can be assigned the following mental ray materials or shaders:

<table>
<thead>
<tr>
<th>Shader</th>
<th>Library</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bump (page 2–1716)</td>
<td>3ds Max</td>
</tr>
<tr>
<td>DGS Material (page 2–1580)</td>
<td>3ds Max</td>
</tr>
<tr>
<td>Dielectric</td>
<td>base</td>
</tr>
<tr>
<td>Dielectric Material (page 2–1719)</td>
<td>3ds Max</td>
</tr>
<tr>
<td>Edge</td>
<td>lume</td>
</tr>
<tr>
<td>Facade</td>
<td>lume</td>
</tr>
<tr>
<td>Glass</td>
<td>lume</td>
</tr>
<tr>
<td>Glow</td>
<td>lume</td>
</tr>
<tr>
<td>Landscape</td>
<td>lume</td>
</tr>
<tr>
<td>Material to Shader (page 2–1722)</td>
<td>3ds Max</td>
</tr>
<tr>
<td>Metal</td>
<td>lume</td>
</tr>
<tr>
<td>Ocean</td>
<td>lume</td>
</tr>
<tr>
<td>Opacity</td>
<td>base</td>
</tr>
<tr>
<td>Reflect</td>
<td>base</td>
</tr>
<tr>
<td>Refract</td>
<td>base</td>
</tr>
<tr>
<td>Shader List (page 2–1723)</td>
<td>3ds Max</td>
</tr>
<tr>
<td>Stain</td>
<td>lume</td>
</tr>
<tr>
<td>Translucency</td>
<td>lume</td>
</tr>
<tr>
<td>Transmat</td>
<td>physics</td>
</tr>
<tr>
<td>Transparency</td>
<td>base</td>
</tr>
<tr>
<td>Two Sided</td>
<td>base</td>
</tr>
</tbody>
</table>
Note: Unlike a standard 3ds Max material, if you assign the Surface component a bitmap with tiling turned off, the original surface color does not “show through.” In renderings, you see only the untiled map, and none of the rest of the object.

**Shadow**—Assigns a shadow shader. Default=locked to parent material.

The shadow component can be assigned the following shaders:

<table>
<thead>
<tr>
<th>Shader</th>
<th>Library</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edge Shadow</td>
<td>lume</td>
</tr>
<tr>
<td>Facade</td>
<td>lume</td>
</tr>
<tr>
<td>Glass</td>
<td>lume</td>
</tr>
<tr>
<td>Glow</td>
<td>lume</td>
</tr>
<tr>
<td>Material to Shader (page 2–1723)</td>
<td>3ds Max</td>
</tr>
<tr>
<td>Metal</td>
<td>lume</td>
</tr>
<tr>
<td>Shader List (page 2–1723)</td>
<td>3ds Max</td>
</tr>
<tr>
<td>Shadow Transparency</td>
<td>base</td>
</tr>
<tr>
<td>Translucency</td>
<td>lume</td>
</tr>
<tr>
<td>Transmat</td>
<td>physics</td>
</tr>
<tr>
<td>Water Surface Shadow</td>
<td>lume</td>
</tr>
</tbody>
</table>

**Photon Volume**—Assigns a photon volume shader. Photon volume shaders affect how an object’s volume responds to photons; that is, they control how the volume behaves when generating caustics and global illumination.

The photon volume component can be assigned the following shaders:

<table>
<thead>
<tr>
<th>Shader</th>
<th>Library</th>
</tr>
</thead>
<tbody>
<tr>
<td>Material to Shader (page 2–1723)</td>
<td>3ds Max</td>
</tr>
<tr>
<td>Parti Volume Photon</td>
<td>physics</td>
</tr>
<tr>
<td>Shader List (page 2–1723)</td>
<td>3ds Max</td>
</tr>
</tbody>
</table>

**Extended Shaders group**

**Displacement**—Assigns a displacement shader (page 3–96). Default=locked to parent material.

The displacement component can be assigned the following shaders:

<table>
<thead>
<tr>
<th>Shader</th>
<th>Library</th>
</tr>
</thead>
<tbody>
<tr>
<td>3D Displacement (page 2–1714)</td>
<td>3ds Max</td>
</tr>
<tr>
<td>Material to Shader (page 2–1723)</td>
<td>3ds Max</td>
</tr>
<tr>
<td>Ocean</td>
<td>lume</td>
</tr>
</tbody>
</table>
**Volume**—Assigns a volume shader (page 3–95).

The volume component can be assigned the following shaders:

<table>
<thead>
<tr>
<th>Shader</th>
<th>Library</th>
</tr>
</thead>
<tbody>
<tr>
<td>Beam</td>
<td>lume</td>
</tr>
<tr>
<td>Material to Shader</td>
<td>3ds Max</td>
</tr>
<tr>
<td>Mist</td>
<td>lume</td>
</tr>
<tr>
<td>Parti Volume Photon</td>
<td>physics</td>
</tr>
<tr>
<td>Shader List</td>
<td>3ds Max</td>
</tr>
<tr>
<td>Submerge</td>
<td>lume</td>
</tr>
</tbody>
</table>

**Environment**—Assigns an environment shader.

The environment shader provides an environment local to the material. It is visible if the material is reflective or transparent.

The environment component can be assigned the following shaders:

<table>
<thead>
<tr>
<th>Shader</th>
<th>Library</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment</td>
<td>3ds Max</td>
</tr>
<tr>
<td>Material to Shader</td>
<td>3ds Max</td>
</tr>
<tr>
<td>Shader List</td>
<td>3ds Max</td>
</tr>
</tbody>
</table>

**Advanced Shaders group**

**Contour**—Assigns a contour shader (page 3–96).

The contour component can be assigned the following shaders:

<table>
<thead>
<tr>
<th>Shader</th>
<th>Library</th>
</tr>
</thead>
<tbody>
<tr>
<td>Combi</td>
<td>contour</td>
</tr>
<tr>
<td>Curvature</td>
<td>contour</td>
</tr>
<tr>
<td>Depth Fade</td>
<td>contour</td>
</tr>
<tr>
<td>Factor Color</td>
<td>contour</td>
</tr>
<tr>
<td>Layer Thinner</td>
<td>contour</td>
</tr>
<tr>
<td>Simple</td>
<td>contour</td>
</tr>
</tbody>
</table>

**Light Map**—Assigns a light map shader.

**Warning:** No light map shaders are provided with 3ds Max. This option is for users who have access to light map shaders via other shader libraries or custom shader code.

**Optimization group**

**Flag Material as Opaque**—When on, indicates that the material is fully opaque. This tells the mental ray renderer that it doesn't need to process transparency for this material, or to use the shadow shader. This can improve rendering time. Default=off.

**DirectX Manager Rollout**

Material Editor > DirectX Manager rollout

Let's select a DirectX viewport shader for viewing Direct3D hardware shaders. DirectX shaders require the Direct3D graphics driver (page 3–844), which uses DirectX. With DirectX shading, materials in a viewport more accurately represent how the material will appear in another application, or on other hardware such as a game engine.

DirectX viewport shaders are especially useful for previewing texture-baked materials (page 3–144). 3ds Max provides two DirectX shaders:

- LightMap shader (page 2–1614)
- Metal Bump shader (page 2–1614)

**Note:** This rollout does not appear for Multi/Sub-Object and Shell materials, which are simply containers of other materials.
Standard Material

Material Editor > Type button > Material/Map Browser > Standard

See also

DirectX 9 Shader Material (page 2–1613)

Interface

DX Display of Standard Material—When on, displays the active material as a DX shader. You can save the material as an FX file by clicking Save As .FX File.

For full support of this feature, DX9 must be active.

Warning: Not all standard 3ds Max features can be represented by DX shaders, and you it is possible to create a standard material that is more complex than a DX video card can display. DX shaders do support the most commonly used material components: diffuse color (or texture), specular highlights, opacity, bump mapping, and reflections.

Save as .FX File—Click to display a Save Effect File dialog that lets you save the active material as an FX file (page 3–946).

Enable Plugin Material—Turn on to use the chosen DirectX shader in shaded viewports. Default=off.

When not enabled, viewports continue to use the default viewport (interactive) renderer (page 3–1030) (or the ActiveShade renderer (page 3–17), if that has been chosen).

This toggle is unavailable if no shader plug-in has been chosen from the drop-down list, and when DX Display Of Standard Material is on.

Plug-in drop-down list—Use the drop-down list to choose a DirectX viewport shader.

The list is unavailable when DX Display Of Standard Material is on.

Standard Material

Standard material is the default material in the Material Editor sample slots. There are several other kinds of material types (page 2–1457).

The Standard material type provides a fairly straightforward way to model surfaces. In the real world, the appearance of a surface depends on how it reflects light. In 3ds Max, a standard material simulates a surface’s reflective properties. If you don’t use maps (page 3–968), a standard material gives an object a single, uniform color.

This topic introduces the controls for Standard material, exclusive of mapping.

Standard Color Components

A surface of a "single" color usually reflects many colors. Standard materials typically use a four-color model to simulate this. (There are some variations depending on which shader (page 2–1466) you use.)

- Ambient color (page 3–908) is the color of the object in shadow.
- **Diffuse** (page 3–929) is the color of the object in direct, "good" lighting.

- **Specular** (page 3–1014) is the color of shiny highlights.
  Some shaders generate the specular color, rather than letting you choose it.

- **Filter** (page 3–939) is the color transmitted by light shining through the object.
  The Filter color component isn’t visible unless the material’s Opacity is less than 100 percent.

  Note: *Raytrace material* (page 2–1512) uses a different, six-color model to simulate surfaces. Several components are similar to those in Standard Material, but they behave differently in Raytrace.

When we describe an object’s color in conversation, usually we mean its diffuse color. The choice of an ambient color depends on the kind of lighting. For moderate indoor lighting, it can be a darker shade of the diffuse color, but for bright indoor lighting and for daylight, it should be the complement of the primary (key) light source. The specular color should be either the same color as the key light source, or a high-value, low-saturation version of the diffuse color.

For more tips on choosing color components, see *Choosing Colors for Realism* (page 2–1400).

**Warning:** When you change the shading type of a material, you lose the settings (including map assignments) for any parameters that the new shader does not support. If you want to experiment with different shaders for a material with the same general parameters, copy the material to a different *sample slot* (page 2–1420) before you change its shading type. That way, you can still use the original material if the new shader doesn’t give you the effect you want.

**Other Standard Material Components**

A standard material’s specular color appears in highlights. You can control the size and shape of the highlight. A polished surface has a small and strong highlight. A matte surface has a large, weak highlight, or no highlight at all.

Standard materials also have controls for making the object appear transparent, and for making it self-illuminating so that it appears to glow.

Along with the material’s color components, *components* also refers to the parameters that control highlights, transparency, self-illumination, and so on.

**See also**

- *Material Components* (page 2–1399)
- *Choosing Colors for Realism* (page 2–1400)

**Interface**

The interface for a standard material is organized into several rollouts:

- *Shader Basic Parameters Rollout* (page 2–1466)
- *Basic Parameters Rollout (Standard Material)* (page 2–1470)
- *Extended Parameters Rollout (Standard Material)* (page 2–1471)
- *SuperSampling Rollout* (page 2–1459)
- *Maps Rollout (Standard Material)* (page 2–1474)
- *Dynamics Properties Rollout* (page 2–1479)
- *DirectX Manager Rollout* (page 2–1464)

**Shader Basic Parameters Rollout**

The Shader Basic Parameters rollout lets you choose the type of shader to use with a *Standard* (page 2–1465) material. Some additional controls affect how the material appears.
Procedures

To set a material’s shading type:
1. On the Shader Basic Parameters rollout, open the shader drop-down list.
2. Click the name of the shader type to use for the active material.

To use Wire mode:
- On the Shader Basic Parameters rollout, turn on Wire. The material is now shaded as a wireframe mesh. The wire portions of the geometry do not change; color components, shininess, and so on, remain the same.
- Tip: For a wireframe material, turn on the 2-Sided option as well.

You have two choices for how wireframe materials are rendered. The controls for tuning wireframe shading are on the Extended Parameters (page 2–1471) rollout.
- If you choose Pixels, the thickness of the wires maintains the same apparent thickness regardless of the scale of the geometry or how near or far the object is positioned. In other words, pixel wires have a constant display size as if the wires were traced over an image.
- If you choose Units, the wires behave as if they were modeled in the geometry. They appear thinner at a distance and thicker at close range. Scaling a wireframe object does scale wire width.

Interface

<table>
<thead>
<tr>
<th>Shader Basic Parameters Rollout</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blinn</td>
</tr>
</tbody>
</table>

shader drop-down list—Chooses a shader. The material’s Basic Parameters rollout can change to show the controls for the shader you choose. Default shader=Blinn.

There are seven different shaders. Some are named for what they do; others are named for their creators. These are the basic material shaders:
- **Anisotropic** (page 2–1480): For surfaces with elliptical, “anisotropic” highlights. These highlights are good for modeling hair, glass, or brushed metal.
- **Blinn** (page 2–1480): For rounder, softer highlights than Phong shading
- **Metal** (page 2–1481): For metallic surfaces
- **Multi-Layer** (page 2–1481): For surfaces with more complex highlights than Anisotropic
- **Oren-Nayar-Blinn** (page 2–1482): For matte surfaces such as fabric or terra-cotta
- **Phong** (page 2–1482): For surfaces with strong, circular highlights
- **Strauss** (page 2–1483): For metallic and nonmetallic surfaces. The Strauss shader has a simpler interface than other shaders.
- **Translucent** (page 2–1484): Similar to Blinn shading, the Translucent shader also lets you specify translucency, where light is scattered as it passes through the material.

For more information about the shaders, including illustrations, see Understanding Shaders (page 2–1468).

**Wire**—Renders the material in wireframe mode (page 3–1034). You can set the size of the wire in Extended Parameters (page 2–1471).

**2-Sided**—Makes the material 2-sided (page 3–901). Applies the material to both sides of selected faces.

**Face Map**—Applies the material to the faces of the geometry. If the material is a mapped material, it requires no mapping coordinates (page 3–967). The map is automatically applied to each facet of the object.
**Faceted**—Renders each face of a surface as if it were flat.

---

**Understanding Shaders**

For standard materials, a shader is an algorithm that tells 3ds Max how to calculate surface rendering. Each shader has a unique set of characteristics in order to serve a particular purpose. Some are named for what they do well, such as the Metal shader. Others are named for the person who developed them, such as the Blinn and Strauss shaders. The default shader in 3ds Max is the Blinn shader.

*Note:* In addition to the shaders listed below, 3ds Max supports plug-in shader types.

The following list describes the shaders supplied with the software:

- **Anisotropic:** Used for brushed metal or hair. Creates a highlight that is stretched and angled, rather than the standard circular highlight.
- **Blinn:** Has the same features as the Phong shader, but its mathematics are more accurate. This is the default shader for Standard materials.
- **Metal:** Used for making metals.
- **MultiLayer:** Two anisotropic shaders in one. Used to make two different highlights with independent controls. Simulates materials such as a metal that is covered with a shiny coat of wax.
- **Oren-Nayar-Blinn:** An adaptation of the Blinn shader. It gives objects a porous, non-plastic appearance, and is suitable for surfaces like skin.
Understanding Shaders

- **Phong**: A classic shading method that was the first to enable specular highlights. Suitable for plastic surfaces.

- **Strauss**: Suitable for metals. Allows you to control the degree of metallic characteristics of the material.

- **Translucent Shader**: Translucent shading is similar to Blinn shading, but it also lets you specify translucency. A translucent object allows light to pass through, and also scatters light within the object. You can use translucency to simulate frosted and etched glass.

Comparing Shader Parameters

A shader is an algorithm that tells the program how to calculate surface rendering. Each shader has a unique set of characteristics in order to serve a particular purpose.

**Compare the parameters of different shader types:**

1. Open the Material Editor and click an available sample slot.
2. In the list on the Shader Basic Parameters rollout, change Blinn to Anisotropic.

The Blinn Basic Parameters rollout changes to the Anisotropic Basic Parameters rollout. Observe the differences in the available basic parameters.
3. Select each shader type from the list and compare its parameters with the others. Some parameters are shared in common, but each shader has its own unique combination of settings.

For more information on shader types, see Shader Basic Parameters Rollout (page 2–1466).

**Basic Parameters Rollout (Standard Material)**

The Basic Parameters rollouts for Standard materials contain controls that let you set the color of your material, the shininess, the transparency, and so on, and specify maps (page 3–968) to use for the various components of the material.

*Example: The Basic Parameters rollout for the Anisotropic shader.*

Basic Parameters rollouts vary depending on which shader is chosen.

The Basic Parameters rollout changes depending on which kind of shader you choose in the Shader Basic Parameters (page 2–1466).

Note: The Strauss shader’s Basic Parameters rollout is simpler than those for other shaders. See Strauss Shader (page 2–1483) for a description.

**Component Controls**

The first part of the Basic Parameters rollout contains controls for overall material components. They are described in the following topics:

- *Color Controls* (page 2–1485) let you choose the material’s color components, or replace them with maps.
Extended Parameters Rollout (Standard Material)

Material Editor > Standard material > Extended Parameters rollout

The Extended Parameters rollout is the same for all shading types of Standard material. It has controls related to transparency and reflection, as well as options for Wire mode.

This topic contains tables of the Index of Refraction for some common physical materials. These can be used to create Standard materials with realistic transparency.

Additive Opacity and the Alpha Channel

By default, additive opacity does not generate an alpha value. In other words, the alpha value is zero, indicating no transparency. This gives correct results with backgrounds in renderings, but if you want to composite objects with additive opacity using video post (page 3–311) or a different compositing program, you might want to have additive opacity render with transparency. To do so, add the following line to the [Renderer] section of the 3dsmax.ini file, and then restart 3ds Max:

```
AlphaOutOnAdditive=1
```

To revert to the default method of rendering additive opacity, in the 3dsmax.ini file, change the value of AlphaOutOnAdditive back to 0 (zero), and then restart 3ds Max.

- **Self-Illumination** (page 2–1487) makes a material appear lit from within. Self-illumination is not available for the Strauss shader (page 2–1483).
- **Opacity** (page 2–1488) controls how opaque or transparent a material is.
- **Diffuse Level** (page 2–1489) controls the brightness of the diffuse color component. Diffuse Level is available only for the Anisotropic (page 2–1480), Multi-Layer (page 2–1481), and Oren-Nayar-Blinn (page 2–1482) shaders.
- **Roughness** (page 2–1490) controls how quickly the diffuse component blends into the ambient component. Roughness is available only for the Multi-Layer (page 2–1481) and Oren-Nayar-Blinn (page 2–1482) shaders.

Highlight Controls

The second part of the Basic Parameters rollout contains controls for specular highlights, which in some ways are the greatest difference between the various shaders. See these topics for a description:

- **Anisotropic Highlights** (page 2–1480)
- **Blinn, Oren-Nayar-Blinn, and Phong Highlights** (page 2–1493)
- **Metal Highlights** (page 2–1494)
- **Multi-Layer Highlights** (page 2–1495)

For information on highlights with the Strauss shader, see Strauss Shader (page 2–1483).

Translucency Controls

For the Translucent shader (page 2–1484), an additional group on the Basic Parameters rollout contains controls for translucency (page 2–1491).
Interface

Advanced Transparency group

These controls affect the opacity falloff (page 3–984) of a transparent material.

Note: For the Translucent shader (page 2–1484), these controls do not appear. They are replaced by the Translucency controls (page 2–1491) on the Basic Parameters rollout.

**Falloff**—Chooses whether falloff is in or out, and how great it is.

- **In**—Increases transparency toward the inside of the object, as in a glass bottle.
- **Out**—Increases transparency toward the outside of the object, as in a cloud of smoke.

**Amt (Amount)**—Specifies the amount of transparency at the outside or inside extreme.

**Type**—These controls choose how transparency is applied.

- **Filter** (page 3–939) computes a filter color that it multiplies by the color behind the transparent surface. Click the color swatch to change the filter color. Click the button to assign a map to the filter color component.

  The filter, or transmissive color, is the color transmitted through transparent or semi-transparent materials such as glass. You can use the filter color with volumetric lighting to create effects such as colored light through a stained-glass window. *Ray-traced shadows (page 3–1000) cast by transparent objects are tinted with the filter color.*

- **Subtractive** (page 3–1017) subtracts from the color behind the transparent surface.
- **Additive** (page 3–906) adds to the color behind the transparent surface.

**Index of Refraction**—Sets the index of refraction (IOR) used by refraction maps and raytracing. The IOR controls how severely the material refracts transmitted light. Left at 1.0, the IOR of air, the object behind the transparent object does not distort. At 1.5 the object behind distorts greatly, like a glass marble. At an IOR slightly less than 1.0, the object reflects along its edges, like a bubble seen from under water. Default=1.0.

Common IORs (assuming the camera is in air or a vacuum) are:

<table>
<thead>
<tr>
<th>Material</th>
<th>IOR Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vacuum</td>
<td>1.0 (exactly)</td>
</tr>
<tr>
<td>Air</td>
<td>1.0003</td>
</tr>
<tr>
<td>Water</td>
<td>1.333</td>
</tr>
<tr>
<td>Glass</td>
<td>1.5 (clear glass) to 1.7</td>
</tr>
<tr>
<td>Diamond</td>
<td>2.417</td>
</tr>
</tbody>
</table>

In the physical world, the IOR results from the relative speeds of light through the transparent...
material and the medium the eye or the camera is in. Typically this is related to the object’s density; the higher the IOR, the denser the object.

You can also use a map to control the index of refraction. IOR maps always interpolate between 1.0 (the IOR of air) and the setting in the IOR parameter. For example, if the IOR is set to 3.55 and you use a black-and-white Noise map to control IOR, the IORs rendered on the object will be set to values between 1.0 and 3.55; the object will appear denser than air. If, on the other hand, your IOR is set to 0.5, then the same map values will render between 0.5 and 1.0, as if the camera were under water and the object was less dense than the water.

Here are some more IOR values for various materials:

<table>

</table>

**Wire group**

**Size**—Sets the size of the wire in *wireframe mode* (page 3–1034). You can set either pixels or current units.

**In**— Chooses how to measure wire.

- **Pixels**—(The default.) Measures wire in pixels. With pixels, wires maintain the same apparent thickness regardless of the scale of the geometry or how near or far the object is positioned.
- **Units**—Measures wire in 3ds Max units. With units, the wires appear thinner at a distance and thicker at close range, as if they were modeled in the geometry.

**Reflection Dimming group**

These controls dim reflection maps that are in shadow.
Chapter 16: Material Editor, Materials, and Maps

Reflection dimming

Above: None
Below: 0.0 (100% dimming)

Apply—Turn on to use reflection dimming. When off, the reflection-mapped material is not affected by the presence or absence of direct light. Default=off.

Dim Level—The amount of dimming that takes place in shadow. At 0.0, the reflection map is completely dark in shadow. At 0.5, the reflection map is half dimmed. At 1.0, the reflection map is not dimmed and the material appears as if Apply were turned off. Default=0.0.

Refi. Level—Affects the intensity of the reflection that is not in shadow. The Reflection Level value multiplies the illumination level of the lit area of the reflection, to compensate for dimming. In most cases, the default value of 3.0 keeps the reflection in the lit area at about the same level it would appear if reflection dimming were not on.

Maps Rollout (Standard Material)

Material Editor > Standard material > Maps rollout

A material’s Maps rollout lets you access and assign maps (page 3–968) to various components of the material.

You can choose from a large variety of map types. To find descriptions of these types, and how to set their parameters, see Map Types (page 2–1617).

Assigning the Same Map to Different Parameters

Applying the same map to different parameters is useful in some cases. For example, using a pattern to map both self-illumination and opacity can make the pattern appear to glow and hover in space.

Blending Map Amounts for Opacity and Other Material Components

When you map a scalar component (such as Specular Level, Glossiness, Self-Illumination, and Opacity), the component’s value in the Basic Parameters (page 2–1470) rollout is blended with its associated map Amount in the Maps rollout.

For example, when the Opacity spinner is set to 0, the map Amount spinner completely controls Opacity. That is, reducing the Amount value increases the transparency of the entire surface. On the other hand, when Opacity is 100, reducing the map’s Amount value increases the opacity of the entire surface. You can adjust a Checker Opacity map so that the opaque areas remain opaque, while the transparent areas become semi-transparent.

Other scalar components behave in the same way. Setting the map’s Amount to 100 applies all of the map. Setting the Amount to 0 is the equivalent of turning the map off. Intermediate Amount
values are blended with the value of the scalar component.

When you load old 3ds Max files or bring earlier materials from the Browser into the Materials Editor, the spinner values for Opacity, Specular Level, Glossiness, and Self-Illumination are altered, where necessary, to maintain the equivalent material effect.

Procedures

To assign a map:

1. In the Maps rollout, click a map button.
   A modal Material/Map Browser (page 2–1412) is displayed.
2. Use the Browse From buttons to choose where you want to look.
   If you choose Material Library and the dialog’s display area is blank, you need to open a library file. Click the Open button and then choose the library to browse.
3. Use the display buttons to choose how you view maps.
   
   - View List shows each map by name.
   
   - View List + Icons shows a small preview and each map’s name.
   
   - View Small Icons shows a small preview for each map.
   
   - View Large Icons shows a large preview for each map.
   
   Tip: You can resize the Browser dialog to increase the size of the display area. This is especially useful when you view large icons.
4. Double-click the map you want.

To use the same map for different parameters:

1. In the Maps rollout, use a map button to assign a map.
   The Material Editor is now at the map level, and displays controls for the map parameters.
2. Click Go To Parent to return to the material level, and then open the Maps rollout.
3. Drag the assigned map button to another map button.
   The Copy (Instance) Map dialog (page 2–1451) is displayed.
4. Choose Copy or Instance, and then click OK.
   If you choose Swap, the Material Editor swaps the two button assignments.

To view the parent material’s parameters:

- If you are currently at the map level in the Material Editor, click Go To Parent.
   The parameters for the map’s parent material are displayed. Also, the Show End Result and Go To Parent buttons become unavailable.

To view a map’s parameters:

- If you are currently at the material level in the Material Editor, click the button that corresponds to the map.
   The parameters for the map are displayed. Also, the Show End Result (page 2–1446) and Go To Parent (page 2–1446) buttons become available.

In the Basic Parameters rollout, if a map has been assigned to a color component or parameter, the corresponding button displays a letter M. In the Maps rollout, if a map has been assigned, the corresponding button displays the map name.
To view a map's location:
- Click Material/Map Navigator to view the Navigator.

The Material/Map Navigator (page 2–1447) displays the hierarchy of the current material, which contains the map.

To go to a map using the Navigator:
- In the Material/Map Navigator (page 2–1447), click the name of the map, or the green or red parallelogram to the left of the map's name.

The Navigator goes to the level of the map, and the Material Editor displays the controls for the map you clicked.

As the Navigator’s map tree shows, maps for basic material components and parameters are one level below the material itself.

To preview a map in a sample slot:
1. Go to the level of the map, as described in previous procedures.
   The Material Editor displays the map’s parameters.
2. Turn off Show End Result (page 2–1446).
   The sample slot shows the map instead of the material. If the map contains sub-maps, these are also visible.
   By default, the sample slot displays a map with no three-dimensional shading. You can change this in the Material Editor Options dialog (page 2–1436).

To view the map interactively:
1. Select an object.
2. In the object's creation parameters, make sure that Generate Mapping Coords is on.
   If the object type does not have a Generate Mapping Coordinates toggle, you need to assign mapping coordinates by applying a UVW Map modifier (page 1–922).
3. In the Material Editor, assign the mapped material to the object.
4. If you are at the material level (the top level), click the appropriate map button to go to the map level.
5. Turn on Show Map In Viewport (page 2–1445).
   The map appears on objects assigned the material in all shaded viewports. Now when you adjust the map, the viewports update to display the adjustments.

Turning on Show Map In Viewport for one map automatically turns this button off for all other maps the material has.

Viewports can display 2D maps such as Checker and Bitmap.

Viewports can also display most kinds of 3D maps. The exceptions are Particle Age and Particle MBlur. Also, the appearance of the Falloff map in viewports give only a vague indication of how it will appear when rendered.

Show Map In Viewport is unavailable if the active map type cannot display in viewports.

Displaying mapped materials in a viewport can slow performance. If you don't need to view the texture, turn off its viewport display.

To turn off interactive texture display:
1. Go to the map level.
   If you are at the material level, click the appropriate map button to go to the map level.
2. Turn off Show Map in Viewport (page 2–1445).
   The object is shaded but the map no longer appears.
To turn a map off:
- In the Maps rollout, turn off the map’s check box.
  The check box is to the left of the map’s name.

To turn a map on:
- In the Maps rollout, turn on the map’s check box.
  The check box is to the left of the map’s name.

To change a map’s strength:
- In the Maps rollout, adjust the map’s Amount spinner.
  The material’s sample slot reflects the change.
  Note: Adjusting a map’s output (in the map’s Output rollout) can also change the map’s strength.

To move directly to an ancestor:
1. Below the Material Editor toolbar, click the arrow to the right of the map’s name field (page 2–1448).
   A drop-down list of ancestors is displayed.
2. Click a name in the Ancestor list.
   With this list, you can skip intermediate levels in the tree.
   The Ancestor drop-down list shows only part of the tree. It does not show side branches and siblings. To view these, use the Material/Map Navigator (page 2–1447) or the Go Forward To Sibling (page 2–1447) and Go To Parent (page 2–1446) buttons on the Material Editor toolbar.

To change a map type:
1. At the level of a map, click the button labeled Type below the Material Editor toolbar.
   A modal Material/Map Browser (page 2–1412) is displayed. If you were at a map, it lists only maps (if you were at a material when you clicked Type, the Browser lists only materials).
2. Choose a map type from the list, and then click OK.
   If you change a map type and the new map type can have component maps, a Replace Map dialog is displayed. This dialog gives you a choice between discarding the original map or using it as a component map.
   If the new map type does not have components, it simply replaces the original map type.

To create a standalone map tree:
1. Activate a sample slot.
2. Click Get Material (page 2–1439).
3. In the Material/Map Browser (page 2–1412), make sure Browse From is set to New.
4. Double-click the name of the map type (not a material type) you want to use, or drag the map to a sample slot.
   The sample slot now contains a standalone map not associated with material parameters.
5. Use the Material Editor to modify the map as you would any other map.
   By default, the sample slot displays a map with no three-dimensional shading. You can change this in the Material Editor Options dialog (page 2–1436).
The Maps rollout contains a wide button for each map type. Click this button to select a bitmap file stored on disk or to select a procedural map type (page 3–997). After you select a map, its name and type appears on the button. Use the check box to the left of the button to turn the effect of the map off and on. When the check box is off, the map is not computed and has no effect in the renderer.

The Amount spinner determines the amount that the map affects the material expressed as a percentage of full intensity. For example, a diffuse map at 100% is completely opaque and covers the base material. At 50%, it is semi-transparent and the base material (the diffuse, ambient, and other colors of the material without mapping) shows through.

- Ambient Color Mapping (page 2–1497)
- Diffuse Color Mapping (page 2–1498)
- Diffuse Level Mapping (page 2–1499)
- Diffuse Roughness Mapping (page 2–1500)
- Specular Color Mapping (page 2–1500)
- Glossiness Mapping (page 2–1502)
- Glossiness and Specular Level Settings (page 3–950)
- Self-Illumination Mapping (page 2–1502)
- Opacity Mapping (page 2–1503)
- Filter Color Mapping (page 2–1503)
- Anisotropy Mapping (page 2–1504)
- Orientation Mapping (page 2–1505)
- Metalness Mapping (page 2–1506)
- Bump Mapping (page 2–1506)
- Reflection Mapping (page 2–1508)
- Refraction Mapping (page 2–1509)
- Displacement Mapping (page 2–1511)

The Maps rollout can have unused, disabled control rows at the bottom. This is because the number of components that can be mapped varies depending on the current shader (page 2–1466). The last four rows are always Bump, Reflection, Refraction, and Displacement, in that order.

Note: The sub-material and sub-map buttons for most materials and maps have check boxes beside each button. These turn that branch of the material or map off or on. For example, in the Top/Bottom material, the Top Material and Bottom Material buttons each have check boxes. Similarly, the Checker map has two map buttons, one for each color. Each button has check box beside it that lets you turn off that color’s map.
**Ambient and Diffuse Map Lock**

In the Maps rollout, the lock button to the right of the Diffuse Color map button locks ambient mapping to diffuse mapping. It is on by default. Usually it makes sense to use the same map for the ambient and diffuse components. To use different maps for ambient and diffuse, turn off the lock button. The map button for Ambient Color becomes available.

---

**Dynamics Properties Rollout**

The Dynamics Properties rollout lets you specify surface properties that affect the animation of an object upon collision with another object. If there are no collisions in your simulation, these settings have no effect. The dynamics properties are used by the *Dynamics utility* (page 2–686).

Since the Dynamics Properties rollout is available at the top level of any material (including submaterials), you can specify different surface dynamic properties for each face in an object. There are also controls in the Dynamics utility that let you adjust the surface properties at the object level, but only the Materials Editor lets you alter the surface properties at the sub-object level, through use of a *Multi/Sub-Object material* (page 2–1594).

As a default, the values in the Dynamics Properties rollout provide a surface that's similar to Teflon-coated hardened steel.

**Interface**

<table>
<thead>
<tr>
<th>Dynamics Properties</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bounce Coefficient</strong></td>
<td>1.0</td>
</tr>
<tr>
<td><strong>Static Friction</strong></td>
<td>0.0</td>
</tr>
<tr>
<td><strong>Sliding Friction</strong></td>
<td>0.0</td>
</tr>
</tbody>
</table>

---

**Bounce Coefficient**—Sets how far an object bounces after hitting a surface. The higher the value, the greater the bounce. A value of 1 represents a "perfectly elastic collision," or a bounce in which no kinetic energy is lost. Default=1.0.

If you’ve seen the desktop toy with four ball bearings swinging back and forth on strings and hitting one another, you’ve seen an example that comes very close to a bounce coefficient of 1. Generally, hardened steel or a super ball have a bounce near 1, while lead has a bounce near 0.

**Static Friction**—Sets how difficult it is for the object to start moving along a surface. The higher this value, the more difficult. Default=0.0.

If something weighs ten pounds and sits on Teflon (a static friction of near 0), it takes almost no force to make it move sideways. On the other hand, if it sits on sandpaper, then the static friction might be very high, on the order of 0.5 to 0.8. A static friction near 1 is very difficult to create in the real world without adhesives or friction material.

**Sliding Friction**—Sets how difficult it is for the object to keep moving over a surface. The higher this value, the more difficult for the object to keep moving. Default=0.0.

Once two objects begin to slide over one another, static friction disappears and sliding friction takes over. Generally, sliding friction is lower than static friction due to surface tension effects. For example, once steel starts sliding over brass (a value of static friction that might run from 0.05 to 0.2), the sliding friction drops to a significantly lower value, on the order of .01 to 0.1. For some materials, such as specific friction materials like brake linings, sliding friction is just as high as static friction because it is used in conjunction with a nearly frictionless material such as hardened polished steel.
**Basic Material Shaders**

**Anisotropic Shader**

The Anisotropic shader creates surfaces with elliptical, "anisotropic" highlights. These highlights are good for modeling hair, glass, or brushed metal. The basic parameters are similar to those for Blinn or Phong shading (page 2–1480), except for the Specular Highlight parameters, and Diffuse Level controls such as those for Oren-Nayar-Blinn shading (page 2–1482).

Anisotropic highlights are elliptical, with differing U and V dimensions.

Anisotropy measures the difference between sizes of the highlight as seen from two perpendicular directions. When anisotropy is 0, there is no difference at all. The highlight is circular, as in Blinn or Phong shading. When anisotropy is 100, the difference is at its maximum. In one direction the highlight is very sharp; in the other direction it is controlled solely by Glossiness.

For more complex highlights, see the Multi-Layer shader (page 2–1481).

---

**Blinn Shader**

Blinn shading is a subtle variation on Phong shading. The most noticeable difference is that highlights appear rounder. In general, you don’t need to use the Soften parameter (described in Blinn, Oren-Nayar-Blinn, and Phong Highlights (page 2–1493)) as often as you do with Phong shading.

Blinn shading tends to have soft, round highlights.

With Blinn shading, you can obtain highlights produced by light glancing off the surface at low angles. These highlights are lost when you increase the value of Soften using Phong shading.

The Blinn and Phong shaders have the same basic parameters (page 2–1470).
Metal Shader

Material Editor > Standard material > Shader Basic Parameters rollout > Metal shader > Metal Basic Parameters rollout

Metal shading provides realistic-looking metallic surfaces and a variety of organic-looking materials.

Metal shading has a distinct curve for specular highlights. Metal surfaces also have glancing highlights. Metal materials calculate their own specular color, which can vary between the material’s diffuse color and the color of the light. You can’t set a metal material’s specular color.

Metal shading has distinctive highlights.

Because there’s no separate specular highlight, the two specular highlight spinners behave differently than the spinners for Blinn and Phong shading (page 2–1480). The Specular Level spinner still controls intensity, but the Glossiness spinner affects both the intensity and size of the specular areas.

Tip: When you create a metal material, make sure the backlight (page 2–1432) is on in the sample slot.

Shader Basic Parameters Rollout (page 2–1466)
Basic Parameters Rollout (Standard Material) (page 2–1470)
Blinn, Oren-Nayar-Blinn, and Phong Highlights (page 2–1493)

Multi-Layer Shader

Material Editor > Standard material > Shader Basic Parameters rollout > Multi-Layer shader > Multi-Layer Basic Parameters rollout

The Multi-Layer shader is similar to the Anisotropic shader (page 2–1480), but it has a set of two specular highlight controls. The highlights are layered, letting you create complex highlights that are good for highly polished surfaces, special effects, and so on.

Highlights in the Multi-Layer shader can be anisotropic. Anisotropy measures the difference between sizes of the highlight as seen from two perpendicular directions. When anisotropy is
0, there is no difference at all. The highlight is circular, as in Blinn or Phong shading. When anisotropy is 100, the difference is at its maximum. In one direction the highlight is very sharp; in the other direction it is controlled solely by Glossiness.

Shader Basic Parameters Rollout (page 2–1466)
Basic Parameters Rollout (Standard Material) (page 2–1470)
Multi-Layer Highlights (page 2–1495)

Oren-Nayar-Blinn Shader

The Oren-Nayar-Blinn shader is a variant of the Blinn shader (page 2–1480). It contains additional "advanced diffuse" controls, Diffuse Level and Roughness, that you can use to give the material a matte effect. This shader is good for matte surfaces such as fabric, terra-cotta, and so on.

Oren-Nayar-Blinn shading typically has a matte appearance.

See also
Shader Basic Parameters Rollout (page 2–1466)

Phong Shader

Phong shading smoothes the edges between faces and renders highlights realistically for shiny, regular surfaces. This shader interpolates intensities across a face based on the averaged face normals of adjacent faces. It calculates the normal for every pixel of the face.

Phong-shaded highlights are typically less regular than Blinn highlights.

Phong shading can accurately render bump, opacity, shininess, specular, and reflection maps.

The Blinn and Phong shaders have the same basic parameters (page 2–1470).

Shader Basic Parameters Rollout (page 2–1466)
Basic Parameters Rollout (Standard Material) (page 2–1470)
Blinn, Oren-Nayar-Blinn, and Phong Highlights (page 2–1493)

Strauss Shader

Material Editor > Standard material > Shader Basic Parameters rollout > Strauss shader > Strauss Basic Parameters rollout

The Strauss shader is for modeling metallic surfaces. It uses a simpler model and has a simpler interface than the Metal shader (page 2–1481).

Sample of Strauss shading

Note: The Strauss shader’s Basic Parameters rollout differs a great deal from the Basic Parameters rollouts for other shaders, and is described in this topic.

See also

Shader Basic Parameters Rollout (page 2–1466)

Procedures

To change the color of a Strauss material:

1. Click the Color swatch.
   
   The Color Selector (page 1–161) is displayed.
   
   Right-clicking the color swatch also displays the Color Selector.

2. In the Color Selector, change the values of the color.
   
   As you change color values, the color also changes in the sample in the sample slot.

To reduce a material’s opacity:

- Change Opacity to a value less than 100%.
  
  The material becomes more transparent. An object that is fully transparent (0% Opacity) is nearly invisible except for the light it reflects (the specular highlights).

To preview transparency in the sample slots, view the sample object against a background. Click the checkered Background (page 2–1433) button to the right of the sample slots.

Transparent materials render more realistically when you turn on 2-Sided in the material’s Shader Basic Parameters (page 2–1466).

To increase or decrease the size and intensity of highlights:

- Change the Glossiness value.
  
  The width of the Highlight curve and the highlights in the preview change. At 0% glossiness, the curve is at its maximum width. At 100% glossiness, the curve is extremely narrow.

  Increasing Glossiness also dims the diffuse color.

To make the material appear more metallic:

1. Increase the Glossiness value.
   
   The metallic effect requires visible highlights.

2. Increase the value of Metalness.
   
   Highlights become more focused, and the (diffuse) color component is dimmed.
Chapter 16: Material Editor, Materials, and Maps

**Interface**

- **Color**—Controls the color of the material. This corresponds to the diffuse color (page 3–929) you specify for other kinds of shaders. With the Strauss shader, you control only this color. The shader calculates the ambient and specular color components.

  Click the map button to assign a map to the color component. See Diffuse Mapping (page 2–1498). This button is a shortcut: you can also assign color mapping in the Maps (page 2–1474) rollout.

- **Glossiness**—Affects the size and intensity of the specular highlight. As you increase the value, the highlight gets smaller and the material appears shinier. Default=25.

  Glossiness also controls the strength of reflection maps assigned to a Strauss material.

  Click the map button to assign a map to the glossiness component. See Glossiness Mapping (page 2–1502). This button is a shortcut: you can also assign glossiness mapping in the Maps (page 2–1474) rollout.

- **Metalness**—Changes the metallic appearance of a material. Increasing the Metalness value increases the metallic appearance, with glancing as well as primary highlights. Because a metallic appearance principally depends on highlights, the Metalness value has little effect unless you also increase the Glossiness value. Default=0.

  Tip: When you create a metal material, make sure the backlight (page 2–1432) is on in the sample slot.

- **Opacity**—Sets the opacity/transparency of the material as a percentage. The effect is best previewed against a pattern background (page 2–1433) in the sample slot. You can control opacity falloff (page 3–984) in the Extended Parameters. Default=100.

  Click the map button to assign a map to the opacity component. See Opacity Mapping (page 2–1503). This button is a shortcut: you can also assign opacity mapping in the Maps rollout (page 2–1474).

- **Highlight graph**—This curve shows the effect of adjusting the value of Glossiness. As you decrease Glossiness, the curve grows shorter; as you increase it, the curve grows taller.

**Translucent Shader**

The bust on the right has been made translucent.

Translucent shading is similar to Blinn shading, but it also lets you specify translucency. A translucent object allows light to pass through, and also scatters light within the object. You can use translucency to simulate frosted and etched glass.

Translucency is inherently a two-sided effect: with the translucent shader, backface illumination appears on front faces. To generate translucency,
both sides of the material receive diffuse light, though only one side is visible in renderings and shaded viewports unless you turn on 2-Sided (in the Shader Basic Parameters rollout).

If you use *radiosity* (page 3–51), it will process light transmitted by translucency. The accuracy of this depends on the mesh: the more subdivided the faces are, the more accurate the solution will be (at a cost of processing time).

For specular highlights, you have a choice: to model materials like translucent plastic, you can choose to have highlights on both sides; to model materials like frosted glass, which is reflective on one side only, you can choose to have highlights on only one side. This is controlled by the Backside Specular toggle in the translucent highlight controls.

Tip: To simulate frosted glass, a fine-grained bump map can also help.

The translucent effect appears only in renderings. It does not appear in shaded viewports.

**Note:** The translucent shader does *not* simulate the scattering of light within the object. Because of this, it is better at simulating thin objects such as glass or paper, than at thick objects. For thicker objects, the light passing through might saturate excessively. To avoid this, try reducing the HSV Value of the material’s Translucent Color.

Translucent materials also capture shadows cast on the backfaces of the material. However, because the translucent shader doesn’t scatter light, for thicker objects the effect is not an accurate simulation of real-world translucency.

**Warning:** Do not use shadow maps with the translucent shader. Shadow maps result in artifacts at the edge of translucent objects.

*Shader Basic Parameters Rollout (page 2–1466)*

---

**Basic Parameters for Standard Materials**

**Color Controls**

Material Editor > Standard material > Anisotropic, Blinn, Metal, Multi-Layer, Oren-Nayar-Blinn, or Phong Basic Parameters rollout > First group in the rollout (unlabeled)

Color controls set the colors for different color components. You can set the color by clicking the color swatch to display the *Color Selector (page 1–161).*

**Note:** The Metal shader does not have a Specular component, because it generates the specular color automatically. The Multi-Layer shader can have two different Specular color components, so for this material the Specular color swatches are found in the Specular Highlights group. The Strauss shader has only a single color component, which corresponds to Diffuse.
1. Specular color
2. Diffuse color
3. Ambient color

Procedures
To change a color component:
1. Click the color swatch next to the color component you want to change.
   The Material Editor displays a Color Selector (page 1–161).
   Right-clicking the color swatch also displays the Color Selector.
2. Use the Color Selector to change the values of the color component.
   As you change color values, the color component also changes in the sample slot.

To copy one color component to another:
1. Drag the color swatch of the color you want to copy to the color swatch of the other color component.
   A Copy or Swap Colors dialog (page 2–1452) is displayed.
2. Click Copy to replace the second color swatch with the color you dragged. Click Swap to swap the two color components.

To lock two color components:
1. Click the lock button between Ambient and Diffuse or between Diffuse and Specular.
   The Material Editor displays an alert that asks whether you want to lock the two color components.
2. Click Yes.
   The color above replaces the color below. In other words, Ambient replaces Diffuse and Diffuse replaces Specular.
   If two colors are locked, and you lock the other two, all three component colors are replaced by the active color.
   While two colors are locked, adjustments to one color component affect the other as well.

To unlock two color components:
1. Click the lock button to turn it off.
   The two colors remain the same until you change one of them, or both.

Interface

Ambient—Controls the ambient color (page 3–908). The ambient color is the color in shadow (indirect light).
Diffuse—Controls the diffuse color (page 3–929). The diffuse color is the color in direct light.
Specular—Controls the specular color (page 3–1014). The specular color is the color of the highlight on a shiny object. You can control the size and shape of highlights in the Specular Highlights group, described below.
Copying and Locking Color Components

For convenience in changing color components, the Material Editor lets you copy one color component to another by dragging, and to lock two color components together with the lock buttons to the left of the Ambient and Diffuse, and Diffuse and Specular color swatches.

When you drag and drop a color swatch, the Copy or Swap Colors dialog asks if you want to copy the color or swap the two colors.

In general, materials with two identical color components do not look realistic, and except for materials that are close to solid black, you should avoid using copied or locked color components in materials you use in a scene. Color copying and locking are best used as conveniences when you design a new basic material.

Shortcut Map Buttons

The small buttons to the right of the color swatches access the Material/Map Browser, where you select a map for that component. These buttons are shortcuts: you can also use the corresponding buttons in the Maps rollout. If you have assigned a map to one of these color components, the button displays the letter M. An uppercase M means that the corresponding map is assigned and active. A lowercase m means that the map is assigned and inactive (turned off).

The lock button to the right of the Diffuse map button locks Ambient mapping to Diffuse mapping. It is on by default. Usually it makes sense to use the same map for the ambient and diffuse components. To use different maps for ambient and diffuse, turn off the lock button. A map shortcut button for Ambient appears.

Self-Illumination Setting

These controls make the material self illuminated. Self-illumination creates the illusion of incandescence by replacing shadows on the surface with the diffuse color. As you increase self-illumination, the self-illumination color takes over from the ambient color. At a setting of 100, the material shows no shaded areas, although it can show specular highlights.

The self-illumination color appears in viewports. (In releases prior to 3ds Max 5, viewports showed the self-illumination value but not the color.)

Note: The Strauss shader does not have self-illumination.

There are two ways to specify self-illumination. You can turn on the check box and use a self-illumination color, or turn off the check box and use a monochrome spinner, which is comparable to using a gray scale self-illumination color.

Self-illuminated materials do not show shadows cast onto them, and they are unaffected by the lights in the scene. The brightness (Value in the HSV color description) remains the same regardless of the scene’s lighting.

To make a visible light source in a scene, you can combine a geometric object with a light object, and give the geometric object a self-illuminating surface. For example, you could create a lofted light bulb shape, assign it a self-illuminating white or yellowish material, and place an omni light in the same location.

To make a material both self-illuminating and transparent, use the Additive transparency type in
An object that is self-illuminated using a percentage value and a color

Procedure
To make a material self-illuminating:

1. Click the color swatch in the Self-Illumination group.

2. In the Color Selector (page 1–161), choose a color for self-illumination.

3. Use the color’s Value parameter (in the HSV model) to increase or decrease the amount of self-illumination (page 3–1009).

You can also set self-illumination with a monochrome spinner. To do so, turn off the self-illumination check box and adjust the spinner.

The self-illumination color is mixed with the material’s diffuse color. The closer to black the self-illumination color, the more diffuse color is used.

As self-illumination increases, the sample object appears flatter and more luminous.

Interface

Color check box—When on, the material uses a special self-illumination color. When off, the material uses the diffuse color for self-illumination, and displays a spinner to control the self-illumination amount. Default=off.

Color swatch—When Color is on, the color swatch shows the self-illumination color. To change the color, click the swatch and then use the Color Selector (page 1–161). Adjusting the Value (in the color’s HSV description (page 3–1001)) adjusts the amount of self-illumination. The greater the Value, the more the self-illumination color dominates both the ambient and diffuse color components.

Mono spinner—When Color is off, the diffuse component is used as the self-illumination color, and this spinner lets you adjust the amount of self-illumination. At 0, there is no self-illumination. At 100, the diffuse color takes over from the ambient color.

Click the map button to assign a map to the self-illumination component. See Self-Illumination Mapping (page 2–1502). This button is a shortcut: you can also assign self-illumination mapping in the Maps rollout (page 2–1474).

Opacity

Material Editor > Standard material > Anisotropic, Blinn, Metal, Multi-Layer, Oren-Nayar-Blinn, or Phong Basic Parameters rollout > Opacity group (unlabeled)

Opacity controls whether a material is opaque, transparent, or translucent. (A more physically accurate way to generate translucency is to use the Translucent shader (page 2–1484).)
Controlling opacity using the Opacity setting (left) or an opacity map (right).

**Procedure**

**To reduce a material’s opacity:**

- Change Opacity to a value less than 100%.

  The material becomes more transparent. An object that is fully transparent (0% Opacity) is nearly invisible except for the light it reflects (the specular highlights).

  To preview transparency in the sample slots, view the sample object against a background. Click the checkered Background button (page 2–1433) to the right of the sample slots.

  Transparent materials render more realistically when you turn on 2-Sided in the material’s Shader Basic Parameters (page 2–1466).

**Interface**

Opacity—Sets the opacity/transparency of the material as a percentage. The effect is best previewed against a pattern background (page 2–1433) in the sample slot. You can control opacity falloff (page 3–984) in the Extended Parameters.

Click the map button to assign a map to the opacity component. See Opacity Mapping (page 2–1503). This button is a shortcut: you can also assign opacity mapping in the Maps rollout (page 2–1474).

**Diffuse Level**

Material Editor > Standard material > Anisotropic, Multi-Layer, or Oren-Nayar-Blinn Basic Parameters rollout > Diffuse Level group (unlabeled) or Advanced Diffuse group

Diffuse Level controls the brightness of the material’s diffuse component.

Note: The Blinn, Metal, Phong, and Strauss shadifiers do not have Diffuse Level control.

**Procedure**

**To adjust the diffuse level:**

- Change the value of Diffuse Level.

  The material grows lighter or darker. Lowering the Diffuse Level dims the material’s diffuse color without affecting the specular highlight. Diffuse Level is intended primarily so you can create a map (page 2–1499) that makes portions of the material very dark.
Interface

Diffuse Level—Increasing this value increases diffuse brightness, and decreasing it reduces diffuse brightness without affecting the specular highlight. You can increase the diffuse level over and above the diffuse color’s Value (in its HSV description (page 3–1001)). This parameter can range from 0 to 400. Default=100.

Click the map button to assign a map to the diffuse level parameter. See Diffuse Level Mapping (page 2–1499). This button is a shortcut: you can also assign diffuse level mapping in the Maps rollout (page 2–1474).

Roughness

Material Editor > Standard material > Multi-Layer or Oren-Nayar-Blinn Basic Parameters rollout > Advanced Diffuse group (unlabeled for Multi-Layer)

Roughness controls how quickly the diffuse component blends into the ambient component.

Note: The Roughness parameter is available only with the Oren-Nayar-Blinn (page 2–1482) and Multi-Level (page 2–1481) shaders, and with the Arch & Design material (mental ray) (page 2–1549).

Procedure

To adjust the roughness:

• Change the value of Roughness.

Increasing roughness makes the material have a flatter, more matte appearance.

Interface

Roughness—As you increase this value, the matte appearance of the material increases. It also grows darker and appears more flat. At 0, the roughness is the same as it is with Blinn shading (page 2–1480). Default=50.

Click the map button to assign a map to Roughness. This button is a shortcut: you can also assign Diffuse Roughness mapping in the Maps rollout (page 2–1474). See Diffuse Roughness Mapping (page 2–1500).
**Translucency Setting**

Material Editor > Standard material > Shader Basic Parameters rollout > Translucent shader > Translucent Basic Parameters rollout > Translucency group

The translucency controls are available for the Translucent shader (page 2–1484).

**Warning:** Do not use shadow maps with the translucent shader. Shadow maps result in artifacts at the edge of translucent objects.

**Procedure**

**To make a material translucent:**
- Increase the HSV Value (V) (page 3–1001) of the Translucent Color.
  
  As the Value increases, the material becomes more translucent. The Hue of the Translucent Color tints the light that is scattered within the material.

  Translucent materials render more realistically when you turn on 2-Sided in the material’s Shader Basic Parameters (page 2–1466). The translucent effect does not appear in shaded viewports.

**Example of translucency**

---

**Interface**

<table>
<thead>
<tr>
<th>Translucent Clr</th>
<th>Opacity:</th>
<th>Filter Color</th>
</tr>
</thead>
</table>

**Translucent Clr (Color)**—Specifies a translucency color. This is the color of light that is scattered within the material. It does not need to be the same as the filter color, which is light transmitted by the material. The two color values are multiplied. Click the color swatch to change the translucent color. Click the button to assign a map to the translucent color component.

**Filter Color**—Specifies a filter color (page 3–939) that is multiplied by the translucent color. Click the color swatch to change the filter color. Click the button to assign a map to the filter color component.

The filter, or transmissive color, is the color transmitted through transparent or semi-transparent materials such as glass. You can use the filter color with volumetric lighting to create effects such as colored light through a stained-glass window. Ray-traced shadows (page 3–1000) cast by transparent objects are tinted with the filter color.

**Opacity**—Sets the opacity/opacity (page 2–1488) of the material as a percentage. The effect is best previewed against a pattern background (page 2–1433) in the sample slot.

Click the map button to assign a map to the opacity component. See Opacity Mapping (page 2–1503). This button is a shortcut: you can also assign opacity mapping in the Maps rollout (page 2–1474).
Specular Highlight Controls

Anisotropic Highlights

Material Editor > Standard material > Anisotropic Basic Parameters rollout > Specular Highlight group

Material Editor > Raytrace material > Raytrace Basic Parameters rollout > Shading: Anisotropic > Specular Highlight group

Anisotropic highlights are good for modeling hair, glass, or brushed metal.

Note: For the Raytrace material (page 2–1512), the Specular Color component appears in the Specular Highlight group. Also, highlight controls that don’t pertain to the current shader are labeled “N / A.”

Procedures

To increase or decrease the size of a highlight:

- Change the Glossiness value.

  The width of the Highlight curves and the highlights in the preview change. At 0% glossiness, the curves are at their maximum width. At 100% glossiness, both curves are extremely narrow.

To increase or decrease the strength of a highlight:

- Change the value of Specular Level.

  The intensity of the Highlight curves and the highlights in the preview change. At 0% specular level, there is no highlight. At 100% specular level, the curves are at their maximum height with no overloading. At values greater than 100%, the curves are overloaded: they grow wider, and a wider area is at the maximum highlight intensity.

  The shape of the Highlight curves affects the blending between the specular and diffuse color regions of the material. The steeper the curve, the less blending there is and the sharper the edge of the specular highlight.

To adjust the shape (anisotropy) of the highlight:

- Change the value of Anisotropy.

  The width of the white highlight curve and the highlights in the preview change. At 0% anisotropy, both highlight curves are the same and the highlight is circular, as in Blinn and Phong shading. At 100% anisotropy, the white highlight curve and the highlights are extremely narrow.

To adjust the orientation of the highlight:

- Change the value of Orientation.

  Highlights in the preview show the change in orientation. The display of the highlight curve does not change.

Interface

Specular Level—Affects the intensity of the specular highlight. As you increase the value, the highlight grows brighter. Default=5.

Click the map button to assign a map to the specular level component. See Specular Level Mapping (page 2–1501). This button is a shortcut: you can also assign specular level mapping in the Maps rollout (page 2–1474).

Glossiness—Affects the size of the specular highlight. As you increase the value, the highlight gets smaller and the material appears shinier. Default=25.

Click the map button to assign a map to the glossiness component. See Glossiness Mapping
Blinn, Oren-Nayar-Blinn, and Phong Highlights

Material Editor > Standard material > Blinn, Oren-Nayar-Blinn, or Phong Basic Parameters rollout > Specular Highlight group

Material Editor > Raytrace material > Raytrace Basic Parameters rollout > Shading: Blinn, Oren-Nayar-Blinn, or Phong > Specular Highlight group

The Blinn (page 2–1480), Oren-Nayar-Blinn (page 2–1482), and Phong (page 2–1482) shaders all have circular highlights and share the same highlight controls. Blinn and Oren-Nayar-Blinn highlights are somewhat softer and rounder than Phong highlights.

Note: For the Raytrace material (page 2–1512), the Specular Color component appears in the Specular Highlight group. Also, highlight controls that don’t pertain to the current shader are labeled “N/A.”

Procedures

To increase or decrease the strength of a highlight:

- Change the value of Specular Level.

The intensity of the Highlight curve and the highlight in the preview change. At 0% specular level, there is no highlight. At 100% specular level, the curve is at its maximum height with no overloading. At values greater than 100%, the curve is overloaded: it grows wider, and a wider area is at the maximum highlight intensity.

The shape of the Highlight curve affects the blending between the specular and diffuse color regions of the material. The steeper the curve, the less blending there is and the sharper the edge of the specular highlight.

To increase or decrease the size of a highlight:

- Change the Glossiness value.

The width of the Highlight curve and the highlight in the preview change. At 0% glossiness, the curve is at its maximum width. At 100% glossiness, the curve is extremely narrow.

Interface

Specular Level—Affects the intensity of the specular highlight. As you increase the value, the highlight grows brighter. Default=5.

Click the map button to assign a map to the specular level component. See Specular Level Mapping (page 2–1502). This button is a shortcut: you can also assign specular level mapping in the Maps rollout (page 2–1474).

Glossiness—Affects the size of the specular highlight. As you increase the value, the highlight...
gets smaller and the material appears shinier. Default=25.

Click the map button to assign a map to the glossiness component. See Glossiness Mapping (page 2–1502). This button is a shortcut: you can also assign specular level mapping in the Maps rollout (page 2–1474).

**Soften**—Softens the effect of specular highlights, especially those formed by glancing light. When Specular Level is high and Glossiness is low, you can get harsh backlights on surfaces. Increase the value of Soften to mitigate this effect. At 0, there is no softening. At 1.0, the maximum amount of softening is applied. Default=0.1.

Note: The Soften control was a check box in releases prior to 3ds Max 2. When you load a material created in an earlier version of 3ds Max, if Soften was originally off, the new Soften value is 0.0. If Soften was originally on, the new Soften value is 0.6.

**Highlight graph**—This curve shows the effect of adjusting the values of Specular Level and Glossiness. As you decrease Glossiness, the curve grows wider; as you increase Specular Level, the curve grows taller.

---

**Metal Highlights**

Metal-shaded materials generate their own specular color. Also, the highlight curve for the Metal shader differs in shape from the curve for Blinn Oren-Nayar-Blinn, and Phong highlights (page 2–1493).

Note: For the Raytrace material (page 2–1512), the Specular Color component appears in the Specular Highlight group. Also, highlight controls that don’t pertain to the current shader are labeled “N/A.”

---

**Procedures**

To increase or decrease the size and intensity of a highlight:

- Change the Glossiness value.
  
  The width of the Highlight curve and the highlights in the preview change. At 0% glossiness, the curve is at its maximum width. At 100% glossiness, the curve is extremely narrow.

To increase or decrease the strength of a highlight:

- Change the value of Specular Level.
  
  The intensity of the Highlight curve and the highlight in the preview change. At 0% specular level, there is no highlight. At 100% specular level, the curve is at its maximum height with no overloading. At values greater than 100%, the curve is overloaded: it grows wider, and a wider area is at the maximum highlight intensity.

Increasing the Specular Level also dims the diffuse color.

The shape of the Highlight curve affects the blending between the specular and diffuse color regions of the material. The steeper the curve, the less blending there is and the sharper the edge of specular and glancing highlights.

---

**Interface**

**Specular Level**—Affects the intensity of the specular highlight. As you increase the value, the highlight grows brighter and the diffuse color grows dimmer. Default=5.
Click the map button to assign a map to the specular level component. See Specular Level Mapping (page 2–1501). This button is a shortcut: you can also assign specular level mapping in the Maps (page 2–1474) rollout.

**Glossiness**—Affects the size of the specular highlight. As you increase the value, the highlight curve grows narrower and the highlight gets smaller. Default=25.

Click the map button to assign a map to the glossiness component. See Glossiness Mapping (page 2–1502). This button is a shortcut: you can also assign specular level mapping in the Maps (page 2–1474) rollout.

**Highlight graph**—This curve shows the effect of adjusting the values of Specular Level and Glossiness. As you decrease Glossiness, the curve grows wider; as you increase Specular Level, the curve grows taller.

---

**Multi-Layer Highlights**

*Material Editor > Standard material > Multi-Layer Basic Parameters rollout > First Specular Layer/Second Specular Layer groups*

Multi-layer highlights consist of two layers, each of them anisotropic. The highlights are transparent to each other. Where they overlap, the Multi-Layer shader blends their colors.

**Procedures**

**To increase or decrease the size of a highlight (specular) layer:**

- Change the Glossiness value.

  The width of the Highlight curves and the highlights in the preview change. At 0% glossiness, the curves are at their maximum width. At 100% glossiness, both curves are extremely narrow.

**To increase or decrease the strength of a highlight (specular) layer:**

- Change the value of Specular Level.

  The intensity of the Highlight curves and the highlights in the preview change. At 0% specular level, there is no highlight. At 100% specular level, the curves are at their maximum height with no overloading. At values greater than 100%, the curves are overloaded: they grow wider, and a wider area is at the maximum highlight intensity.

  The shape of the Highlight curves affects the blending between the specular and diffuse color regions of the material. The steeper the curve, the less blending there is and the sharper the edge of the specular highlight.

**To adjust the shape (anisotropy) of a highlight (specular) layer:**

- Change the value of Anisotropy.

  The width of the white highlight curve and the highlights in the preview change. At 0% anisotropy, both highlight curves are the same and the highlight is circular, as in Blinn and Phong shading. At 100% anisotropy, the white highlight curve and the highlights are extremely narrow.

**To adjust the orientation of a highlight (specular) layer:**

- Change the value of Orientation.

  Highlights in the preview show the change in orientation. The display of the highlight curve does not change.
The First Specular Layer and Second Specular Layer groups have identical controls, which can have different settings.

**Color**—Controls the specular color (page 3–1014) of this highlight. The specular color is the color of the highlight on a shiny surface.

**Level**—Affects the intensity of this specular highlight. As you increase the value, the highlight grows brighter. Default: First layer=5, Second layer=0.

Click the map button to assign a map to the specular level component. See *Specular Level Mapping* (page 2–1501). This button is a shortcut: you can also assign specular level mapping in the Maps rollout (page 2–1474).

**Glossiness**—Affects the size of this specular highlight. As you increase the value, the highlight gets smaller and the material appears shinier. Default=25.

Click the map button to assign a map to the glossiness component. See *Glossiness Mapping* (page 2–1502). This button is a shortcut: you can also assign specular level mapping in the Maps rollout (page 2–1474).

**Anisotropy**—Controls the anisotropy, or shape, of this highlight. At 0, the highlight is round. At 100, the highlight is extremely narrow. One axis of the Highlight graph changes to show changes in this parameter. Default=0.

**Orientation**—Changes the orientation of this highlight. The sample slot shows changes in orientation. This is a value in degrees that can range from 0 to 9,999. Default=0.

**Highlight graph**—These two intersecting curves show the effect of adjusting the values of Level, Glossiness, and Anisotropy. As you decrease Glossiness, the curves grow wider; as you increase Specular Level, the curves grow taller. As you adjust Anisotropy, the white curve changes to show how wide or narrow the highlight is.

---

## Translucent Highlights

Like the Blinn shader, the Translucent shader has circular highlights.

### Procedures

**To increase or decrease the strength of a highlight:**

- Change the value of Specular Level.

The intensity of the Highlight curve and the highlight in the preview change. At 0% specular level, there is no highlight. At values greater than 100%, the curve is overloaded: it grows wider, and a wider area is at the maximum highlight intensity. At 100% specular level, the curve is at its maximum height with no overloading.

The shape of the Highlight curve affects the blending between the specular and diffuse color regions of the material. The steeper the curve,
the less blending there is and the sharper the edge of the specular highlight.

**To increase or decrease the size of a highlight:**
- Change the Glossiness value.

  The width of the Highlight curve and the highlight in the preview change. At 0% glossiness, the curve is at its maximum width. At 100% glossiness, the curve is extremely narrow.

**Interface**

**Specular Level**—Affects the intensity of the specular highlight. As you increase the value, the highlight grows brighter. Default=0.

Click the map button next to the spinner to assign a map to the specular level component. See *Specular Level Mapping (page 2–1501).* This button is a shortcut: you can also assign specular level mapping in the *Maps rollout (page 2–1474).*

**Glossiness**—Affects the size of the specular highlight. As you increase the value, the highlight gets smaller and the material appears shinier. Default=10.

Click the map button next to the spinner to assign a map to the glossiness component. See *Glossiness Mapping (page 2–1502).* This button is a shortcut: you can also assign specular level mapping in the *Maps rollout (page 2–1474).*

**Backside specular**—When on, both sides of the material receive a specular highlight. When off, only the front side of the material receives a highlight. Default=on.

Leave Backside Specular on to model materials like translucent plastic. Turn it off to model materials like frosted glass.

Tip: When Backside Specular is turned off, the front side is always the one that receives a specular highlight. You can change this by reversing the normals of surfaces that have the translucent-shaded material.

---

**Mapping Standard Material Components**

**Ambient Color Mapping**

You can select a bitmap file or *procedural map* (page 3–997) to map an image to the material’s *ambient color* (page 3–908). The image is painted on the shaded parts of the object.

By default, diffuse mapping maps the ambient component as well, so you seldom need to use a different map for diffuse and ambient components.
If you do want to apply a separate ambient map, first click to turn off the lock button to the right of the long Map buttons in the Maps rollout (page 2–1474). This unlocks ambient and diffuse mapping. The Map button for ambient color becomes available. You can then click the ambient button to select a map.

Note: Ambient color mapping is not visible in viewports or renderings unless the level of ambient light is greater than default value of black. Choose Rendering > Environment, then adjust the level of ambient light using the Environment dialog (page 3–272).

Procedure

To map the ambient color:

1. Make sure the ambient and diffuse components have their maps unlocked. Click to turn off the lock button. The Map button for ambient color becomes available.
2. Click the Map button for Ambient color.
   The Material/Map Browser (page 2–1447) is displayed.
3. Choose from the list of map types, and then click OK.
   The Material Editor is now at the map level, and displays controls for the map parameters.
4. Use the map controls to set up the map.

Diffuse Color Mapping

Material Editor > Standard material > Maps rollout > Diffuse button (or Color button for theStrauss shader)

Applying a texture by mapping the diffuse color

You can select a bitmap file or procedural map (page 3–997) to assign a pattern or texture to a material’s diffuse color (page 3–929). The colors of the map replace the material’s diffuse color component. This is the most common kind of mapping.

Mapping the diffuse color is like painting an image on the surface of the object. For example, if you want a wall to be made out of brick, you can choose a map with an image of bricks, such as Bricks (page 2–1658).

By default, diffuse mapping applies the same map to the ambient color (page 3–908) as well. You seldom need to use a different map for diffuse and ambient components.

It isn’t strictly necessary to lock the ambient and diffuse maps. By turning the lock off and using a different map for each component, you can obtain interesting blend effects. But in general, the purpose of diffuse mapping is to simulate a single surface that is more complex than a basic material, and for this purpose the lock should be on.
Procedure

To map the diffuse color:

1. Make sure the ambient and diffuse components have their maps locked. This button is to the right of the map shortcut buttons for Ambient and Diffuse on the Basic Parameters rollout, and on the Maps rollout in a similar position. It is on by default. When it is on, the map button for the ambient color component is unavailable.

2. Click the Map button for Diffuse color.
   
   The Material/Map Browser (page 2–1447) is displayed.

3. Choose from the list of map types, and then click OK.
   
   The Material Editor is now at the map level, and displays controls for the map parameters.

4. Use the map controls to set up the map.

Diffuse Level Mapping

Material Editor > Standard material > Shader Basic Parameters rollout > Anisotropic, Oren-Nayar-Blinn, or Multi-Level shader > Maps rollout > Diffuse Level button

You can select a bitmap file or procedural map (page 3–997) to control the Diffuse Level parameter. White pixels in the map leave the diffuse level unchanged. Black pixels reduce the diffuse level to 0. Intermediate values adjust the diffuse level accordingly.

The diffuse level parameter is available with the Anisotropic (page 2–1480), Oren-Nayar-Blinn (page 2–1482), and Multi-Level (page 2–1481) shaders.

Reducing the Amount of the diffuse level map reduces the map’s effect, and increases the effect of the Diffuse Level value on the Basic Parameters.
Chapter 16: Material Editor, Materials, and Maps

Rollout. When the Amount is 0 percent, the map isn't used at all.

Procedure
To map the diffuse level value:
1. Click the Map button for Diffuse Level.
   The Material/Map Browser (page 2–1447) is displayed.
2. Choose from the list of map types, and then click OK.
   The Material Editor is now at the map level, and displays controls for the map parameters.
3. Use the map controls to set up the map.

Diffuse Roughness Mapping

You can select a bitmap file or procedural map (page 3–997) to control the Roughness parameter on the Basic Parameters rollout. White pixels in the map increase roughness. Black pixels reduce roughness to 0. Intermediate values adjust roughness accordingly.

Note: The Roughness parameter is available only with the Oren-Nayar-Blinn (page 2–1482) and Multi-Level (page 2–1481) shaders, and with the Arch & Design material (mental ray) (page 2–1549).

Reducing the Amount of the Diffuse Roughness map reduces the map’s effect, and increases the effect of the Roughness value on the Basic Parameters rollout. When the Amount is 0 percent, the map isn’t used at all.

Procedure
To map the roughness value:
1. Click the Map button for Diffuse Roughness (Diff. Roughness).
   The Material/Map Browser (page 2–1447) is displayed.
2. Choose from the list of map types, and then click OK.
   The Material Editor is now at the map level, and displays controls for the map parameters.
3. Use the map controls to set up the map.

Specular Color Mapping

Mapping the specular highlight

You can select a bitmap file or procedural map (page 3–997) to apply an image to the material’s specular color component (page 3–1014). The map’s image appears only in the specular highlight areas.

When the amount spinner is at 100, all specular color is provided by the map.

Specular mapping is used primarily for special effects such as placing an image in a reflection. The important thing to remember is that, unlike
Specular Level or Glossiness mapping, which alter the intensity and location of specular highlights, specular mapping alters the color of specular highlights.

**Procedure**

To map the specular color:

1. Click the Map button for Specular color.
   
   The Material/Map Browser (page 2–1447) is displayed.

2. Choose from the list of map types, and then click OK.
   
   The Material Editor is now at the map level, and displays controls for the map parameters.

3. Use the map controls to set up the map.

**Specular Level Mapping**

Material Editor > Standard material > Maps rollout > Specular Level button

**Mapping the specular level: the sea reflects more than the land.**

You can select a bitmap file or procedural map (page 3–997) to alter the intensity of specular highlights, based on the intensity of the bitmap. White pixels in the map produce full specular highlights. Black pixels remove the specular highlights completely, and intermediate values reduce the specular highlights accordingly.

Mapping the specular level component is different from mapping specular color. Mapping the specular level alters the intensity of highlights, while specular mapping alters the color of highlights.

Specular level mapping usually works best when you assign the same map to both Specular Level and Glossiness. (In the Maps (page 2–1474) rollout, you can do this by dragging from one map button to another.)

**Procedure**

To map the specular level value:

1. Click the Map button for the Specular Level value.
   
   The Material/Map Browser (page 2–1447) is displayed.

2. Choose from the list of map types, and then click OK.
   
   The Material Editor is now at the map level, and displays controls for the map parameters.

3. Use the map controls to set up the map.
Chapter 16: Material Editor, Materials, and Maps

Glossiness Mapping

Material Editor > Standard material > Maps rollout > Glossiness button

An object with glossiness mapping. The sea appears more reflective than the land.

You can select a bitmap file or procedural map (page 3–997) that affects where specular highlights appear. A map assigned to glossiness determines which areas of the whole surface are more glossy and which areas are less glossy, depending on the intensity of colors in the map. Black pixels in the map produce full glossiness. White pixels remove glossiness completely, and intermediate values reduce the size of the highlight.

Mapping the glossiness component is different from mapping specular color. Mapping glossiness alters the location of highlights, while specular mapping alters the color of highlights.

Glossiness mapping usually works best when you assign the same map to both Glossiness and Specular Level. (In the Maps rollout, you can do this by dragging from one map button to the other.)

(Glossiness was known as Shininess prior to 3ds Max 3.)

Procedure
To map the glossiness value:

1. Click the Map button for the Glossiness value.
   The Material/Map Browser (page 2–1447) is displayed.

2. Choose from the list of map types, and then click OK.
   The Material Editor is now at the map level, and displays controls for the map parameters.

3. Use the map controls to set up the map.

Self-Illumination Mapping

Material Editor > Standard material > Maps rollout > Self-Illumination button

Mapping self-illumination

You can select a bitmap file or procedural map (page 3–997) to map the self-illumination (page 3–1009) value. This makes portions of an object appear to glow. White areas of the map render as fully self-illuminating. Black areas render with no self-illumination. Gray areas render as partially self illuminating, depending on the grayscale value.

Self-illumination means that the glowing area is not affected by lights in the scene (its ambient
color component goes away), and does not receive shadows.

Procedure
To map the self-illumination value:
1. Click the Map button for Self-Illumination.
   The Material/Map Browser (page 2–1447) is displayed.
2. Choose from the list of map types, and then click OK.
   The Material Editor is now at the map level, and displays controls for the map parameters.
3. Use the map controls to set up the map.

Opacity Mapping
Material Editor > Standard material > Maps rollout > Opacity button

The gray levels of an opacity map determine the amount of opacity.

You can select a bitmap file or procedural map (page 3–997) to make an object partially transparent. Lighter (higher-value) areas of the map render as opaque; darker areas render as transparent; and values in between are semi-transparent.

Setting the Amount to 100 applies all of the map. Transparent areas are fully transparent. Setting the Amount to 0 is the equivalent of turning the map off. Intermediate Amount values are blended with the Opacity value on the Basic Parameters rollout. Transparent areas of the map become more opaque.

Specular highlights are applied to transparent areas of the opacity map, as well as to opaque areas, creating the effect of glass. If you want the transparent areas to look like holes, map the specular level (page 2–1502) as well.

Procedure
To map the opacity value:
1. Click the Map button for Opacity.
   The Material/Map Browser (page 2–1447) is displayed.
2. Choose from the list of map types, and then click OK.
   The Material Editor is now at the map level, and displays controls for the map parameters.
3. Use the map controls to set up the map.

Filter Color Mapping
Material Editor > Standard material > Maps rollout > Filter Color button

Mapping filter color
The filter, or transmissive color, is the color transmitted through transparent or semi-transparent materials such as glass.

You can select a bitmap file or procedural map (page 3–997) to map the filter color component. This map applies a transparent-color effect based on the intensity of the map’s pixels.

You can combine a mapped filter color with volumetric lighting (page 3–288) to create effects such as colored light through a stained-glass window. Ray-traced shadows (page 3–1000) cast by transparent objects are tinted by the filter color.

(In version 1 and 2, you specified the filter color on the Basic Parameters rollout (page 2–1470). As of version 3, the filter color is specified on the Extended Parameters rollout (page 2–1471).)

Procedure

To map the filter color:

1. Click the Map button for Filter color.
   The Material/Map Browser (page 2–1447) is displayed.
2. Choose from the list of map types, and then click OK.
   The Material Editor is now at the map level, and displays controls for the map parameters.
3. Use the map controls to set up the map.
Procedure

To map the anisotropy value:

1. Click the Map button for Anisotropy.
   
The Material/Map Browser (page 2–1447) is displayed.

2. Choose from the list of map types, and then click OK.
   
The Material Editor is now at the map level, and displays controls for the map parameters.

3. Use the map controls to set up the map.

Orientation Mapping

Material Editor > Standard material > Shader Basic Parameters rollout > Anisotropic or Multi-Level shader > Maps rollout > Orientation button

The orientation parameter is available with the Anisotropic (page 2–1480) and Multi-Level (page 2–1481) shaders.

Reducing the Amount of the orientation map reduces the map’s effect, and increases the effect of the Orientation value on the Basic Parameters rollout. When the Amount is 0 percent, the map isn’t used at all.

The effect of mapping orientation, like anisotropy, is not very apparent unless the specular level is fairly high and glossiness is fairly low.

Tip: Using an instance of the same map to control both anisotropy and orientation can give you good control over anisotropic highlights.

Procedure

To map the orientation value:

1. Click the Map button for Orientation.
   
The Material/Map Browser (page 2–1447) is displayed.

2. Choose from the list of map types, and then click OK.
   
The Material Editor is now at the map level, and displays controls for the map parameters.

3. Use the map controls to set up the map.

Mapping anisotropy orientation

You can select a bitmap file or procedural map (page 3–997) to control the Orientation parameter. Orientation controls the position of the anisotropic highlight. Mapping orientation changes the highlight’s position. Black and white values have little effect. Maps with a good deal of grayscale values, such as Noise (page 2–1674) or Falloff (page 2–1670), can be very effective. You can also get a good effect using the same map for orientation mapping and bump mapping (page 2–1506).
Chapter 16: Material Editor, Materials, and Maps

Metalness Mapping

Material Editor > Standard material > Shader Basic Parameters rollout > Strauss shader > Maps rollout > Metalness button

Mapping metalness
Top: No mapping
Bottom: Mapping metalness with noise map

You can select a bitmap file or procedural map (page 3–997) to control the Metalness parameter. White pixels in the map increase metalness. Black pixels reduce metalness to 0. Intermediate values adjust metalness accordingly.

The metalness parameter is available with the Strauss shader (page 2–1483).

Reducing the Amount of the metalness map reduces the map's effect, and increases the effect of the Metalness value on the Basic Parameters rollout. When the Amount is 0 percent, the map isn't used at all.

Procedure

To map the metalness value:

1. Click the Map button for Metalness.
   
   The Material/Map Browser (page 2–1447) is displayed.

2. Choose from the list of map types, and then click OK.
   
   The Material Editor is now at the map level, and displays controls for the map parameters.

3. Use the map controls to set up the map.

Bump Mapping

Material Editor > Standard material > Maps rollout > Bump button

An object with two different bump maps.

You can select a bitmap file or procedural map (page 3–997) to use for bump mapping. Bump mapping makes an object appear to have a bumpy or irregular surface. When you render an object with a bump-mapped material, lighter (whiter) areas of the map appear to be raised, and darker (blacker) areas appear to be low.

Note: The effect of a bump map is not previewed in viewports. You must render the scene to see the bump effect.
Bump mapping uses the intensity of the map to affect the surface of the material. In this case, the intensity affects the apparent bumpiness of the surface: white areas protrude, and black areas recede.

Use bump maps when you want to take the smoothness off a surface, or to create an embossed look. Keep in mind, however, that the depth effect of a bump map is limited. If you want extreme depth in a surface, you should use modeling techniques instead. For example, the Displace modifier (page 1–629) pushes surfaces or faces in and out based on the intensity of a bitmap image. (Displacement mapping (page 2–1511) is another way to do emboss a surface.)

Grayscale images can make effective bump maps. Maps that shade between white and black generally work better than maps with hard edges between the white and black areas.

The bump map Amount adjusts the degree of bumpiness. Higher values render as higher relief; low values render as low relief.

The bumps are a simulation created by perturbing face normals before the object is rendered. Because of this, bumps don't appear on the silhouette of bump-mapped objects.

Tip: If you render a bump-mapped material and notice aliasing in the highlights, try turning on supersampling (page 2–1459) and rendering again.

Note: Most controls on the Output rollout (page 2–1621) don't affect bump mapping. Only the Invert toggle is considered; it reverses the direction of the bumps.

Procedure
To assign a bump map:

1. Click the Map button labeled Bump.

   The Material/Map Browser (page 2–1412) is displayed.

2. Choose from the list of map types (page 2–1617), and then click OK.

   The Material Editor is now at the map level, and displays controls for the map parameters.

   (If you choose Bitmap as the map type, you first see a file dialog that lets you choose the image file.)

3. Use the map controls to set up the map.

   Tip: To avoid aliasing caused by a 2D bump map, go to the bump map's Coordinates rollout. Set Blur to be in the range 0.3 to 0.6, and increase Blur Offset to be greater than 0.0. The default Blur and Blur Offset values work well for mapping other material components, but for bump mapping, lower Blur and higher Blur Offset values give better results.

   To remove a bump map from a material:

   Tip: You can disable the map without removing it. Simply turn off the toggle immediately to the left of the map button on the Special Effects rollout.

   1. If the Material Editor is displaying the map controls, click the Type button (page 2–1449) to display the Material/Map Browser. If the map controls aren’t visible, click the Bump map button to display them, and then click the Type button.

   2. In the Browser, choose NONE as the map type, and then click OK.

   The map is removed.
Reflection Mapping

You can select a bitmap file or procedural map (page 3–997) to use as a reflection map.

You can create three kinds of reflection: basic reflection maps, automatic reflection maps, and flat-mirror (page 3–942) reflection maps.

- A basic reflection map creates the illusion of chrome, glass, or metal by applying a map to the geometry so that the image looks like a reflection on the surface.
- An automatic reflection map uses no mapping at all, but looks outward from the center of the object, and maps what it sees onto the surface. Another way to generate reflections automatically is to assign a Raytrace map (page 2–1698) to be the reflection map.
- A flat-mirror reflection map is applied to a series of coplanar faces and reflects objects facing it, exactly like a real mirror.

Reflection maps don’t need mapping coordinates (page 3–967) because they’re locked to the world, not to the geometry. The illusion of a reflection is created because the map doesn’t move with the object, but with changes in the view, as do real reflections.

The most common use of reflection maps in a realistic scene is to add just a touch of reflection to an otherwise non-reflective surface. By default, reflection map strength is 100 percent, as it is for other maps. For many kinds of surfaces, however, reducing the strength gives the most realistic result. A polished table top, for example, primarily shows a wood grain; the reflections are secondary.

Reflection maps look more realistic if you increase the Glossiness and Specular Level values in the Basic Parameters rollout (page 2–1470). They are also affected by the diffuse (page 3–929) and ambient (page 3–908) color values. The darker the color, the stronger the mirror effect.

Even when the Amount spinner is at 100, the reflection map is tinted by the ambient, diffuse, and specular (page 3–1014) colors.

In metal materials, the Diffuse color tints the reflection map. Specifically, the color from the reflection map is multiplied by the diffuse color (including a diffuse map, if one exists). The value (in the HSV (page 3–1001) description) of the diffuse color controls the reflection map intensity. If the diffuse color value is 255, the reflection is at full intensity; if the value is 0, the map is not visible.

In non-metal materials, the Specular color multiplies only reflection maps. The value (in the HSV (page 3–1001) description) of the specular color affects the reflection intensity. If the specular color value is 255, the reflection is at full intensity; if the value is 0, the map is not visible.

Procedures

To create an automatic reflection:

1. In the Maps rollout, click the Map button labeled Reflection.
2. In the Material/Map Browser (page 2–1447), choose the Reflect/Refract map type, and then click OK.

Adjusting the map’s Strength slider in the parent material’s Maps rollout controls how reflective the material is. At 100 percent, the material is fully reflective.

**To assign a bitmap as a reflection map:**
1. In the Maps rollout, click the Map button labeled Reflection. In the Material/Map Browser (page 2–1447), double-click Bitmap.
2. In the Bitmap Parameters rollout, click the Bitmap button.
3. Use the file dialog to choose the bitmap file.
4. Reduce the Reflection map’s Amount to get the effect you want.

Refractions are similar to reflections. Bitmaps simulate reflections, while Reflect/Refract maps generate them based on the scene’s background and geometry.

---

**Refraction Mapping**

Material Editor > Standard material > Maps rollout > Refraction button

Refractions show the scene or background through a refractive object.

---

You can select a bitmap file or a procedural map (page 3–997) such as Reflect/Refract (page 2–1699) to use for refraction mapping.

Refraction mapping is similar to reflection mapping. It maps the view onto the surface in such a way that the image looks like you’re seeing it through the surface, rather than being reflected off it.

Like a reflection map, a refraction map’s orientation is locked to the view rather than to the object. That is, as you move or rotate the object, the position of the refracted image remains fixed.

**Setting the Index of Refraction**

The physical properties of refractive objects often distort the image. A special parameter adjusts this distortion. It is in the parent material’s Extended Parameters rollout (page 2–1471).

**Index of Refraction**—The index of refraction (IOR) controls how severely the material refracts transmitted light. Left at 1.0, the IOR of air, the object behind the transparent object does not distort. At 1.5 the object behind distorts greatly (like a glass marble). At an IOR slightly less than 1.0, the object reflects along its edges (like a bubble seen from under water). Default=1.5 (the IOR of typical glass).

Common IORs (assuming the camera is in air or a vacuum) are:

<table>
<thead>
<tr>
<th>Material</th>
<th>IOR Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vacuum</td>
<td>1.0 (exactly)</td>
</tr>
<tr>
<td>Air</td>
<td>1.0003</td>
</tr>
<tr>
<td>Water</td>
<td>1.333</td>
</tr>
<tr>
<td>Glass</td>
<td>1.5 to 1.7</td>
</tr>
<tr>
<td>Diamond</td>
<td>2.419</td>
</tr>
</tbody>
</table>

In the physical world, the IOR results from the relative speeds of light through the transparent material and the medium the eye or the camera is
in. Typically this is related to the object’s density. The higher the IOR, the denser the object.

You can also use a map to control the index of refraction. IOR maps always interpolate between 1.0 (the IOR of air) and the setting in the IOR parameter. For example, if you set the IOR to 3.55 and use a black-and-white Noise map to control IOR, the IORs rendered on the object will be set to values between 1.0 and 3.55; the object will appear denser than air. If, on the other hand, you set the IOR to 0.5, then the same map values will render between 0.5 and 1.0: as if the camera is under water and the object is less dense than the water.

Here are some more IOR values for various materials:

</tbody>
</table>

Tip: The Reflect/Refract (page 2–1699) map type used as a Refraction map doesn’t effectively model a material surrounding an object, such as a pencil in a glass of water. For this effect, use either the Thin Wall Refraction (page 2–1703) or the Raytrace map type (page 2–1698).

**Procedures**

To create an automatic refraction:

1. In the Maps rollout, click the Map button labeled Refraction.

2. In the Material/Map Browser (page 2–1447), choose the Reflect/Refract (page 2–1699) map type, and then click OK.

At a Refraction Amount of 100 percent, the material is extremely refractive, regardless of the material’s Opacity setting. At a Refraction Amount of 0 percent, the map is turned off. When the Amount is less than 100 percent, both the Reflect/Refract map and the Opacity setting control transparency.
To assign a bitmap as a refraction map:
1. In the Maps rollout, click the Refraction map button.
2. Use the Material/Map Browser (page 2–1447) to choose the Bitmap type.
3. Use the file dialog to choose the bitmap file.
   For bitmapped refractions, you don’t necessarily want to reduce the map strength.

Displacement Mapping

Material Editor > Standard material > Maps rollout > Displacement button

Using displacement mapping to alter a surface

A displacement map displaces the geometry of surfaces. The effect is similar to using the Displace (page 1–629) modifier. Unlike bump mapping (page 2–1506), displacement mapping actually changes the geometry of the surface or patch tessellation. Displacement maps apply the gray scale of the map to generate the displacement. Lighter colors in the 2D image push outward more strongly than darker colors, resulting in a 3D displacement of the geometry.

Warning: A displacement map generates many triangular faces per surface, sometimes over 1M faces per surface. While displacement mapping can create good effects, there is a large cost in terms of time and memory.

The displacement Amount is measured as a percentage of the diagonal of the bounding box for the object that contains the patch or surface. This makes the displacement effect consistent for all surfaces in an object, and it also means that when you scale the object, the displacement is scaled with it.

You can apply a displacement map directly to the following kinds of objects:
- Bezier patches (page 1–993)
- Editable meshes (page 1–996)
- Editable polymeshes (page 1–1022)
- NURBS surfaces (page 1–1078)

For other kinds of geometry such as primitives, extended primitives, compound objects, and so on, you can’t apply displacement mapping directly. To use displacement mapping with these kinds of objects, apply a Disp Approx (page 1–628) (Displacement Approximation) modifier. This makes the object’s surface displaceable. Disp Approx works with any kind of object that you can convert to an editable mesh.

Displacement mapping isn’t visible in viewports unless you apply a modifier to make it so.
- For NURBS surfaces, you can make displacement mapping visible in viewports and editable as a mesh object by using the Displace NURBS (page 1–515) world space modifier.
- For editable meshes and objects with Disp Approx applied to them, use the Displace Mesh (page 1–514) modifier to obtain the same effect.

Note: If you apply a UVW Map (page 1–922) modifier to the surface, all maps obtain their coordinates from the modifier except for the displacement map, which always obtains its coordinates from the original surface or the Disp Approx modifier.

Under certain circumstances, such as when the underlying mesh is fairly simple, displacement
mapping of an editable mesh can cause problems because of the way the underlying mesh is tessellated. (These problems don’t occur when you apply displacement mapping to a NURBS surface.) When this happens, smoothing does not work properly and you can see the underlying wireframe mesh in the surface itself. To correct this problem, use these techniques:

- Avoid applying displacement mapping to large areas of a single color. Map the diffuse color and use a small amount of variation, such as slight amount of noise, in the map you use for the diffuse color.
- Add a small amount of noise to the map you use for displacement. This can complicate the tessellation enough to ease the problem.
- Add detail to the mesh. The more initial faces, and the smoother the mesh curvature, the more even the displacement mapping will be.

**Procedures**

To apply a displacement map to a NURBS surface, editable mesh, or patch:

1. In a material’s Maps rollout, click the map button for Displacement.
   
   The Material/Map Browser (page 2–1447) is displayed.

2. Choose from the list of map types, and then click OK.
   
   The Material Editor is now at the map level, and displays controls for the map parameters.

3. Use the map controls to set up the map.
   
   For example, if you chose Bitmap as the map type, you now need to select the bitmap file to use.

To apply a displacement map to other kinds of objects:

1. Select the object. Go to the Modify panel and choose Disp Approx from the Modifiers drop-down list.

You can adjust the Disp Approx modifiers parameters, or you can leave them at their default settings.

2. Go to the Material Editor.

3. In a material’s Maps rollout, click the map button for Displacement.

   The Material/Map Browser (page 2–1447) is displayed.

4. Choose from the list of map types, and then click OK.

   The Material Editor is now at the map level, and displays controls for the map parameters.

5. Use the map controls to set up the map.

   For example, if you chose Bitmap as the map type, you now need to select the bitmap file to use.

---

**Raytrace Material**

Material Editor > Type button > Material/Map Browser > Raytrace

Balls using raytrace material to reflect each other

Raytrace material is an advanced surface shading material. It supports the same kinds of diffuse
Raytrace Material

It can also create fully raytraced reflections and refractions. It supports fog, color density, translucency (page 3–1027), fluorescence (page 3–942), and other special effects.

The reflections and refractions Raytrace material generates are more accurate than those produced by the Reflect/Refract (page 2–1699) map. Rendering raytraced objects can be slower than using Reflect/Refract. On the other hand, Raytrace is optimized for rendering 3ds Max scenes. You can further optimize it for your scene by excluding specific objects from raytracing.

Note: If you want accurate, raytraced reflections or refractions in a standard material you can use the Raytrace map (page 2–1698), which uses the same raytracer. The Raytrace map and material share global parameter settings.

Important: Raytrace map and Raytrace material use a surface's normal to decide whether a ray is entering or exiting a surface. If you flip the normals of an object, you can get unexpected results. Making the material 2-Sided doesn't correct the problem as it often does with reflections and refractions in Standard materials.

In some cases, the colors in the Basic Parameters rollout of Raytrace material behave differently from colors in standard materials. Standard material has a diffuse shading model that does an excellent job of rendering solid, nonreflective objects such as plastic, ceramic, and so on. In effect, this model applies color to the object. The color components in Raytrace material, on the other hand, attempt to model their physical counterparts in nature.

In Raytrace material, the surface reflects its Diffuse color component without specular reflection, while the Reflect color component controls the amount of specular reflection. These two material components are layered together. The results you see depend on the layering effect. For example, if the material is not transparent and completely reflective, no diffuse color is visible. If the material is not transparent and completely nonreflective, only the diffuse color is visible.

The Dynamics Properties rollout for the Raytrace material contains the same controls as the dynamics properties for a standard material (page 2–1465).

Raytrace material has a large user interface with a lot of controls. In general, if you are using Raytrace to create reflections and refractions, the controls in the Basic Parameters rollout are the only ones you need to adjust. The Extended Parameters rollout for Raytrace has controls for special effects. The Raytracer Controls rollout affects the raytracer itself. Use the Raytracer Controls to turn the raytracer on or off, and to toggle other options. Use the Global Raytracer Settings dialog (page 2–1528) (Rendering > Raytrace Globals) to set options globally (for all Raytrace materials and maps in the scene), including recursion depth.

Interface

Raytrace material has the following rollouts, which are described in these topics:

Raytrace Basic Parameters Rollout (page 2–1514)
Raytrace Extended Parameters Rollout (page 2–1519)
Raytracer Controls Rollout (page 2–1521)
SuperSampling Rollout (page 2–1459)
Raytrace Maps Rollout (page 2–1523)
Raytrace Dynamics Properties Rollout (page 2–1527)

The following dialogs are also part of the Raytrace material's interface:

Raytracer Global Parameters Rollout (page 2–1528)
Raytracing Acceleration Parameters Dialog (page 2–1531)
Raytrace Exclude/Include Dialog (page 2–1531)

Raytrace Antialiaser Dialog: Fast Adaptive Antialiaser (page 2–1533)

Raytrace Antialiaser Dialog: Multiresolution Adaptive Antialiaser (page 2–1534)

Raytrace Basic Parameters Rollout

Main toolbar > Material Editor > Type button > Material/Map Browser > Raytrace > Basic Parameters rollout

Menu bar > Tools menu > Material Editor > Type button > Material/Map Browser > Raytrace > Basic Parameters rollout

The Basic Parameters rollout for a Raytrace material (page 2–1512) controls the material’s shading, color components, reflectivity or refractivity, and bumps.

Interface

The basic parameters in this rollout are similar to the basic parameters for standard materials, but the color components of a Raytrace material behave differently.

As with standard materials, you can use a map for Raytrace color components and various other parameters. The small buttons to the right of the color swatches and parameters take you to the Material/Map Browser (page 2–1412), where you select a map of corresponding type. These are shortcuts that also have corresponding buttons in the Maps rollout. If you have assigned a map to one of these colors, the button displays the letter M. An uppercase M means that the corresponding map is assigned and active. A lowercase m means that the map is assigned and inactive (turned off).

Shading drop-down list—Chooses a shader. Depending on the shader you choose, the Specular Highlight can change to show the controls for that shader. The alternatives are:

- Anisotropic: (page 2–1492) For surfaces with elliptical, "anisotropic" highlights.
- Blinn: (page 2–1493) For rounder, softer highlights than Phong shading.
- Metal: (page 2–1494) For metallic highlights.
- Oren-Nayar-Blinn: (page 2–1493) For matte surfaces such as fabric or terra-cotta.
- Phong: (page 2–1493) For surfaces with strong, circular highlights. Phong is the default shading type.

2-Sided—Same as for standard materials. When on, shades and raytraces both sides of faces. By default, objects are one-sided in order to speed up rendering.

If you have a 2-sided, reflective and refractive object, and you use the raytrace map (page 2–1698) rather than the material, the raytracer runs until it hits the maximum recursion level. This can be time-consuming.

Wire—Same as for standard materials. When on, renders the material in wireframe mode (page 3–1034). You can specify the wire size in the Extended Parameters rollout.
With pixels, wires maintains the same apparent thickness regardless of the scale of the geometry or how near or far the object is positioned. With units, the wires appear thinner at a distance and thicker at close range, as if they were modeled in the geometry.

**Face Map**—Applies the material to the faces of the geometry. If the material is a mapped material, it requires no mapping coordinates (page 3–967). The map is automatically applied to each facet of the object.

**Faceted**—Renders each face of a surface as if it were flat.

Note: Raytrace material has the same SuperSampling (page 2–1459) options as a Standard material.

**Ambient**—This is not the same as the standard ambient color. For Raytrace material, this controls an ambient absorption factor: that is, how much the material absorbs ambient light. Setting Ambient to white is the same as locking the ambient and diffuse colors in a standard material. Default=black.

- **Ambient Color check box**—When on, the material uses an ambient color. When off, the material uses a spinner to set a grayscale value only. Default=on.

- **Color swatch**—When on, the color swatch shows the ambient color. To change the color, click the swatch and then use the Color Selector (page 1–161).

- **Mono spinner**—When the check box is off, the ambient component is gray, and this spinner lets you adjust the gray value.

Click the map button to assign a map to the ambient component. See Ambient Mapping (page 2–1497). This button is a shortcut: you can also assign ambient mapping on the Raytrace Maps rollout (page 2–1523).

**Diffuse**—Sets the diffuse color. This is the same as the standard diffuse color. It is the color that the object reflects, without specular reflection. Reflection and transparency effects are layered on top of the diffuse result. When Reflect is 100% (pure white), the diffuse color isn’t visible. (This differs from the standard material.) Default=50% gray.

**Reflect**—Sets the specular reflection color. This is the color that the reflected environment (that is, the rest of the scene) is filtered through. The color’s Value controls the amount of reflection. If your reflect color is saturated and the diffuse color is black, the effect is like colored chrome (for example, colored Christmas tree balls). Default=black (no reflection).

If raytracing is off (on the Raytracer Controls rollout), the object still reflects the environment, but ignores other objects in the scene. The environment can be the background color, the environment map, or the map in the Raytrace material’s Environment component.

Tip: If you turn off raytraced reflections, set the Reflect color to a color other than black, and use a Reflect/Refract map for the local environment (see the Environment parameter, below), you get the same effect as a reflection map in a standard material. This can improve rendering time.

Note: Raytrace reflects and transmits the IDs in material effects channel (page 2–1443) (G-buffer (page 3–946)), so it can create glowing reflections, and so on.

- **Reflect Color check box**—When on, the material uses a reflection color. When off, the material uses a spinner to set a grayscale value only. Default=on.

- **Color swatch**—When the check box is on, the color swatch shows the reflection color. To change the color, click the swatch and then use the Color Selector (page 1–161).
Chapter 16: Material Editor, Materials, and Maps

- **Mono spinner**—When the check box is off, the reflection color component is gray, and this spinner lets you adjust the gray value.

- **Fresnel**—Clicking the check box a second time displays this option. When active, applies a Fresnel effect to the reflection. This can add a bit of refraction to the reflecting object, depending on the viewing angle of the object.

Click the map button to assign a map to the reflect component. This button is a shortcut: you can also assign reflect mapping in the *Raytrace Maps rollout* (page 2–1523).

**Luminosity**—Similar to the Standard material’s self-illumination component, except that it does not depend on the diffuse color. You can have a blue diffuse object with red luminosity. Default=black.

Note: When Luminosity is off, the name of this control changes to Self-Illum (Self-Illumination).

- **Luminosity check box**—When on, the material uses a luminosity color. When off, the material uses a spinner to set a grayscale value only for self-illumination. Default=on.

- **Color swatch**—When the check box is on, the color swatch shows the luminosity color. To change the color, click the swatch and then use the *Color Selector* (page 1–161).

- **Mono spinner**—When the check box is off, the luminosity color component is gray, and this spinner lets you adjust the gray value.

Click the map button to assign a map to the luminosity component. This button is a shortcut: you can also assign reflect mapping in the *Raytrace Maps rollout* (page 2–1523).

**Transparency**—Similar to the standard material’s filter color for transmitted light, combined with the standard material’s opacity controls. This color filters scene elements that are behind the object with Raytrace material. Black is opaque, white is fully transparent, and any value in between filters objects behind the raytraced object. A fully saturated color in both the diffuse and transparency components gives the effect of tinted glass. If you want more of an opaque look, pick the color you want as a transparent color, copy it to the diffuse color, make the diffuse color fully saturated, and then adjust the transparency to get the effect you want. Default=black (no transparency).

If raytracing is turned off (in the Raytracer Controls rollout), the object still refracts the environment mapping, but ignores other objects in the scene.

Note: By separating the diffuse, reflect, and transparency components, Raytrace material gives you a great deal of control over how the object reacts to its environment. For example, an object might diffusely reflect red, specularly reflect green, and transmit blue. This is not a real-world effect, but it can be useful.

- **Transparency Color check box**—When on, the material uses a transparency color. When off, the material uses a spinner to set a grayscale value only. Default=on.

- **Color swatch**—When the check box is on, the color swatch shows the transparency color. To change the color, click the swatch and then use the *Color Selector* (page 1–161).

- **Mono spinner**—When the check box is off, the transparency color component is gray, and this spinner lets you adjust the gray value.

Click the map button to assign a map to the transparency component. See *Filter Color Mapping* (page 2–1503). This button is a shortcut: you can also assign reflect mapping in the *Raytrace Maps rollout* (page 2–1523).

**Index of Refr. (Refraction)**—The index of refraction (IOR) controls how severely the material refracts transmitted light. At 1.0, the IOR of air, the object behind the transparent object does not distort. At
1.5, the object behind distorts greatly, like a glass marble. At an IOR slightly less than 1.0, the object reflects along its edges, like a bubble seen from under water. Default=1.0.

Common IORs (assuming the camera is in air or a vacuum) are:

<table>
<thead>
<tr>
<th>Material</th>
<th>IOR Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vacuum</td>
<td>1.0 (exactly)</td>
</tr>
<tr>
<td>Air</td>
<td>1.0003</td>
</tr>
<tr>
<td>Water</td>
<td>1.333</td>
</tr>
<tr>
<td>Glass</td>
<td>1.5 to 1.7</td>
</tr>
<tr>
<td>Diamond</td>
<td>2.419</td>
</tr>
</tbody>
</table>

In the physical world, the IOR results from the relative speeds of light through the transparent material and the medium the eye or the camera is in. Typically this is related to the object’s density, and the higher the IOR, the denser the object.

You can also use a map to control the IOR. IOR maps always interpolate between 1.0 (the IOR of air) and the setting in the IOR parameter. For example, if the IOR is set to 3.55 and you use a black-and-white Noise map to control IOR, the IORs rendered on the object will be set to values between 1.0 and 3.55. The object will appear denser than air. If, on the other hand, your IOR is set to 0.5, then the same map values will render between 0.5 and 1.0, as if the camera were under water and the object was less dense than the water.

Here are some more IOR values for various materials:

### Specular Highlight group

The controls in this group affect the appearance of specular highlights. Specular highlights simulate
the surface of the raytraced object reflecting the lights in the scene. Changing the color or intensity of lights in the scene can change the appearance of specular highlights.

As in standard materials, as you adjust the values in this group the highlight curve at the right changes to give you an idea of the effect. The material preview in the sample slot also updates.

**Specular Color**—Sets the specular color (page 3–1014), assuming there are white lights in the scene.

Click the color swatch to display the Color Selector (page 1–161) and change the highlight color.

Click the map button to assign a map to the specular color. See Specular Mapping (page 2–1500). This button is a shortcut: you can also assign specular level mapping in the Raytrace Maps rollout (page 2–1523).

The remaining controls in the Specular Highlight group depend on the active shader, as shown next to “Shading:” at the top of this rollout. These highlight controls are the same as for the Standard material shaders.

These are the highlight controls available to Raytrace materials:

- Anisotropic highlights (page 2–1492)
- Blinn, Oren-Nayar-Blinn, and Phong highlights (page 2–1493)
- Metal highlights (page 2–1494)

Note: Highlight controls that don’t pertain to the current shader are labeled “N/A.”

**Environment**—Specifies an environment map that overrides the global environment map. Both Reflect and Transparency use the scene-wide environment map unless you use this button to specify another map. With this control, you can use different environment maps on a per-object basis, or provide an environment to specified objects when the scene as a whole has none.

This map overrides the scene-wide environment for both reflection and refraction. To override for refraction alone, see the Transparency Environment control in the Extended Parameters rollout.

Use the check box to turn this map on or off.

Tip: You can use any map as the Raytrace environment, including the Reflect/Refract (page 2–1699) map. Reflect/Refract map is often adequate for getting the required look, and it usually renders more quickly than raytracing the entire scene, especially if the Raytrace material is transparent. If you are using Raytrace material just to get the glass to look right on a car’s headlight or on a light bulb hanging in the middle of a room, turn off the raytracer and use an environment map instead.

**Lock button**—Locks the Environment map to the Transparency Environment map (found on the Extended Parameters rollout (page 2–1519)). When on, the Transparency Environment map controls are disabled, and a map applied to the Raytrace Environment applies to the Transparency Environment as well. When off, the Transparency Environment map controls are enabled, and the Transparency Environment can have a different map assigned to it. Default=on.

Changing this button’s setting here also changes it on the Extended Parameters rollout (page 2–1519) and the Maps rollout (page 2–1523).

**Bump**—This is the same as bump mapping (page 2–1506) for Standard materials. Click the button to assign the map. Use the spinner to change the bump Amount. Use the check box to turn the map on or off.
**Raytrace Extended Parameters Rollout**

Material Editor > Type button > Material/Map Browser > Raytrace > Extended Parameters rollout

The Extended Parameters rollout for a Raytrace material (page 2–1512) controls the material’s special effects, transparency properties, and advanced reflectivity.

**Interface**

Except for the wireframe controls, the controls in the Extended Parameters rollout for Raytrace material are specific to the Raytrace material.

**Special Effects group**

The controls in this group are special effects. They are powerful, but you might need to experiment to use them effectively.

**Extra Lighting**—Adds light to the surface of objects with the Raytrace material. You can view this as an ambient lighting color that you can control on a per-material basis, but don’t confuse it with the ambient absorption from the Basic Parameters rollout.

By mapping this parameter, you can simulate radiosity: the ambient light that results from reflected light in a scene. One effect of radiosity is color bleeding. For example, in strong light a white shirt next to an orange wall will show a reflected orange color.

**Translucency**—Creates a translucent effect (page 3–1027). The Translucency color is a non-directional diffuse reflection. The diffuse color on an object depends upon the angle between the surface normal and the position of the light source. By ignoring the surface normal alignment, this color component simulates translucent materials.

For thin objects, the appearance can be like shining a light on the back of a piece of rice paper. You can cast shadows onto the back of the paper and see them projected through the paper; this works well
with a projector light. On thicker objects, you can get some good wax-like effects.

**Fluorescence and Fluor. Bias**—Creates an effect similar to black light on a black light poster. The light from a black light is largely ultraviolet, outside the visible spectrum. Under black light, *fluorescent* (page 3–942) paints flare or glow. The fluorescence in Raytrace material takes whatever light it sees in the scene, applies the Bias to it, and then, regardless of the color of the lights in the scene, illuminates the fluorescent material as if it were lit by white light.

At 0.5, The Bias makes Fluorescence behave just like diffuse coloring. Bias values higher than 0.5 increase the fluorescent effect, making the object brighter than other objects in the scene. Bias values lower than 0.5 make the object dimmer than other objects in the scene. You can get some chromatic shifting effects with this.

Tip: Full saturation and value for the Fluorescence color help give the effect of commercial fluorescent paints.

Tip: A slight amount of Fluorescence can add to the realism of skin and eyes.

**Wire group**

*Size*—Sets the size of the wire in *wireframe mode* (page 3–1034). You can set either pixels (the default) or current units.

*In*—Chooses how to measure wire. With pixels, wires maintain the same apparent thickness regardless of the scale of the geometry or how near or far the object is positioned. With units, the wires appear thinner at a distance and thicker at close range, as if they were modeled in the geometry.

*Pixels*—(The default.) Measures wire in pixels. 

*Units*—Measures wire in 3ds Max units.

**Advanced Transparency group**

The controls in this group let you further tune transparency effects.

**Transp. (Transparency Environment)**—Similar to the environment map in Basic Parameters, but overrides the scene’s environment map for transparency (refraction) only. Transparent objects refract this map, while reflections still reflect the scene (or the Basic Parameters Environment map, if one is chosen).

Click the button to choose the Transparency Environment map. Use the check box to toggle the effect of the map.

**Lock button**—Locks the Transparency Environment map to the Environment map (found on the *Basic Parameters rollout* (page 2–1514)). When on, the Transparency Environment map controls are disabled, and a map applied to the Raytrace Environment applies to the Transparency Environment as well. When off, the Transparency Environment map controls are enabled, and the Transparency Environment can have a different map assigned to it. Default=on.

Changing this button’s setting here also changes it on the *Basic Parameters rollout* (page 2–1514) and the *Maps rollout* (page 2–1523).

**Density**—The density controls are for transparent materials. If the material is opaque (the default), they have no effect.

**Color**—Sets a transmission color based on thickness. While filter (Transparency) color tints objects behind the transparent object, the density color gives the appearance of color within the object itself, like tinted glass.

To use, first make sure the object is transparent. Click the color swatch to display the Color Selector. Choose a color, and then turn on the check box.
The Amount controls the amount of density color. Reducing this value reduces the density color
effect. Range=0 to 1.0. Default=1.0.

A thin piece of tinted glass is mainly clear, while
a thick piece of the same glass has more color.
The Start and End controls help you simulate this
effect. They are expressed in world units. Start
is the position in the object where the density
color begins to appear. (Default=0.0.) End is the
position in the object where the density color
reaches its full Amount value. (Default=25.0) To
have a lighter effect, increase the End value. To
have a heavier effect, reduce the End value.

The object must be at least as thick as the Start
value before the density color is visible.

You can map this color component.

**Fog**—Density fog is also a thickness-based effect.
It fills the object with a fog that is both opaque and
self illuminated. The effect is like smoke trapped
in a glass, or wax at the tip of a candle. Colored fog
in tubular objects can resemble neon tubes.

To use, first make sure the object is transparent.
Click the color swatch to display the Color Selector.
Choose a color, and then turn on the check box.

The Amount controls the amount of density fog.
Reducing this value reduces the density fog effect
and makes the fog translucent. Range=0 to 1.0.
Default=1.0.

The Start and End controls let you adjust the fog
effect based on the object’s dimensions. They are
expressed in world units. Start is the position in
the object where the density fog begins to appear.
(Default=0.0.) End is the position in the object
where the density fog reaches its full Amount
value. (Default=25.0) To have a lighter effect,
increase the End value. To have a heavier effect,
reduce the End value.

You can map this color component.

**Render objects inside raytraced objects**—Turns the
rendering of objects inside raytraced objects on
or off. Default=on.

**Render atmospherics inside raytraced
objects**—Turns the rendering of atmospheric
effects inside raytraced objects on or off.
Atmospheric effects include fire, fog, volume light,
and so on. Default=on.

**Reflections group**

Controls in this group give you finer control over
reflections.

**Type**—When set to **Default**, reflections are layered
with the Diffuse color. For example, if the material
is not transparent and completely reflective, no
diffuse color is visible. When set to **Additive**, reflections are added to the Diffuse color, as in
Standard materials (page 2–1465). The diffuse
component is always visible.

**Gain**—Controls reflection brightness. The lower
the gain value, the brighter the reflection. At a gain
of 1.0, no reflection is visible. Default=0.5.
### Interface

![Raytracer Controls](image)

**Local Options group**

**Enable Raytracing**—Turns the raytracer on or off. Default=on.

Even with ray tracing off, Raytrace material and Raytrace map still reflect and refract the environment, including both the environment map for the scene, and the environment map assigned to the Raytrace material.

**Raytrace Atmospherics**—Turns the ray tracing of atmospheric effects on or off. Atmospheric effects include fire, fog, volume light, and so on. Default=on.

**Enable Self Reflect/Refract**—Turns self reflection/refraction on or off. Default=on.

Can an object reflect itself? For example, a teapot’s body reflects the teapot’s handle, but a sphere will never reflect itself. If you don’t need this effect, you can improve render time by turning off this toggle.

**Tip:** If you have a transparent object such as glass, and Enable Self Reflect/Refract is on, you don’t have to make the object 2-sided (page 3–901). The raytracer sees back faces when exiting refractive objects.

**Reflect/Refract Material IDs**—When on, the material reflects effects assigned to material IDs in the renderer’s G-buffer (page 3–946) on or off. Default=on.

By default, Raytrace material and Raytrace map reflect effects assigned to a material’s ID, so that G-buffer effects are not lost. For example, if a ray traced object reflects a lamp made to glow with the Video Post Glow filter (Lens Effects Glow), the reflection glows as well.

**Ray trace Enable group**

These two check boxes turn ray tracing of reflections or refractions on or off for this material. If you are using the Raytrace material to create only reflections or refractions, turn off the one you aren’t using to improve rendering time.

**Raytrace Reflections**—Turns ray tracing of reflective objects on or off. Default=on.

**Raytrace Refractions**—Turns ray tracing of transparent objects on or off. Default=on.

**Local Exclude**—Displays the local Exclude/Include dialog (page 2–1531).

An object that is excluded locally is excluded from this material only.

**Tip:** Using exclusion lists is one of the best and simplest ways to speed up the raytracer.

**Bump Map Effect**—Adjusts the effect of bump maps on ray traced reflections and refractions. Default=1.0.

**Falloff End Distance group**

**Reflect**—Dims reflections to black at this distance. Default=100.0.

**Refract**—Dims refractions to black at this distance. Default=100.0.

**Note:** The toggles for Reflect Falloff and Refract Falloff aren’t animatable.
Raytraced Reflection and Refraction Antialiaser group

Controls in this group let you override the global antialiasing settings for raytraced maps and materials. They are unavailable if antialiasing is turned off globally. To turn on antialiasing globally, choose Rendering > Raytrace Globals to display the Global Raytracer Settings dialog (page 2–1528).

On—When on, uses antialiasing. Default=unavailable unless global antialiasing is on; on if global antialiasing is turned on.

Drop-down list—Chooses which antialiasing settings to use. There are three alternatives:

Use Global Antialiasing Settings—(The default.) Uses the global antialiasing settings.

Fast Adaptive Antialiaser—Uses the Fast Adaptive antialiaser, regardless of the global setting.

Multiresolution Adaptive Antialiaser—Uses the Multiresolution Adaptive antialiaser, regardless of the global setting.

...—The button with the ellipsis to the right of the drop-down list displays another dialog to let you set antialiasing controls locally. The dialog displayed depends on which alternative you chose in the drop-down list, as follows:

Use Global Antialiasing Settings—Clicking ... displays the Global Raytracer Settings dialog (page 2–1528).

Fast Adaptive Antialiaser—Clicking ... displays the Fast Adaptive Antialiaser dialog (page 2–1533).

Multiresolution Adaptive Antialiaser—Clicking ... displays the Multiresolution Adaptive Antialiaser dialog (page 2–1534).

When you change settings for an antialiaser locally, you don’t affect the global settings for that antialiaser.

Raytrace Maps Rollout

As with a standard material, the Maps rollout for a Raytrace material (page 2–1512) contains map buttons for the components of the Raytrace material that can be mapped.

You can choose from a large variety of map types. See Map Types (page 2–1617) to find descriptions of these types, and how to set their parameters.

Assigning the Same Map to Different Parameters

Applying the same map to different parameters is useful in some cases. For example, using a pattern as both a self-illumination map and an opacity map can make the pattern appear to glow and hover in space.

Blending Map Amounts for Opacity and Other Material Components

The Specular Level, Glossiness, Self-Illumination, and Opacity values in the four spinners in the Basic Parameters rollout are blended with their associated map Amount values in the Maps rollout.

When the Opacity spinner is set to 0, the map Amount spinner completely controls Opacity. That is, reducing the Amount value increases the transparency of the entire surface. On the other hand, when Opacity is 100, reducing the map Amount value increases the opacity of the areas where the Opacity map is less than 1. For example, you can now adjust a Checker Opacity map so that the solid areas remain solid, while the clear areas are semi-transparent.

The Specular Level, Glossiness, and Self-Illumination channels all behave in the same way. A setting of 100 applies all of the map; a setting of 0 is the equivalent of turning the map off.
When you load old 3ds Max files or bring earlier materials from the Browser into the Materials Editor, the spinner values for Opacity, Specular Level, Glossiness, and Self-illumination are altered, where necessary, to maintain the equivalent material effect.

Procedures

To assign a map:

1. Click a map button.
   A modal Material/Map Browser (page 2–1412) is displayed.

2. Use the Browse From buttons to choose where you want to look.
   If you choose Material Library and the dialog’s display area is blank, you need to open a library file. Click the Open button and then choose the library to browse.

3. Use the display buttons to choose how you view maps.
   • View List shows each map by name.
   • View List + Icons shows a small preview and each map’s name.
   • View Small Icons shows a small preview for each map.
   • View Large Icons shows a large preview for each map, along with the map’s name.
   Tip: You can resize the Browser dialog to increase the size of the display area. This is especially useful when you view large icons.

4. Double-click the map you want.

To use the same map for different parameters:

1. In the Maps rollout, use a map button to assign a map.
   The Material Editor is now at the map level, and displays controls for the map parameters.

2. Click Go To Parent to return to the material level, and then open the Maps rollout.

3. Drag the assigned map button to another map button.
   The Copy (Instance) Map dialog (page 2–1451) is displayed.

4. Choose Copy or Instance, and then click OK.
   If you choose Swap, the Material Editor swaps the two button assignments.

To view the parent material’s parameters:

• If you are currently at the map level in the Material Editor, click Go To Parent.
   The parameters for the map’s parent material are displayed. Also, the Show End Result and Go to Parent buttons become unavailable.

To view a map’s parameters:

• If you are currently at the material level in the Material Editor, click the button that corresponds to the map.
   The parameters for the map are displayed. Also, the Show End Result (page 2–1446) and Go to Parent (page 2–1446) buttons become available.

   In the Basic Parameters rollout, if a map has been assigned to a color component or parameter, the corresponding button displays a letter M. In the Maps rollout, if a map has been assigned, the corresponding button displays the map name.

To view a map’s location:

• Click Material/Map Navigator to view the Navigator.
   The Material/Map Navigator (page 2–1447) displays the hierarchy of the current material, which contains the map.
To go to a map using the Navigator:

- In the Material/Map Navigator (page 2–1447), click the name of the map, or the green or red parallelogram to the left of the map’s name.

  The Navigator goes to the level of the map, and the Material Editor displays the controls for the map you clicked.

  As the Navigator’s map tree shows, maps for basic material components and parameters are one level below the material itself.

To preview a map in a sample slot:

1. Go to the level of the map, as described in previous procedures.

   The Material Editor displays the map’s parameters.

2. Turn off Show End Result (page 2–1446).

   The sample slot shows the map instead of the material. If the map contains sub-maps, these are also visible.

   By default, the sample slot displays a map with no three-dimensional shading. You can change this in the Material Editor Options dialog (page 2–1436).

To view the map interactively:

1. Select an object.

2. In the object’s creation parameters, make sure that Generate Mapping Coords is on.

   If the object type does not have a Generate Mapping Coordinates toggle, you need to assign mapping coordinates by applying a UVW Map modifier (page 1–922).

3. In the Material Editor, assign the mapped material to the object.

4. If you are at the material level (the top level), click the appropriate map button to go to the map level.

5. Turn on Show Map in Viewport (page 2–1445).

   The map appears on objects assigned the material in all shaded viewports. Now when you adjust the map, the viewports update to display the adjustments.

   Turning on Show Map In Viewport for one map automatically turns this button off for all other maps the material has.

   Viewports can display 2D maps such as Checker and Bitmap. They cannot display other kinds of maps such as 3D maps. Show Map in Viewport is unavailable if the active map type cannot display in viewports.

   Tip: Displaying mapped materials in a viewport can slow performance. If you don’t need to view the texture, turn off its viewport display.

To turn off interactive texture display:

1. Go to the map level.

   If you are at the material level, click the appropriate map button to go to the map level.

2. Turn off Show Map in Viewport (page 2–1445).

   The object is shaded but the map no longer appears.

To turn a map off:

- Turn off the map’s check box.

  The check box is to the left of the map’s name on the Maps rollout.

To turn a map on:

- Turn on the map’s check box.

  The check box is to the left of the map’s name on the Maps rollout.
To change a map’s strength:

- Adjust the map’s Amount spinner in the Maps rollout.

The material’s sample slot reflects the change.

Note: Adjusting a map’s output (in the map’s Output rollout) can also change the map’s strength.

To move directly to an ancestor:

1. Click the arrow to the right of the map’s name (page 2–1448) field.

A drop-down list of ancestors is displayed.

2. Click a name in the Ancestor list.

With this list, you can skip intermediate levels in the tree.

The Ancestor drop-down list shows only part of the tree. It does not show side branches and siblings. To view these, use the Material/Map Navigator (page 2–1447).

You can also use the Go Forward to Sibling (page 2–1447) and Go to Parent (page 2–1446) buttons.

To change a map type:

1. At the level of a map, click the button labeled Type below the Material Editor toolbar.

A modal Material/Map Browser (page 2–1412) is displayed. If you were at a map, it lists only maps (if you were at a material when you clicked Type, the Browser lists only materials).

2. Choose a map type from the list, and then click OK.

If you change a map type and the new map type can have component maps, a Replace Map dialog is displayed. This dialog gives you a choice between discarding the original map or using it as a component map.

If the new map type does not have components, it simply replaces the original map type.

### Interface

The Maps rollout for Raytrace contains a wide button for each map type. Click this button to select a bitmap file stored on disk or to select a procedural-map type (page 3–997). After you select a map, its name and type appears on the button. Use the check box to the left of the button to turn the effect of the map off and on. When the check box is off, the map is not computed and has no effect in the renderer.

The Amount spinner determines the amount that the map affects the material, expressed as a percentage of full intensity. For example, a diffuse map at 100% is completely opaque and covers the base material. At 50%, it is semi-transparent and the base material (the diffuse, ambient, and other colors of the material without mapping) shows through.
Lock button—Locks the Environment map to the Transparency Environment map. When on, the Transparency Environment map controls are disabled, and a map applied to the Raytrace Environment applies to the Transparency Environment as well. When off, the Transparency Environment map controls are enabled, and the Transparency Environment can have a different map assigned to it. Default=on.

Changing this button’s setting here also changes it on the Basic Parameters rollout (page 2–1514), and the Extended Parameters rollout (page 2–1519).

Diffusion Mapping

The Diffusion map component lets you apply an additional, second texture to modify the Diffuse component. Typically, you will want to reduce the Amount of this map to allow the main Diffuse map to show through.

For example, you might have a clean, bright image for a billboard. You use this image as the Diffuse map, and then use a second map as a Diffusion map to apply soot and city grime.

Tip: Animating the Amount can change the appearance of the material over time, letting the Diffusion map either conceal or reveal the underlying Diffuse map.

Note: Show Map In Viewport does not display the Diffusion map.

Raytrace Dynamics Properties Rollout

As with a standard material, the Dynamics Properties rollout for a Raytrace material (page 2–1512) lets you specify surface properties that affect the animation of an object upon collision with another object. If there are no collisions in your simulation, these settings have no effect.

Since the Dynamics Properties rollout is available at the top level of any material (including sub-materials), you can specify different surface dynamic properties for each face in an object. There are also controls in the Dynamics utility that let you adjust the surface properties at the object level, but only the Materials Editor lets you alter the surface properties at the sub-object level, through use of a Multi/Sub-Object material (page 2–1594).

As a default, the values in the Dynamics Properties rollout provide a surface that’s similar to Teflon-coated hardened steel.

Interface

<table>
<thead>
<tr>
<th>Dynamics Properties</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bounce Coefficient</strong>: 1.0</td>
</tr>
<tr>
<td><strong>Static Friction</strong>: 0.0</td>
</tr>
<tr>
<td><strong>Sliding Friction</strong>: 0.0</td>
</tr>
</tbody>
</table>

Bounce Coefficient—Sets how far an object bounces after hitting a surface. The higher the value, the greater the bounce. A value of 1 represents a "perfectly elastic collision," or a bounce in which no kinetic energy is lost. Default=1.0.

If you’ve seen the desktop toy with four ball bearings swinging back and forth on strings and hitting one another, you’ve seen an example that comes very close to a bounce coefficient of 1. Generally, hardened steel or a super ball have a bounce near 1, while lead has a bounce near 0.

Static Friction—Sets how difficult it is for the object to start moving along a surface. The higher this value, the more difficult. Default=0.0.

If something weighs ten pounds and sits on Teflon (a static friction of near 0), it takes almost no force to make it move sideways. On the other hand, if it sits on sandpaper, then the static friction might be very high, on the order of 0.5 to 0.8. A static
friction near 1 is very difficult to create in the real world without adhesives or friction material.

**Sliding Friction**—Sets how difficult it is for the object to keep moving over a surface. The higher this value, the more difficult for the object to keep moving. Default=0.0.

Once two objects begin to slide over one another, static friction disappears and sliding friction takes over. Generally, sliding friction is lower than static friction due to surface tension effects. For example, once steel starts sliding over brass (a value of static friction that might run from 0.05 to 0.2), the sliding friction drops to a significantly lower value, on the order of .01 to 0.1. For some materials, such as specific friction materials like brake linings, sliding friction is just as high as static friction because it is used in conjunction with a nearly frictionless material such as hardened polished steel.

**Raytracer Global Parameters Rollout**

Parameters in the Global Raytracer Settings dialog globally control the raytracer itself. That is, they affect all Raytrace materials and Raytrace maps in your scene. They also affect the generation of Advanced Ray-traced shadows (page 3–1000) and Area shadows (page 3–911).

Note: These controls adjust ray-trace settings for the scanline renderer only. The settings of these controls have no impact on the mental ray renderer, which has its own ray-tracing controls.

**Interface**

**Ray Depth Control group**

Ray depth is also known as recursion depth. This is how many times a ray is allowed to bounce before it is considered lost or trapped.
**Maximum Depth**—Sets the maximum recursion depth. Increasing this value potentially increases the realism of your rendered scene, at a cost of rendering time. You can reduce this value to reduce rendering time. Range=0 to 100. Default=9.

**Cutoff Threshold**—Sets a cutoff threshold for adaptive ray levels. If the contribution of any ray to the final pixel color drops below the cutoff threshold, the ray is terminated. Default: 0.05 (5% of the final pixel color). This can speed up your rendering time considerably.

**Color to use at Max Depth**—As a rule, when a ray reaches the maximum depth, it is rendered the same color as the background environment. You can override the color returned at maximum depth by either selecting a color, or setting an alternative environment map. This can make the "lost" ray invisible in the scene.

Tip: If you are having trouble with getting complex objects to render, especially glass, specify the maximum recursion color to something obvious, like magenta, and your background color to something that contrasts, like cyan. The chances are that a lot of your rays are getting lost in either maximum recursion or just being shot off into the world, totally missing anything you think they should strike. Try rendering the scene again. If this is the problem, try reducing the Maximum Depth value.

- **Specify**—Specifies what color the raytracer returns when the ray is considered lost or trapped. Click the color swatch to change this color.

- **Background**—(The default.) Returns the background color when the ray is considered lost or trapped. For Raytrace material, the background color is the global environment background, or is set locally in the Raytracer Parameters rollout (page 2–1704).

**Global Ray Antialiaser group**

Controls in this group let you set global antialiasing for raytraced maps and materials.

* Above: No antialiasing
* Below: Antialiasing of reflections

Tip: Turning on Supersample for a Raytraced material (in the Raytrace Basic Parameters rollout (page 2–1514)) usually provides adequate antialiasing. Use one of the raytrace antialiasers (Fast Adaptive or Multiresolution Adaptive) when you want to blur reflections or refractions.

- **On**—When on, uses antialiasing. Default=off.
- **Drop-down list**—Chooses which antialiasing settings to use. There are two alternatives:
  - **Fast Adaptive Antialiaser**—(The default.) Uses the Fast Adaptive antialiaser.
  - **Multiresolution Adaptive Antialiaser**—Uses the Multiresolution Adaptive antialiaser.

...—The button with the ellipsis to the right of the drop-down list displays another dialog to let you set antialiasing controls globally. The dialog displayed depends on which alternative you chose in the drop-down list, as follows:
• **Fast Adaptive Antialiaser**—Clicking ... displays the *Fast Adaptive Antialiaser dialog* (page 2–1533).

• **Multiresolution Adaptive Antialiaser**—Clicking ... displays the *Multiresolution Adaptive Antialiaser dialog* (page 2–1534).

**Global Raytrace Engine Options group**

These options are comparable to the local options on *Extended Parameters rollout* (page 2–1519) and the *Raytracer Controls rollout* (page 2–1521). Their setting affects all Raytrace materials and Raytrace maps in the scene, unless you set local overrides.

**Note:** In versions prior to 3ds Max 5, these controls were found on the Raytracer Options dialog, which is no longer present.

**Enable Raytracing**—Turns the raytracer on or off. Default=on.

Even with raytracing off, Raytrace material and Raytrace map still reflect and refract the environment, including both the environment map for the scene, and the environment map assigned to the Raytrace material.

**Raytrace Atmospherics**—Turns the raytracing of atmospheric effects on or off. Atmospheric effects include fire, fog, volume light, and so on. Default=on.

**Enable Self Reflect/Refract**—Turns self reflection/refraction on or off. Default=on.

Can an object reflect itself? For example, a teapot's body reflects the teapot's handle, but a sphere will never reflect itself. If you don't need this effect, you can improve render time by turning off this toggle.

**Tip:** If you have a transparent object such as glass, and Enable Self Reflect/Refract is on, you don't have to make the object *2-sided* (page 3–901). The raytracer sees back faces when exiting refractive objects.

**Reflect/Refract Material IDs**—When on, the material reflects effects assigned to material IDs in the renderer’s *G-buffer* (page 3–946) on or off. Default=on.

By default, Raytrace material and Raytrace map reflect effects assigned to a material's ID, so that G-buffer effects are not lost. For example, if a raytraced object reflects a lamp made to glow with the Video Post Glow filter (Lens Effects Glow), the reflection glows as well.

**Render objects inside raytraced objects**—Turns the rendering of objects inside raytraced objects on or off. Default=on.

**Render atmospherics inside raytraced objects**—Turns the rendering of atmospheric effects inside raytraced objects on or off. Atmospheric effects include fire, fog, volume light, and so on. Default=on.

**Enable Color Density / Fog Effects**—Turns the color density and fog features on or off.

**Acceleration Controls**—Click to display the *Raytracing Acceleration Parameters dialog* (page 2–1531), which lets you adjust settings.

**Exclude**—Click to display the *Raytrace Exclude/Include dialog* (page 2–1531), which lets you exclude objects from ray-tracing.

**Show Progress Dialog**—When on, rendering displays a window with progress bars titled Raytrace Engine Setup. Default=on.

**Show Messages**—When on, displays a window, Raytrace Messages, that shows status and progress messages from the raytrace engine. Default=off.
Raytracing Acceleration Parameters Dialog

The controls in this dialog let you override the default acceleration values and specify your own requirements. Typically you don’t need to use them, but if you are familiar with the requirements of your scene, they can help you optimize raytrace rendering for your specific needs and time constraints.

Raytracing subdivides the scene, organizing it into a tree for raytrace purposes. A node in this tree is known as a "voxel." Voxel trees are dynamic, and you can't explicitly specify the structure of the tree. (If you set Max. Divisions to 2, the tree is an octree, which is possibly a more familiar data structure.)

Tip: If your scene is very unbalanced (for example, it has a giant planet object and a cluster of small spacecraft objects) keep the Balance setting low.

Interface

Face Limit—Sets the maximum number of faces allowed in a lattice voxel before it is subdivided. Default=10.

Balance—Determines the sensitivity of the subdivision algorithm. Increasing this value uses more memory but can increase performance. Default=4.0.

Max. Divisions—Sets the initial lattice dimension. For example, 4 is a 4 x 4 x 4 lattice. Default=30.

Max. Depth—Sets the maximum number of lattice subdivisions. Default=8.

Raytrace Exclude/Include Dialog

These dialogs let you specify which objects the raytracer will and won’t see. This is a good optimization when you are working with complex scenes and all you really need is for an object to reflect itself or some other, simpler elements in the scene.

The global dialog affects all Raytrace materials and Raytrace maps in your scene. The local dialog affects only the current material or map.
Tip: Another good use for exclusion can be when you are working on a scene where the world-space scale of objects is not realistic. For example, consider an animation of a space dog-fight, with a planet and its moon in the background. You would use a planet that was actually much smaller, relative to the fighters, than an actual planet. (For example, the planet might be only five times bigger than the fighters, and the moon only half as big as the fighters.) If the fighters are reflective, the reflections of the planet and moon will be incorrect and will give away the fact that you are using miniatures. In this case, raytrace the reflective fighters, and laser blasts, and so on, but exclude the planet and moon props from the raytracer. Create an environment map that represents the planet and moon at their correct scale, and make that the Raytrace material’s local environment. When you render, the scale of the planet and moon geometry appears to be correct, and the reflections on the fighters will behave as your eye expects.

Exclude/Include—Choose whether raytracing will exclude or include the objects named in the list on the right.

Illumination / Shadow Casting / Both—For the raytracer, this is turned off (always set to Illumination).

Scene Objects—Select objects from the Scene Objects list on the left, then use the arrow buttons to add them to the exclusion list on the right.

The Exclude/Include dialog treats a group as an object: you can exclude or include all objects in a group by selecting the group’s name in the Scene Objects list. If a group is nested within another group, it isn’t visible in the Scene Objects list.

Search Field—The edit box above the Scene Objects list lets you search for object names by entering names that use wildcards.

Display Subtree—When on, indents the list according to the object hierarchy.

Case Sensitive—When on, uses case sensitivity when searching object names.

Selection Sets—Displays a list of named selection sets. Choosing a selection set from this list selects those objects in the Scene Objects list.

Clear—Clears all entries from the Exclude/Include list on the right.

OK—Closes the dialog and retains the exclude or include operations you performed.

Cancel—Closes the dialog and cancels the exclude or include operations you performed.

Both the Global and the Local Exclude/Include dialogs contain the following controls:
Raytrace Antialiaser Dialog: Fast Adaptive Antialiaser

Rendering menu > Raytracer Settings > Global Raytracer Settings dialog > Global Ray Antialiaser group > Turn on global antialiasing. > Choose Fast Adaptive Antialiaser from the drop-down list. > ... button

Material Editor > Type button > Material/Map Browser > Raytrace material > Raytracer Controls rollout > Raytraced Reflection and Refraction Antialiaser group (enabled only if antialiasing is globally enabled) > Choose Fast Adaptive Antialiaser from the drop-down list. > ... button

Material Editor > Type button > Material/Map Browser > Raytrace map > Raytracer Parameters rollout > Raytraced Reflection and Refraction Antialiaser group (enabled only if antialiasing is globally enabled) > Choose Fast Adaptive Antialiaser from the drop-down list. > ... button

The Fast Adaptive Antialiaser dialog changes settings for the Raytrace material and maps Fast Adaptive antialiaser. You can use this dialog either globally, from the Global Raytracer Settings dialog (page 2–1528), or locally, from the Raytracer Controls rollout (page 2–1521). When you locally change settings for an antialiaser, you don’t affect the global settings for that antialiaser.

Interface

Blur / Defocus (Distance Blur) group

Blur Offset — Affects the sharpness or blurriness of the reflections or refractions without regard to distance. You can use Blur Offset to soften or defocus the details of a reflection or refraction. The value is specified in pixels. Default=0.0.

Tip: The default Blur Offset setting usually produces good results. If you see aliasing in reflections or refractions, increase its value in increments of 0.5 until the aliasing goes away.

See Blur/Blur Offset (page 3–918).

Blur Aspect — This is an aspect ratio that changes the shape of the blur. Usually you will not need to change it. Default=1.0.

Tip: If you see aliasing that occurs mostly along horizontal lines, try increasing Blur Aspect to 1.5. This changes the shape of the blurred effect. The reverse is also true. If aliasing occurs mostly along vertical lines, try decreasing Blur Aspect to 0.5.

Defocusing — Defocusing is a blur based on distance. With Defocus, objects near the surface are not blurred, but objects farther away are blurred. The rays cast are spread as they leave the Raytrace material object’s surface. Default=0.0.

Tip: Increasing the value of Defocusing can give a good distance blurring effect. Small adjustments are usually adequate. Try starting with a value less than 0.1, and increase or decrease it as necessary. Also try adjusting Reflect Falloff in Raytrace material or Attenuation in Raytrace map to get the best distance blurring effect.

Defocus Aspect — This is an aspect ratio that changes the shape of the defocusing. Usually you will not need to change it. Default=1.0.

Blur Offset is similar to blur offset for Bitmaps, while defocus is based on distance.
Raytrace Antialiaser Dialog: Multiresolution Adaptive Antialiaser

The Multiresolution Adaptive Antialiaser dialog changes settings for the Raytrace material and maps Multiresolution Adaptive antialiaser. You can use this dialog either globally, from the Global Raytracer Settings dialog (page 2–1528), or locally, from the Raytracer Controls rollout (page 2–1521). When you locally change settings for an antialiaser, you don’t affect the global settings for that antialiaser.
Blur Aspect—This is an aspect ratio that changes the shape of the blur. Usually you will not need to change it. Default=1.0.

Tip: If you see aliasing that occurs mostly along horizontal lines, try increasing Blur Aspect to 1.5. This changes the shape of the blurred effect. The reverse is also true. If aliasing occurs mostly along vertical lines, try decreasing Blur Aspect to 0.5.

Defocusing—Defocusing is a blur based on distance. With Defocus, objects near the surface are not blurred, but objects farther away are blurred. The rays cast are spread as they leave the Raytrace material object's surface. Default=0.0.

Tip: Increasing the value of Defocusing can give a good distance blurring effect. Small adjustments are usually adequate. Try starting with a value less than 0.1, and increase or decrease it as necessary. Also try adjusting Reflect Falloff in Raytrace material or Attenuation in Raytrace map to get the best distance blurring effect.

Defocus Aspect—This is an aspect ratio that changes the shape of the defocusing. Usually you will not need to change it. Default=1.0.

Architectural Material

The settings for an Architectural material are physical properties, so it provides the greatest possible realism when used with photometric lights (page 2–1301) and radiosity (page 3–51). With this combination of features, you can create lighting studies with a high degree of accuracy.

It is not recommended that you use the Architectural material with standard 3ds Max lights in the scene, or with the Light Tracer. The point of this material is to provide accurate modeling. Use it with photometric lights and radiosity. The mental ray renderer, on the other hand, can render the Architectural material, with some limitations described below.

Tip: If you don't need the degree of realism that the Architectural material provides, you can use a standard material (page 2–1465) or other material type.

Material Templates

When you create a new material, you can choose from a variety of templates. A template is simply a set of preset material parameters, which approximates the kind of material you want to create, and gives you a starting point. See Templates Rollout (page 2–1536).

Rendering Architectural Materials with the mental ray Renderer

The mental ray Renderer (page 3–78) can render Architectural materials. There are some limitations, as follows:

- Emit Energy (Based on Luminance): This setting is ignored. The Architectural material does not contribute to the scene's lighting.
- Sampling Parameters: These settings are ignored, as the mental ray renderer uses its own sampling.

Tip: When rendering with mental ray, instead of the Architectural material, we highly recommend that you use the Arch & Design material (page 2–1549) instead. This material was designed especially for mental ray and provides superior flexibility, rendering characteristics, and speed.

Interface

Templates Rollout (page 2–1536)
Physical Qualities Rollout (page 2–1536)
Special Effects Rollout (page 2–1539)
Advanced Lighting Override Rollout (page 2–1540)
SuperSampling Rollout (page 2–1459)
mental ray Connection Rollout (page 2–1461)

**Templates Rollout**

The Templates rollout gives you a list of material types to choose from. A template is simply a set of preset parameters for the Physical Qualities rollout, which approximates the kind of material you want to create, and gives you a starting point. Once you choose a template, you can adjust its settings and add maps (page 2–1617) to enhance realism and improve the material’s appearance.

The templates do not affect the Diffuse Color on the Physical Qualities rollout, only the numeric settings.

**Interface**

- **Template drop-down list**—Chooses the kind of material you are designing. Each template provides preset values for the various material parameters.

These are the material templates provided with 3ds Max. The purpose of most templates is clear, so the table doesn’t comment on all of them.

**Physical Qualities Rollout**

When you create a new Architectural material (page 2–1535) or edit an existing one, the settings on the Physical Qualities rollout are the ones you are most likely to need to adjust.

**Procedure**

**To match a material’s luminance to a light:**

**Warning:** Only photometric lights give correct luminance. Also, the mental ray renderer disregards the Emit Energy setting.
Click to turn on Set Luminance From Light (below the Luminance setting), then in a viewport, click the light.

After you choose the light, the button turns off once more.

Tip: If you are using a radiosity solution (page 3-51), make sure to turn on Emit Energy (Based On Luminance) for any material whose luminance is greater than zero. This control is on the Advanced Lighting Override rollout (page 2-1540).

- **Diffuse Map**—These controls assign a map to the material’s diffuse component. To assign a map, click the oblong button (labeled “None” by default). This displays the Material/Map Browser. In the Browser, choose the map type, and then click OK. If you choose Bitmap as the map type, an additional dialog prompts you to choose the particular bitmap file to use.

While a map is assigned to the material, its name appears as the map button’s label.

Diffuse Color—Controls the diffuse color (page 3-929). The diffuse color is the color this material has in direct light. Click the color swatch to display the Color Selector (page 1-161) and change the diffuse color.

- **Set color to texture average**—Click to change the diffuse color to an average of the colors in the current diffuse map. (If no map is assigned, this button has no effect.)

This button is useful when you are going to reduce the diffuse map’s Amount. When the diffuse map pattern appears over an average of itself, for most kinds of materials the effect is more realistic than when the pattern appears over an unrelated color.

**Warning:** This button will change the diffuse color even if the diffuse map is turned off.

- **Amount spinner**—The spinner at the left sets the amount of diffuse map to use. This value is a percentage: at 100.0, only the map is visible; at lower amounts, the diffuse color shows through; at 0.0, the map is not visible at all.

- **On/off**—The check box between the spinner and the map button is an on/off switch. When on, the map appears in the material. When off, the map does not appear.

Shininess—Sets the shininess of the material. This value is a percentage: at 100.0, the material is as shiny as possible; at lower values, it is less shiny; at 0.0, it is not shiny at all.

In general, the shinier a material is, the smaller its specular highlights appear. Specular highlights are reflections of the lights that illuminate the material. (The index of refraction can also affect the size of highlights.) Shininess also controls how much the material reflects other objects in the scene.

Note: Shininess alone is not sufficient to produce specular reflections and highlights on a surface. You must also consider the Index Of Refraction (IOR), described below.

The amount spinner for a shininess map scales the map. If no map is assigned, the spinner value is used by itself.
Transparency—Controls how transparent the material is. This value is a percentage: at 100.0, the material is completely transparent; at lower values, the material is partly opaque; and at 0.0, the material is completely opaque.

Tip: The effect of transparency is best previewed against a pattern background. If the material preview doesn’t show a pattern of colored checks, right-click the material preview or the map preview, and choose Background from the pop-up menu.

The amount spinner for a transparency map scales the map. If no map is assigned, the spinner value is used by itself.

Translucency—Controls how translucent the material is. A translucent object transmits light, but also scatters it within the object. This value is a percentage: at 0.0, the material is completely opaque; at 100.0, the material is as translucent as possible.

The amount spinner for a translucency map scales the map. If no map is assigned, the spinner value is used by itself.

Index of Refraction—The index of refraction (IOR) controls how severely the material refracts transmitted light, and how reflective the material appears. At 1.0, the IOR of air, the object behind the transparent object does not distort. At 1.5, the object behind distorts greatly, like a glass marble. Range=1.0 to 2.5.

Common IORs (assuming the camera is in air or a vacuum) are:

<table>
<thead>
<tr>
<th>Material</th>
<th>IOR Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vacuum</td>
<td>1.0 (exactly)</td>
</tr>
<tr>
<td>Air</td>
<td>1.0003</td>
</tr>
<tr>
<td>Water</td>
<td>1.333</td>
</tr>
<tr>
<td>Glass</td>
<td>1.5 to 1.7</td>
</tr>
<tr>
<td>Diamond</td>
<td>2.419</td>
</tr>
</tbody>
</table>

In the physical world, the IOR results from the relative speeds of light through the transparent material and the medium the eye or the camera is in. Typically this is related to the object’s density: the higher the IOR, the denser the object.

The IOR affects how shiny a material appears; or, in the case of transparent materials such as water or glass, the amount of distortion. For nontransparent materials, the higher the IOR, the more light is reflected from the material, and the shinier the material appears.

A refractive index of 1.0 means that all light is transmitted into the material. In this case, even if the material has a high Shininess value, the surface appears perfectly diffuse, and shows no specular highlights.

Luminance cd/m²—When its luminance is greater than 0.0, the material appears to glow, and if you turn on Emit Energy (see below), it contributes energy to the radiosity solution (page 3–51). Luminance is measured in candelas per meter squared.

The amount spinner for a luminance map scales the map. If no map is assigned, the spinner value is used by itself.

Set luminance from light—Obtains the material’s luminance from a light in the scene. Click to turn on this button, then click a light in a viewport. The material’s luminance is set to match the luminance of the light, and the button is turned off once more.

2-Sided—When on, makes the material 2-sided (page 3–901). Applies the material to both sides of selected faces.

Raw Diffuse Texture—When on, excludes the material from lighting and exposure control. This makes the material render with a completely flat look, using the pure RGB values of the diffuse color or map. Default=off.
Special Effects Rollout

When you create a new Architectural material (page 2–1535) or edit an existing one, the settings on the Special Effects rollout let you assign maps that create bumps or displacement, adjust light intensity, or control transparency.

Interface

Bump controls—These controls assign a bump map (page 2–1506) to the material. To assign a map, click the oblong button (labeled “None” by default). This displays the Material/Map Browser. In the Browser, choose the map type, and then click OK. If you choose Bitmap as the map type, an additional dialog prompts you to choose the particular bitmap file to use.

While a map is assigned to the material, its name appears as the map button’s label.

Displacement controls—These controls assign a displacement map (page 2–1511) to the material. To assign a map, click the oblong button (labeled “None” by default). This displays the Material/Map Browser. In the Browser, choose the map type, and then click OK. If you choose Bitmap as the map type, an additional dialog prompts you to choose the particular bitmap file to use.

While a map is assigned to the material, its name appears as the map button’s label.

• Amount spinner—The spinner at the left sets the amount of bump mapping to use. At 1000.0, bump mapping has its greatest effect; at lower amounts, the bumps are less pronounced; at 0.0, the bumps are not visible at all. Negative values reverse the direction of the bump effect. Range: −1000.0 to 1000.0.

• On/off—The check box between the spinner and the map button is an on/off switch. When on, the map is used in the material. When off, the map is not used.

Intensity controls—These controls assign an intensity map to the material, modulating the material’s brightness. The map is treated as a black-and-white scale of intensity values.

Tip: Applying a low-frequency Noise map (page 2–1674) to the intensity can help reduce the “computer-generated” look of a texture, and add a natural feel to surfaces such as bricks and carpets lit by daylight.

To assign a map, click the oblong button (labeled “None” by default). This displays the Material/Map Browser. In the Browser, choose the map type, and then click OK. If you choose Bitmap as the map type, an additional dialog prompts you to choose the particular bitmap file to use.

• Amount spinner—The spinner at the left sets the amount of displacement mapping to use. At 1000.0, displacement mapping has its greatest effect; at lower amounts, the displacement is less pronounced; at 0.0, the displacement are not visible at all. Negative values reverse the direction of the displacement. Range: −1000.0 to 1000.0.

• On/off—The check box between the spinner and the map button is an on/off switch. When on, the map is used in the material. When off, the map is not used.
While a map is assigned to the material, its name appears as the map button’s label.

- **Amount spinner**—The spinner at the left sets the amount of intensity mapping to use. At 100.0, intensity mapping has its greatest effect; at lower amounts, the effect is less pronounced; at 0.0, the map has no effect; and at values less than 0.0, the material is dimmed. Range: –100.0 to 100.0.

- **On/off**—The check box between the spinner and the map button is an on/off switch. When on, the map is used in the material. When off, the map is not used.

**Cutout controls**—These controls assign a cutout map (page 2–1542) to the material. To assign a map, click the oblong button (labeled “None” by default). This displays the Material/Map Browser. In the Browser, choose the map type, and then click OK. If you choose Bitmap as the map type, an additional dialog prompts you to choose the particular bitmap file to use.

While a map is assigned to the material, its name appears as the map button’s label.

- **Amount spinner**—The spinner at the left sets the amount of cutout mapping to use. This value is a percentage: at 100.0, the map has its full effect; lower amounts have the effect of darkening the map, reducing its effect and increasing transparency. At 0.0, the map is completely black, making objects with this material completely transparent.

- **On/off**—The check box between the spinner and the map button is an on/off switch. When on, the map is used in the material. When off, the map is not used.
Left: Excessive bleeding of the floor color onto the walls and ceiling.
Right: Reducing the floor’s Reflectance Scale causes less bleeding.

You might want to increase Reflectance Scale when the scene includes a large dark area (for example, a black floor). This can lead to a very dark radiosity result. You can maintain the floor’s color but increase reflectance, giving the solution the colors you want while increasing its brightness.

The room is lit only by spotlights pointed at the floor. Increasing reflectance of the floor brightens the entire room.

Tip: Check the reflectance and transmittance display (page 2–1430) to get an idea of how the current material will affect the radiosity solution.

**Interface**

**Warning:** There is no problem with reducing the default scale, but increasing it for any of these parameters might cause colors to “burn out”: if the scale is too great, they render as pure white, appearing overexposed.

**Emit Energy (Based on Luminance)**—When on, the material contributes energy to the radiosity solution, based on the material’s luminance value (see above).

Note: The mental ray renderer (page 3–78) does not use this setting. The Architectural material does not contribute to the scene’s lighting.

Increasing the Luminance (above 0.0) makes an object appear to glow in ordinary renderings, but does not contribute energy to the radiosity solution. To have radiosity processing take a self-illuminating material into account, turn on Emit Energy (Based On Luminance).

Upper left: By default, luminous neon lights do not influence the scene light.
Right: With Emit Energy on, the radiosity solution takes luminance into account.

Tip: When you increase luminance to achieve a special effect in the rendering (for example, to make the globe surrounding a lamp appear to be glowing), probably you shouldn’t turn on Emit Energy (in the example, both the globe and lamp would then add light to the scene). When you
increase luminance because the object really glows (for example a neon light tube), then you should turn on Emit Energy, so that the object contributes light to the scene.

**Color Bleed Scale**—Increases or decreases the saturation of reflected color. Range=0.0 to 100.0. Default=100.0.

**Indirect Bump Scale**—Scales the effect of the base material’s bump mapping (page 2–1506) in areas lit by indirect light. When this value is zero, no bump mapping is done for indirect light. Increasing Indirect Light Bump Scale increases the bump effect under indirect lighting. This value does not affect the Bump amount in areas where the base material is lit directly. Range=–999.0 to 999.0. Default=100.0.

Tip: This parameter is useful because indirect bump mapping is simulated and not always accurate. Indirect Light Bump Scale lets you adjust the effect by hand.

**Reflectance Scale**—Increases or decreases the amount of energy the material reflects. Range=0.0 to 100.0. Default=100.0.

**Transmittance Scale**—Increases or decreases the amount of energy the material transmits. Range=0.1 to 5.0. Default=1.0.

Tip: Don’t use this control to increase self-illumination. Use the material’s Luminance instead. The Luminance control is on the Physical Qualities rollout (page 2–1536).

**Cutout Mapping**

Assigning a bitmap (page 2–1631) or procedural map (page 3–997) to the Cutout component of an Architectural material (page 2–1535) makes the material partially transparent. Lighter (higher-value) areas of the map render as opaque; darker areas render as transparent; and values in between are semi-transparent.

Setting the cutout map’s Amount to 100 applies all of the map. Transparent areas are fully transparent. Setting the Amount to 0 is the equivalent of turning the map off. Intermediate Amount values are blended with the Transparency value on the Physical Qualities rollout. Transparent areas of the map become more opaque.
Procedure

To use a cutout map:

1. Click the Cutout map button.

   The Material/Map Browser (page 2–1412) is displayed.

2. Choose from the list of map types (page 2–1617), and then click OK.

   The Material is now at the map level, and displays map controls.
   (If you choose Bitmap as the map type, you first see a file dialog that lets you choose the image file.)

3. Use the map controls to set up the map.

To remove a cutout map from a material:

Tip: You can disable the map without removing it. Simply turn off the toggle immediately to the left of the map button on the Special Effects rollout.

1. If the Material Editor is displaying the map controls, click the Type button (page 2–1449) to display the Material/Map Browser. If the map controls aren't visible, click the Cutout map button to display them, and then click the Type button.

2. In the Browser, choose NONE as the map type, and then click OK.

   The map is removed.

mental ray Materials

3ds Max comes with several materials created specifically for use with the mental ray renderer (page 3–78). These materials are visible in the Material/Map Browser (page 2–1412) when mental ray is the active renderer.

- **mental ray (page 2–1544)**

  The mental ray material has components for the surface shader, and for the other nine optional shaders that make up a material in mental ray.

- **Arch & Design (page 2–1562)**

  The Arch & Design material is a monolithic material shader designed to support most materials used in architectural and product-design renderings.

- **Car Paint (page 2–1576)**

  Car Paint, available as both a material and a shader, has components for a paint layer with embedded metal flakes, a clear-coat layer, and a Lambertian dirt layer.

- **DGS (page 2–1580)**

  DGS stands for Diffuse, Glossy, and Specular. This material behaves in a physically realistic way.

- **Glass (page 2–1582)**

  The Glass material simulates both the surface properties and the light-transmitting (photon) properties of glass.

- **Subsurface Scattering Materials (page 2–1583)**
The subsurface scattering materials, supported by a shader library from mental images, can model skin and similar organic materials.

Note: When you wire the parameters of an object with a mental ray material assigned, names of material parameters might differ from those in the Material Editor interface. Also, parameters not supported by 3ds Max might appear as blanks in the wiring menu.

mental ray Material

Material Editor > Type button > Material/Map Browser > mental ray

The mental ray material lets you create a material exclusively for use by the mental ray renderer (page 3–78). A mental ray material consists, at the top level, of from one to 10 kinds of shaders, or shading components.

Important: You must assign a shader to the material’s Surface component. Otherwise, the mental ray material will not be visible when you render.

Interface

The interface to the mental ray material consists of two rollouts:

- Material Shaders Rollout (mental ray Material) (page 2–1544)
- Advanced Shaders Rollout (mental ray Material) (page 2–1548)

Material Shaders Rollout (mental ray Material)

Material Editor > Type button > Material/Map Browser > mental ray > Material Shaders rollout

The mental ray material lets you create a material exclusively for use by the mental ray renderer (page 3–78). The Material Shaders rollout provides controls for the main kinds of component shaders you are likely to assign.

Important: You must assign a shader to the material’s Surface component. Otherwise, the mental ray material will not be visible when you render.

See also

Advanced Shaders Rollout (mental ray Material) (page 2–1548)

Interface

Each shader component has a toggle at the left of its name. When the toggle is on, the shader is used in rendering. When the toggle is off, the shader is not used, even if it has been assigned. Clicking the button to the right of the component name displays
the Material/Map Browser (page 2–1412) so you can assign a particular shader to the component.

Basic Shaders group

Surface—Shades the surface of objects that have this material.

In addition to any of the usual 3ds Max materials, the surface component can be assigned the following mental ray materials or shaders:
Note: As of the current version of 3ds Max, the Ambient/Reflective Occlusion shader has been updated to support certain capabilities for texture baking (see this note). If you load a file containing a material that uses the older version of the shader, that same version is still used in the scene, and the shader is renamed "Ambient/Reflective Occlusion (base) (old)". The old version of the shader continues to be used in the scene until you reapply it in the Material Editor.

Note: Unlike a standard 3ds Max material, if you assign the Surface component a bitmap with tiling turned off, the original surface color does not "show through." In renderings, you see only the untiled map, and none of the rest of the object.

**Shadow**—Assigns a shadow shader.

The shadow component can be assigned the following shaders:

<table>
<thead>
<tr>
<th>Shader</th>
<th>Library</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edge Shadow</td>
<td>lume</td>
</tr>
<tr>
<td>Facade</td>
<td>lume</td>
</tr>
<tr>

<tr>
<td>XYZ Generator (page 2–1729)</td>
<td>3ds Max</td>
</tr>
</tbody>
</table>

**Caustics and GI group**

**Photon**—Assigns a photon shader. Photon shaders modify the appearance of caustics and global illumination. They modify light energy (luminous flux) rather than color (radiance).

The photon component can be assigned the following shaders:

<table>
<thead>
<tr>
<th>Shader</th>
<th>Library</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edge Shadow</td>
<td>lume</td>
</tr>
<tr>
<td>Facade</td>
<td>lume</td>

**Photon Volume**—Assigns a photon volume shader. Like a photon shader, a photon volume shader modifies caustics and global illumination, but it affects photons that pass through the inside of the object, rather than photons that collide with its surface.

The photon volume component can be assigned the following shaders:

<table>
<thead>
<tr>
<th>Shader</th>
<th>Library</th>

### Optimization group

**Flag Material as Opaque**—When on, indicates that the material is fully opaque. This tells the mental ray renderer that it doesn’t need to process transparency for this material, or to use the shadow shader (if one has been assigned). This can improve rendering time. Default=off.

### Advanced Shaders Rollout (mental ray Material)

Material Editor > Type button > Material/Map Browser > mental ray > Advanced Shaders rollout

Note: The mental ray material appears in the Browser only if the mental ray renderer is the currently active renderer.

The mental ray material lets you create a material exclusively for use by the mental ray renderer (page 3–78). The Advanced Shaders rollout provides controls for two component shaders that aren’t always used.

### Interface

<table>

<td>contour</td>
</tr>
</tbody>
</table>

Note: Contours don’t render unless you have also enabled them on the Render Scene dialog > Renderer panel > Camera Effects rollout (page 3–101).

**Light Map**—Assigns a light map shader to the material.

Warning: No light map shaders are provided with 3ds Max. This option is for users who have access to light map shaders via other shader libraries or custom shader code.

Each shader component has a toggle at the left of its name. When the toggle is on, the shader is used in rendering. When the toggle is off, the shader is not used, even if it has been assigned. Clicking the button to the right of the component name displays the Material/Map Browser (page 2–1412) so you can assign a particular shader to the component.
Arch & Design Material (mental ray)

Material Editor > Type button > Material/Map Browser > Arch & Design Material

Material Editor > any material > Click a Map button. > Material/Map Browser > Car Paint Shader

Note: The Car Paint material and shader appear in the Browser only if the mental ray renderer is the currently active renderer.

The mental ray Arch (architectural) & Design material improves the image quality of architectural renderings and improves workflow and performance in general and for glossy surfaces such as floors in particular. Special features include advanced options for reflectivity and transparency, ambient occlusion settings, and the ability to round off sharp corners and edges as a rendering effect.

Interface

Main material parameters rollout (page 2–1549)
BRDF rollout (page 2–1554)
Special Effects rollout (page 2–1555)
Advanced Rendering Options rollout (page 2–1557)
Fast Glossy Interpolation rollout (page 2–1559)
Special Purpose Maps rollout (page 2–1561)
General Maps rollout (page 2–1562)

Templates rollout

Provides access to Arch & Design material presets for quickly creating different types of materials such as wood, glass, and metal. You can also use these as starting points for generating customized materials. Choose a template from the drop-down list; a description of the material then appears in the left-hand pane.

Note: The Arch & Design material works only with the mental ray renderer, so in order to see it represented accurately in the sample slots, you must first set mental ray to render in the Material Editor. For details, see Assign Renderer Rollout (page 3–35).
Diffuse group

**Diffuse Level**—Diffuse Level (page 2–1489) controls the brightness of the diffuse color component. Range=0.0 to 1.0. Default=1.0.

Note: Because the material is energy conserving, the actual diffuse level used depends on the reflectivity and transparency, as discussed in the introductory section, above.

**Color**—Controls the diffuse color (page 3–929). The diffuse color is the color in direct light. Default=50% gray.

**Roughness**—Roughness (page 2–1490) controls how quickly the diffuse component blends into the ambient component. Range=0.0 to 1.0. Default=0.0.

The diffuse component uses the Oren-Nayar shading model. When the Roughness value is 0.0 this is identical to classical Lambertian shading, but with higher values the surface gets a more “powdery” look, as shown in the following illustration.

Reflection group

**Reflectivity**—The overall level of reflectivity. Range=0.0 to 1.0. Default=0.6.

The Reflectivity and Color values combine to define the level of reflections as well as the intensity of the traditional highlight, also known as the specular highlight.

This value is the maximum value; the actual value also depends on the angle of the surface and comes from the BRDF curve. This curve (see BRDF rollout (page 2–1554)) lets you define 0–degree reflectivity for surfaces facing the view and 90–degree reflectivity for surfaces perpendicular to the view.

Note: In the preceding illustration, the high reflectivity automatically “subtracts” from the white diffuse color. If this didn’t happen, the material would become unrealistically overbright, and would break the laws of physics.

**Color**—The overall color of reflected light. Default=white.

**Glossiness**—Defines the surface “glossiness,” ranging from 1.0 (a perfect mirror) to 0.0 (a diffusely reflective surface). Default=1.0.
**Glossy Samples**—Defines the maximum number of samples (rays) that mental ray shoots to create glossy reflections. Higher values cause slow rendering but create a smoother result. Lower values render faster but create a grainier result. Generally 32 is enough for most cases.

Available only when Glossiness does not equal 1.0. Because a Glossiness value of 1.0 creates a “perfect mirror,” it is meaningless to shoot multiple rays for this case, hence only one reflection ray is shot.

**Note:** If you set Glossy Samples to 0, the reflections take the form of a “perfect mirror” and only one ray is shot, regardless of the actual value of Glossiness. You can use this to boost performance for surfaces with very weak reflections. The highlight still respects the Glossiness value.

Glossy reflections need to trace multiple rays to yield a smooth result, which can affect performance. For this reason, the material includes the following two special features designed to enhance performance:

**Fast (interpolate)**—When on, a smoothing algorithm allows rays to be reused and smoothed. The result is faster and smoother glossy reflections at the expense of accuracy. Interpolation is explained in greater detail in the section on the Fast Glossy Interpolation rollout (page 2–1559).

**Note:** This method works best on flat surfaces.

**Highlights+FG only**—When on, mental ray traces no actual reflection rays. Instead, only the highlights are shown, as well as soft reflections emulated with the help of using Final Gathering.

The Highlights+FG Only mode takes no additional rendering time compared to a non-glossy (diffuse) surface, yet can yield surprisingly convincing results. While it might not be completely convincing for “hero” objects in a scene, it can work very well for less-essential scene elements. It tends to work best on materials with weak reflections or extremely glossy (blurred) reflections, as shown in the following illustration:

*The two cups on the left use real reflections, while those on the right use Highlights+FG Only.*

**Metal material**—Metallic objects actually influence the color of their reflection, whereas other materials do not. For example, a gold bar will have gold colored reflections, but a red glass orb does not have red reflections. This is supported through the Metal Material option:

- When off, the Reflection Color parameter defines the color, and the Reflectivity parameter together with the BRDF settings defines the intensity and colors of reflections.
- When on, the Diffuse Color parameter defines the color of reflections, and Reflectivity parameter sets the “weight” between diffuse reflections and glossy (metallic) reflections.

*Left: Non-metallic reflections (Metal Material is off). Reflections clearly contain the color of the objects they reflect and are not influenced by the color of the materials.*

*Center: Metallic reflections (Metal Material is on). Now the color of reflections are influenced by the color of the object.*

*Right: A variant of this with Reflectivity=0.5, creating a 50:50 mix between colored reflections and diffuse reflections*
Refraction group

**Transparency**—Defines the level of refraction. Range=0.0 to 1.0. Default=0.0.

Due to the material’s energy-conserving nature, the value set in the Transparency parameter is the maximum value; the actual value depends on the reflectivity as well as the BRDF curve.

**Color**—Defines the color of refraction. While this color can be used to create “colored glass,” a slightly more accurate method to do this is described in the Colored Glass section (page 2–1570) of the Tips & Tricks topic.

**Glossiness**—Defines the sharpness of the refraction/transparency, ranging from 1.0 (completely clear transparency) to 0.0 (extremely diffuse or blurry transparency). Default=1.0.

![Images of glasses with different levels of refraction](image)

Glossy refraction needs to trace multiple rays to yield a smooth result, which can affect performance. For this reason, the material includes the following special feature designed to enhance performance:

**Fast (interpolate)**—When on, a smoothing algorithm allows rays to be reused and smoothed. The result is faster and smoother glossy refraction at the expense of accuracy. Interpolation is explained in greater detail in the section on the Fast Glossy Interpolation rollout (page 2–1559).

Note: This method works best on flat surfaces.

**Glossy Samples**—Defines the maximum number of samples (rays) that mental ray shoots to create glossy refraction. Higher values cause slow rendering but create a smoother result. Lower values render faster but create a grainier result, like frosted glass. Generally 32 is enough for most cases.

Available only when Glossiness does not equal 1.0. Because a Glossiness value of 1.0 creates a perfectly clear (non-blurry) transparency, it is meaningless to shoot multiple rays for this case, hence only one refraction ray is shot.

Note: If you set Glossy Samples to 0, the refraction takes the form of a “perfect lens” and only one ray is shot, regardless of the actual value of Glossiness. You can use this to boost performance for draft renderings.

**IOR**—The Index of Refraction, which is a measurement of how much a ray of light bends when entering a material.

The direction in which light bends depends on whether it is entering or exiting the object. The Arch & Design material use the direction of the surface normal as the primary cue for figuring out whether it is entering or exiting. It is therefore important to model transparent, refractive objects with the surface normals pointing in the proper direction.

The IOR can also be used to define the BRDF curve, which is what happens in the class of transparent materials known as “dielectric” materials, and is illustrated here:

![Images of glasses with different IOR values](image)
The leftmost cup looks completely unrealistic and is almost invisible. Because an IOR of 1.0, which equals that of air, is impossible in solid matter, we get no change in reflectivity across the material and hence perceive no edges or changes of any kind. On the other hand, the center and rightmost cups have realistic changes in reflectivity guided by the IOR.

Instead of basing the reflectivity on the IOR, you can instead use the BRDF mode to set it manually:

**Different types of transparency**

As in the previous illustration, the leftmost cup acquires its curve from the index of refraction. The center cup has a manually defined curve, which has been set to a 90 degree reflectivity of 1.0 and a 0 degree reflectivity of 0.2; this looks a bit more like metallized glass. The rightmost cup uses the same BRDF curve, but instead is set to thin-walled transparency (page 2–1558). Clearly, this method is better for making non-refractive objects than simply setting IOR to 1.0, as we tried above.

**Translucency group**

Translucency is handled as a special case of transparency; in order to use translucency there must first exist some level of transparency. The implementation of translucency in the Arch & Design material is a simplification concerned solely with the transport of light from the back of an object to its front faces and is not true SSS (subsurface scattering) effect. You can create an SSS-like effect by using glossy transparency coupled with translucency, but this is neither as fast nor as powerful as the dedicated SSS shaders (page 2–1583).

**Translucency**—When on, the remaining Translucency become available and take effect when rendering.

**Weight**—Determines how much of the existing transparency is used as translucency. For example, if Weight=0.0, all of the transparency is used as transparency. If Weight=0.3, 30 percent of the transparency is used as translucency.

**Translucency**—When on, the remaining Translucency become available and take effect when rendering.

**Weight**—Determines how much of the existing transparency is used as translucency. For example, if Weight=0.0, all of the transparency is used as transparency. If Weight=0.3, 30 percent of the transparency is used as translucency.

**Color**—The translucency color.
Anisotropy group

**Anisotropy**—Controls the anisotropy, or shape, of the highlight. At 1.0, the highlight is round; that is, no anisotropy. At 0.01, the highlight is elongated. One axis of the highlight graph changes to show changes in this parameter. Default=1.0.

![Image of anisotropy settings](image)

**Rotation**—Changes the orientation of the highlight. The sample slot shows changes in orientation. This value can range from 0.0 to 1.0, with 1.0=360 degrees. So, for example, 0.25=90 degrees and 0.5=180 degrees. Default=0.0.

![Image of rotation settings](image)

*Tip:* When using texture-mapped Anisotropy Rotation, make sure the texture is not antialiased (filtered). You can achieve this by setting the map’s Blur parameter to 0.0. Otherwise the antialiased pixels cause local vortices in the anisotropy that appear as seam artifacts.

**Automatic/Map Channel**—Lets you optionally apply anisotropy to a specific map channel.

If the Map Channel setting is Automatic, the base rotation follows the object’s local coordinate system. If it is any other value (in other words, a specific map channel), the space that defines the stretch directions of the highlights is derived from that channel’s texture space.

**Warning:** Deriving the anisotropy from the texture space creates only one space per triangle and can cause visible seams between triangles.

Also see *Brushed Metal* (page 2–1575).

**BRDF rollout**

**BRDF** stands for bidirectional reflectance distribution function. As explained in the introduction (page 2–1566), this property lets the material’s reflectivity be ultimately guided by the angle from which the object surface is viewed.

![Image of BRDF settings](image)

0 degree (green) and 90 degree (red) view angles

**[BRDF method]**—Lets you choose how the BRDF curve is defined:

- **By IOR (fresnel reflections)**—How the reflectivity depends on the angle is guided solely by the
material’s index of refraction. This is known as Fresnel reflections and follows the behavior of most dielectric materials such as water and glass.

- **Custom Reflectivity Function**—When chosen, the following settings determine reflectivity based on angle of view.
  - **0 deg. refl.**—Defines the reflectivity for surfaces directly facing the viewer (or incident ray).
  - **90 deg. refl.**—Defines the reflectivity of surfaces perpendicular to the viewer.
  - **Curve shape**—Defines the falloff of the BRDF curve.

This mode is used for most hybrid materials or for metals. Most materials exhibit strong reflections at grazing angles; hence the 90 degree reflectivity parameter can generally be kept at 1.0, using the Reflectivity parameter to guide the overall reflectivity instead. Metals tend to be fairly uniformly reflective and the 0 degree reflectivity value is high (0.8–1.0), but many other layered materials, such as linoleum and lacquered wood have lower 0 degree reflectivity values, in the range 0.1–0.3). For further information, see Quick Guide to Some Common Materials (page 2–1569).

**Reflectivity vs. Angle graph**—Depicts the combined Custom Reflectivity Function settings.

### Special Effects rollout

</tr>
<tr>
<td><strong>Blend with other materials</strong></td>
</tr>
</tbody>
</table>

Provides settings for ambient occlusion (page 2–1567) (AO) and round corners/edges.

**Ambient Occlusion group**

- **Ambient Occlusion**—When on, enables AO and makes the remaining group controls available.
- **Samples**—The number of samples (rays) shot for creating AO. Higher values yield smoother results but render more slowly, while lower values render faster but look grainier. Values in the range 16–64 cover most situations.
- **Max Distance**—Defines the radius within which mental ray looks for occluding objects. Smaller values restrict the AO effect to small crevices only but are much faster to render. Larger values cover larger areas but render more slowly.

The following illustrations show the raw AO contribution with two different distances:
Use AO as Detail Enhancement for GI/FG—Applies short-distance AO, multiplying it with the existing indirect illumination (Final Gathering or GI/photons) to bring out small details.

The following illustration depicts a model helicopter that is lit almost exclusively by indirect light:

Note how the helicopter does not feel “grounded” in the left image and the shadows under the landing skids are far too vague. The right image uses AO to “punch out” the details and the contact shadows.

Shadow Color—Sets the darkness of the AO shadows. It is used as the multiplier value for completely occluded surfaces. In practice, a black color makes the AO effect very dark; a middle-gray color makes the effect less noticeable (brighter), and so on.

Custom/Global Ambient Light Color—You can specify a color for the ambient light used in AO, or use the global color specified on the Environment panel (page 3–272) > Common Parameters rollout.

This parameter is used for doing more traditional AO; that is, supplying an imagined “ever-present ambient light” that is then attenuated by the AO effect to create shadows.

While traditional AO is generally used when rendering without other indirect light, you can also combine it with existing indirect light. Bear in mind that this “ever-present ambient light” is inherently non-physical, but can possibly help lighten some troublesome dark corners.

Round Corners group
This effect rounds off corners and straight edges as a rendering effect only; it has no effect on geometry.

The rounding effect happens to convex corners and surfaces that actually intersect. Concave corners that merely touch will not display the effect. To get the effect to work in concave corners the objects must be pushed into each other a little. The effect is intended for straight edges and is not guaranteed to work properly for highly curved, complex intersections.

Round Corners—When on, rounds off corners and straight edges at render time.

Fillet Radius—Specifies the radius of the filleted corners and/or edges.

Blend with other materials—By default, the rounding effect happens only between surfaces of the same material, but if you turn this on the filleting is performed against any material.

In the following image, the molten chocolate is rounded off against the submerged objects even though they use different materials. In actuality, the molten chocolate is a completely flat plane.
Reflections group

**Max Distance**—Allows limiting reflections to a certain distance, which both speeds up rendering and avoids pulling distant objects into extremely glossy reflections.

**Fade to end color**—When on, reflections fade to this color. When off, reflections fade to the environment color. The former tends to be more useful for indoor scenes; the latter, for outdoor scenes.

Available only when Max Distance is on.

Refraction group

The optimization settings for refraction (transparency) are nearly identical to those for reflections. The exception is that of Color At Max Distance, which behaves differently.
Max Distance—Allows limiting refraction to a certain distance.

Color at Max Distance—When on, the material simulates physically correct absorption. At the distance specified by Max Distance, the refracted image has the color given by Color At Max Distance, but the rays are not limited in reach. At twice the distance, the influence of Color At Max Distance is double, at half the distance half, etc.

When off, transparency rays simply fade to black. This is like smoked glass and other highly absorbent materials. Transparency just stops at the specified distance. This has the same performance advantage as using the Max Distance for reflections: Tracing shorter rays is much faster.

Available only when Max Distance is on.

Max Trace Depth—When this trace depth is reached, the material refracts black.

Cutoff Threshold—The level at which refraction is rejected; that is, not traced. It’s a relative value: For example, the default setting of 0.01 means that rays that contribute less than 1 percent to the final pixel are ignored. A setting of 0.25 means that mental ray discards rays that contribute less than a quarter of the value of the final pixel.

Advanced Reflectivity group

Visible area lights cause no Highlights—When on, mental ray area lights (Omni (page 2–1298) and Spotlight (page 2–1299)) with the Show Icon In Renderer property on create no specular highlights. Default=on.

The Show Icon In Renderer check box is found on the light’s Area Light Parameters rollout. When on, the light is visible and reflects in any glossy, reflective objects. If both the reflection of the visible area light and the highlight is rendered, the light is added twice, causing an unrealistic brightening effect. When on, this switch causes visible area lights to lose their highlights and instead only appear as reflections. Note that this does not apply to the Highlights+FG Only mode, which doesn’t actually reflect anything.

Skip reflections on inside (except total internal reflection)—Most reflections inside transparent objects are very faint, except in the special case that occurs at certain angles known as total internal reflection (TIR). When on, this option saves rendering time by ignoring the weak reflections completely but retaining the TIRs. Default=on.

Advanced Transparency Options group

The options give you control over some of the deepest details of the Arch & Design material.

Glass/Translucency treat objects as...—

• Solid—The object behaves as if it is made of a solid, transparent substance.
• Thin-walled—The object behaves as if made of wafer-thin sheets of a transparent material.

For more information, see Solid vs. Thin-Walled (page 2–1567).
When Caustics are enabled, transparent objects:—When not rendering caustics, the Arch & Design material uses a shadow shader to create transparent shadows. For objects such as window panes this is perfectly adequate, and actually creates a better result than using caustics, because the direct light is allowed to pass more or less undisturbed through the glass into a space such as a room.

Traditionally, enabling caustics in mental ray causes all materials to stop casting transparent shadows and instead start to generate refractive caustics. In most architectural scenes this is undesirable; you might want a glass decoration on a table to generate caustic effect, but still want the windows to the room to let in normal direct light. This switch makes this possible at the material level.

- Refract light and generate Caustic effects—The material refracts light and generates caustics.
- Use Transparent Shadows—No caustics are produced; the material and object simply transmit the light, with greater shadowing in thicker areas.

In the following illustration, the left side shows the result with Use Transparent Shadows chosen, and the right side shows the result with Refract Light And Generate Caustic Effects chosen. You can freely mix the two modes in the same rendering. Photons are automatically treated accordingly by the built-in photon shader, shooting straight through as direct light in the former case, and being refracted as caustics in the latter.

Back Face Culling—When on, enables a special mode that makes surfaces invisible to the camera when seen from the reverse side. You can use this to create “magic walls” in a room. If all walls are planes with the normals facing inwards, the Back Face Culling switch allows the room to be rendered from “outside.” The camera can see into the room, but the walls will still exist and cast shadows, bounce photons, etc. while being invisible when the camera goes outside.

Left: Back Face Culling=off; Right: Back Face Culling=on

Transparency propagates Alpha channel—Defines how transparent objects treats any alpha channel information in the background. When on, refraction and other transparency effects propagate the alpha of the background “through” the transparent object. When off, transparent objects have an opaque alpha.

Indirect Illumination Options

FG/GI multiplier—Allows tweaking of how strongly the material responds to indirect light.

FG Quality—A local multiplier for the number of final gather rays shot by the material.

Fast Glossy Interpolation rollout

Glossy reflections and refraction can be interpolated, which causes them to render faster and look smoother. Interpolation works by precalculating glossy reflection in a grid across the image. The number of samples (rays) taken at each point is govern by the Reflection > Glossy Samples or Refraction > Glossy Samples parameters, as in the non-interpolated case.
Note that interpolation can cause *artifacts*. Because it is done on a low-resolution grid, it can lose details. And because it blends neighbors of this low-resolution grid, it can cause oversmoothing. For this reason it is useful primarily with flat surfaces. Interpolation does not work well with wavy, highly detailed surfaces or surfaces that use bump maps.

**Interpolation grid density**—The resolution of the grid used for interpolating glossy reflections and refraction. Choose a setting from the drop-down list.

Within the grid, data is stored and shared across the points. Using a lower grid resolution is faster, but causes greater loss of detail information.

**Reflective interpolation group**

**Neighboring points to look up**—Defines how many stored grid points (in an N by N group around the currently rendered point) is looked up to smooth out reflective glossiness. The default is 2, and higher values will “smear” the glossiness more, but are hence prone to more oversmoothing artifacts.

In the following illustration, the reflection of the left cup in the floor does not use interpolation, and some grain is evident (here intentionally exaggerated). The floor tiles under the other two cups use a half-resolution interpolation with point lookup set to 2 (center) and 4 (right), respectively.

![Left: No interpolation; Center: Looking up two points; Right: Looking up four points.](image)

The preceding image also illustrates one of the consequences of using interpolation: The foot of the left cup, which is near the floor, is reflected quite sharply, and only the parts of the cup far from the floor are blurry. However, the interpolated reflections of the right cups have a base level of blurriness, due to the smoothing of interpolation, which makes even the closest parts somewhat blurry. In most scenes with weak glossy reflections this discrepancy will never be noticed, but in other cases this can make things like legs of tables and chairs feel “unconnected” with a glossy floor, if the reflectivity is high. To resolve this, you can use the High Detail Distance setting (see following).

**High detail distance**—Allows tracing of a second set of detail rays to create a “clearer” version of objects within the specified radius.

In the following illustration, all three floor tiles use interpolation but the two on the right use different distances for the detail distance.
This also allows an interesting trick: Set Reflection > Glossy Samples to 0, which renders reflections as if they were mirror-perfect, but also use interpolation to introduce blur into this reflection, and perhaps use High Detail Distance to make nearby parts less blurry. This is a fast way to obtain a glossy reflection.

The floor tiles in the following illustration are rendered with mirror reflections, and the blurriness comes solely from the interpolation. This renders as fast as or faster than pure mirror reflections, yet gives a satisfying illusion of true glossy reflections, especially when utilizing the High Detail Distance option, as on the right.

**Refraactive interpolation group**

**Neighboring points to look up**—Defines how many stored grid points (in an N by N group around the currently rendered point) are looked up to smooth out refractive glossiness. The default is 2; higher values tend to “smear” the glossiness more, but are hence prone to more oversmoothing artifacts.

**Special Purpose Maps rollout**

Lets you apply bump, displacement, and other maps. Each left-justified setting has a check box for enabling and disabling the map, and a button for defining the map.

**Bump**—Lets you apply a bump map and multiplier.

**Do not apply bumps to the diffuse shading**—When off, the bumps apply to all shading components: diffuse, highlights, reflections, refractions, etc. When on, bumps are applied to all components except the diffuse. This means bumps are seen in reflections, highlights, etc. but the diffuse shading shows no bumps. It is as if the material’s diffuse surface is smooth, but is covered by a bumpy lacquer coating.
Chapter 16: Material Editor, Materials, and Maps

Displacement—Lets you apply a displacement map and multiplier.

Cutout—Lets you apply an opacity map to completely remove parts of objects. A classic example is to map an image of a tree to a flat plane and use opacity to cut away the parts of the tree that are not there.

Environment—Lets you apply an environment map and shader.

Additional Color/Self illum.—Lets you apply any shader. The output of this shader is added on top of the shading done by the Arch & Design material and can be used for self-illumination-type effects, as well as adding any additional shading you want.

General Maps rollout

This rollout enables application of maps or shaders to any of the Arch & Design material parameters. Of course, you can apply a shader to a parameter at its standard location in the user interface by clicking its Map button, so the principal value of this rollout is that it also lets you toggle a parameter’s shader, using the check box, without removing the map.

Arch & Design Material (mental ray) – Overview

This topic serves as an introduction to the Arch & Design material for mental ray. For a detailed reference to the material interface, see Arch & Design Material (mental ray) (page 2–1549). For a variety of suggestions for using the material to create specific effects, see Arch & Design Material (mental ray) – Tips & Tricks (page 2–1569).

What is the Arch & Design material?

The mental ray Arch & Design material is a monolithic material shader designed to support most materials used in architectural and product-design renderings. It supports most hard-surface materials such as metal, wood and glass. It is especially tuned for fast glossy reflections and refractions (replacing the DGS material (page 2–1580)) and high-quality glass (replacing the dielectric material (page 2–1719)).
The major features are:

- **Easy to use, yet flexible** - controls are arranged logically in a most-used-first fashion.
- **Templates** - allow fast access to settings combinations for common materials.
- **Physically accurate** - the material is energy conserving, making it impossible to create shaders that break the laws of physics.
- **Glossy performance** - advanced performance boosts including interpolation, emulated glossiness, and importance sampling.
- **Tweakable BRDF** (bidirectional reflectance distribution function) - the user can define how reflectivity depends on angle.
- **Transparency** - “Solid” or “thin” materials: transparent objects such as glass can be treated as either solid (refracting, built out of multiple faces) or thin (nonrefracting, can use single faces).
- **Round corners** - simulate fillets to allow sharp edges to still catch the light in a realistic fashion.
- **Indirect Illumination control** - set the final gather accuracy or indirect illumination level on a per-material basis.
- **Oren-Nayar diffuse** - allows “powdery” surfaces such as clay.
- **Built-in Ambient Occlusion** - for contact shadows and enhancing small details.
- **All-in-one shader** - photon and shadow shader built in.
- **Waxed floors, frosted glass and brushed metals** - all fast and easy to set up.

**Physics and the display**

The Arch & Design material attempts to be physically accurate, hence its output has a high dynamic range. How visually pleasing the material looks depends on how colors inside the renderer are mapped to colors displayed on the screen.

When working with the Arch & Design material it is highly recommended that you operate through a tone mapper/exposure control such as the Logarithmic Exposure Control (page 3–297), or at the very least use gamma correction.

**A note on gamma**

Describing all the details of gamma correction is beyond the scope of this topic; this is just a brief overview.

The color space of a normal, off-the-shelf computer screen is not linear. The color with RGB value 200 200 200 is not twice as bright as a color with RGB value 100 100 100, as one might expect.

This is not a bug because, due to the fact that our eyes see light in a non-linear way, the former color is actually perceived to be about twice as bright as the latter. This makes the color space of a normal computer screen roughly perceptually uniform. This is a good thing, and is actually the main reason 24-bit color (with only 8 bits or 256 discrete levels for each of the red, green and blue components) looks as good as it does to our eyes.

The problem is that physically correct computer graphics operates in a true linear color space where a value represents actual light energy. If one simply maps the range of colors output to the renderer naively to the 0-255 range of each RGB color component it is incorrect.

The solution is to introduce a mapping of some sort. One of these methods is called *gamma correction*.

Most computer screens have a gamma of about 2.2 (known as the sRGB color space), but most software defaults to a gamma of 1.0, which makes everything look too dark (especially midtones), and light does not “add up” correctly.

Using a gamma of 2.2 is the theoretically correct value, making the physically linear light inside...
the renderer appear in a correct linear manner on screen.

However, because the response of photographic film isn’t linear either, users find that this theoretically correct value looks too bright and washed out. A common compromise is to render to a gamma of 1.8, making things look more photographic; that is, as if the image had been shot on photographic film and then developed.

**Tone mapping**

Another method for mapping the physical energies inside the renderer to visually pleasing pixel values is known as tone mapping. This can be accomplished either by rendering to a floating-point file format and using external software, or with a plug-in that allows the renderer to do it on the fly. In 3ds Max such plug-ins are known as exposure controls and are accessed from the Environment dialog.

**Note:** When using the Logarithmic Exposure Control, the need for gamma correction is largely replaced. You should use either gamma correction or the Logarithmic Exposure Control but not both.

**Use Final Gathering and Global Illumination**

The Arch & Design material is designed to be used in a realistic lighting environment; one that incorporates full direct and indirect illumination.

mental ray provides two basic methods for generating indirect light: Final Gathering and Global Illumination. For best results, be sure to use at least one of these methods.

At the very least, enable Final Gathering, or use Final Gathering combined with Global Illumination (photons) for quality results. Performance tips for using Final Gather and Global Illumination can be found here (page 2–1569).

If you use an environment for your reflections, make sure the same environment (or a blurred copy of it) is used to light the scene through Final Gathering. In 3ds Max this means you should include a Skylight (page 2–1296) in your scene set to Use Scene Environment, or use Daylight system (page 1–418) with Skylight set to mr Sky.

**Use physically correct lights**

Traditional computer-graphics light sources live in a cartoon universe where the intensity of the light doesn’t change with the distance. The real world doesn’t agree with that simplification. Light decays when leaving a light source due to the fact that light rays diverge from their source and the intensity of the light changes over distance. This decay of a point light source is $1/d^2$; in other words, light intensity is proportional to the inverse of the square of the distance to the source.

One of the reasons for this traditional oversimplification is the fact that in the early days of computer graphics, tone mapping was not used and problems of colors blowing out to white in the most undesirable ways was rampant. (Raw clipping in sRGB color space is displeasing to the eye, especially if one color channel clips earlier than the others. Tone mapping generally solves this by “soft clipping” in a more suitable color space than sRGB.)

However, as long as only Final Gathering (FG) is used as indirect illumination method, such traditional simplifications still work. Even light sources with no decay still create reasonable renderings. This is because FG is concerned only with the transport of light from one surface to the next, not with the transport of light from the light source to the surface.

It’s when working with Global Illumination (GI) (that is, with photons) the troubles arise.

When GI is enabled, light sources shoot photons. For the Arch & Design material (or any other
mental ray material) to be able to work properly, it is imperative that the energy of these photons to match the direct light cast by that same light. And since photons model light in a physical manner, decay is built in.

Hence, when using GI:

- Light sources must emit photons at the correct energy.
- The direct light must decay in a physically correct way to match the decay of the photons.

Therefore it is important to make sure the light shader and the photon emission shader of the lights work well together.

In 3ds Max this is most easily solved by using the photometric lights (page 2–1301). All of these lights are guaranteed to have their photon energy in sync with their direct light. It is built in and automatic and one does not need to worry about it.

Features

The Shading Model

From a usage perspective, the shading model consists of three components:

- **Diffuse** - diffuse channel /including Oren Nayar “roughness”).
- **Reflections** - glossy anisotropic reflections (and highlights).
- **Refraction** - glossy anisotropic transparency (and translucency).

Direct and indirect light from the scene cause diffuse reflections as well as translucency effects. Direct light sources also create specular highlights.

Ray tracing is used to create reflective and refractive effects, and advanced importance-driven multi-sampling is used to create glossy reflections and refraction.

The rendering speed of the glossy reflections/refraction can further be enhanced by interpolation as well as “emulated” reflections with the help of Final Gathering.

Conservation of Energy

One of the most important features of the material is that it is automatically energy conserving. This means that it makes sure that diffuse + reflection + refraction <= 1. In other words, no energy is magically created and the incoming light energy is properly distributed to the diffuse, reflection and refraction components in a way that maintains the first law of thermodynamics.

In practice, this means, for example, that when adding reflectivity, the energy must be taken from somewhere, and hence the diffuse level and the transparency will be automatically reduced accordingly. Similarly, adding transparency happens at the cost of the diffuse level.

The rules are as follows:
• Transparency takes energy from diffuse; that is, at 100% transparency, there is no diffuse at all.

• Reflectivity takes energy from both diffuse and transparency; that is, at 100% reflectivity there is neither diffuse nor transparency.

• Translucency is a type of transparency, and the Translucency Weight parameter defines the percentage of transparency vs. translucency.

Conservation of energy also means that the level of highlights is linked to the glossiness of a surface. A high Reflection Glossiness value causes a narrow, intense highlight, while a lower value causes a wider, less intense highlight. This is because the energy is now spread out and dissipated over a larger area.

BRDF - how reflectivity depends on angle

In the real world, the reflectivity of a surface is often view-angle dependent. A fancy term for this is bidirectional reflectance distribution function (BRDF); that is, a way to define how much a material reflects when seen from various angles.

Many materials exhibit this behavior. The most obvious examples are glass, water, and other dielectric materials with Fresnel effects (where the angular dependency is guided strictly by the index of refraction), but other layered materials such as lacquered wood and plastic display similar characteristics.

The Arch & Design material allows this effect to be defined by the index of refraction, and also allows an explicit setting for the two reflectivity values for:

• 0 degree faces (surfaces directly facing the camera)
• 90 degree faces (surfaces 90 degrees to the camera)

For more information, see BRDF rollout (page 2–1554).

Reflectivity features

The final surface reflectivity is in reality caused by the sum of three components:

• The diffuse effect
• The actual reflections
• Specular highlights that simulate the reflection of light sources

Diffuse, reflections, and highlights

In the real world, highlights are just glossy reflections of the light sources. In computer graphics it’s more efficient to treat these separately. However, to maintain physical accuracy the material automatically keeps highlight intensity, glossiness, anisotropy, etc. in sync with the intensity, glossiness and anisotropy of reflections. Thus, there are no separate controls for these as both are driven by the reflectivity settings.
Transparency features

The material supports full glossy anisotropic transparency and includes a translucent component, described in detail here (page 2-1553).

Solid vs. Thin-Walled

The transparency/translucency property can treat objects as either solid or thin-walled.

If all objects were treated as solids at all times, every window pane in an architectural model would have to be modeled as two faces: an entry surface that refracts the light slightly in one direction, and immediately following it an exit surface, where light is refracted back into the original direction.

Not only does this entail additional modeling work, it is a waste of rendering power to simulate refraction that has very little net effect on the image. Hence the material allows modeling the entire window pane as a single flat plane, foregoing any actual refraction of light.

Cutout opacity

Beyond the “physical” transparency, which models an actual property of the material, the material provides a completely separate, non-physical “cutout opacity” channel to allow “billboard” objects such as trees, or to cut out objects such as a chainlink fence with an opacity mask.

Special Effects

Built-in Ambient Occlusion

Ambient Occlusion (AO) is a method spearheaded by the film industry for emulating the look of true global illumination by using shaders that calculate the extent to which an area is occluded, or prevented from receiving incoming light.

Used alone, an AO shader, such as the separate mental ray Ambient/Reflective Occlusion shader, creates a grayscale output that is dark in areas light cannot reach and bright in areas where it can:

The following image illustrates the main results of AO: dark crevices and areas where light is blocked.
by other surfaces, and bright areas that are exposed to the environment.

One important aspect of AO is that the user can tune the distance it looks in for occluding geometry.

Using a radius creates a localized AO effect; only surfaces within the given radius are considered as occluders (which is also faster to render). The practical result is that the AO provides nice "contact shadow" effects and makes small crevices visible.

The Arch & Design material gives you two ways to utilize its built-in AO:

- Traditional AO for adding an omnipresent ambient light that is then attenuated by the AO to create details.
- Use AO for detail enhancement together with existing indirect lighting methods such as Final Gathering or photons.

The latter method is especially interesting when using a highly smoothed indirect illumination solution, such as a high photon radius or an extremely low final gather density, which could otherwise lose small details. By applying the AO with short rays these details can be brought back.

### Round corners

Computer-generated imagery tends to look unrealistic, partly because edges of objects are geometrically sharp, whereas most edges in the real world are slightly rounded, chamfered, worn, or filleted in some manner. This rounded edge tends to “catch the light” and create highlights that make edges more visually appealing.

The Arch & Design material can create the illusion of rounded edges at render time. This feature is intended primarily to speed up modeling, so that you need not explicitly fillet or chamfer edges of objects such as a tabletop.

The function is not a displacement; it is merely a shading effect, like bump mapping, and is best suited for straight edges and simple geometry, not advanced, highly curved geometry.
Performance Features
Finally, the Arch & Design material contains a large set of built-in functions for optimal performance, including but not limited to:

- Advanced importance sampling with ray rejection thresholds
- Adaptive glossy sample count
- Interpolated glossy reflection/refraction with detail enhancements
- Ultra-fast emulated glossy reflections (Highlights+FG Only mode)
- The option to ignore internal reflections for glass objects
- The choice between traditional transparent shadows, suitable for objects such as a window pane, and refractive caustics, suitable for solid glass objects, on a per-material basis.

Arch & Design Material (mental ray) – Tips & Tricks
This topic contains information to help you more effectively use the Arch & Design material (page 2–1549) for mental ray.

See also
Arch & Design Material (mental ray) – Overview (page 2–1562)
Arch & Design Material (mental ray) (page 2–1549)

Final Gather Performance
The final gather algorithm in mental ray 3.5 is vastly improved from earlier versions, especially in its adaptiveness. This means you can often use much lower ray counts and much lower densities than in previous versions of mental ray.

In many cases, you can render still images with such extreme settings as 50 rays and a density of 0.1. If this causes “oversmoothing” artifacts, you can use the built-in ambient occlusion (page 2–1555) to solve those problems.

When using final gather together with GI (photons), make sure the photon solution is fairly smooth by first rendering with Final Gather disabled first. If the photon solution is noisy, increase the photon search radius until it “calms down,” and then enable Final Gather.

Quick Guide to Some Common Materials
Following are some quick rules of thumb for creating various materials. Each assumes the basic default settings as a starting point.

General Rules of Thumb for Glossy Wood, Flooring, etc.
These are the kind of “hybrid” materials you might require for architectural renderings; lacquered wood, linoleum, etc.

For these materials, set BRDF to Custom Reflectivity Function; that is, you’ll define a custom BRDF curve. Start out with 0 degree reflectivity of 0.2, 90 degree reflectivity of 1.0, and apply a suitable texture map to the Diffuse Color. Set Reflectivity between 0.6 and 1.0.

How glossy is the material? Are reflections clear or blurry? Are they strong or weak?

- For clear, fairly strong reflections, keep Reflection Glossiness at 1.0.
- For slightly blurry but strong reflections, set a lower Reflection Glossiness value. If performance becomes an issue try turning on Fast (interpolate).
- For slightly blurry but also very weak reflections, you can “cheat” by applying a lower Reflection Glossiness value for broader highlights while setting Reflection Glossy Samples to 0. This shoots only one mirror ray...
for reflections, but if they are very weak, the viewer can often not really tell.

- For moderately blurry surfaces, set an even lower Reflection Glossiness value and maybe increase the Reflection Glossy Samples value. Again, for improved performance turn on Fast (interpolate).

- For extremely blurry surfaces or surfaces with very weak reflections, try turning on Highlights+FG Only.

A typical wooden floor could use Reflection Glossiness of 0.5, Reflection Glossy Samples of 16, Reflectivity of 0.75, a nice wood texture for Diffuse Color, perhaps a slight bump map. If bumpiness should appear only in the lacquer layer, turn on Special Purpose Maps rollout > Do Not Apply Bumps To The Diffuse Shading.

Linoleum flooring could use the same settings but with a different texture and bump map, and probably with slightly lower Reflectivity and Reflection Glossiness values.

Ceramics

Ceramic materials are glazed; that is, they’re covered by a thin layer of transparent material. They follow rules similar to the general materials mentioned above, but choose By IOR (fresnel reflections) and set IOR to about 1.4 and Reflectivity to 1.0.

Set the Diffuse Color to a suitable texture or color, such as white for white bathroom tiles.

Stone Materials

A stone object usually has a fairly matte finish, or has reflections that are so blurry they are nearly diffuse. You can simulate the “powdery” character of stone with the Diffuse Roughness parameter; try 0.5 as a starting point. Porous stone such as brick would have a higher value.

Stone would have a very low Reflection Glossiness (lower than 0.25) and one can most likely use Highlights+FG Only to good effect for very good performance. Use a nice stone texture for Diffuse Color, some kind of bump map, and perhaps a map that varies the Reflection Glossiness value.

The Reflectivity would be around 0.5-0.6 with By IOR (fresnel reflections) off and 0 degree reflectivity at 0.2 and 90 degree reflectivity at 1.0

Glass

Glass is a dielectric, so By IOR (fresnel reflections) should definitely be on. The IOR of standard glass is 1.5. Set Diffuse Level to 0.0, Reflectivity to 1.0 and Transparency to 1.0. This is enough to create basic, completely clear refractive glass.

If this glass is for a window pane, turn Thin-walled on. If this is a solid glass block, turn Thin-walled off and consider if caustics are necessary or not, and set Refractive Caustics accordingly.

If the glass is frosted, set Refraction Glossiness to an unsuitable value. Turn the Refraction Samples for good quality or turn on Fast (interpolate) for performance.

Colored glass

For clear glass, use the tips in the preceding section. Colored glass, however, is a different story.

Many shaders set the transparency at the surface of the glass. And indeed this is what happens if one simply sets a Refractive Color to some value, such as blue. For glass with Thin-walled turned on this works perfectly. But for solid glass objects this is not an accurate representation of reality.

The scene in following illustration contains two glass blocks of different sizes, a sphere with a spherical hole inside it, and a glass horse.

Note: The spherical hole was created by inserting a second sphere with its normals flipped inside the
outer sphere. Don’t forget to flip the normals of such surfaces or they will not render correctly.

In the above illustration the ray enters from the left, and at the entry surface it drops in level and gets slightly darker (the graph illustrates the level schematically). It retains this color throughout its travel through the medium and then drops in level again at the exit surface.

For simple glass objects this is quite sufficient. For any glass using Thin-walled it is by definition the correct thing to do, but for any complex solid it is not. It is especially wrong for negative spaces inside the glass (like the sphere in our example) because the light rays have to travel through four surfaces instead of two, getting two extra steps of attenuation at the surface.

In real colored glass, light travels through the medium and is attenuated as it goes. In the Arch & Design material this is accomplished by turning on Advanced Rendering Options > Refraction > Max Distance, setting the Color At Max Distance, and setting the Refraction Color to white. This is the result:

The result is clearly much more satisfactory: The thick glass block is a deeper blue than the thin one, and the hollow sphere now looks correct. In diagram form it looks as follows:
The ray enters the medium and is attenuated throughout its travel. The strength of the attenuation is such that precisely the Max Distance (d in the figure) the attenuation matches that of Color At Max Distance. In other words, at this depth the attenuation is the same as was received immediately at the surface with the previous scene. The falloff is exponential, so at double the Max Distance value the effect is that of Color At Max Distance squared, and so on.

There is one minor tradeoff:

To render the shadows of a material correctly using this method, you must either use caustics or make sure mental ray is rendering shadows in Segments mode (see Shadows and Displacement Rollout (mental ray Renderer) (page 3–114)).

Using caustics naturally gives the most correct-looking shadows (the above image was rendered without caustics), but requires that the scene has caustic photons enabled and contains a physical light source that shoots caustic photons.

On the other hand, the mental ray Segments shadows have a slightly lower performance than the more widely used Simple shadow mode. But if it is not used, the shadow intensity will not take the attenuation through the media into account properly. However, the image might still look pleasing.

Water and Liquids

Water, like glass, is a dielectric with an IOR of 1.33. Hence, the same principles as for glass (above) apply to bodies of water, which truly need to refract their environment. An example is water running from a tap. Colored liquids use the same principles as colored glass.

Water into wine

To create a liquid in a container, as in the preceding image, it is important to understand how the Arch & Design material handles refraction through multiple surfaces vs. the real-world behavior of light in such circumstances.

What is important for refraction is the transition from one medium to another with a different IOR. Such a transition is known as an interface.

For lemonade in a glass, imagine a ray of light travelling through the air (IOR=1.0). When it enters the glass, it is refracted by the IOR of the glass (1.5). The ray then leaves the glass and enters the liquid; that is, it passes through an interface from a medium of IOR 1.5 to another medium of IOR 1.33.

One way to model this in computer graphics is to make the glass one separate closed surface, with the normals pointing outward from the surface of
the glass and an IOR of 1.5, and a second, closed surface for the liquid, with the normals pointing outward and an IOR of 1.33, leaving a small air gap between the container and the liquid.

This approach works, but can cause a problem: When light goes from a higher IOR to a lower there is a chance of an effect known as total internal reflection (TIR). This is the effect you see when diving into a swimming pool and then looking up: You can see the objects above the surface only in a small circle straight above. Anything below a certain angle shows only a reflection of the pool and things below the surface. The larger the difference in the IOR of the two media, the greater the chance of TIR.

So in our example, as the ray goes from glass (IOR=1.5) to air, there is a large chance of TIR. But in reality the ray would move from a medium of IOR=1.5 to one of IOR=1.33, which is a much smaller step with a much smaller chance of TIR.

In the most common case of an interface with air, the IOR to use is the IOR of the media (because the IOR of air is 1.0), whereas in an interface between two different media, the situation is different.

To correctly model this scenario, then, we need three surfaces, each with a different Arch & Design material applied:

- the air-glass surface (blue), with normals pointing out of the glass, covering the area where air directly touches the glass, having an IOR of 1.5
- the air-liquid surface (green), with normals pointing out of the liquid, covering the area where air directly touches the liquid, having an IOR of 1.33
- the glass-liquid surface (red), with normals pointing out of the liquid, covering the area where the glass touches the liquid, having an IOR of 0.8

The three interfaces for a liquid in a glass

By setting suitable Max Distance and Color At Max Distance values for the two liquid materials (to get a colored liquid), we obtain the glass on the left in the preceding rendered image.

Ocean and Water Surfaces

A water surface is a slightly different matter than a visibly transparent liquid.

The ocean isn’t blue; it is reflective. Not much of the light that penetrates the surface of the ocean gets anywhere of interest. A small amount of light is scattered back up again, doing a bit of literal subsurface scattering.
To make an ocean surface with the Arch & Design material, follow these steps:

1. Set Diffuse Level to 0.0, Reflectivity to 1.0, and Transparency to 0.0. That’s right: No refraction is necessary.

2. Set IOR to 1.33 and turn on By IOR (fresnel reflections). Apply an interesting wobbly shader to Bump (Ocean (lume) works well here) and your ocean is basically done.

This ocean has reflections guided only by the IOR. But this might work fine; try it. Just make sure there is something there for it to reflect. Add a sky map, objects, or a just a blue gradient background. There must be something or it will be completely black.

For a more tropical look, try setting Diffuse Color to a slightly blue-green color, set the Diffuse Level to a fairly low number such as 0.1, and turn on Do Not Apply Bumps To The Diffuse Shading.

Now you have a base color in the water that emulates the small amount of scattering that occurs in the top level of the ocean.

Metal

Metals are reflective, which means they need something to reflect. The best looking metals come from having a true HDRI environment, either from a spherically mapped HDRI photo, or something like the mental ray physical sky.

To create classic chrome, turn off By IOR (fresnel reflections), set Reflectivity to 1.0, 0 degree reflectivity to 0.9 and 90 degree reflectivity to 1.0. Set Diffuse Color to white, and turn on Metal Reflections.

This creates an almost completely reflective material. Tweak the Reflection Glossiness parameter for various levels of blurry reflections. Also consider using the Round Corners effect (page 2–1556), which tends to work very well with metallic objects.

Metals also influence the color of their reflections. Because you turned on Metal Reflections, this is already happening; try setting the Diffuse Color to a golden color to create gold.

Try various levels of Reflection Glossiness (with the help of Fast (interpolate) for performance, when necessary).

You can also change the Reflectivity value. This has a slightly different meaning when Metal Material is on; it blends between the reflections (colored by the Diffuse Color) and normal diffuse shading. This allows a blend between the glossy reflections...
and the diffuse shading, both driven by the same color. For example, an aluminum material would need a bit of diffuse blended in, whereas chrome would not.

**Gold, silver, and copper**

**Brushed Metal**

Brushed metal is an interesting special case. In some cases, creating a brushed metal requires only turning down the Reflection Glossiness to a level where you obtain a very blurred reflection. This is sufficient when the brushing direction is random or the brushes are too small to be visible even as an aggregate effect.

For materials that have a clear brushing direction and/or where the actual brush strokes are visible, creating a convincing look is slightly more involved.

The tiny grooves in a brushed metal surface all work together to cause anisotropic reflections. This can be illustrated by the following schematic, which simulates the brush grooves by modeling many tiny adjacent cylinders, shaded with a simple Phong shader:

![Many small adjacent cylinders](image)

As you can see, the specular highlights in the cylinders work together to create an aggregate effect which is the anisotropic highlight.

Also note that the highlight isn’t continuous; it is actually broken up into small, adjacent segments. So the primary visual cues that a material is brushed metal are:

- Anisotropic highlights that stretch out in a direction perpendicular to the brushing direction
- A discontinuous highlight with breaks in the brushing direction

Many attempts to simulate brushed metals have looked only at the first effect: the anisotropy. Another common mistake is to think that the highlight stretches in the brushing direction. Neither is true.

Hence, to portray brushed metals, it is necessary to simulate these two visual cues. The first is simple: Use Anisotropy and Anisotropy Rotation to make anisotropic highlights. The second can be done in several ways:

- with a bump map
- with a map that varies the Anisotropy or Reflection Glossiness values
- with a map that varies the Reflection Color

Each has advantages and disadvantages, but the one we suggest here is the last one. The reason for
choosing this method is that it works well with interpolation.

1. Create a map for the brush streaks. The possible ways to do this include painting a map in a paint program, or using a Noise map that has been stretched heavily in one direction. The map should vary between middle-gray and white.

2. Apply this map to the Reflection Color in a scale suitable for the brushing.

3. Set Diffuse Color to white (or the color of the metal) but set Diffuse Level to 0.0 (or a small value).

4. Make sure Metal Material is on.

5. Set Reflection Glossiness to 0.75.

6. Set Anisotropy to 0.1 or a similar value. Use Anisotropy Rotation to align the highlight properly with the map. If necessary use Anisotropy Channel to base it on the same texture space as the map.

---

**Car Paint Material/Shader (mental ray)**

- **Material Editor > Type button > Material/Map Browser > Car Paint Material**
- **Material Editor > any material > Click a Map button. > Material/Map Browser > Car Paint Shader**

Note: The Car Paint material and shader appear in the Browser only if the mental ray renderer is the currently active renderer.

Car Paint is available as both a mental ray material and shader; both have identical parameters, and support the following unique characteristics of real-world car paint:

- The lowest surface, applied directly to the car body, is a thin layer of pigment. The properties of this layer are such that the perceived color changes depending on the viewing angle as well as the incident angle of the incoming light.

- Tiny metal flakes are suspended within this layer. The flakes reflect light and can be seen glittering on a sunny day, due to individual flakes reflecting sunlight directly at the observer.

- On top of this is a clear-coat layer, which can be more or less reflective and more or less glossy, depending on the quality of the layer and any added wax coating. Most notably, this layer tends to exhibit a pronounced Fresnel effect, reflecting more light at glancing angles.

- Includes a Lambertian dirt layer for that "unwashed" look.

Ambient/Extra light—The ambient light component.

Note: This parameter is treated differently from the ambient/ambience parameter pair of many other base shaders in that it is influenced by the additional Diffuse Coloring parameters, and hence represents incoming light, rather than the object’s “ambient color.”

Base color—The base diffuse color of the material.

Edge color—The color seen at glancing angles (that is, edges), which tends to appear much darker. For deep metallic paints seen on sports cars it tends to be almost black.

Edge bias—The falloff rate of the color towards the edge. Higher values make the edge region narrower; lower values make it wider. The useful range is 0.0 to approximately 10.0, where the value 0.0 turns the effect off.
glittery reflections of, for example, an HDRI environment. The value 0.0 turns the effect off.

This effect should generally be very subtle; a value of 0.1 is often enough. The final intensity of reflections also depends on the Flake Color and Flake Weight values.

**Flake specular exponent**—The Phong specular exponent for the flakes.

**Flake density**—The density of the flakes. The useful range is from 0.1 to approximately 10.0, where lower values indicate sparser flakes and higher values indicates denser flakes.

**Flake decay distance**—The distance at which the influence of the flakes fades out. A value of 0.0 disables fading. Any positive value causes the Flake Weight value to be modulated so that it reaches zero at this distance.

Because flakes are relatively small, using can introduce rendering artifacts if their visual density becomes significantly smaller than a pixel. If the oversampling of the rendering is set high, small flakes can also potentially trigger massive oversampling and hence overlong rendering times needlessly, because the averaging caused by the oversampling will essentially cancel out the flake effect. If you experience these issues, use Flake Decay Distance to counteract them.

![Using flake decay. The flake strength diminishes with distance. The same intentionally low oversampling as in the previous image has been used.](image)

**Flake strength**—The difference between the orientation of the flakes. The useful range is 0.0 to 1.0 where 0.0 means that all flakes are parallel to the surface, while higher values vary the orientation of flakes increasingly.

**Flake scale**—The size of the flakes. The procedural texture is calculated in object space, and will hence follow the object. Thus, the scale is influenced by any scale transformation on the object.

### Specular reflections rollout

<table>

</tr>
</tbody>
</table>

**Specular Color #1**—The color of the primary specular highlight.

**Specular Weight #1**—A scalar multiplier applied to Specular Color #1.

**Specular exponent #1**—The Phong exponent of Specular Color #1.

**Specular Color #2**—The color of the secondary specular highlight.

**Specular Weight #2**—A scalar multiplier applied to Specular Color #2.

*Flakes at different distances with no flake decay. The farthest flakes might cause flicker in animations, or trigger unnecessary oversampling and long render times (rendered here with low oversampling for illustrative purposes).*
Specular exponent #2—The Phong exponent of Specular Color #2.

Glazed specularity #1—Enables a special mode on the primary specular highlight called glazing. By applying a threshold to the specular highlight, it makes the surface appear more polished and shiny. For a new sports car with a lot of wax, turn this on. For a beat-up car in the junkyard, turn it off.

Left to right: Flake specularity only; standard specularity; "glazed" mode enabled; "glazed" mode specularity with flakes

Glossy reflections spread—Sets the amount of glossiness. Cars are generally near-mirrors so this value should be kept small.

Max distance—Limits the reach of reflective rays.

Single environment sampling—Optimizes lookup of environment maps.

Dirty layer (lambertian) rollout

Real cars are rarely clean. This shows the dirt layer (hand-painted dirt-placement map), including a bump map applied in the dirty regions.

A simple Lambertian dirt layer covers the underlaying paint and clear-coat layers.

Reflection color—The color of the reflections in the clear-coat layer. This is generally white.

Edge factor—Clear coat tends to reflect more at glancing angles (edges). This parameter defines the "narrowness" of this edge.

Edge reflections weight—The reflective strength at the edge (generally 1.0).

Facing reflections weight—The reflective strength at facing angles (generally low: 0.1 - 0.3).

Glossy reflection samples—Enables a glossy clear coat. This parameter sets the number of glossy reflection rays traced. A value of 0 disables glossiness.

Glossy reflections spread—Sets the amount of glossiness. Cars are generally near-mirrors so this value should be kept small.

Max distance—Limits the reach of reflective rays.

Single environment sampling—Optimizes lookup of environment maps.

Dirty layer (lambertian) rollout

Real cars are rarely clean. This shows the dirt layer (hand-painted dirt-placement map), including a bump map applied in the dirty regions.

A simple Lambertian dirt layer covers the underlaying paint and clear-coat layers.

Reflection color—The color of the reflections in the clear-coat layer. This is generally white.

Edge factor—Clear coat tends to reflect more at glancing angles (edges). This parameter defines the "narrowness" of this edge.

Edge reflections weight—The reflective strength at the edge (generally 1.0).

Facing reflections weight—The reflective strength at facing angles (generally low: 0.1 - 0.3).

Glossy reflection samples—Enables a glossy clear coat. This parameter sets the number of glossy reflection rays traced. A value of 0 disables glossiness.

Glossy reflections spread—Sets the amount of glossiness. Cars are generally near-mirrors so this value should be kept small.

Max distance—Limits the reach of reflective rays.

Single environment sampling—Optimizes lookup of environment maps.

Dirty color—The color of the dirt.

Dirt weight—The amount of dirt in the layer. This is typically connected to a texture shader to obtain variations in the dirt across the surface. If the value is 0.0, no dirt is added.

Advanced options rollout
Irradiance weight (indirect illumination)—The influence of indirect light (photons and final gathering) on the surface. It is internally divided by pi (3.14159); for example, a value of 1.0 means the standard 1.0/pi weight.

Global weight—A global tuning parameter that affects the entire diffuse, flake, and specular subsystems. It does not affect reflections or dirt.

Shaders rollout

This rollout enables application of maps or shaders to any of the Car Paint parameters. Of course, you can apply a shader to a parameter by clicking its Map button, so the principal value of this rollout is that it also lets you toggle a parameter’s shader, using the check box, without removing the map.

DGS Material (mental ray)

DGS Material (physics_phen)

Note: The DGS material appears in the Browser only if the mental ray renderer is the currently active renderer.

DGS stands for Diffuse, Glossy, Specular. This material is a mental ray phenomenon (a scripted shader tree) that provides a physically accurate simulation of a surface. Using DGS materials with the mental ray renderer is comparable to using the Architectural material (page 2–1535) with the default scanline renderer.

The DGS material’s basic components appear on the Parameters rollout. You can assign shaders to these components, creating a material of greater complexity. Buttons for assigning shaders are on both the Parameters rollout and the Shaders rollout.

Interface

Parameters rollout

Note: The button to the right of each control is a shortcut shader button. Clicking one of these buttons displays the Material/Map Browser (page 2–1412) so you can assign a shader to this component. When a map or a shader has been assigned to a component, this button displays the letter “M,” and the comparable button on the Shaders rollout displays the map or shader name.

Diffuse—Click the color swatch to display a Color Selector (page 1–161) and change the material’s diffuse color.

Glossy Highlights—Click the color swatch to display a Color Selector and change the color of glossy highlights.

Specular—Click the color swatch to display a Color Selector and change the color of mirror reflections. When the specular color is white, the material is 100 percent reflective, like a mirror. When the specular color is black, the material does not reflect any of its surroundings.

Shiny—Sets the width of glossy highlights. The larger this value, the smaller the highlights. Default=30.0.

Transparency—Specifies the transparency. The effective range of Transparency is from 0.0 to 1.0. At 0.0 the material is fully opaque. At 1.0 it is fully transparent. Default=0.0.
Warning: You can set the value of Transparency to be greater than 1.0, but this has no effect. An anomaly of the user interface for shaders in the mental ray and lume libraries is that spinner values are not “clamped” to lie within their effective ranges, as they are for controls in 3ds Max.

The value of Transparency also indirectly specifies the reflectivity of the material, which is calculated as 1.0 minus the Transparency value.

Index Of Refraction—Specifies the IOR. In the physical world, the IOR results from the relative speeds of light through the transparent material and the medium the eye or the camera is in. Typically this is related to the object’s density. The higher the IOR, the denser the object. Default=1.5.

See Extended Parameters Rollout (Standard Material) (page 2–1471) for a list of IOR values for commonly encountered materials.

Note: When the IOR equals 1.0, there is no refraction, and calculating the transparency can take less time than when the material is refractive.

Shaders rollout

The controls on this rollout let you assign a map or shader to one of the basic parameters of the DGS material. This is comparable to mapping a component of a standard material; by adding shaders, you can create a shader tree that generates complex effects.

Click the button for a component to display the Material/Map Browser (page 2–1412) and assign the map or shader. Use the toggle at the left to turn the effect of the map off or on.

The button to the right of each main shader button is for shaders that can return multiple parameters. If a shader that returns multiple parameters is assigned to the component, the button's tooltip shows the parameter name. Clicking the button displays a Connect Parameter To Shader dialog (page 2–1713), which lets you change which parameter is being used.

Important: UV Coordinates (page 2–1728) and XYZ Coordinates (page 2–1730) are the only shaders with multiple return values provided with 3ds Max. You might encounter multiple return values in shaders provided with other shader libraries or custom shader code.

For all the DGS material components, the available mental ray shaders are the same:

</table>
The Glass material simulates both the surface properties and the light-transmitting (photon) properties of glass. It is a mental ray phenomenon (a scripted shader tree) that is equivalent to a mental ray material (page 2–1544) with a Dielectric Material shader (page 2–1719) assigned to both its Surface and Photon components, with the parameter settings identical for both. A dielectric material, such as glass, is a material whose surface transmits most light that strikes it at angles close to perpendicular (90 degrees), but reflects most light that strikes at glancing angles (close to zero degrees).

Note: This material does not use a shadow shader, so shadows will always be opaque unless you generate caustics.

Adjacent Refractive Materials

Two controls, Outside Light Persistence and Index Of Refraction (Out), are for situations where you are modeling two adjacent refractive materials. Consider a drink in a martini glass. The glass has an index of refraction (IOR) of 1.5, while the alcohol in the glass has an IOR of about 1.3. To create a physically accurate model of this situation, use three glass materials: one for the glass itself, one for the alcohol, and a third material for the surfaces where they touch each other. For this third material, set the “inside” IOR to 1.3, and the outside IOR to 1.5.

Light Persistence—In conjunction with the Persistence Distance, controls the percentage of light that the volume transmits. For example, if the color is set to R=G=B=0.5 and the Persistence Distance is set to 2.0, then objects with a thickness of 2.0 units will appear 50 per cent transparent. Default=white (R=G=B=1.0).

Because transparency depends on the thickness of the object, objects with varying thickness show different transparency depending on the angle from which they are viewed.

Index Of Refraction—Specifies the Index Of Refraction (IOR). In the physical world, the IOR results from the relative speeds of light through the transparent material and the medium the eye or the camera is in. Typically this is related to the object’s density. The higher the IOR, the denser the object. Default=1.5.

See Extended Parameters rollout (Standard Material) (page 2–1471) for a list of IOR values for commonly encountered materials.
**Outside Light Persistence**—In conjunction with the Persistence Distance, controls the percentage of light transmitted on the other side of a surface. When set to the default of black, this control has no effect. See the section “Adjacent Refractive Materials,” above. Default=black (R=G=B=0.0).

**Index Of Refraction (out)**—Sets the IOR on the other side of a surface. When set to the default of zero, this control has no effect. See the section “Adjacent Refractive Materials,” above. Default=0.0.

**Persistence Distance**—In conjunction with the Light Persistence color, controls the percentage of light that the volume transmits. It is the distance at which light transmission is reduced to the percentage specified by the Light Persistence RGB values. Default=1.0.

If you specify an Outside Light Persistence color, that setting also uses the Persistence Distance.

**Ignore Normals**—When on, the renderer does not use normals to decide whether a light ray is entering or leaving the object. Normally, the material uses normals to decide whether a ray is entering or leaving an object. (It is entering if the normal points toward the ray, leaving if the normal points away from the ray.) This can present a problem for rendering objects whose normals are not unified. If Ignore Normals is on, the material decides whether a ray is entering or leaving the object by counting the number of times the ray has intersected the object. Default=off.

**Opaque Alpha**—When on, refracted rays that touch the environment don’t generate a transparent alpha value. (This is how 3ds Max usually treats the environment.) When off, refracted rays that touch the environment render a transparent alpha value, which can help if you plan to use the rendering as part of a composite. Default=off.

**Phong Coefficient**—When greater than zero, generates Phong highlights on the material. The highlights appear in the sample slot. In general, this value must be greater than 10 for highlights to be apparent. Default=0.0.

---

**Subsurface Scattering (SSS) Materials**

Material Editor > Type button > Material/Map Browser > Choose SSS Fast Material (mi), SSS Fast Skin Material (mi), SSS Fast Skin Material+Displace (mi), or SSS Physical Material (mi), and then click OK.

Note: The SSS materials appear in the Browser only if the mental ray renderer is the currently active renderer.

The subsurface scattering (SSS) materials are provided especially to model skin and other organic materials whose appearance depends on more than one layer of light scattering. 3ds Max provides four of these materials. Each material is a top-level wrapper (a “phenomenon”) for shaders whose controls are documented in the *Standard mental ray Shader Libraries* document. Click a link to see the mental images documentation for the shader.

**Tip:** When you follow a link to the documentation for mental images library shaders, scroll up a bit in your browser. The links tend to go past the title of the section, and there might be introductory content above the link location. If the link goes to the beginning of a section, scroll down instead.

<table>
<thead>
<tr>

</tr>
<tr>
<td>SSS Physical Material (mi)</td>
<td>miss_physical</td>
</tr>
</tbody>
</table>

Also see [Subsurface Scattering Shaders](#) and the topics that follow it for more general information. See [Physically Correct Subsurface Scattering](#) for background information and tips about the Physical material.
Note: The SSS Physical Material can also be used as a shader for the Surface and Photon components of a mental ray material (page 2–1544).

For a downloadable tutorial offering a practical demonstration of using the SSS Fast Skin material, see this Web page.

**Light Controls for the SSS Physical Material**

The SSS Physical material includes light controls that correspond to the lights array in the parameters for the misss_physical shader.

**Lights**—When on, the material is illuminated only by those lights specified in the list. When Lights is turned off, all lights in the scene affect the material. Default=off.

The remaining light controls are available only when Lights is on.

- **List of lights**—Displays the lights you have chosen to illuminate this material.
- **Add**—Adds a light to the list. Click Add to turn it on, then click the light object in a viewport.
- **Replace**—Replaces a light in the list. Highlight a light’s name in the list, click Replace to turn it on, then click the replacement light object in a viewport.
- **Delete**—Deletes a light from the list. Highlight a light’s name in the list, then click Delete.

**Matte/Shadow Material**

Material Editor > Type button > Material/Map Browser > Matte/Shadow

The Matte/Shadow material allows you to make whole objects (or any subsets of faces) into matte objects (page 3–971) that reveal the current environment map (page 3–934).

Simply rendering the framed photo against a background shows the photo in front of the background.

A matte object hides parts of the photo, revealing the background to make it appear the photo is behind the goblets.

It can also receive shadows cast on it from non-matte objects in the scene. Using this technique, you can cast shadows on backgrounds by building matte proxy objects and placing them in front of similarly shaped objects in the background.
Matte/Shadow material can also have reflections.

Note: The Matte/Shadow effect is visible only when you render the scene. It isn’t visible in viewports.

**Procedures**

**To render objects seamlessly against a background environment:**

There are three ways you can render objects to blend seamlessly into a background environment:

1. By assigning a Matte/Shadow Material
2. By assigning a 100% self-illuminated diffuse texture to an object using Camera Mapping
3. By assigning a 100% self-illuminated diffuse texture using Environment/Screen projection

Use the Plate Match/MAX R2.5 antialiasing whenever you are trying to match foreground objects with an unfiltered background, or trying to match the antialiasing qualities of the 3ds Max 2.5 renderer. See the description of Antialiasing Filter in the description of the Default Scanline Renderer (page 3–38).

**Example: To see the effect of Affect Alpha and Matte Reflection:**

1. Create a scene with one or more objects on a box platform, and one or more shadow-casting spotlights.
   Tip: If you use only one spotlight, increase its Multiplier value.
2. Assign a Matte/Shadow material to the box, and render the scene with default Matte/Shadow parameters (Opaque Alpha is on, and Affect Alpha is off).
3. In the rendered frame window (page 3–5) that is displayed, click Display Alpha Channel.
   The objects all appear as white silhouettes, including the platform.
4. On the Matte/Shadow Basic Parameters rollout, turn off Opaque Alpha, and turn on Receive Shadows and Affect Alpha.
5. Press F9 (Render Last (page 3–25)).
   The silhouette of the box no longer appears, but the other objects and their shadows appear.
6. On the Matte/Shadow Basic Parameters rollout, click the Map button in the Reflection group, and use the Material/Map Browser (page 2–1412) to assign a Flat Mirror (page 2–1695) map to the box’s material.
7. Press F9 (Render Last (page 3–25)).
8. In the rendered frame window, turn off Display Alpha Channel.

   The reflections of the objects appear on the box, even though the box itself is invisible.
Interface

Matte group

Opaque Alpha—Determines whether or not the matte material appears in the alpha channel. If you turn off Opaque Alpha, the matte object will not make an alpha channel, and the image can be used for compositing, just as if there are no matte objects in the scene. Default=off.

Atmosphere group

These options determine whether fog effects are applied to the matte surfaces, and how they are applied.

Apply Atmosphere—Turns the fogging of matte objects on and off.

When applying fog, you can choose between two different methods. You can either apply fog as if the matte surface is at an infinite distance from the camera or you can apply it as if the matte surface is actually at that point on the object being shaded. In other words, you can apply the fog to the matte surface in either 2D or 3D. The following controls determine how this is applied:

At Background Depth—This is the 2D method. The scanline renderer (page 3–1006) fogs the scene, and then renders its shadows. In this case, the shadows won’t be lightened by the fog. If you want to lighten the shadows, you need to turn up the shadow brightness.

At Object Depth—This is the 3D method. The renderer first renders the shadows, and then fogs the scene. Since this varies the amount of fog over the 3D matte surface, the generated matte/alpha channels don’t blend perfectly into the background. Use At Object Depth when the matte object is meant to be a 3D object in the scene that the 2D background represents.

Shadow group

This group determines whether the matte surfaces receive shadows that are cast upon them, and how they receive them.

Receive Shadows—Renders shadows on the matte surfaces. Default=on.

Affect Alpha—When on, shadows cast on a matte material are applied to the alpha channel. This lets you render bitmaps with alpha channels that you can composite later. Default=on.

Affect Alpha is available only when Opaque Alpha (in the Matte group box) is turned off.

When Affect Alpha is on, the higher the Shadow Brightness value, the more transparent the shadow, allowing the background to show through more, and making the shadow appear brighter.

Shadow Brightness—Sets shadow brightness. At 0.5, the shadows will not be attenuated on the matte surface; at 1.0, the shadows are brightened to the color of the matte surface; and at 0.0 they are darkened to completely obliterate the matte surface.

Color—Displays a Color Selector (page 1–161) to let you choose the color of the shadow. Default=black.

Setting shadow color is especially useful when you’re using a Matte/Shadow material to composite
your shadows against a background image, such as video. It lets you tint your shadows to match pre-existing shadows in the image.

**Reflection group**

Controls in this group determine whether the matte surfaces can have reflections. You create matte reflections using a shadow map.

Tip: Matte reflections don’t successfully create an alpha channel unless you render them against a black background.

**Amount**—Controls the amount of reflection to use. This is a percentage that can range from 0 to 100. This control is unavailable unless you have assigned a map. Default=50.

You can animate this parameter.

**Map**—Displays the Material/Map Browser so you can assign a map to use for reflections. The reflection is independent of the environment unless you choose a Reflect/Refract or Flat Mirror map.

---

**Compound Materials**

Compound materials combine two or more sub-materials. Compound materials are similar to compositor maps, but they exist at the material level. Applying a compound material to an object creates a compound effect that often uses mapping. You load or create compound materials using the Material/Map Browser.

Using a filter control, you can choose whether the Browser lists maps or materials or both.

Different types of materials create different effects, behave in particular ways, or are provided as ways to combine multiple materials.

Note: The sub-material buttons and sub-map buttons for most materials and maps have check boxes beside each button. These let you turn that branch of the material or map on or off. For example, in the Top/Bottom material, the Top Material and Bottom Material buttons each have check boxes. Similarly, the Checker map has two map buttons, one for each color. Each button has a check box beside it that lets you disable that color’s map.

These are the different types of compound materials:

**Blend** (page 2–1588): Combines two materials by mixing their pixel colors, as Mix maps do.

**Composite** (page 2–1589): Mixes up to 10 materials, using additive colors, subtractive colors, or opacity mixing.

**Double-Sided** (page 2–1591): Stores two materials. One material is rendered on the object’s outer faces (the usual side for one-sided materials, as determined by face normals), and the other is rendered on the object’s inner faces.

**Morpher Material** (page 2–1592): Morpher materials use the Morpher modifier to manage multiple materials over time.

**Multi/Sub-Object** (page 2–1594): Lets you assign more than one material to the same object. Stores two or more sub-materials, which you assign at the sub-object level by using the Mesh Select modifier. You can also assign the sub-materials to whole objects by using the Material modifier.

**Shellac** (page 2–1597): Superimposes one material on another.

**Top/Bottom** (page 2–1599): Stores two materials. One material is rendered on an object’s top faces and the other is rendered on the object’s bottom faces, depending on whether a face normal points up or down.
Chapter 16: Material Editor, Materials, and Maps

**Procedure**

**To have the Browser list only materials:**
- At the top of the Show group, leave Materials on and turn off Maps.

*Note:* This option is available only at the material level in the Material Editor.

---

**Blend Material**

Material Editor > Type button > Material/Map Browser > Blend

A Replace Map (page 2–1456) dialog is displayed. This dialog asks whether you want to discard the original material in the slot, or retain it as a sub-material.

Blend materials have similar controls to Mix maps.

**To specify a component material:**
- In the Blend Basic Parameters rollout, click one of the two material buttons.

The parameters for the sub-material are displayed. By default, a sub-material is a Standard material with Blinn shading.

**To control the mix amount:**
- In the Basic Parameters rollout, adjust the Mix Amount value.

You can also control the mix amount by using a map.

**Procedures**

**To create a Blend material:**
1. Activate a sample slot in the Material Editor.
2. Click the Type button.
3. In the Material/Map Browser (page 2–1412), choose Blend and then click OK.

The Blend material lets you mix two materials on a single side of the surface. Blend has an animatable Mix Amount parameter that lets you draw material morphing (page 3–974) function curves to control the way that the two materials are blended over time.

*Note:* If even one sub-material has its shading set to Wire (see Shader Basic Parameters Rollout (page 2–1466)), the entire material displays and renders as a wire material.

---

*Blend material combines bricks and stucco.*

*Map used to reveal brick beneath stucco*
is visible; when it is close to full intensity, the other component is visible.

Tip: Using a Noise map for the mixing map can give good effects that have a natural appearance.

Mix Amount is unavailable while a map is assigned to this parameter. If Use Curve is turned off, the mixing map is used as is. If Use Curve is on, you can shift the effect of the mixing map’s gradient ramp to reveal more of one material and less of the other.

**Interface**

<table>
<thead>
<tr>
<th>Material Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Material 1/2</td>
<td>Set the two materials to be blended. Use the check boxes to turn the materials on and off.</td>
</tr>
<tr>
<td>Interactive</td>
<td>Chooses which of the two materials is displayed on object surfaces in viewports by the interactive renderer.</td>
</tr>
<tr>
<td>Mask</td>
<td>Sets a map to use as a mask. The degree of blending between the two materials depends on the intensity of the mask map. Lighter (whiter) areas of the mask show more of Material 1, while darker (black) areas of the mask show more of Material 2. Use the check box to turn the mask map on or off.</td>
</tr>
<tr>
<td>Mix Amount</td>
<td>Determines the proportion of the blend (percentage). 0 means only Material 1 is visible on the surface; 100 means only Material 2 is visible. Unavailable if you have assigned a mask map and the mask’s check box is on. You can animate this parameter. Create Material Preview (page 2–1434) is useful for testing the effect.</td>
</tr>
</tbody>
</table>

**Mixing Curve group**

The mixing curve affects how gradual or how sharp the transition between the two colors being blended will be. It affects the blend only when a mask map is assigned.

**Tip:** For mottled effects, blend two standard materials using a noise map as a mask.

**Use Curve**—Determines whether the Mixing Curve affects the mix. This control is available only when a mask is assigned and active.

**Transition Zone**—These values adjust the level of the Upper and Lower limits. If the two values are the same, the two materials meet at a definite edge. Wider ranges give more gradual blending from one sub-material to the other. The mixing curve displays the effect of changing these values.

---

**Composite Material**

Composite material composites (page 3–922) up to 10 materials. The materials are superimposed from top to bottom, as listed in the rollout. Materials are combined using additive opacity (page 3–906), subtractive opacity (page 3–1017), or mixed using an Amount value.
Note: If even one sub-material has its shading set to Wire (see Shader Basic Parameters Rollout (page 2–1466)), the entire material displays and renders as a wire material.

**Interface**

**Base Material**—Displays the Material/Map Browser (page 2–1412), where you assign the base material. By default, the base material is a Standard material. The other materials are composited by superimposing them on top of this material, in order from top to bottom.

**Mat 1 through Mat 9**—Each of these nine groups contains controls for a material to composite. By default, no materials are assigned.

**Check box**—When on, uses the material in the composite. When off, doesn’t use it. Default=on.

**Button**—Displays the Material/Map Browser (page 2–1412), where you assign a material to composite.

**ASM buttons**—These buttons control how the material is composited. Default=A.

- **A**—When on, this material uses *additive opacity* (page 3–906). Colors in the material are summed based on their opacity.
- **S**—When on, this material uses *subtractive opacity* (page 3–1017). Colors in the material are subtracted based on their opacity.
- **M**—When on, this material mixes materials based on the Amount. Both color and opacity are blended as they are when you use a *Blend material* (page 2–1588) with no mask.

**Amount spinner**—Controls the amount of mixing. Default=100.0.

For additive (A) and subtractive (S) compositing, the Amount can range from 0 to 200. When the Amount is 0, no compositing happens, and the material below is not visible. When the Amount is 100, the composite is complete. When the amount is greater than 100, compositing is "overloaded": transparent portions of the material become more opaque, until the material below is no longer visible.

For mix (M) compositing, the Amount can range from 0 to 100. When the Amount is 0, no compositing happens, and the material below is not visible. When the amount is 100, compositing is complete, and only the material below is visible.
Double-Sided Material

Material Editor > Type button > Material/Map Browser > Double-Sided

On the right, a double-sided material creates a pattern for the inside of the trash can.

The Double-Sided material lets you assign two different materials to the front and back faces of an object.

Note: If even one sub-material has its shading set to Wire (see Shader Basic Parameters Rollout (page 2–1466)), the entire material displays and renders as a wire material.

Procedures

To create a double-sided material:
1. Activate a sample slot in the Material Editor.
2. Click the Type button.
3. In the Material/Map Browser, choose Double-Sided and then click OK.

A Replace Map dialog (page 2–1456) is displayed. This dialog asks whether you want to discard the original material in the slot, or retain it as a sub-material.

The Double-Sided material controls let you choose the two materials, and the translucency of the material overall.

To choose the outer material:
- Click the button labeled Facing Material.
  The parameters for the sub-material are displayed. By default, a sub-material is a Standard material with Blinn shading.

To choose the inner material:
1. Go back to the parent material (parameters for the Double-Sided material).
2. On the Double-Sided Basic Parameters rollout, click the button labeled Back Material.
  The parameters for the sub-material are displayed. By default, a sub-material is a Standard material with Blinn shading.

To make the material translucent:
- Set Translucency to a value greater than 0.
  The Translucency control affects the blending of the two materials. When Translucency is 0, there is no blend. When Translucency is 100.0 percent, the outer material is visible on inner faces and the inner material is visible on outer faces. At intermediate values, the specified percentage of the inner material “bleeds through” and is visible on outer faces.

Interface

Translucency—Sets the amount that one material shows through the other. This is a percentage that can range from 0.0 to 100.0. At 100 percent, the outer material is visible on inner faces and the inner material is visible on outer faces. At intermediate values, the specified percentage of
the inner material "bleeds through" and is visible on outer faces. Default=0.0.

You can animate this parameter.

**Facing Material and Back Material**—Click to display the Material/Map Browser (page 2–1412) and choose a material for one side or the other.

Use the check boxes to turn the materials on or off.

---

**Morpher Material**

Material Editor > Type button (labeled Standard by default) > Material/Map Browser > Morpher material

*Procedures (page 2–1592) Interface (page 2–1593)*

The Morpher material works hand-in-hand with the Morpher modifier. You can use it to make the cheeks of a character blush, or to wrinkle a character’s forehead when the eyebrows are raised. With the Morpher modifier’s channel spinners, you can blend materials the same way you morph the geometry.

The Morpher material has 100 material channels that map directly to the 100 channels in the Morpher modifier. After you apply the Morpher material to an object and bind it to the Morpher modifier, you use the channel spinners in the Morpher modifier to morph materials and geometry. Empty channels in the Morpher modifier, with no geometry morph data, can be used to morph materials only.

*Note:* The mental ray renderer (page 3–78) does not support the Morpher material.

*Note:* If even one sub-material has its shading set to Wire (see Shader Basic Parameters Rollout (page 2–1466)), the entire material displays and renders as a wire material.

See also

Morpher Modifier (page 1–729)

---

**Applying the Morpher Material**

An object must have at least one Morpher modifier in its modifier stack. You can assign the material to an object and bind it to the object’s Morpher modifier in either of two ways.

- After the Morpher modifier is applied to an object, use the Assign New Material command in the Global Parameter rollout of the Morpher modifier. This is the simplest way, and applies the Morpher Material to the object and binds the material to the Morpher modifier at the same time.

- Open the Material Editor, select the Morpher material, and click Choose Morph Object in the Parameters rollout, then click the object in the viewports. After clicking the object, a dialog displays in the viewports, select the Morpher modifier from the dialog (an object may have multiple Morpher modifiers). This binds the Morpher material to the Morpher modifier.

*Note:* You can bind a Morpher material to only one Morpher modifier.

**Procedures**

Example: To apply and use the Morpher material:

1. Create a sphere in the Perspective viewport.

2. On the Modify panel, right-click the sphere’s entry in the modifier stack display, and choose Convert To: Editable Mesh.

3. From the Modifier List, choose Morpher. This applies the Morpher modifier to the sphere.

4. On the Morpher modifier’s Global Parameters rollout, click Assign New Material. The Morpher material is now applied to the object and bound to the Morpher modifier.
5. Open the Material Editor, and click Pick Material from Object (the eyedropper), then click the sphere in the viewports. The Material Editor displays the Morpher material parameters.

6. On the Morpher Material Parameters rollout, click the Mat 1 slot.

8. On the Basic Parameters rollout, click the Diffuse color swatch.

9. On the Color Selector, choose a bright yellow, and close the color selector. Leave the Material Editor open.

10. Turn on the Auto Key button, then move the time slider to frame 50.

11. Select the sphere, and then open the Modify panel.

12. On the Morpher modifier’s Channel List rollout, set the channel 1 spinner to 100.

    In the Material Editor, the color of the sample sphere changes to yellow.

13. On the main toolbar, click Render.

    The sphere is yellow. If you render an animation the sphere changes from a grey color to yellow.

**Interface**

The Morpher material interface is on a Parameters rollout in the Material Editor.

**Modifier Connection group**

**Choose Morph Object**—Click this option, then select an object in the viewports that has a Morpher modifier applied to it. Clicking an object in the viewports displays the Choose Morpher modifier dialog. Choose a Morpher modifier, and click Bind.
Chapter 16: Material Editor, Materials, and Maps

Name Field—Displays the name of object to which the Morpher material is applied. If no object has been specified, the field displays "No Target".

Refresh—Updates the channel data.

Marker List—This list is identical to the marker list in the Morpher modifier. Markers you save in the Morpher modifier appear here.

Base Material group

Base material button—Click to apply a base material to the object. The base material represents what the model looks like before any channel blending takes place.

Channel Material Setup group

Map #—100 material channels are available. The scroll bar allows you to scroll through all the channels. Double-click a channel to jump to the material parameters for that channel.

There is a one-to-one correspondence between the channels in the Morpher material and the Morpher modifier. A material in channel 1 of the Morpher material is controlled by the channel 1 spinner in the Morpher modifier.

Material on/off toggle—Turns a channel on and off. Channels that are off do not affect the morph result.

Mixing Calculation Options group

The system can slow down if there are many active materials being blended. Options in this group allow you to control when the morph result will be computed.

Constantly—Choose to compute the material morph result all the time.

When Rendering—Choose to compute the material morph result at render time.

Never Calculate—Choose to bypass material blending.

Multi/Sub-Object Material

The Multi/Sub-Object material lets you assign different materials at the sub-object level of your geometry. You create a multi-material, assign it to an object, and then use the Mesh Select modifier (page 1–719) to select faces and choose which of the sub-materials in the multi-material are assigned to the selected faces.

If the object is an editable mesh (page 1–996), you can drag and drop materials to different selections of faces, building a Multi/Sub-Object material on...
Multi/Sub-Object Material

the fly. See Drag and Drop Sub-Object Material Assignment (page 2–1424).

You can also create a new Multi/Sub-Object material by dragging to faces selected with the Edit Mesh modifier (page 1–634).

Sub-material IDs do not depend on the order of the list, and you can enter new ID values.

The Make Unique button (page 2–1442) in the Material Editor lets you make an instanced sub-material into a unique copy.

At the Multi/Sub-Object material level, the sample slot’s sample object shows a patchwork of the sub-materials. When you edit a sub-material, the sample slot display depends on the setting of the Simple Multi Display Below Top Level toggle in the Material Editor Options dialog (page 2–1436).

Using Multi/Sub-Object Materials

Here are some usage tips with regards to mesh editing and managing sub-materials.

• When working at sub-object levels of Editable Meshes, Polys, Patches and Splines, or with objects that have Edit Mesh, Spline or Patch modifiers applied to them, you can browse by sub-material names if the object has a multi-sub-object material applied to it.

• Sub-materials that are not assigned to an object, or surface of an object, can be ‘cleaned’ from the Multi-Sub-Object material by using the Clean MultiMaterial utility (page 2–1742).

• Duplicate maps, assigned to materials, can be changed to instances by using the Instance Duplicate Maps utility (page 2–1744).

Procedures

To create a Multi/Sub-Object material:

1. Activate a sample slot in the Material Editor.
2. Click the Type button.

3. In the Material/Map Browser (page 2–1412), choose Multi/Sub-Object and then click OK.

A Replace Map dialog (page 2–1456) is displayed. This dialog asks whether you want to discard the original material in the slot, or retain it as a sub-material.

The controls for a Multi/Sub-Object material are essentially a list of the sub-materials it contains.

To assign a sub-material:

• On the Multi/Sub-Object Basic Parameters rollout, click a sub-material button.

The parameters for the sub-material appear. By default, a sub-material is a Standard material with Blinn shading.

To make one of the sub-materials a solid color:

• On the Multi/Sub-Object Basic Parameters rollout, click the color swatch next to the sub-material button.

In the Color Selector (page 1–161), choose a color.

The color swatches for sub-materials are shortcuts. They assign the color you choose to the sub-material’s Diffuse component.

To assign one of the sub-materials to a sub-object selection:

1. Select the object, and assign a Multi/Sub-Object material to it.

2. On the Modify panel (page 3–758), apply Mesh Select (page 1–719) to the object.

3. Click Sub-Object and choose Face as the sub-object category.

4. Select the faces to which you will assign a sub-material.
5. Apply a Material modifier (page 1–714), and set the material ID value to the number of the sub-material you want to assign. The viewport updates to show the sub-material assigned to the selected faces.

The material ID values in the Multi/Sub-Object material and the material ID numbers in the Select Face rollout correspond. If you set the ID to a number that doesn't correspond to a material contained in the Multi/Sub-Object material, the faces render as black.

Warning: Some geometric primitives do not use 1 as the default material ID, and some, such as hedra or box, have multiple material IDs by default.

Tip: You can also use the Edit Mesh modifier (page 1–634) to assign a contained material to selected faces. Apply Edit Mesh to the object, go to the Face sub-object level, and select the faces to assign. Then on the Edit Surface rollout, set the material ID value to the ID of the sub-material. (You can drag and drop (page 2–1424) a Multi/Sub-Object material to an Edit Mesh modifier as you can to an editable mesh object.)

To add a new sub-material:
- Click Add.

A new sub-material is added to the end of the list. By default, the new sub-material’s ID number is one greater than the highest material ID already in use.

To remove a sub-material:
1. Select the sub-material by clicking its small sample sphere in the Multi/Sub-Object Basic Parameters rollout.

The small sample sphere is surrounded by a black and white border to show the sub-material is selected.

If the list of sub-materials is longer than the rollout will hold, you can use the scroll bar at the right to display other parts of the list.

2. Click Delete.

The sub-material is removed. Deleting a sub-material is an undoable operation.

Interface

Number—This field displays the number of sub-materials contained in the Multi/Sub-Object material.

Set Number—Sets the number of sub-materials make up the material. At the Multi/Sub-Object material level, the sample slot’s sample object shows a patchwork of the sub-materials. (When you edit a sub-material, the sample slot display depends on the setting of the Simple Multi Display Below Top Level toggle on the Material Editor Options dialog (page 2–1436).)

Reducing the number of sub-materials removes sub-materials from the end of the list. You can
undo Set Number when you have used it to delete materials.

**Add**—Click to add a new sub-material to the list. By default, the new sub-material’s ID number is one greater than the highest material ID already in use.

**Delete**—Click to delete the currently chosen sub-material from the list. You can undo deleting a sub-material.

**Sort list controls**

These buttons appear above three of the columns in the sub-materials list.

**ID**—Click to sort the list so it begins with the sub-material that has the lowest material ID, and ends with the sub-material that has the highest material ID.

**Name**—Click to sort the list by the names you have entered in the Name column.

**Sub-Material**—Click to sort the list by the sub-material names that appear on the Sub-Material buttons.

**List of sub-materials**

Each sub-material has a single entry in this list. The rollout displays up to 10 sub-materials at a time. If the Multi/Sub-Object material contains more than 10 sub-materials, you can scroll the list using the scrollbar at the right.

Each sub-material in the list has the following controls:

**Small sample sphere**—The small sample sphere is a "mini-preview" of the sub-material. Click it to select this sub-material. You must select a sub-material before you delete it.

**ID**—Shows the ID number assigned to this sub-material. You can edit this field to change the ID number. If you assign two sub-materials the same ID, a warning message appears at the top of the rollout.

When the Multi/Sub-Object material is applied to an object, faces in the object assigned the same material ID number render with this sub-material.

You can click Sort by ID to sort the sub-material list by this value, from lowest to highest.

Note: Sometimes the Sub-Material button shows a material number. This is not the sub-material ID.

**Name**—Lets you enter a custom name for the material. A sub-material name appears in the Name (page 2–1448) field when you’re at the level of the sub-material. It also appears in the Browser and the Navigator.

**Sub-Material button**—Click the sub-material button to create or edit one of the sub-materials. Each of the sub-materials is a complete material in its own right, with as many maps (page 3–968) and levels as you want.

By default, each sub-material is a Standard material (page 2–1465) with Blinn shading (page 2–1480).

**Color swatch**—Click the color swatch to the right of the Sub-Material button to display the Color Selector (page 1–161) and choose a diffuse color for the sub-material.

**On/Off toggle**—Turns the sub-material on or off. When a sub-material is off, it appears black in the sample slot and on objects in the scene. Default=on.

---

**Shellac Material**

Material Editor > Type button > Material/Map Browser > Shellac

Shellac material mixes two materials by superimposing one over the other. Colors in the superimposed material, called the "shellac" material, are added to colors in the base material.
A Shellac Color Blend parameter controls the amount of color mixing.

Interface

- **Base Material**—Goes to the level of the base sub-material. By default, the base material is a Standard material with Blinn shading.

- **Shellac Material**—Goes to the level of the shellac material. By default, the shellac material is a Standard material with Blinn shading.

- **Shellac Color Blend**—Controls the amount of color mixing. At 0.0, the shellac material has no effect. Increasing the Shellac Color Blend value increases the amount of shellac material color blended into the base material color. There is no upper limit on this parameter. Large values “overload” the shellac material colors. Default=0.0.

You can animate this parameter.

**Note:** If even one sub-material has its shading set to Wire (see Shader Basic Parameters Rollout (page 2–1466)), the entire material displays and renders as a wire material.
Top/Bottom Material

Material Editor > Type button > Material/Map Browser > Top/Bottom

Top/bottom material gives the pot a charred bottom.

The Top/Bottom material lets you assign two different materials to the top and bottom portions of an object. You can blend the materials into one another.

The object’s top faces are those whose normals point up. The bottom faces have normals that point down. You can choose whether "up" and "down" refer to the scene’s world coordinates or to the object’s local coordinates.

Note: If even one sub-material has its shading set to Wire (see Shader Basic Parameters Rollout (page 2–1466)), the entire material displays and renders as a wire material.

Procedures

To create a top/bottom material:
1. Activate a sample slot in the Material Editor.
2. Click the Type button.
3. In the Material/Map Browser (page 2–1412), choose Top/Bottom and then click OK.

A Replace Map (page 2–1456) dialog is displayed. This dialog asks whether you want to discard the original material in the slot, or retain it as a sub-material.

The Top/Bottom material controls let you choose the two materials, and also the transition between them.

To choose the top or bottom material:
- On the Top/Bottom Basic Parameters rollout, click the Top Material button or the Bottom Material button.

The parameters for the sub-material appear. By default, a sub-material is a Standard material with Blinn shading.

To swap the two component materials:
- In the Basic Parameters rollout, click Swap.

The remaining controls, described in the "Interface" section, affect the transition between top and bottom.

Interface

Top/Bottom Basic Parameters

Top Material: [Material Editor > Type button > Material/Map Browser > Top/Bottom]

Swap

Bottom Material: [Material Editor > Type button > Material/Map Browser > Top/Bottom]

Coordinates:
- World
- Local

Blend: [0–1]
Position: [0–1]

Top Material and Bottom Material—Click to display the parameters for the top or bottom sub-material. By default, a sub-material is a Standard material with Blinn shading.

The check box to the right of each button lets you turn off that material, making it invisible in the scene and in the sample slot.

Swap—Swaps the position of the top and bottom materials
Coordinates group

Controls in this group let you choose how the software determines the boundary between top and bottom.

World—Faces point up or down according to the scene's world coordinates. When you rotate the object, the boundary between top and bottom faces remains in place.

Local—Faces point up or down according to the object's local coordinates. When you rotate the object, the material rotates with it.

Blend—Blends the edge between the top and bottom sub-materials. This is a percentage that can range from 0 to 100. At 0, there is a sharp line between the top and bottom sub-materials. At 100, the top and bottom sub-materials tint each other. Default=0.

You can animate this parameter.

Position—Determines where the division between the two materials lies on an object. This is a percentage that can range from 0 to 100. 0 is at the bottom of the object, and displays only the top material. 100 is at the top of the object, and displays only the bottom material. Default=50.

You can animate this parameter.

Shell Material

The Shell material is a container for other materials, like Multi/Sub-Object. It also lets you control which material is used in which renderings.

Note: The Material/Map Browser lists the Shell material when you assign a new material. You can apply two materials to a single object this way, but changing a material's type to Shell does not generate a baked texture that is saved to disk.

Procedures

To load a shell material into a sample slot:
1. Click an unused sample slot.
2. Click Pick Material From Object.
3. In a viewport, click an object that has a baked material.

The sample slot now contains the baked material, and the Shell Material Parameters rollout is displayed.

Interface

Original Material—Displays the name of the original material. Click the button to view that material and adjust its settings.

Baked Material—Displays the name of the baked material. Click the button to view that material and adjust its settings.

In addition to the color and mapping of the original material, the baked material can include shadows from lighting, and other information.

Also, a baked material has a fixed resolution.

Viewport—Use these buttons to choose which material appears in shaded viewports: the original...
material (upper button) or the baked material (lower button).

**Render**—Use these buttons to choose which material appears in renderings: the original material (upper button) or the baked material (lower button).

---

**Advanced Lighting Override Material**

Material Editor > Type button > Material/Map Browser > Advanced Lighting Override

This material lets you directly control the radiosity properties of a material. Advanced Lighting Override is always a supplement to a base material, which can be any renderable material. The Advanced Lighting Override material has no effect on ordinary renderings. It affects the radiosity solution (page 3–51) or light tracing (page 3–44). Advanced Lighting Override has two main uses:

- Adjusting the material properties used in a radiosity solution or light tracing
- Creating special effects such as having self-illuminating objects contribute energy to the radiosity solution

As the rollout for the Advanced Lighting Override material states, you don’t have to apply this material to obtain a radiosity solution, and most models will never require it.

**Important:** The mental ray renderer (page 3–78) does not support the Advanced Lighting Override material.

---

**Obtaining a Better Image**

Materials that use default settings can be highly reflective. This can lead to overexposed or washed-out radiosity solutions. In general, the best way to adjust this is to reduce the HSV Value (V) of a material color; or, for a bitmapped material, reduce the RGB Level. In some situations, Radiosity Override can improve the appearance of the radiosity solution. Examples of situations where Radiosity Override can help include color bleeding and large dark areas:

- You might want to reduce Reflectance Scale or Color Bleed when a large area of color (for example, a red carpet in a room with white walls) creates excessive color bleeding. This might be physically accurate, but the eye adjusts for such effects, and the radiosity result might look better with less reflectance or less color bleeding.

![Left: Excessive bleeding of the floor color onto the walls and ceiling. Right: Radiosity Override material reduces the floor’s reflectance, causing less bleeding.](image)

- You might want to increase Reflectance Scale when the scene includes a large dark area (for example, a black floor). This can lead to a very dark radiosity result. You can maintain the floor’s color but increase reflectance, giving the solution the colors you want while increasing its brightness.

![The room is lit only by spotlights pointed at the floor. Increasing reflectance of the floor brightens the entire room.](image)
Tip: Check the *reflectance and transmittance display* (page 2–1430) to get an idea of how the current material will affect the radiosity solution or light-traced rendering.

**Creating Special Effects**

*Self-illumination* (page 2–1487) makes an object appear to glow in ordinary renderings, but does not contribute energy to the radiosity solution. To have radiosity processing take a self-illuminating material into account, make this material the base material of Advanced Lighting Override, then increase the value of Luminance Scale.

![Upper left: By default, self-illuminated neon lights do not influence the scene light. Right: Advanced Lighting Override material scales the neon lights’ Luminance so the radiosity solution can take it into account.](image)

Luminance scale takes *self-illumination mapping* (page 2–1502) into account. You can use this to model effects such as a computer monitor in a darkened room.

The Special Effects group of the Advanced Lighting Override material also has a control for adjusting the quality of *bump mapping* (page 2–1506) in areas of indirect lighting.

---

**Procedures**

**To adjust a material’s reflectance and transmittance:**

1. Create a material for your scene.
2. Click the Type button and choose Advanced Lighting Override.
3. In the *Replace Material dialog* (page 2–1456), choose Keep Old Material As Sub-Material, and click OK.
4. Adjust the Reflectance Scale and Transmittance Scale parameters. As you do, watch the Reflectance and Transmittance display, and make sure the values are good for a radiosity solution. For example, 85 percent reflectance is about the highest that will work with radiosity. Most real-world materials have much lower reflectance.

See *Reflectance and Transmittance Display* (page 2–1430) for some reflectance properties of real-world materials.

**To make a self-illuminating material emit radiosity energy:**

1. Create a material that is self-illuminating.
2. Click the Type button and choose Advanced Lighting Override.
3. In the *Replace Material dialog* (page 2–1456), choose Keep Old Material As Sub-Material, and click OK.
4. Increase the value of Luminance Scale to have the material emit energy for radiosity processing.
Override Material Physical Properties group

These parameters directly control the base material’s advanced lighting properties.

**Warning:** There is no problem with reducing the default scale, but increasing it for any of these parameters might cause colors to “burn out”: if the scale is too great, they render as pure white, appearing overexposed.

**Reflectance Scale**—Increases or decreases the amount of energy the material reflects. Range=0.1 to 5.0. Default=1.0.

**Color Bleed**—Increases or decreases the saturation of reflected color. Range=0.0 to 1.0. Default=1.0.

**Transmittance Scale**—Increases or decreases the amount of energy the material transmits. Range=0.1 to 5.0. Default=1.0.

Note: This parameter affects only radiosity. It has no effect on light tracing.

**Special Effects group**

These parameters relate to specific components in the base material.

**Luminance Scale (cd/m²)**—When greater than zero, scales the self-illumination component (page 2–1487) of the base material. Use this parameter to have self-illuminating objects contribute energy to the radiosity or light-traced solution. Cannot be less than zero. Default=0.0.

Typically, a value of 500 or more will give good results.

**Indirect Light Bump Scale**—Scales the effect of the base material’s bump mapping (page 2–1506) in areas lit by indirect light. When this value is
zero, no bump mapping is done for indirect light. Increasing Indirect Light Bump Scale increases the bump effect under indirect lighting. This value does not affect the Bump amount in areas where the base material is lit directly. Cannot be less than zero. Default=1.0.

Tip: This parameter is useful because indirect bump mapping is simulated and not always accurate. Indirect Light Bump Scale lets you adjust the effect by hand.

**Base Material**—Click to go to the base material and adjust its components. You can also replace the base material with a different material type.

To return from the base material to the Advanced Lighting Override level, click Go To Parent.

---

**Lightscape Material**

Material Editor > Type button > Material/Map Browser > Lightscape Mtl

The Lightscape material lets you set radiosity behavior for 3ds Max materials you want to use in existing Lightscape radiosity meshes.

Note: This material is for use with Lightscape. It is *not* meant for use with the advanced lighting solution in 3ds Max. For adjusting a material’s radiosity properties in 3ds Max, use the Advanced Lighting Override material (page 2–1601).

**Important:** The mental ray renderer (page 3–78) does not support the Lightscape material.

---

**Interface**

### Radiosity Mapping group

**Brightness**—Controls the brightness of the displayed image on your monitor. The setting of this control does not affect the actual lighting levels in the model. Note: The default value is exactly the same as the values set in the Import Lightscape Solution dialog.

**Contrast**—Controls the contrast between light and dark regions in the model. Note: The default value is exactly the same as the values set in the Import Lightscape Solution dialog.

**Ambient Light**—Controls the amount of 3ds Max ambient light that will be mixed in with the radiosity calculations. If the value is 0, none of the 3ds Max ambient light is used. If the value is 1, the 3ds Max ambient light value is added into the radiosity calculations. Default=0.0.

**Bump Amount**—This value controls the strength of the bump map that is applied to the lighting from Lightscape, as opposed to lighting done by 3ds Max. It can be separately controlled from the bump amount in the 3ds Max material, so you can adjust the bumps in Lightscape lighting to match the bumps in 3ds Max lighting. Default=5.0.

**Daylight**—Determines whether you want natural daylight to be used in the calculation. Note: The default value is exactly the same as the values set in the Import Lightscape Solution dialog.
**Exterior Scene**—Used for exterior daylight simulations. Note: The default value is exactly the same as the values set in the Import Lightscape Solution dialog.

**Apply Changes to All Lightscape Materials**—Determines whether or not the changes you make in this dialog are applied to every Lightscape Radiosity material. Default=off.

**Disable Radiosity**—Determines whether or not the radiosity is calculated. This option provides a quick way to see the effect of the Lightscape-specific illumination. Default-off.

**Base Material**—Displays the base 3ds Max material to which the radiosity illumination is applied. (The base material displays on the object while the Lightscape Radiosity material adds radiosity effects.) Use this button to change the base material on the object.

---

**Ink ’n Paint Material**

Material Editor > Type button > Material/Map Browser > Ink ’n Paint

The Ink ’n Paint material creates cartoon effects. Rather than the three-dimensional, realistic effect most other materials provide, Ink ’n Paint provides flat shading with “inked” borders.

---

Because Ink ’n Paint is a material, you can create a scene that combines 3D-shaded objects with flat-shaded cartoon objects.

*Snake rendered with ink ’n paint*

Rendering that combines realistic shading with cartoon shading

In the Ink ’n Paint material, ink and paint are two separate components, with customizable settings.
Chapter 16: Material Editor, Materials, and Maps

Left: The paint component only
Right: The ink component only

Tip: Ink ’n Paint uses the Raytracer Settings (page 2–1528), so adjusting raytrace acceleration can have an effect on the speed of Ink ’n Paint. Also, while you work with Ink ’n Paint, disabling antialiasing can speed up the material, until you’re ready to create final renderings. (Turning off Ink really speeds it up.)

Note: Motion blur does not work with Ink ’n Paint. (Typically, hand-drawn cartoons are not motion blurred.)

Note: Shadows don’t appear on objects shaded with Ink ’n Paint unless the value of Paint Levels is 4 or greater.

Warning: Ink ’n paint will only give correct results when rendered from a camera or perspective view. It does not work in orthographic views.

Using Ink ’n Paint

You can use Ink ’n Paint on multiple objects, but in general, it tends to work best if you do the following:

1. Collect the objects for cartoon rendering into a single surface model such as an Editable Mesh.

2. Assign different material ID values (page 3–969) to portions of the model you want to color differently.

   Typically, you would do this at the Element sub-object level, although you can certainly apply different material IDs to faces and polygons as well.

3. Create a Multi/Sub-Object material (page 2–1594). In it, create a sub-material for each of the colors in the model. Make each sub-material an Ink ’n Paint material, then assign colors and maps using each sub-material’s Paint controls. If necessary, adjust the Ink controls as well.

   Tip: ActiveShade (page 3–17) works with the Ink ’n Paint material, and can be a good way to preview the material’s effect.

Interface

Basic Material Extensions rollout

2-Sided—Makes the material 2-sided (page 3–901). Applies the material to both sides of selected faces.

Face Map—Applies the material to the faces of the geometry. If the material is a mapped material, it requires no mapping coordinates (page 3–967). The map is automatically applied to each facet of the object.

Faceted—Renders each face of a surface as if it were flat.
**Fog BG when not painting**—When paint is turned off, the painted areas of the material color are the same as the background. This toggle, when on, lets the background in paint areas be affected by fog between the camera and the object. Default=off.

**Opaque alpha**—When on, the alpha channel is opaque even if ink or paint is turned off. Default=off.

**Bump**—Adds bump mapping to the material.
- **Toggle**—When on, enables the bump map.
- **Spinner**—Controls the bump map amount.
- **Map button**—Click to assign a map to use for bump mapping.

**Displacement**—Adds displacement mapping to the material.
- **Toggle**—When on, enables the displacement map.
- **Spinner**—Controls the displacement map amount.
- **Map button**—Click to assign a map to use for displacement mapping.

**Paint Controls rollout**

Paint is the main color of the material.

There are three main components of the “paint” of Ink ‘n Paint. Each has several associated controls, most of which are documented toward the end of this section.

**Lighted**—The fill color for the lighted side of objects. Default=light blue.

Turning off this component makes the object invisible, except for the ink. Default=on.

*Left: A lighted character*  
*Right: Lighted and Highlight both turned off to render only the ink*

**Paint Levels**—The number of shades of color that are rendered, from light to dark. Lower values make objects look flatter. Range=1 to 255. Default=2.

*Increasing the value of Levels increases the number of shades of the basic color seen in the lighted area.*

**Shaded**—The value in the spinner at the left is the percent of the Lighted color that appears on the unlighted side of objects. Default=70.0.

Turning off this component displays a color swatch, which you can use to assign a distinct color to shaded areas. Default=on.
Increasing the value of Shaded increases the saturation of the shaded area. You can also use Shaded to assign a distinct color for shading.

**Highlight**—The color of the specular highlight. Default=white.

When this component is off, there is no specular highlight. Default=off.

Tip: A specular highlight can destroy the illusion of 2D. Use this component sparingly.

**Glossiness**—The size of the specular highlight. The greater the Glossiness, the smaller the highlight. Default=50.0.

---

*Increasing glossiness decreases the size of the highlight.*

**Color component controls:**

These are the controls that are duplicated for each of the paint components. Each has an on/off toggle, a main control, and then on the right, a set of map controls.

- **Check box**—The check box at the left of the rollout enables or disables that particular component. In the case of Shaded, it toggles between a percentage value (of the Lighted color) or a distinct Shaded color.

- **Color swatch or spinner**—The main control for each component. Click a color swatch to display a Color Selector (page 1–161) and set the color of the component. In the case of Shaded, this control can also be a percentage spinner.

- **Map spinner**—The spinner to the right of the main control is the percentage of the map to use. Default=100.0.
Ink 'n Paint Material

Mapping the Lighted component
Right rear: The original, unmapped material
Left: Lighted component with a falloff map applied
Right front: Lighted component with a bitmap applied

- Map check box—The check box between the spinner and the button enables or disables the map. Default=off until a map is assigned, then on.

- Map button—Click the button to assign a map to this component.
  While a map is assigned and enabled, at 100 percent it completely overrides the main color component. At lower percentages, the map is blended with the color.

Ink Controls rollout
Ink is the linework, the outlines, in the material.

Except for Ink Width, each of the ink components has an on/off toggle and a color swatch. Click the color swatch to display a Color Selector (page 1–161) and change the ink component's color. Each ink component, Ink Width included, also has a set of map controls.

Ink—When on, the rendering is “inked.” When off, no ink lines appear. Default=on.
Ink Quality—Affects the shape of the brush and the number of samples it uses. When Quality equals 1, the brush is a “+” shape, and samples are taken over an area of 5 pixels. When Quality equals 2, the brush is octagonal and the samples are taken over an area of 9 to 15 pixels. When Quality equals 3, the brush is nearly circular, and samples are taken over an area of 30 pixels. Range=1 to 3. Default=1.

Tip: For most models, increasing the Quality value introduces only a very subtle change, and can take considerably longer to render. Do so only when a sub-object’s ink shows too many artifacts in the finished rendering, using the default Ink Quality. (Don’t rely on the ActiveShade preview, which will tend to be aliased.)

Ink Width—The width of the ink, in pixels. This is specified by the spinner labeled Min (minimum) unless Variable Width is on. When Variable

Width is on, the Max (maximum) spinner is also enabled, and the ink width can vary between the minimum and maximum values. Default: Min=2.0, Max=4.0.

Variable Width—When on, the ink’s width can vary between the minimum and maximum Ink Width values. Ink with Variable Width looks a bit more streamlined than ink with a constant width. Default=off.

The thickness of ink can be mapped.

Left: Thickness mapped with a gradient map
Right: Thickness mapped with a noise map

Clamp—When Variable Width is on, sometimes the scene lighting causes some ink lines to become so thin they nearly disappear. If this happens, turn on Clamp, which forces the ink width to
always remain between the Min and Max values, regardless of the lighting. Default=off.

**Outline**—The ink where the outer edges of the object appear against the background or in front of a different object. Default=on.

**Intersection Bias**—Use this to adjust artifacts that might appear when two objects intersect each other. In effect, this moves the inked object closer to the rendering point of view, or farther away, so Ink ’n Paint can decide which object is in front. Positive values push the object away from the point of view, negative values pull it closer. Default=0.0.

**Overlap**—The ink used when a portion of an object overlaps itself. Default=on.

**Overlap Bias**—Use this to adjust artifacts that might appear in ink that traces the overlap. It says how far the overlap has to be in front of the rear surface for Overlap ink to turn on. Positive values push the object away from the point of view, negative values pull it closer. Default=10.0.

**Underlap**—Similar to Overlap, but applies ink to the farther surface rather than the nearer one. Default=off.

**Underlap Bias**—Use this to adjust artifacts that might appear in ink that traces the underlap. It says how far the underlap has to be behind the front surface for Underlap ink to turn on. Positive values push the object away from the point of view, negative values pull it closer. Default=0.0.

**SmGroup**—The ink drawn between the boundaries of smoothing groups (page 3–1013). In other words, it inks the edges of the object that have not been smoothed. Default=on.

**Mat ID**—The ink drawn between different material ID values (page 3–969). Default=on.

Tip: If two Ink ’n Paint materials overlap in the viewport, and both have Mat ID on, you will often get a doubly thick ink line where they overlap. To correct this, turn off the Mat ID component for one of these materials.

**Inking the edges between sub-materials**

- **Only Adjacent Faces**—When on, inks the material ID edge between adjacent faces, but not between one object and another. When off, inks the material ID edge between two objects or other non-adjacent faces. Default=on.
Intersection Bias—When Only Adjacent Faces is turned off, use this to adjust any artifacts that appear at the boundary between two objects with different material IDs. Default=0.0.

Map controls—There are map controls for each of the ink components: Width, Outline, Overlap, Underlap, SmGroup, and Mat ID. These work the same as they do for the material’s paint components, as described above.

The Overlap bias is probably too high. Decrease it. If Underlap is turned on, this might also have too high a bias.

Another possible reason is that you have a self-intersecting object, or an object built by attaching smaller objects, thus creating intersecting faces. In this case, set up the objects to use the Mat ID or SmGroup ink components. If elements already have differing material IDs, try turning off Only Adjacent Faces.

Ink looks sloppy on sloping parts of the object. The Overlap or Underlap bias might be too low. Try increasing it.

Ink looks sloppy between interpenetrating objects.

Find out which ink component is the sloppy one. Then adjust its bias control.

Ink lines disappear or are too narrow when Variable Width is on.

Turn on Clamp. You can also try to see if reducing the lighting level helps. Or, you can try turning off Variable Width, then assigning a Falloff map (page 2–1670) to the Ink Width component.

Tip: To isolate which ink component is causing a problem, you can try assigning each component a different, distinctive (and easy to read) color, then rendering the image.

Warning: Ink ‘n paint will only give correct results when rendered from a camera or perspective view. It does not work in orthographic views.

Mapping the outline and overlap components to simulate the look of drawing on paper

Troubleshooting

Here are some commonly encountered problems, and potential solutions:

• Internal ink lines are missing.
The DirectX 9 Shader material enables you to shade objects in viewports using DirectX 9 (DX9) shaders. With DirectX shading, materials in a viewport more accurately represent how the material will appear in another application, or on other hardware such as a game engine. You can use this material only when you are using the Direct3D Display driver and DirectX 9.0 is chosen as the Direct3D version.

DX9 shaders are FX files. Several sample FX files are provided in the \3ds Max 9\maps\fx directory (the name of the 3ds Max root directory might differ on your system).

See also
DirectX Shader group
FX File

Interface
DirectX 9 Shader rollout

Shader button—Click to display a file dialog that lets you select a DX9 FX effect (FX) file. By default, the default.fx file is chosen.

Reload—Click to reload the active FX file. To update an FX file, you can edit it and then click Reload. You don’t have to restart 3ds Max to see the effect of the changes to the shader.

Shader-specific rollouts
The rollouts that appear below the DirectX 9 Shader rollout and above the Software Rendering rollout are the interface to the shader you chose. These rollouts are specific to each shader.

Software Rendering rollout

Specifies a material that controls software shading and rendering of objects to which the DirectX 9 Shader material is applied. Viewports use DX9 shading unless the Software or OpenGL driver is active. Renderings always use software shading.

Usually you will want to choose a material that clearly identifies which objects in your scene have the DirectX 9 Shader material applied.

Note: The DirectX 9 Shader material has no specific settings for software shading. Any type of 3ds Max material will do. Scenes from previous versions that used DX9-specific settings are assigned a Standard material with equivalent rendering properties.

Note: If DirectX 9 is not available on your system, but you assign the DirectX 9 Shader material anyway (by using the Material/Map Browser’s Incompatible option), this is the only rollout that appears in the Material Editor.
DirectX Viewport Shaders

LightMap Shader Rollout

When you have chosen LightMap as the DirectX viewport shader (page 2–1464), this rollout appears. The LightMap shader can display both a base texture and a lighting map. Typically both these maps come from rendering to textures (texture baking) (page 3–144). The base texture typically would be a completed map, a blend map, or a diffuse map. You can choose these map types, as well as lighting map, to render as elements of a baked texture (page 3–146).

Note: In order to use the LightMap shader, you must have 3ds Max configured to use the Direct3D graphics driver. To change the graphics driver configuration, refer to the Viewport Preferences (page 3–821) topic.

Interface

Base Texture group

Button—Shows the name of the base texture. Click the button to display that material’s parameters, and adjust them if necessary.

Toggle—When on, shaded viewports display the base texture. When off, it is not displayed.

If both the Base Texture and Light Map toggles are off, the material appears black in viewports.

Mapping Channel—Shows the map channel (page 3–966) this texture uses.

Light Map group

Button—Shows the name of the lighting map.

Toggle—When on, shaded viewports display the lighting map. When off, it is not displayed.

If both the Base Texture and Light Map toggles are off, the material appears black in viewports.

Mapping Channel—Shows the map channel this texture uses.

Metal Bump Shader Rollout

When you have chosen Metal Bump as the DirectX viewport shader (page 2–1464), this rollout appears. The Metal Bump shader can display a variety of texture-baked maps (page 3–144), including normal maps for an embossed effect. It is good for displaying shiny surfaces.

Note: In order to use the Metal Bump shader, you must have 3ds Max configured to use the Direct3D graphics driver. To change the graphics driver configuration, refer to the Viewport Preferences (page 3–821) topic.

The Metal Bump shader’s results are alway visible in viewports, regardless of the object type.

Warning: The Metal Bump shader lets you adjust settings to get various effects in shaded viewports. These settings will not necessarily apply when you display the texture-baked object on other Direct3D devices.

See also

Baked Texture Elements (page 3–146)
**Interface**

**Ambient & Diffuse group**

**Ambient Color**—When not black, tints the object’s ambient color. Click the color swatch to display a Color Selector (page 1–161) and choose the ambient color. Default=black.

**Diffuse Color**—When not white, tints the diffuse color. Click the color swatch to display a Color Selector and choose the diffuse color. Default=white.

**Texture 1**—Displays a texture map for the diffuse color. Typically this would be a texture-baked diffuse map, completed map, or blend map.

See the section “Map Controls,” below, for a description of the individual controls.

**Texture 2**—Displays a second texture map for the diffuse color. Typically this would be a texture-baked lighting map or shadows map.

See the section “Map Controls,” below, for a description of the individual controls.

**Use Alpha**—When on, displays the alpha channel. When off, does not. Default=off.

**Mix Amount**—Adjusts the mixing of the two texture maps in shaded viewports.

**Specular group**

**Enable**—When on, enables specular highlights for the object. Default=off.

**Specular Color**—Specifies a specular color for the object. Click the color swatch to display a Color Selector and choose a color. Default=white.

**Texture**—Displays a specular map for the object. Typically this would be a texture-baked specular map.

See the section “Map Controls,” below, for a description of the individual controls.

**Bump group**

**Normal**—Displays a normal map for the object. Typically this would be a texture-baked normals map.

See the section “Map Controls,” below, for a description of the individual controls.

**Bump**—Displays a bump map for the object. Typically this would be a bump map used for the original material.

See the section “Map Controls,” below, for a description of the individual controls.

**Bump Intensity**—Adjusts the intensity of the bumps in shaded viewports.

**Reflection group**

**Cubemap**—Displays a reflection map projected cubically (around the scene). Typically this would be an environment map.
Reflection Intensity—Adjusts the intensity of reflections in shaded viewports.

Pick object and create—Click to choose an object and have the program generate the reflections used in the viewport.

Sync Standard Material
When on, adjustments you make to the Metal Bump shader update settings in the active standard material, letting you save the changes you made. When off, the standard material is unchanged. Default=off.

Map Controls
In this rollout, all texture maps have the same general controls. The rollout appears only when you are using the DirectX viewport shader.

Toggle—When on, the map is used in viewports. When off, it is not used. Default=on if a map is assigned, off otherwise.

Map button—Click to choose the texture map to use for this component of the object.

Map Channel—Specifies the map channel (page 3–966) used by this map.

This control is not present for the cubic reflection map.

XRef Material
Material Editor > Type button > Material/Map Browser > XRef Material

The XRef material lets you externally reference a material applied to an object in another scene file. As with XRef objects (page 3–394), the material resides in a separate source file. You can set the material properties only in the source file. When you change them in the source file and then save it, the material’s appearance can change in the master file that contains the XRef.

Note: If an XRef object has a material applied to it in the original source file (and Merge Materials is turned off when you reference the source file), then that material is automatically externally referenced in the scene, and can be loaded in the Material Editor if you browse from the scene. When you explicitly use the Material Editor to create an XRef material, you don’t have to have any XRef objects from that particular source file. However, the record’s source file and material do appear in the XRef Objects dialog (page 3–397).

The Show Map In Viewport button works for an XRef material only if the same button is turned on in the source file. Otherwise, it is disabled.

Interface

Highlight Corresponding XRef Record in the XRef Objects Dialog—Click to open the XRef Objects dialog (page 3–397) that highlights the source file’s current record with its object displayed in the XRef Entities list. If no file and object have yet been selected for the material, the XRef Objects dialog is displayed, and lets you browse for the file and material to use.

File name field—Displays the path and file name of the scene file containing the source of the XRef material. You can edit this to point to a different path and file.
**Types of Maps**

The most common use for maps (page 3–968) is to improve the appearance and realism of Materials (page 3–971). You can also use maps to create environments (page 3–272) or projections from lights (see Advanced Effects Rollout (page 2–1341)).

Maps can simulate textures, applied designs, reflections, refractions, and other effects. Used with materials, maps add details without adding complexity to the geometry of an object. (Displacement mapping (page 2–1511) can add complexity.)

**File name display**—Displays the file name only, without the path.

**Path button**—Click to display the Open File dialog from which you can specify a different path and file name for the source file. After you choose the file, 3ds Max displays the XRef Merge dialog (page 3–406) that lets you choose the object whose material you want to reference.

**Object name field**—Displays the name of the source object pointed to in the source file.

**Object name and material**—Displays the name of the source object followed by the material name in parentheses. For example, “Shaker (Chrome).”

**Path button**—Click to display the XRef Merge dialog (page 3–406) pointing to the scene in the XRef File Name field. Here, you can specify a different object whose material you want to reference.

**Status line**—Displays the status of the material. For example, if the file and object are both found, this field says “Status: XRef Resolved.”

**Accessing Map Types**

You use the Material/Map Browser (page 2–1412) to load a map or create a map of a particular type. The Browser groups maps into categories according to their type. You can choose whether the Browser lists maps, materials, or both; you can choose which map types.

**To list map types by category:**

1. Open the Material Editor.
2. Click Get Material to display the Material/Map Browser.
3. On the left side of the Material/Map Browser, in the Show group, turn off Materials. Leave Maps turned on.
4. In the lower set of buttons, choose the category you want listed, or choose All to show all map types.
   The list is displayed in the right panel of the Browser.

**To open the Browser from the Material Editor:**

As you work with materials, you can open the Material/Map Browser from the Material Editor.

1. Open the Material Editor.
2. On the Material Editor toolbar, click Get Material to display the Material/Map Browser.

**Understanding Map Types**

Different types of maps create different effects and behave in particular ways.

- **2D maps** (page 2–1624) are two-dimensional images that are typically mapped onto the surface of geometric objects, or used as environment maps to create a background for the scene. The simplest 2D maps are
bitmaps; other kinds of 2D maps are generated procedurally.

- 3D maps (page 2–1662) are patterns generated procedurally in three dimensions. For example, Marble has a grain that goes through the assigned geometry. If you cut away part of an object with Marble assigned as its texture, the interior matches the exterior.
- Compositors (page 2–1687) are for compositing other colors or maps.
- Color Modifiers (page 2–1692) alter the color of pixels in a material.
- The “Other” category includes maps that create reflections and refractions (page 2–1695). It also includes mental ray shaders (page 2–1710), Normal Bump maps, (page 2–1731) and Camera Per-Pixel Projection maps (page 2–1732).

**Maps and mental ray Shaders**

When the mental ray renderer (page 3–78) is active, the Material/Map Browser also lists mental ray shaders. Shaders are similar to maps, but use yellow icons. You assign them the way you do maps. The mental ray shaders don’t fit into the map categories described in the previous section, and aren’t described in this topic. See mental ray Shaders (page 2–1710) for links to shader descriptions.

**Maps and Mapping Coordinates**

Maps have a spatial orientation. When you apply a material with maps in it to an object, the object must have mapping coordinates. These are specified in terms of UVW axes local to the object.

Most objects have a Generate Mapping Coordinates toggle. You can turn this on to provide default mapping coordinates. If the object has this toggle, it is also turned on automatically when you render the scene, or use Show Map In Viewport (page 2–1445).

Some objects, such as editable meshes, don’t have automatic mapping coordinates. For these types of objects, you can assign coordinates by applying a UVW Map modifier (page 1–922). If you assign a map that uses a mapping channel, but don’t apply a UVW Map modifier to the object, the renderer displays a warning that lists objects that require
mapping coordinates. You can also use UVW Map
to change an object’s default mapping.

See Mapping Coordinates (page 2–1405).

UVW Mapping Coordinate Channels
Each object can have from 1 to 99 UVW mapping
cordinate channels. The default mapping (from
the Generate Mapping Coordinates toggle) is
always UVW 1. The UVW Map modifier can send
cordinates to any of these channels.

Each map in a material can use any UVW channel
(if present), or other type of mapping that depends
on whether the map is 2D or 3D.

You can set the mapping channel used by NURBS
surface (page 1–1101) sub-objects in their creation
or modification parameters.

Mapping for 2D Maps
You can position a 2D map on the surface of an
object by using a map channel, any assigned vertex
color, or the local or world coordinate systems. You
can also choose different environment mappings.
See Coordinates Rollout (2D) (page 2–1625).

Mapping for 3D Maps
You can position a 3D map within the volume of an
object by using a map channel, any assigned vertex
color, or the local or world coordinate systems. See
Coordinates Rollout (3D) (page 2–1663).

Noise for Maps
Random noise values increase the complexity of
maps and can give them a more natural look. For
2D maps, see Noise Rollout (2D) (page 2–1630).
For 3D maps, you can assign a separate Noise map.
See Noise Map (page 2–1674).

Real-World Mapping
Real-world mapping is an alternative mapping
paradigm in 3ds Max that is off by default. The
idea behind real-world mapping is to simplify
the correct scaling of texture-mapped materials
applied to geometry in the scene. This feature lets
you create a material and specify the actual width
and height of a 2D texture map in the Material
Editor. When you assign that material to an object
in the scene, the texture map appears in the scene
with correct scaling.

For real-world mapping to work, two requirements
must be met. First, the correct style of UV texture
cordinates must be assigned to the geometry.
Essentially, the size of the UV space needs to
correspond to the size of the geometry. To this
end, a new option called Real-World Map Size has
been added to many of the dialogs and rollouts
that let you generate texture coordinates (see list at
the end of this topic). Any dialog or rollout that
lets you turn on Generate Mapping Coords also
lets you enable Real-World Map Size. Also, you
can toggle this option globally on the Preferences
dialog > General panel (page 3–815).

Most object parameters settings now include a Real-World
Map Size toggle.

The second requirement is available in the
Material Editor. All 2D texture maps, such as
Bitmap, provide a Use Real-World Scale check box on the Coordinates rollout (page 2–1625). Like Real-World Map Size, this check box is off by default, but when on, the U/V parameter names change to Width/Height and the Tiling label changes to Size. You can then specify the horizontal/vertical offsets and size of the texture map in current system units (page 3–850).

Following is a list of affected features (note links to topics with more extensive information):

- Bevel Modifier
- Bevel Profile Modifier
- Box Primitive
- Capsule Extended Primitive
- C-Ext Extended Primitive
- ChamferBox Extended Primitive Create panel > Geometry button
- ChamferCyl Extended Primitive

Output Rollout

Material Editor > Select sample slot. > Get Material > Material/Map Browser > Turn on 2D Maps and 3D Maps. > Choose a map type (Bitmap, Cellular, Falloff, Gradient, Gradient Ramp, Mix, Noise, or Output). > Double-click a map type to apply it to sample slot. > Output rollout (displayed near the bottom of the Material Editor)

After applying a map and setting its internal parameters, you can adjust its output parameters to determine the final appearance of the map.

Note: Most controls on the Output rollout are for color output, and don’t affect bump mapping (page 2–1506). Only the Invert toggle is considered; it reverses the direction of the bumps.

Interface

These controls appear on the Output rollout for a number of 2D and 3D maps:

- **Invert**—Reverses the hues of the map, like a negative color photo. Default=off.

- **Clamp**—When on, this parameter limits the values of the colors to no greater than 1.0. Turn this on when you’re increasing the RGB Level, but don’t want the map to appear self-illuminated. Default=off.

Note: If you set the RGB Offset to a value greater than 1.0 while Clamp is on, all colors become white.

- **Alpha from RGB Intensity**—When on, an alpha channel is generated based on the intensity of the RGB channels in the map. Black becomes transparent and white becomes opaque. Intermediate values are translucent according to their intensity. Default=off.

- **Enable Color Map**—Turn on to use the Color Map. See “Color Map group.” Default=off.

- **Output Amount**—Controls the amount of the map being mixed into a composite material. Affects the saturation and alpha value of the map. Default=1.0.

- **RGB Offset**—Adds to the RGB values of the map colors by the amount set by the spinner, which affects the tonal value of the colors. Eventually the map becomes white and self-illuminated. Lowering the value decreases the tonal value toward black. Default=0.0.

- **RGB Level**—Multiplies the RGB values of the map colors by the amount set by the spinner, which affects the saturation of the color. Eventually the map becomes fully saturated and self-illuminated (page 3–1009). Lowering the value decreases the saturation and makes the map colors grayer. Default=1.0.

- **Bump Amount**—Adjusts the amount of bumpiness. This value has an effect only when the map is used as a bump map. Default=1.0.

For example, suppose you have a map instanced for both the Diffuse and the Bump components. If you want to adjust the amount of bumpiness
without affecting the Diffuse colors, adjust this value, which changes the amount of bumpiness without affecting the map’s use in other material components.

**Color Map group**

At the bottom of the Output rollout, the Color Map group is inactive until you turn on Enable Color Map.

The Color Map graph lets you adjust the tonal range of an image. The point at 1,1 controls highlights, the point at 0.5,0.5 controls midtones, and the point at 0,0 controls shadows.

You adjust the shape of the graph by adding points to the line and moving or scaling them. You can add Corner, Bezier-Smooth, or Bezier-Corner points. When a move or scale option is active, points can be selected much like objects in a viewport, by clicking a point, dragging a region around one or more points, and holding down Ctrl to add or subtract from the selection.

When you select an individual point, its exact coordinates are displayed in the two fields below the graph at the lower left. You can enter values directly in these fields, but the values are automatically constrained as they are when you manually move or scale a point.

You can zoom into the graph to make detailed adjustments. As you zoom in, the graph updates to show decimal measurements along the left vertical axis. You can pan anywhere on the graph with the horizontal and vertical scroll bars, use a button option, or the middle mouse button. Points can be deleted, and you can reset the graph to its default at any time.

**RGB/Mono**—Specifies a map curve to either filter the RGB channels separately (RGB) or in combination (Mono).

**Copy Curve Points**—When turned on, points added to a Mono graph are copied when you switch to an RGB graph. If you start with an RGB graph, the points are copied to a Mono graph. You can animate the control points but not the Bezier handles.

**Important:** When Copy Curve Points is on, animation created in Mono mode is carried over to RGB mode and you can switch channels. The reverse doesn’t work.

The following controls affect the points on the graph:

**Move flyout**

+ Moves a selected point in any direction, limited by the unselected points on either side.

←→ Constrains movement to the horizontal.

↑↓ Constrains movement to the vertical.

On a Bezier smooth point, you can move the point or either handle.

**Scale Point**—Changes the output amount of control points while maintaining their relative position. On a Bezier corner point, this control is effectively the same as a vertical move. On a
Bezier smooth point, you can scale the point itself or either handle. As with the move controls, scale is limited by the unselected points on either side.

**Add Point flyout**

- Adds a Bezier corner point anywhere on the graph line. The point makes a sharp angle when moved.
- Adds a Bezier smooth point anywhere on the graph line. Handles attached to the point create smooth curves when moved.

When either Add Point button is active, you can use Ctrl+click to create the other type of point. This eliminates the need to switch between buttons.

- **Delete Point**—Removes selected points.
- **Reset Curves**—Returns graph to its default, a straight line between 0,0 and 1,1.

The following controls affect the view of the graph. The change in view does not affect the graph’s results.

- **Pan**—Drags the graph in any direction within the viewing window.
- **Zoom Extents**—Shows the entire graph.
- **Zoom Horizontal Extents**—Shows the entire horizontal range of the graph. The scale of the curve will be distorted.
- **Zoom Vertical Extents**—Shows the entire vertical range of the graph. The scale of the curve will be distorted.
- **Zoom Horizontally**—Compresses or expands the graph in a horizontal direction.
- **Zoom Vertically**—Compresses or expands the view of the graph in a vertical direction.
- **Zoom**—Zooms in or out around the cursor.
- **Zoom Region**—Draws a rectangular region around any area of the graph, then zooms to that view.

### Missing Map Coordinates Dialog

The Missing Map Coordinates dialog is displayed when you attempt to render one or more objects with materials whose maps use a map channel (page 3–966) other than channel 1. (Channel 1 is an exception because channel 1 mapping coordinates are automatically turned on when you assign a mapped material to an object.) Only maps with Show Map In Viewport toggled on are listed as missing.

To use other map channels, you must assign a UVW Map modifier (page 1–922) to the object. In UVW Map, set Map Channel to match the value used in the material.

If the material has multiple maps that use multiple channels, you must assign a separate UVW Map modifier for each channel besides channel 1.

If the object is a NURBS surface sub-object (page 1–1177), you don’t need to use UVW Map. Instead, set the map channel on the surface sub-object’s Material Properties rollout (page 1–1149).

The Missing Map Coordinates dialog is also displayed when you open a MAX file that
references bitmaps that can’t be found in their original location, or are at a location not specified via the Configure User Paths dialog (page 3–808). To open the MAX file, click the Browse button on the Missing Map Coordinates dialog. This opens the Configure User Paths dialog so you can assign one or more paths for the MAX file to access. These settings are then stored with the MAX file.

Note: When you open a MAX file that references bitmaps that can’t be found, you might also see a Missing Map/Photometric Files dialog (page 3–503), which lets you browse for the missing files.

**Interface**

The following objects require map coordinates and may not render correctly:

(JMA/1): Sphere01

The list shows the map channel followed by the name of the object.

**Continue**—Proceeds with the rendering. The objects listed will not show maps in the material assigned to them, and might not be visible at all.

**Cancel**—Cancels rendering.

---

**2D**

2D Maps are two-dimensional images that are typically mapped onto the surface of geometric objects, or used as environment maps to create a background for the scene. The simplest 2D maps are bitmaps; other kinds of 2D maps are generated procedurally.

**Bitmap (page 2–1631)**: An image saved as an array of pixels in one of a number of still-image file formats, such as .tga, .bmp, and so on, or an animation file such as .avi, .mov, or .iff. (Animations are essentially sequences of still images.) Any of the bitmap (or animation) file types that 3ds Max supports can be used as a bitmap in a material.

**Checker (page 2–1638)**: Combines two colors in a checker pattern. You can replace either color with a map.

**Combustion (page 2–1639)**: Works in conjunction with the Autodesk Combustion product. You can paint directly on a bitmap or object and have the result update in the Material Editor and viewports. The map can include other Combustion effects. Painting and other effects can be animated.

**Gradient (page 2–1650)**: Creates a linear or radial ramp of three colors.

**Gradient Ramp (page 2–1652)**: Creates a great variety of ramps, using as many colors, maps, and blends as you choose.

**Swirl (page 2–1656)**: Creates swirled (spiraling) patterns of two colors or maps.

**Tiles (page 2–1658)**: Creates bricks or other tiled materials with colors or material mappings. Includes commonly defined architectural brick patterns, but you can also customize patterns.
Coordinates Rollout (2D)

In the Coordinates rollout, by adjusting coordinate parameters, you can move a map relative to the surface of the object to which it is applied and achieve other effects.

Tiling

Often when you apply a bitmap, especially as a texture pattern, you want the pattern to repeat. This effect is known as tiling, as in a tiled floor or fountain. You control tiling directly from the Coordinates rollout for any 2D map.

As with tiling, you can mirror in the U dimension, the V dimension, or both. The Tiling parameter for each dimension specifies how many copies of the map are shown. Each copy is flipped relative to its neighbors.

Tiling and Mirroring Combined

Because mirroring defaults to two reflected images of the map, the meaning of the Tiling value differs when Mirror is set.

In a single mapping dimension (U or V), a value of 1.0, the default, shows two copies of the bitmap; a value of 2.0 shows four copies; a value of 1.5 shows three copies; and so on. Mirroring in both dimensions multiplies the effect.

Mirroring and tiling a map

In default mapping, tiling is active, but because the map is scaled to fit the object, you don't see the effect of tiling unless you offset the UV coordinates or rotate the map. In this case, the portions of the surface from which the bitmap has moved away are filled by other portions of the map. Tiling wraps the object with the map image.

Mirroring

Mirroring a map is an effect related to tiling. It repeats the map and flips the repeated copy.
Decals

Decals are useful for mapping single designs, small elements such as stickers, or light switches.

A 2D map used as a decal appears only once and is not repeated as with tiling. Wherever the decal doesn’t appear on the surface, the surface is rendered as a basic material, with the component colors specified at the material level. With map trees, a decal might appear on top of a different bitmap or other map type.

Decal mapping

Procedures

To set tiling:

1. In the Coordinates rollout, make sure Tile is turned on for the U or V coordinate, or for both.
2. Set the Tiling value for the corresponding coordinates.

In the Material Editor, the sample slot changes to show the tiling value you chose.

- The Tiling value is the number of times the bitmap repeats along the specified dimension. A value of 1.0, the default, maps the bitmap exactly once; a value of 2.0 maps the bitmap twice, and so on. Fractional values map a fractional portion of the bitmap in addition to copies of the whole map. For example, a value of 2.5 maps the bitmap two and a half times.
- Tiling values less than one increase the size of the map relative to the object. For example, a value of 0.5 maps half of the bitmap.
- Tiling is uniform if both the U and V dimensions are tiled by the same amount.

To preview the effect of tiling:

- In the Material Editor, use the Tiling flyout to choose a 1x, 2x, 3x, or 4x tiling preview.

The button you choose changes tiling in the active sample slot to 1.0, 2.0, 3.0, or 4.0 in both U and V.

The flyout setting has no effect on the material or its mapping. It does not change the Tiling value or the check box setting. It only helps you preview the effect of changing these settings.

To set mirroring:

1. On the Coordinates rollout, make sure Mirror is turned on for the U or V coordinate, or both. Mirror and Tile are exclusive settings: if one is set when you choose the other, the original setting turns off.
2. Set the Mirror value for the corresponding coordinate or coordinates.

The material preview changes to show the Mirror value you chose.

To create a decal:

1. In the Material Editor, choose a bitmap as a diffuse map.
2. On the map’s Coordinates rollout, turn off both Mirror and Tile for both the U and V coordinates. Change the mapping to Planar from Object XYZ.
3. Adjust the U and V Tiling parameters to scale the decal.
Changing the Tiling value changes the size of the mapped bitmap as it does when you tile the map, but with Mirror and Tile turned off, the bitmap appears only once.

4. Adjust the U and V Offset parameters to position the decal.

Note: You can also use the Parameters rollout’s Cropping and Placement controls to achieve a decal effect.

To offset the position of a map:

- On the Coordinates rollout, set the U and V values to be between 0.0 and 100, or between -100 and 0.0.

On the surface of the object, the map shifts in the directions you chose.

UV offsets are especially useful when you have turned tiling off and want the bitmap to appear in a single location.

To rotate the map:

- On the Coordinates rollout, set the Angle U, V, and W spinners.

Positive angles rotate the map in the clockwise direction; negative angles rotate it counterclockwise.

The angle can be up to 360 degrees, which rotates the map completely and has no visible effect unless you are animating the map’s rotation.

You can also click Rotate to use the Rotate Mapping Coordinates dialog, which lets you change the rotation by dragging the mouse.

To increase or decrease antialiasing:

- On the map’s Coordinates rollout, increase or decrease the Blur value.

For diffuse maps and other maps besides bump maps, the Blur value is most effective in the 0.5-20 range. Lower values decrease antialiasing; higher values increase it.

The Blur Offset parameter adjusts the image before antialiasing Blur is applied. If all you need is antialiasing, leave Blur Offset at its default of 0.0.

To make a map image fuzzier:

- On the map’s Coordinate’s rollout, increase the Blur Offset value.

Blur Offset is a very strong parameter. The Blur Offset spinner has increments of 0.001. Values greater than 0.1 are likely to be too high.

To make a map image sharper:

- On the map’s Coordinates rollout, decrease the Blur Offset value to a value below 0.0.

The negative Blur Offset value sharpens the image.

Interface

These controls appear on the Coordinates rollout for many 2D maps:

Texture—Applies the map as a texture map to a surface. Select the type of coordinates from the Mapping list:

Environment—Uses the map as an environment map (page 3–934). Select the type of coordinates from the Mapping list:
Mapping list—Options vary depending on choice of Texture or Environ mapping:

- **Explicit Map Channel**—Uses any map channel. When selected, the Map Channel field becomes active, and you can choose any channel from 1 to 99.

- **Vertex Color Channel**—Uses assigned vertex colors as a channel. See *Editable Mesh* (page 1–996) for details on assigning vertex color.

- **Planar from Object XYZ**—Uses planar mapping based on the object’s local coordinates (disregarding the pivot point location). For rendering purposes, planar mapping doesn’t project through to the back of the object unless you turn on Show Map On Back.

- **Planar from World XYZ**—Uses planar mapping based on the scene’s world coordinates (disregarding the object’s bounding box). For rendering purposes, planar mapping doesn’t project through to the back of the object unless you turn on Show Map On Back.

- **Spherical Environment, Cylindrical Environment, Shrink-wrap Environment**—Project the map into the scene as though it were mapped to an invisible object in the background. See *Environment Map* (page 3–934).

- **Screen**—Projects as a flat backdrop in the scene.

- **Show Map on Back**—When on, planar mapping (Planar from Object XYZ, or with the UVW Map modifier) projects through to render on the back of the object. When off, planar mapping doesn’t render on the object’s back. Default=on.

  This toggle is available only when Tiling is off in both dimensions. Its effect is visible only when you render the scene.

  Note: In viewports, planar mapping always projects to the back of the object, whether Show Map On Back is turned on or not. To override this, turn off Tiling.

- **Use Real-World Scale**—When turned on, applies the map to objects using the real-world Width and Height values instead of UV values. Default=on.

  When Real-World Scale is on, the texture placement is relative to the corner of the texture map so alignment with architectural objects like walls is more efficient. When off, the texture placement is relative to the center of the texture map.

- **Offset**—Changes the position of the map in *UV coordinates* (page 3–1028). The map moves in relation to its size. For example, if you want to shift the map its full width to the left, and half its width downward from its original position, you enter -1 in the U Offset field and 0.5 in the V Offset field.

- **UV/VW/WU**—Changes the mapping coordinate system used for the map. The default UV coordinates project the map onto the surface like a slide projector. The VW and WU coordinates rotate the map so that it is perpendicular to the surface.

- **Tiling**—Determines the number of times the map is tiled (page 3–1022) (repeated) along each axis.

- **Mirror**—Mirrors (page 3–1022) the map left-to-right (U axis) and/or top-to-bottom (V axis).

- **Tile**—Turns tiling on or off in the U or V axis.
When Use Real-World Scale is off

**Offset (UV)**—Changes the position of the map in UV coordinates (page 3–1028). The map moves in relation to its size. For example, if you want to shift the map its full width to the left, and half its width downward from its original position, you enter -1 in the U Offset field and 0.5 in the V offset field.

**UV/VW/WU**—Changes the mapping coordinate system used for the map. The default UV coordinates project the map onto the surface like a slide projector. The VW and WU coordinates rotate the map so that it is perpendicular to the surface.

**Tiling**—Determines the number of times the map is tiled (page 3–1022) (repeated) along each axis.

**Mirror**—Mirrors (page 3–1022) the map left-to-right (U axis) and/or top-to-bottom (V axis).

**Tile**—Turns tiling on or off in the U or V axis.

When Use Real-World Scale is on

**Offset (Width/Height)**—Move the map horizontally or vertically along the width or height of the object to which the material is applied. The offset distance is relative to the lower-left corner of the map.

**UV/VW/WU**—Changes the mapping coordinate (page 3–967) system used for the map. The default UV coordinates project the map onto the surface like a slide projector. The VW and WU coordinates rotate the map so that it is perpendicular to the surface.

**Size**—Determines the real world width and height of the map.

For example, if you scan a piece of marble that is 12” x 8” and then assign this image as the Diffuse Map, you can type 12” (or 1’) and 8” as the Width and Height. This ensures that the scale of the marble is correct in the rendered scene.

**Note:** The default setting for the texture size can be set using the Default Texture Size option in the Material Editor Options Dialog (page 2–1436).

**Mirror**—Mirrors (page 3–1022) the map horizontally and/or vertically.

**Tile**—Turns horizontal and/or vertical tiling on or off.

**Note:** If the Use Real-World Size switch is turned off in the Material Editor, the Real-World Map Size settings in modifiers like UVW Map or for primitives like Box will not work. Likewise, moving vertices at a sub-object level or scaling an object, in general, will not honor the Use Real-World Scale settings.

**Angle U/V/W**—Rotates the map about the U, V, or W axis (in degrees).

**Rotate**—Displays a schematic Rotate Mapping Coordinates dialog that lets you rotate the map by dragging on an archball diagram (similar to
the arcball used to rotate viewports, although dragging inside the circle rotates along all three axes, and dragging outside it rotates about the W axis only). The Angle UVW values change as you drag in the dialog.

**Blur**—Affects the sharpness or blurriness of the map based on its distance from the view. The farther away the map is, the greater the blurring. The Blur value blurs maps in world space. Blur is primarily used to avoid *aliasing* (page 3–907).

**Blur Offset**—Affects the sharpness or blurriness of the map without regard to its distance from the view. Blur Offset blurs the image itself in object space. Use this option when you want to soften or defocus the details in a map to achieve the effect of a blurred image.

See *Blur/Blur Offset* (page 3–918).

### Noise Rollout (2D)

You can add a random noise to the appearance of your material. Noise perturbs the UV mapping of pixels by applying a fractal noise function.

Noise patterns can be very complex and are a versatile way to create apparently random patterns. They are also good for simulating surfaces found in nature, as is characteristic of fractal images.

Noise parameters interact closely with each other. Slight variations in each can create noticeably different effects.

Note: Noise settings aren’t displayed in viewports.

---

Above: A checker map and a bitmap
Below: The same maps with noise applied

### Procedures

**To add noise to a material:**

1. In the Noise rollout, select On.
2. Adjust the three noise parameters to get an effect you like.

**To remove noise from a material:**

- In the Noise rollout, turn off On.

Noise is no longer applied to the map.

**To animate the noise effect:**

1. Turn on the Auto Key button.
2. Move to a non-zero frame.
3. In the Noise rollout, turn on Animate.

By default, animation keys are set at either end of the active frame range.

4. Change the Phase value at different keyframes.

### Interface

<table>
<thead>
<tr>
<th>Noise</th>
<th>Amount</th>
<th>Level</th>
<th>Phase</th>
</tr>
</thead>
<tbody>
<tr>
<td>On</td>
<td>1.0</td>
<td>1.0</td>
<td>0.0</td>
</tr>
</tbody>
</table>
These controls appear on the Noise rollout for many 2D maps:

**On**—Determines whether the Noise parameters affect the map.

**Amount**—Sets the strength of the fractal function, expressed as a percentage. If the amount is 0 there is no noise. If the amount is 100 the map becomes pure noise. Default=1.0.

**Levels**—Or iterations: the number of times the function is applied. The effect of the level is dependent on the Amount value. The stronger the amount, the greater the effect of increasing the Levels value. Range=1 to 10; Default=1.

**Size**—Sets the scale of the noise function relative to geometry. At very small values, the noise effect becomes white noise. At large values, the scale can exceed the scale of the geometry, in which case it has little or no effect. Range=0.001 to 100; Default=1.0.

**Animate**—Determines whether animation is on the noise effect. This parameter must be turned on if you intend to animate the noise.

**Phase**—Controls the speed of the animation of the noise function.

---

**Bitmap 2D Map**

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Bitmap

Bitmaps shown in Material Editor sample slots

A *bitmap* is an image produced by a fixed matrix of colored pixels, like a mosaic. Bitmaps are useful for creating many kinds of materials, from wood grains and wall surfaces to skin and feathers. You can also use an animation or video file instead of a bitmap to create an animated material.

When you assign the Bitmap map, the Select Bitmap Image File dialog (page 2–1635) opens automatically. Use this dialog to specify a file or sequence as the bitmap image.

The Bitmap map can synchronize the frames of a bitmap sequence to the age of particles to which the map is applied. With this effect, each particle displays the sequence from the start when it is born, rather than being assigned whichever frame is current. This is achieved by turning on the Sync Frames To Particle Age check box. Also, when using Particle Flow, assign the material containing the Bitmap map to a Material Dynamic operator. For more details and a procedure, see Material Dynamic Operator (page 2–191).

Note: To save loading time, if a map with the same name is in two different locations (in two different paths), it is loaded only once. This poses a problem only if your scene includes two maps.
that have different content but the same name. In this case, only the first map encountered will appear in the scene.

**Supported File Types**

The Material Editor supports the following file formats:

- **AVI files** (page 3–609)
- **BMP files** (page 3–610)
- **CIN files (Kodak Cineon)** (page 3–610)
- **DDS files** (page 3–611)
- **GIF files** (page 3–613)
- **IFL files** (page 3–616)
- **JPEG files** (page 3–620)
- **MOV files (QuickTime Movies)** (page 3–621)
- **MPEG files** (page 3–621)
- **PNG files** (page 3–628)
- **PSD files** (page 3–629)
- **RGB files (SGI format)** (page 3–633)
- **RLA files** (page 3–630)
- **RPF files** (page 3–631)
- **TGA files (Targa)** (page 3–633)
- **TIFF files** (page 3–634)
- **YUV files** (page 3–635)

Note: If your scene includes animated bitmaps with materials, projector lights, or environments, the animation file is reloaded once per frame. If your scene uses multiple animations, or if the animations are large files, rendering will be slower.

**See also**

For functionality shared with other 2D maps, see the following topics:

- **Coordinates Rollout (2D)** (page 2–1625)
- **Noise Rollout (2D)** (page 2–1630)
- **Output Rollout** (page 2–1621)

**Procedures**

**To crop an image:**

1. On the Bitmap Parameters rollout, click the Bitmap button and assign a bitmap.
2. In the Cropping/Placement group, turn on Apply to see the results of cropping in the sample slot (and in shaded viewports if Show Map In Viewport is active).
3. Turn on Crop.
4. Click View Image to display the bitmap.

A frame window appears, displaying the image surrounded by a region outline (a dashed line at the outer edges of the image, with handles on the sides and corners).

5. Specify a cropping region by adjusting the spinners at the top of the window, or by dragging the region outline.

**To place an image:**

1. On the Bitmap Parameters rollout, click the Bitmap button and assign a bitmap.
2. In the Cropping/Placement group, turn on Apply to see the results of cropping in the sample slot (and in shaded viewports if Show Map In Viewport is active).
3. Turn on Place.
4. Click View Image.

A frame window appears, displaying the image surrounded by a region outline (a dashed line at the outer edges of the image, with handles on the sides and corners).

5. Move the image by adjusting the spinners at the top of the window, or by dragging the region outline.
The reduced image "decals" on the sample sphere. The diffuse color is visible around the image.

To use the alpha channel that is part of the bitmap:
1. On the Maps rollout, assign the map to the Opacity component.
   (You can assign a copy or instance of this map to other components, such as Diffuse, as well.)
2. Click the map button for the Opacity component.
   This lets you adjust the settings for the Opacity map.
3. In the Bitmap Parameters rollout > Alpha Source group, choose Image Alpha.
   This option is not available if the bitmap does not have an alpha channel.
4. In the Bitmap Parameters rollout > Mono Channel Output group, choose Alpha.
   This option is not available if the bitmap does not have an alpha channel.

The bitmapped material will now have the transparency specified by the alpha channel. Transparency does not appear in viewports or ActiveShade renderings.

To create an alpha channel based on intensity:
- In Bitmap Parameters rollout > Alpha Source group, turn on RGB Intensity.
  The software creates an alpha channel. Full-intensity areas of the image are opaque, zero-intensity areas are transparent, and intermediate colors become partially transparent.

To use a completely opaque bitmap:
- In Bitmap Parameters rollout > Alpha Source group, turn on None (opaque).

The software ignores the bitmap’s alpha channel, if present, and does not create a new one.

Interface

Bitmap Parameters rollout

Bitmap—Selects the bitmap using the standard file browser. After selection, the full path name appears on this button.

Reload—Reloading the bitmap file using the same name and path. You don't need to use the file browser to reload the bitmap after you've updated it in your paint program.

Clicking reload for any instance of the map updates the map in all sample slots and in the scene.

Filtering group

Filtering (page 3–939) options let you select the method of pixel averaging used in antialiasing (page 3–907) the bitmap.

Pyramidal—Requires less memory and is adequate for most purposes.

Summed Area—Requires much more memory, but yields generally superior results.

None—Turns off filtering.
Mono Channel Output group

Some parameters, such as opacity or specular level are a single value as opposed to a material’s three-value color components. Controls in this group determine the source of the Output mono channel in terms of the input bitmap.

**RGB Intensity**—Uses the intensity of the red, green, and blue channels for mapping. The color of the pixels is ignored and only the value or luminance of the pixels is used. The colors are computed as gray values in the range between 0 (black) and 255 (white).

**Alpha**—Uses the intensity of the alpha channel (page 3–907) for mapping.

RGB Channel Output group

The RGB Channel Output determines where the output RGB part comes from. The controls in this group affect only maps for material components that display color: Ambient, Diffuse, Specular, Filter Color, Reflection, and Refraction.

**RGB**—Displays the full color values of the pixels. (Default)

**Alpha as Gray**—Displays tones of gray based on the levels of the alpha channel.

Cropping/Placement group

The controls in this group let you crop the bitmap or reduce its size for custom placement. Cropping a bitmap means to reduce it to a smaller rectangular area than it originally had. Cropping doesn’t change the scale of the bitmap.

Placing a bitmap lets you scale the map and place it anywhere within its tile. Placing can change the bitmap’s scale, but shows the entire bitmap. The four values that specify the placement and size of the cropping or placement region are all animatable.

Cropping and placement settings affect the bitmap only as it’s used for this map and any instances of the map. They have no effect on the bitmap file itself.

**Apply**—Turn on to use the cropping or placements settings.

**View Image**—Displays a rendered frame window (page 3–5) that shows the bitmap surrounded by a region outline. The region outline has handles at its sides and corners. When cropping is on, dragging the handles changes the size of the crop area. You can also drag within the region area to move it.

The frame window has U/V and W/H (width/height) spinners on its toolbar. Use these to adjust the location and size of the image or crop area.

When Place is turned on, dragging the region area handles changes the scale of the bitmap (hold down [Ctrl] to preserve the bitmap’s aspect ratio), and dragging the image changes its location within the tile area.

When Crop is turned on, the UV or XY button at the right of the rendered frame window toolbar lets you switch between using UV or XY coordinates in the toolbar spinners. Also, you can zoom out by pressing [Shift+Z] and zoom in by pressing [Z].

**Crop**—Makes cropping active.

**Place**—Makes placement active.

**U/V**—Adjusts the bitmap location.

**W/H**—Adjusts the width and height of the bitmap or crop area.

**Jitter Placement**—Specifies the amount of random offset. At 0, there is no random offset. Range = 0.0 to 1.0

When Place is turned on, the size and position specified by the spinners or editing window are ignored. The software then chooses a random size and tile position for the image.
Alpha Source group

Controls in this group determine the source of the Output alpha channel in terms of the input bitmap.

Image Alpha—Uses the image’s alpha channel (disabled if the image has no alpha channel).

RGB Intensity—Converts the colors in the bitmap to grayscale tonal values and uses them for transparency. Black is transparent and white is opaque.

None (Opaque)—Does not use transparency.

Premultiplied Alpha—Determines how alpha is treated in the bitmap. When turned on, the default, premultiplied alpha (page 3–997) is expected in the file. When turned off, the alpha is treated as non-premultiplied, and any RGB values are ignored.

Tip: If you apply an alpha image as a Diffuse map, for example, and it doesn’t decal correctly, the bitmap file probably contains non-premultiplied alpha; the RGB values are maintained separately from the alpha values. To correct this, turn off Premultiplied Alpha.

Playback Rate—Lets you speed up and slow down the rate that the animation is applied to the map (for example, 1.0 is normal speed, 2.0 is twice as fast, .333 is 1/3 as fast).

Sync Frames to Particle Age—When on, the software synchronizes the frames of a bitmap sequence to the age of particles to which the map is applied. With this effect, each particle displays the sequence from the start when it is born, rather than being assigned whichever frame is current. Default=off.

When using Particle Flow, assign the material containing the Bitmap map to a Material Dynamic operator. For more details and a procedure, see Material Dynamic Operator (page 2–191).

Note: This functionality is not supported by the mental ray renderer.

End Condition group

Determines what happens after the last frame of the bitmap animation if the animation is shorter than the scene.

Loop—Causes the animation to repeat over and over again from the beginning.

Ping-Pong—Causes the animation to be played forward and then backward repeatedly, making every animated sequence “loop smoothly.”

Hold—Freezes on the last frame of the bitmap animation.

Select Bitmap Image File Dialog

Material Editor > Maps Rollout > Click any map selector button. > Material/Map Browser > Double-click Bitmap. > Select Bitmap Image.

Material Editor > Bitmap map > Bitmap Parameters rollout > Bitmap button

The Select Bitmap Image dialog allows you to choose a file or sequence of files for a map. If
a sequence of files is selected by turning on Sequence, the Image File List Control dialog (page 3–618) is opened when you click Setup or Open.

**Procedures**

To select a bitmap image for a map:

1. In the Material Editor, open the Maps rollout.
2. Click any button in the Map column.
   This adds a map into the channel you’ve selected. For example, clicking in the Map column of the Diffuse channel creates a diffuse or texture map.
   The Material Map Browser is displayed.
3. In the Material/Map Browser, double-click Bitmap.
   The Select Bitmap Image dialog is displayed.
4. In the Select Bitmap Image dialog, navigate the Look In field to select the appropriate directory.
   Note: The Select Bitmap Image File dialog uses the last location where a bitmap was chosen, rather than the default bitmap path defined in Customize > Configure User Paths.
5. Highlight the file name in the file list window.
6. Click Open to close the dialog.

To select a set of still images as a bitmap sequence:

1. In the Material Editor, open the Maps rollout.
2. Click any button in the Map column.
   This adds a map into the channel you’ve selected. For example, clicking in the Map column of the Diffuse channel creates a diffuse or texture map.
   The Material Map Browser is displayed.
3. In the Material/Map Browser, double-click Bitmap.
   The Select Bitmap Image dialog is displayed.
4. In the Select Bitmap Image dialog, navigate the Look In field to select the directory containing the sequence of files.
5. If necessary, change file type to match the file extension of the sequence, or choose All Formats.
6. Turn on Sequence, and choose the name of the first sequential file.
7. Click the Setup button.
   The Image File List Control Dialog opens.
8. Click the Browse button and set the Target path to a writable directory on your hard disk. Do not set the path to a CD-ROM drive.
9. Choose the options you want and click OK.
   The IFL file is written to the target directory.

**Interface**

Tip: You can resize the dialog by dragging an edge or a corner.

**History**—Displays a list of the most recent directories searched. Whenever an image is selected, the path used is added to the top of the history list as the most recently used path. The
history information is saved in the 3dsmax.ini (page 1–18) file.

**Look In**—Opens a navigation window to browse other directories or drives.

**Up One Level**—Moves you up a level in the directory structure.

**Create New Folder**—Lets you create a new folder while in this dialog.

**List**—Displays the contents of a directory without the details.

**Details**—Displays the contents of a directory with all the details.

**List Window**—When details are turned on, the contents of the directory are displayed with Name, Size, Type, Date Modified, and Attributes. You can sort based on each of these columns by clicking the column label.

**File Name**—Displays the file name of the file selected in the list.

**Files of Type**—Displays all the file types that can be displayed. This serves as a filter for the list.

**Open**—Selects the highlighted file and closes the dialog.

**Cancel**—Cancels the selection and closes the dialog.

**Devices**—Lets you choose the hardware output device, for example, a digital video recorder. The device, its driver, and its 3ds Max plug-in must all be installed on your system to use the device.

**Setup**—When Sequence is turned on, and there are sequential files in the directory displayed, this Setup displays an Image File List Control dialog (page 3–618) to create an IFL file.

**Info**—Displays expanded information about the file, such as frame rate, compression quality, file size, and resolution. The information here depends on the type of information that is saved with the file type.

**View**—Displays the file at its actual resolution. If the file is a movie, the Media Player is opened so the file can be played.

**Gamma Group**

**Gamma**—Selects the type of gamma to be used for the selected file. This is unavailable unless Enable Gamma Correction is turned on in the Gamma panel (page 3–824) of the Preferences dialog.

**Use Image's Own Gamma**—Uses the gamma of the incoming bitmap.

**Use System Default Gamma**—Ignores the image’s own gamma and uses the system default gamma instead, as set in the Gamma panel of the Preferences dialog.

**Override**—Defines a new gamma for the bitmap that is neither the image’s own, nor the system default.

**Sequence**—Creates an "Image File List " using the given information. Note that each time an image is selected, an evaluation is done to see if an IFL sequence can be created. If the selected image does not yield a list, this option box is unavailable. In the past, it was necessary to enter a wild card in order to create a list. Now it is possible to use wild card to filter files in the file selector.

**Preview**—Displays the image as a thumbnail in the image window.

**Image Window**—Displays a thumbnail of the selected file.

**Statistics**—Displays the resolution, color depth, file type, and number of frames of the selected file.
Location—Displays the full path for the file. With this information at the bottom of the dialog, you always know exactly where you are.

Checker Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Checker

The Checker map applies a two-color checkerboard pattern to the material. The default checker map is a pattern of black and white squares. Checker maps are 2D procedural maps. The component checkers can be either colors or maps.

Tip: Turning on Noise for a Checker map can be an effective way to create irregular patterns with a natural appearance.

See also

For functionality shared with other 2D maps, see:
Coordinates Rollout (2D) (page 2–1625)
Noise Rollout (2D) (page 2–1630)

Procedures

To create a Checker map:
1. Click a map button to assign a map.
2. Choose Checker in the Material/Map browser, and then click OK.

To change the color of one set of squares:
1. In the Checker Parameters rollout, click a color swatch to display the Color Selector (page 1–161).
2. Adjust the color.
3. Click Close.

To use a map for one set of squares:
• In the Checker Parameters rollout, click a map button to assign a map to a color.

To soften the edge between the two checker colors:
• In the Checker Parameters rollout, increase the value of Soften.

When Soften equals 0.0, there is a hard edge between the checker colors. Low positive values soften or blur the checker boundary. Larger Soften values can blur the entire material.

To swap the two checker components:
• In the Checker Parameters rollout, click Swap.

Interface

Soften—Blurs the edges between the checkers. A little blurs a lot.
Swap—Switches the position of the two checkers.
Color #1—Sets the color of one of the checkers. Click to display the Color Selector (page 1–161).

Color #2—Sets the color of one of the checkers. Click to display the Color Selector (page 1–161).

Maps—Selects a map to use within the area of the checker color. For example, you could put an additional checkerboard within one of the checker colors.

The check boxes enable or disable their associated map.

Combustion Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Combustion

With the Combustion map, you can create maps interactively using the Autodesk Combustion software and 3ds Max at the same time. You use Combustion to paint on a bitmap, and the material updates automatically in the Material Editor and in shaded viewports.

Important: The Combustion map works only if Autodesk Combustion is installed on your system.

Only Combustion 2.1 and later formats are supported. Maps in the Combustion 1 format are not supported in 3ds Max.

Important: The mental ray renderer (page 3–78) does not support the Combustion map.

Noise Rollout (2D) (page 2–1630)

About the 3ds Max and Combustion Integration

You can use Combustion as a material map in 3ds Max. With a Combustion map, you can create a material from a Paint or composite operator, and in turn apply that material to objects in a 3ds Max scene. The Combustion map can include Combustion effects, and it can be animated.

In addition, with Combustion you can import 3ds Max scenes that have been rendered to a rich pixel file (page 3–631) (RPF (page 3–631) or RLA (page 3–630) file). The imported rich pixel rendering becomes an element of your composite. You can adjust its 3D position relative to video elements of the composite, and you can apply Combustion 3D Post effects to objects within it. See the Combustion User's Guide for more information.

Note: Because 3ds Max runs only on Windows, you cannot use Combustion to create material maps on a Macintosh.

Note: The environmental atmospheric effect known as "Combustion" in versions of 3ds Max prior to v4 is now known as the Fire effect (page 3–276).

3ds Max Materials and the Combustion Map

In 3ds Max, a material (page 3–971) is data that you assign to the surface or faces of an object so that it appears a certain way when rendered. Materials affect the color of objects, their shininess, their opacity, and so on.

The Material Editor (page 2–1409) is the portion of 3ds Max that creates and manages materials. In the Material Editor, you can assign maps to a material’s color components and to its numeric components such as opacity. Maps add images, patterns, color adjustments, and other effects to the visual properties of the material.

In the 3ds Max Material Editor, you assign a map by clicking the map button for a component color or other component. This displays the Material/Map Browser, which lets you choose the map type.
3ds Max provides several types of maps (page 3–968). The most basic is a 2D map, a two-dimensional image that is typically mapped onto the surface of geometric objects.

Other uses of 2D maps are as environments to create a background for the scene, as projections from lights, and as displacements to "emboss" geometry.

A Combustion map is a 2D map (page 2–1624). It is a Combustion project used by the 3ds Max Material Editor, so like any Combustion project, it is vector-based, animatable, and fully editable. From within the Material Editor, you can have Combustion create a new project from scratch, or use an existing composite or Paint branch. You can synchronize the Combustion Timeline with the 3ds Max time slider so animated materials synchronize with your 3D scene.

With a Combustion map, you can paint in either program: that is, you can paint either in the Combustion viewport or on 3ds Max objects. Both programs update the paint display. You also have the option of using Combustion to paint on an "unwrapped" projection of 3ds Max object geometry.

In addition, with Combustion effects that require you to pick a point, such as Lens Flare or Ripple, you can use either program, Combustion or 3ds Max, to pick the point.

Tips for Working with a Combustion Map in 3ds Max

- If you have a dual-screen configuration, you can set it up so you can see both the 3ds Max and the Combustion windows at the same time. Otherwise, you need to use [Alt+Tab] to switch between the two windows.
- To work with Combustion, the 3ds Max object must have mapping coordinates (page 3–967). Primitive objects have a Generate Mapping Coordinates toggle, which is automatically enabled when you assign a mapped material to the object. Some objects, such as editable meshes, do not have a Generate Mapping Coordinates toggle. For these kinds of objects, go to the Modify panel and apply a UVW Map modifier (page 1–922).

- Sometimes it can be hard to see how the Combustion operator is oriented to the 3ds Max object’s mapping coordinates. It can help to paint some temporary strokes in Combustion to see how they are aligned in 3ds Max viewports. Displaying the mapping coordinates in Combustion can help. See the procedure, "To display an unwrapped mesh." It can also help to paint directly on the object in a 3ds Max viewport. See the procedure, "To paint directly on the 3D object."

Procedures

To create a new Combustion map:

1. Open the Material Editor.
2. Drag an unused sample slot from the Material Editor to the object you want to paint.
3. In the Material Editor, click the map button for the Diffuse Color component. This button is on the material’s Basic Parameters rollout.

![Material Editor](image)

All standard materials have a Basic Parameters rollout, whose controls vary depending on the chosen shader. The Strauss shader has only one color component, labeled Color.

The Material/Map Browser appears.

4. In the Material/Map Browser, choose Combustion, and click OK.
A Combustion map is assigned to the Diffuse Color, and a black material map appears in the active sample slot.

5. Click to turn on Show Map In Viewport.

In the scene, the object turns black in shaded viewports.

6. In the Parameters rollout, click Edit.

This launches Combustion, which displays the New Workspace dialog.

7. Set up the new project.

The composite or Paint branch that you create in Combustion appears on the object in 3ds Max viewports, as well as in the sample slot for the material with the Combustion map. The workspace name and path are assigned to the material, and appear on the Project button in the material's Combustion Parameters rollout.

For example, you can use the Paint operator in Combustion. When you release the mouse, the stroke appears on the 3ds Max object.

To display an unwrapped mesh:

In the 3ds Max Material Editor, you can use the Unwrap Mesh feature to display your 3D object as a 2D mesh in Combustion. You can adjust the color and size of the mesh.

The mesh display is only an overlay to help you orient paint strokes and other Combustion effects. It is displayed in Combustion but is not a part of the composite or the map.

1. Create a Combustion map.

2. In the 3ds Max Material Editor, enable Unwrap Selected in the Live Edit group.
In Combustion, a mesh appears. This is an "unwrapped" projection of the 3D object.

To set the mesh parameters:
- In Combustion, choose File > Preferences > Mesh.

<table>
<thead>
<tr>
<th>Use</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anti-Alias Mesh</td>
<td>Remove jaggies from the mesh.</td>
</tr>
</tbody>
</table>

To paint directly on the 3D object:
1. Create a Combustion map.
2. In Combustion, select one of the following drawing tools:
   - Freehand
   - Straight Line
   - Rectangle
   - Ellipse
3. In the 3ds Max Material Editor, enable Paint in the Live Edit group of the Combustion Parameters rollout.

In the 3ds Max viewport, a pen cursor appears. Drag the cursor over the object to paint on it.
When you release the cursor, the Paint object also appears in Combustion.

**To animate Combustion Paint strokes:**

1. Create a Combustion map.
2. In Combustion, set the time scale to start at frame number 0. Choose File > Preferences. In the Preferences dialog select General, set Display Time As to Frames (From 0), and then click OK.
3. In the 3ds Max Material Editor, enable Track Time in the Live Edit group of the Combustion Parameters rollout.
   Now the time slider in 3ds Max controls the Timeline indicator in Combustion.
4. In 3ds Max, move the time slider to a frame and create a Paint object.
   The Paint object appears on that frame in both Combustion and 3ds Max.
5. Move to another frame and use Combustion to modify the Paint object. Combustion uses interpolation to determine the appearance of the Paint object between keyframes. If you add a new Paint object, that object simply appears, starting on the frame where you created it.
6. Continue advancing in the clip, adding and modifying Paint strokes and effects to create your animated material. For more information on animating objects in Combustion, refer to the Combustion User's Guide.

   You can add Paint strokes in either program, but to modify them you must use Combustion.

   **Note:** Remember, Combustion tracks the time slider in 3ds Max, but 3ds Max does not track the Timeline indicator in Combustion. If the 3ds Max viewport does not appear to be updating as you paint in Combustion, you might be painting on a different frame than the one displayed in 3ds Max. To find your Paint objects, move to the correct frame in 3ds Max.

**To use an existing Combustion workspace as a material map in 3ds Max:**

1. Open the Material Editor and select an unused sample slot.
2. In the Material Editor, expand the Maps rollout, and click the Map button next to the Diffuse Color component.

   The Material/Map Browser appears.
3. In the Material/Map Browser, choose Combustion, and click OK.

A Combustion map is assigned to the Diffuse Color, and a black material map appears in the active sample slot.

4. In the Combustion Parameters rollout, click the Project bar.

   ![Project button](image)

The Open Project dialog appears.

5. Browse for the workspace file (.cws) that you want to use as a map, and click the Open button. The Combustion workspace name and path appear in the Project button.

To apply the map to an object, drag the sample slot from the Material Editor to the object in a 3ds Max viewport.

To edit the map, click the Edit button in the Parameters rollout. In Combustion, the workspace corresponding to the selected map opens, and you can edit the image.

To paint geometry with a bitmapped material already assigned to it:

1. In 3ds Max, select the object that you want to paint.

2. In the Material Editor, select an unused sample slot.

3. Click the Pick Material From Object button, then click the object in the viewport to put the object’s material in the selected sample slot.

4. Open the Maps rollout and note the name of the bitmap file. Click Map to go to the bitmap level of the material.

5. Click the map's Type button.

   The Material/Map Browser appears.

6. In the Material/Map Browser, choose Combustion to change the type from Bitmap to a Combustion map.

7. On the Paint Parameters rollout, click the blank Project button, and then choose the same bitmap.

8. Click Edit.

   Combustion is launched and the Import Footage dialog appears. Import the same bitmap.

   To paint on the bitmap, select Paint. You can also key or color correct the bitmap, or use it to build a composite. For more information, see the Combustion User’s Guide.

9. In the 3ds Max Material Editor, click Show Map In Viewport.

   In the scene, the object is mapped in shaded viewports.

   ![Object with original bitmap](image)
To paint selected faces:

Use a Multi/Sub-Object material to control the location of your painting. Any sub-material can have a Combustion map, so you can use Combustion to affect only the selected faces.

1. In 3ds Max, select the object you want to paint.

2. In the Modify panel, apply an Edit Mesh modifier to the object. (Choose Edit Mesh from the Modifier drop-down list.)

   If you are working with an editable mesh object, or a patch or NURBS surface, skip step 2. For geometry primitives, an option is to convert the object to a mesh, patch, or NURBS surface before step 3. However, you then lose the ability to adjust object parameters (for example, the radius of a sphere, the height of a box).

3. Choose Face as the sub-object selection level. Select the faces on which you want to paint.

4. Drag a material from a sample slot in the Material Editor onto the selected faces.

5. In the modifier stack display, choose the object again, to disable sub-object selection.

6. In the Material Editor, use Pick Material From Object to grab the material from the geometry.

   You now have a new Multi/Sub-Object material. The original material appears as a sub-material applied to the selected faces.

7. In the Multi/Sub-Object material, go to the material assigned to the faces you want to paint.

   A Multi/Sub-Object material is simply a container for multiple sub-materials assigned to different faces of the same object. Click a Sub-Material button to go to a sub-material.
8. Assign a Combustion map to the Diffuse component of the sub-material applied to the selected faces.

9. Click Edit to launch Combustion.

10. Use the tools in Combustion to modify the material.

To modify a Combustion map:

1. In the Material Editor, select the material you want to modify.

   Material maps created in Combustion are vector-based and fully modifiable.

2. In the Combustion Parameters rollout, click the Edit button.

   The workspace corresponding to the Combustion map opens in Combustion. As you modify the workspace in Combustion the map is updated in 3ds Max.

3. In Combustion, save the workspace before you disable the Edit button in 3ds Max.

To create a displacement map:

In 3ds Max, the Displace modifier (page 1–629) acts as a force field to push and reshape an object’s geometry. You can apply its variable force directly from the modifier gizmo, from a bitmap image, or from a Combustion workspace.

The grayscale component of the image is used to generate the displacement. Lighter colors in the image push outward more strongly than darker colors, resulting in a 3D displacement of the geometry.

1. In 3ds Max, select the object to which you want to apply the displacement map.

   In this example, the displacement is applied to a box primitive.

   In the object’s Parameters rollout, increase the number of Length and Width Segments. The closer the number of segments approaches the resolution of the displacement map, the more accurate is the result.

   In the example, 150 by 150 gives good results.

2. Apply a Displace modifier: in the Modify panel, choose Displace from the Modifier drop-down list.

3. In the Parameters rollout, Image group, click the Map button.
4. The Material/Map Browser appears. Select Combustion and click OK.
   The Map button now reads Map #1 (Combustion).

5. Open the Material Editor, and then click and drag the Map #1 (Combustion) button to an unused sample slot in the Material Editor.
   An Instance (Copy) Map dialog is displayed.

6. Select Instance and click OK.

7. In the Material Editor, Combustion Parameters rollout, click Edit.
   This launches Combustion. In the New dialog, set the Type To Paint, and create a grayscale image to use as a displacement map. For more information, see the Combustion User’s Guide.

8. In 3ds Max, increase the Displacement strength in the modifier Parameters rollout.
   As you increase the strength, you can see the result of the displacement map on the selected object.

9. In Combustion, save your project, then in 3ds Max, disable Edit in the Combustion Parameters rollout to exit Edit mode.
**Interface**

2D Mapping Coordinates

Like any 2D map in 3ds Max, mapping coordinates control how a Combustion map is positioned on objects.

For geometric primitives, mapping coordinates are usually provided automatically. For some kinds of geometry, such as meshes (page 1–996), patches (page 1–993), and NURBS surfaces (page 1–1078), you must apply a UVW Map modifier (page 1–922) to provide mapping coordinates.

Controls in a 2D map's Coordinates rollout (page 2–1625) affect how the map is positioned.

When you work with a Combustion map, these are the important points to remember:

- When you apply a Combustion map to an object, leave mapping set to the default values of Texture and Explicit Map Channel.
- When you use a Combustion map as an environment map, set mapping to Environ and then choose the mapping shape from the Mapping drop-down list.
- The offset, tiling, mirror, and angle controls are useful especially when the size of the projected Combustion map is smaller than the geometry.
- You can choose between UV, VW, and WU projections. (You can also do this from the Combustion Parameters rollout, as described below.) UV projects onto the surface of geometry like a slide projector. VW and WU project the map at right angles to the geometry.
- With a Combustion map, UV is almost always the most useful choice.

**Combustion Parameters rollout**

The Combustion Parameters rollout appears when you assign a Combustion map to a material.

**Project**—Loads the file to use in Combustion. You can load only file types supported by Autodesk Combustion, such as Combustion workspace files (cws), or footage and image file formats supported by Combustion (see the Combustion User's Guide for information on supported footage formats).

**Edit**—Launches Combustion from the 3ds Max Material Editor. If a project is loaded, it is opened in Combustion. If no project is loaded, Combustion displays the New dialog. This dialog lets you specify a project type, name, video format, duration, and background color.

**Live Edit group**

These controls affect how you use Combustion with 3ds Max.
Operator—Switches control to Combustion, where you can select an operator. The results of the operator appear as the image in the Combustion map. The operator does not have to be the last operator in the pipe.

While Combustion is active, you can also adjust the operator. The Combustion map updates to show the results.

Unwrap Selected—Takes the current UVW mapping coordinates of the currently selected 3D object (or the current Face sub-object selection), and displays them in Combustion. This can help you coordinate the map and the mesh as you paint. The Unwrap display is only an overlay. It is displayed in Combustion but is not a part of the composite or the map.

UV List—Changes the mapping coordinate system (the direction in which the map is projected) from UV to VW or UW. UV projects onto the surface of geometry like a slide projector. VW and WU project the map at right angles to the geometry. With a Combustion map, UV is almost always the most useful choice.

UV—Specifies which mapping channel to unwrap and paint. Range=1 to 99.

Track Time—Links the Timeline in Combustion to the time slider in 3ds Max. When Track Time is enabled, you can use the time slider in 3ds Max to navigate between frames in Combustion.

Note: This control is not bidirectional; changing the frame in Combustion does not change the frame in 3ds Max.

Paint—When enabled, displays a paint cursor in 3ds Max viewports. You can then paint directly on the 3D geometry. Dragging the cursor in the viewport over the geometry in 3ds Max creates paint strokes inside Combustion.

Constrain To UV—When enabled, constrains paint strokes to remain within the edges of the UV mapping coordinates. When paint strokes are unconstrained on an object such as a box, they can jump to the other side of the map when you cross a map’s edge. This can give erratic results. To prevent this, enable Constrain To UV.

In general, use the Constrain To UV option when you paint on boxes and other objects with planar maps. Disable this option when you want to paint on spherical maps or anywhere else the mapping has a singularity (where the edges of the map converge to a single point).

Selected Faces—Constrains the Combustion image to only the faces selected. This gives additional control or masking based on faces rather than UV mapping.

Project Info group
These readouts display the format of the Combustion Paint or composite operator. They are active when a Combustion workspace is loaded or Edit mode is active.

Width—Sets horizontal resolution of the frame in pixels.

Height—Sets vertical resolution of the frame in pixels.

Frames—Sets number of frames in the Combustion workspace.

Rate—Sets playback speed in frames per second.

Custom Resolution group
With these controls, you can customize the resolution of the Combustion map.

Enable—Enables the Width and Height controls.

Width and Height—Width changes the horizontal resolution of the map. Height changes the vertical resolution of the map.
Time group
These controls relate frames in the Combustion workspace to frames in the Combustion map. See the controls under "End Condition Group" for how to handle the map when it contains fewer frames than the 3ds Max scene.

Start Frame—Determines which frame of the Combustion sequence is used as the first frame of the Combustion map in 3ds Max.

Duration—Sets how many frames of the Combustion file sequence are used by the Combustion map in 3ds Max.

Filtering group
These controls determine the method for calculating antialiasing (page 3–907):

Pyramidal—Sets the default antialiasing method. This method is faster than Summed Area filtering.

Summed Area—Implements a better method of antialiasing. Summed Area filtering uses more memory than Pyramidal. If it has to use virtual memory, it can dramatically increase rendering time.

None—Performs no antialiasing. This option takes the least time to render, but yields the lowest quality results.

End Condition group
These controls define what the 3ds Max renderer should do when the duration of the Combustion project (or the range of frames used in the Combustion map) is shorter than the rendering sequence in 3ds Max.

Loop—Plays the Combustion project animation repeatedly until the rendering sequence ends.

Ping Pong—Plays the animation forward, then backward, and repeatedly plays forward and backward until the rendering sequence is completed.

Hold—Plays the animation once, then repeatedly displays the last frame of the project until the rendering sequence is completed.

Gradient Map
Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Gradient

Gradient maps used for the stoplight lamps, and for the background of the scene

Gradients shade from one color to another. You specify two or three colors for the gradient; the software interpolates intermediate values. Gradient maps are 2D maps.

Tip: You can swap colors by dragging one color swatch over another, then clicking Swap in the Copy or Swap Colors dialog. To reverse the overall direction of the gradient, swap the first and third colors.

See also
For functionality shared with other 2D maps, see:
Coordinates Rollout (2D) (page 2–1625)
Noise Rollout (2D) (page 2–1630)
Output Rollout (page 2–1621)
Gradient-mapped material tiled and with noise

**Procedures**

**To create a Gradient map:**
1. Click a map button to assign a map.
2. Choose Gradient in the Material/Map Browser, and then click OK.

**To change a gradient color:**
1. In the Gradient Parameters rollout, click a color swatch to display the Color Selector (page 1–161).
2. Adjust the color.
3. Click one of the other color swatches.
4. Adjust the color.

**To choose the kind of gradient:**
- Choose either Linear or Radial.

  A linear gradient shades from one color to another along a line. A radial gradient has one color on the inside and another on the outside, shading in a circular pattern.

**To use a map for a color in the gradient:**
- In the Gradient Parameters rollout, click a map button to assign a map to a color.

**To adjust the position of the second color:**
- Change the Color 2 Position value.

  At the default value of 0.5, the second color is between the first and third colors. For a linear gradient, the second color’s position ranges from the bottom at 0.0 to the top at 1.0. For a radial gradient, the second color’s position ranges from the inside at 0.0 to the outside at 1.0.

**Interface**

<table>
<thead>
<tr>
<th>Gradient Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Maps</strong></td>
</tr>
<tr>
<td>Color #1—Sets the first color.</td>
</tr>
<tr>
<td>Color #2—Sets the second color.</td>

<tr>
<td>Color #3—Sets the third color.</td>
</tr>
<tr>
<td>Color 2 Position—Controls the center point of the middle color.</td>
</tr>
<tr>
<td>Noise—Adjusts the noise amount.</td>
</tr>
<tr>
<td>Gradient Type—Choose Linear or Radial.</td>
</tr>
</tbody>
</table>

**Color #1-3**—Sets the three colors that the gradient interpolates between. Displays the Color Selector (page 1–161). You can drag and drop the colors from one swatch to another.

**Maps**—Displays a map (page 3–968) instead of the color. Maps are blended into the gradient in the same way that the gradient colors are blended. You can add nested procedural gradients in each window to make 5-, 7-, 9-color gradients, or more. The check boxes enable or disable their associated maps.

**Color 2 Position**—Controls the center point of the middle color. The position ranges from 0 to 1. When it is 0, color 2 replaces color 3. When it is 1, color 2 replaces color 1.

**Gradient Type**—Linear interpolates the color based on the vertical position (V coordinate) while radial interpolates based on the distance from the center of the map (center is: U=0.5, V=0.5). With
both of these, you can rotate the gradient using
the angle parameter under Coordinates, which is
animatable.

Noise group

Amount—When nonzero (ranges from 0 to 1),
applies a noise effect. This perturbs the color
interpolation parameter using a 3D noise function
based on U, V, and Phase. For example, a given
pixel is halfway between the first and second color
(the interpolation parameter is 0.5). If noise is
added, the interpolation parameter would be
perturbed by some amount so that it may become
less or more than 0.5.

Regular—Generates plain noise. This is the same
as Fractal noise with the Levels setting at 1. When
the noise type is set to Regular, the Levels spinner
becomes disabled (because Regular is not a fractal
function).

Fractal—Generates noise using a fractal algorithm.
The Levels option sets the number of iterations for
the fractal noise.

Turbulence—Generates fractal noise with an
absolute value function applied to it to make fault
lines. The noise amount must be greater than 0 to
see any effects of turbulence.

Size—Scales the noise function. Smaller values
give smaller chunks of noise.

Phase—Controls the speed of the animation of the
noise function. A 3D noise function is used for the
noise. The first two parameters are U and V and
the third is phase.

Levels—Sets the number of fractal iterations or
turbulence (as a continuous function).

Noise Threshold group

When the noise value is above the Low threshold
and below the High threshold, the dynamic range
is stretched to fill 0–1. This produces a smaller
discontinuity at the threshold transition and thus
causes less potential aliasing.

Low—Sets the low threshold.

High—Sets the high threshold.

Smooth—Helps make a smoother transition from
the threshold value to the noise value. When
smooth is 0, no smoothing is applied. When it is 1,
the maximum amount of smoothing is applied.

Gradient Ramp Map

Gradient ramp used for the layers of the cake

Gradient Ramp is a 2D map similar to the Gradient
map. It shades from one color to another. In this
map, however, you can specify any number of
colors or maps for the gradient. There are a variety
of controls, making highly customized gradients
possible. Almost any parameter of Gradient Ramp
can be animated.

See also

For functionality shared with other 2D maps, see:
Coordinates Rollout (2D) (page 2–1625)
Noise Rollout (2D) (page 2–1630)
Output Rollout (page 2–1621)

Procedure
To create a material with a Gradient Ramp map:

1. Open the Material Editor, and choose an unused sample slot.
2. Close the Basic Parameters rollout, and open the Maps rollout.
3. Click the Map button for Diffuse to display the Material/Map Browser.
4. In the Browser list, click Gradient Ramp. The map appears in the upper-left of the Browser window. Click OK.

Gradient Ramp map is applied to the sample slot as the Browser closes.

5. In the Material Editor, under its toolbar, give the material a name to identify its use in your scene.

When you replace an existing map with a gradient ramp map, choosing to Keep Old Map Submap in the Replace Map dialog, the old map becomes assigned to the first flag as a texture.

Gradient Ramp-mapped material with a colored gradient

Interface

Gradient bar shows default gradient and interpolation types

Gradient bar—Presents an editable representation of the gradient being created. The effect of the gradient moves from left (start point) to right (end point).

By default, three flags appear along the bottom edge of a red/green/blue gradient. Each flag controls a color (or map). The currently selected flag is green, and its RGB value and its position in the gradient (in the range 0 to 100) appear above the gradient bar. Each gradient can have any number of flags.

The gradient bar has the following features:

- Click anywhere along the bottom edge to create additional flags.

- Drag any flag to adjust the position of its color (or map) within the gradient. The start and end flags (Flag #1 at 0 and Flag #2 at 100) cannot be moved. However, other flags can occupy these positions and still be moved.

- More than one flag can occupy a given position. If two flags are at the same position, a slight edge appears between the colors. With three or more flags at the same position, the edge is a hard line.
Right-click options for gradient bar—Right-click in the gradient bar to display a menu with these options:

- **Reset**—Returns gradient bar to defaults.
- **Load Gradient**—Loads an existing gradient (.dgr file) into the gradient bar.
- **Save Gradient**—Saves your current gradient bar as a .dgr file.
- **Copy, Paste**—Copies a gradient and pastes it into another Gradient Ramp map.
- **Load UV Map**—Selects a UV map.
- **Load Bitmap**—Selects a bitmap.
- **Flag Mode**—Toggles flag display.

Right-click options for flags—Right-click any flag to display a menu with the following options:

- **Copy and Paste**—Lets you copy the current key and paste it to replace another key. The other key could be in another Gradient Ramp as well as the current one.
- **Edit Properties**—Choose this option to display the Flag Properties dialog (page 2–1655).
- **Delete**—Deletes the flag.

Gradient Type—Chooses the type of gradient. The following Gradient types are available. These affect the entire gradient.

- **4 Corner**—An asymmetrical linear transition of colors.
- **Box**—A box.
- **Diagonal**—A linear diagonal transition of colors.
- **Lighting**—Based on the light intensity value. No light=far left; brightest light=far right.
- **Linear**—A smooth, linear transition of colors.
- **Mapped**—Lets you assign a map to use as the gradient. Enables the Source Map controls for specifying the map and turning it on and off.
- **Normal**—Based on the angle between the vector from the camera to the object and the surface normal vector at the sample point. The leftmost flag of the gradient is 0 degrees; the rightmost flag is 90 degrees.
- **Pong**—A diagonal sweep that repeats in the middle.
- **Radial**—A radial transition of colors.
- **Spiral**—A smooth, circular transition of colors.
- **Sweep**—A linear sweep transition of colors.
- **Tartan**—A plaid.

Interpolation—Chooses the type of interpolation. The following Interpolation types are available. These affect the entire gradient.

Note: Gradients are ordered from left to right. The “next” flag is to the right of the current flag; the “previous” flag is to the left.

- **Custom**—Sets an individual interpolation type for each flag. Right-click the flag to display the Flag Properties dialog (page 2–1655) and set the interpolation.
- **Ease In**—Weighted more toward the next flag than the current flag.
- **Ease In Out**—Weighted more toward the current flag than the next flag.
- **Ease Out**—Weighted more toward the previous flag than the next flag.
- **Linear**—Constant from one flag to the next. (Default.)
- **Solid**—No interpolation. Transitions are a sharp line.

Source Map—Click to assign a map to a mapped gradient. The check box turns the map on or off.
The Source Map controls are available only when Mapped is the chosen gradient type.

**Noise group**

*Amount*—When nonzero, a random noise effect is applied to the gradient, based on the interaction of the gradient ramp colors (and maps, if present). The higher this value, the greater the effect. Range=0 to 1.

*Regular*—Generates plain noise. Basically the same as fractal noise with levels disabled (because Regular is not a fractal function).

*Fractal*—Generates noise using a fractal algorithm. The Levels option sets the number of iterations for the fractal noise.

*Turbulence*—Generates fractal noise with an absolute value function applied to it to make fault lines. Note that the noise amount must be greater than 0 to see any effects of turbulence.

*Size*—Sets the scale of the noise function. Smaller values give smaller chunks of noise.

*Phase*—Controls the speed of the animation of the noise function. A 3D noise function is used for the noise; the first two parameters are U and V and the third is phase.

*Levels*—Sets the number of fractal iterations or turbulence (as a continuous function).

**Noise Threshold group**

When the noise value is above the Low threshold and below the High threshold, the dynamic range is stretched to fill 0 to 1. This causes a smaller discontinuity at the threshold transition and produces less potential aliasing.

*High*—Sets the high threshold.

*Low*—Sets the low threshold.

*Smooth*—Helps make a smoother transition from the threshold value to the noise value. When Smooth is 0, no smoothing is applied. When Smooth is 1, the maximum amount of smoothing is applied.

**See also**

*Gradient Ramp Map (page 2–1652)*

**Interface**

*Name field*—Select any flag with the spinners. The selected flag turns green on the gradient bar. Use this field to rename a flag to represent its use in the gradient.

*Interpolation*—Disabled unless the Interpolation type for the Gradient Ramp map is set to Custom. The available interpolation types for flags are
similar to the corresponding ones in the Gradient Ramp map:

Note: Gradients are ordered from left to right. The “next” flag is to the right of the current flag; the “previous” flag is to the left.

**Ease In**—Weighted more toward the next flag than the current flag.

**Ease In Out**—Weighted more toward the current flag than the next flag.

**Ease Out**—Weighted more toward the previous flag than the next flag.

**Linear**—Constant from one flag to the next. (Default.)

**Solid**—No interpolation. Transitions are a sharp line.

**Texture**—Assigns a map in place of a color. When unselected, the flag turns blue to indicate a map assignment.

**Color**—Click the color swatch to change the color controlled by the selected flag.

**Position**—Shows the current position of the selected flag. Use the spinners to reposition the flag, or enter a value directly. Position is not available for the start and end flags, because these flags can’t be moved.

**Animation keys**—Animation keys are created by default for Color and Position, and the keys are active, indicated by the green triangles next to the Color and Position labels. You can turn these keys off if you don’t intend to animate the gradient.

---

**Swirl Map**

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Swirl

---

Swirl used to create the whirlpool

Swirl is a 2D procedural map that generates patterns similar to the swirls in two-flavor ice creams. Like other two-color maps, either color can be replaced with other maps, so it’s possible to swirl marble with wood, for example.

**See also**

For functionality shared with other 2D maps, see:

*Coordinates Rollout (2D)* (page 2–1625)

*Noise Rollout (2D)* (page 2–1630)

**Procedure**

To create a Swirl-mapped material:

1. Open the Material Editor, and choose an unused sample slot.

2. Close the Basic Parameters rollout, and open the Maps rollout.

3. Turn on Diffuse Color. Click its Map button to display the Material/Map Browser.

4. In the Browser list, click Swirl. The map appears in the upper-left of the Browser window. Click OK.
Swirl map is applied to the sample slot as the Material/Map browser closes.

5. In the Material Editor, under its toolbar, give the material a name to identify its use in your scene.

**Interface**

**Swirl Color Setup group**

- **Base**—The underlying layer for the swirl effect. Click the color swatch to change. Click None to assign a map in place of a color. The check box enables or disables the map.

- **Swirl**—Mixed with the Base color or map, produces the swirl effect. Click the color swatch to change this color. Click None to assign a map in place of a color.

- **Swap**—Reverses the color or map assignments for Base and Swirl.

- **Color Contrast**—Controls the contrast between Base and Swirl. At 0, the swirl is blurred. Higher values increase the contrast until all colors become black and white, even if Swirl Intensity and Swirl Amount are very high. Range=0 to 4.0; Default=0.4.

**Swirl Intensity**—Controls the intensity of the swirl color. Higher values create a more vibrant mix of colors. At 0, the swirl effect disappears. Range=-10 to 10.0; Default=2.0.

**Swirl Amount**—Controls the quantity of the Swirl color that gets mixed into the Base color. If set to 0, only the base color is used. Range=0 to 3.0; Default=1.0.

**Swirl Appearance group**

- **Twist**—Changes the number of spirals in the swirl effect. Higher values increase the number of spirals. Negative values change the direction of the twist. At 0, the colors are randomly distributed, not swirled. Range=-20.0 to 20.0; Default=1.0.

- **Constant Detail**—Changes the level of detail within a swirl. Lower values minimize the level of detail within the swirl. At 0, all detail is lost. Higher values increase detail until the swirl effect disappears. Values are in whole numbers. Range=0 to 10; Default=4.

**Swirl Location group**

- **Center Position X and Y**—Adjusts the location of the swirl's center on the object.

- **Lock**—X and Y values remain identical as you adjust them. By turning off Lock and adjusting either the X or Y position, you can “slide” the swirl effect across the object. Default=on.

**Configuration group**

- **Random Seed**—Sets a new starting point for the swirl effect. Changes the swirl pattern while maintaining other parameters. Range=0 to 65,535; No default.
Tiles Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Tiles

Tiles used for the walls of a house

Using the Tiles procedural map, you can create brick or stacked tiling of colors or material mappings. There are commonly defined architectural brick patterns available, or you can design custom patterns. With the Tiles map, you can:

- Assign many of the maps available through the Material Editor.
- Load textures and use colors in the pattern.
- Control the number of tiles in columns and rows.
- Control the size of the grout gap and its roughness.
- Apply random variance in the pattern.
- Control the stacking layout by shifting how the tiles line up.

See also

For functionality shared with other 2D maps, see:

* Coordinates Rollout (2D) (page 2–1625)
* Noise Rollout (2D) (page 2–1630)

**Procedures**

**Example: To create a brick wall:**

1. Create a wall using a Box primitive, or use an existing surface in one of your scenes.

2. Open the Material Editor (page 2–1409). Select an unused sample slot.

3. Click the Maps rollout to open it. Click the Map button for Diffuse to display the Material/Map Browser.

4. In the map list, select Tiles, then click OK. The Tiles map is now assigned to the sample slot. On the Material Editor, you see new rollouts appear for this map.

5. On the Standard Controls rollout, use Preset Type to select the type of tiles for the wall. Stack Bond is the default.

6. On the Material Editor toolbar, click Assign Material To Selection to apply the tile map to the wall. Then click Show Map In Viewport to see the applied map.

7. Open the Advanced Controls rollout. Under Tiles Setup, adjust Horizontal and Vertical Count. The default is eight rows high, with three repeats of the pattern in each row. Visually scale the size of the tiles to your scene. Also adjust Texture as well as Color and Fade Variance to fine-tune the appearance of the tiles.

8. Under Grout Setup, adjust parameters for the texture of the grout, gap spacing between tiles, and roughness of the grout. You can also create missing bricks in the map by setting % Holes to a value above 0.

9. Under Miscellaneous, you can vary the color of the tiles by using the Random Seed option.

**Example: To match the tiles on the top and side of a wall:**

1. Select a wall mapped with tile.
2. On the Modify panel, choose Editable Mesh.
3. Turn on Sub-Object > Face.
4. Select the top face of the wall.
5. Open the Material Editor. Drag the wall's tile material to an unused sample slot to duplicate the material.
6. Under Tiles Setup, adjust the horizontal and vertical count of the new material to match the side of the wall.
7. Apply the new tile material to the selected faces on the top of the wall.
8. Under Stacking Layout, align the tiles by using the Line Shift option.

**Interface**

**Standard Controls rollout**

<table>
<thead>
<tr>
<th>Pattern Setup</th>
<th>Standard Controls</th>
</tr>
</thead>
<tbody>
<tr>
<td>Preset Type</td>
<td>Running Bond</td>
</tr>
</tbody>
</table>

**Preset Type**—Lists the commonly defined architectural tile bonds, or patterns, plus a custom pattern, which you design by selecting options under the Advanced Controls and Stacking Layout rollouts. The following illustrations show some of the different bonds:

- Common Flemish
- Fine Running
- Fine Stack
- 1/2 Running
Advanced Controls rollout

Show Texture Swatches—Updates to show the texture assigned by a map for Tiles or Grout.

Tiles Setup group

Texture—Controls the display of the current texture map for the tiles. When on, the texture is used as the tile pattern instead of the color swatch. When turned off, the color of the tiles is displayed; clicking the color swatch displays the Color Selector (page 1–161).

None—Acts as a target where you drag and drop maps for the tiles. When you click this button with a map assigned, the software displays the rollout for the map. You return this button to...
None (removing the assigned map) by dragging and dropping a None map from the Map/Material Browser.

**Horiz. Count**—Controls the number of tiles in a row.

**Vert. Count**—Controls the number of tiles in a column.

**Color Variance**—Controls the color variation among the tiles.

**Fade Variance**—Controls the fading variation among the tiles.

**Grout Setup group**

**Texture**—Controls the display of the current texture map for the grout. When on, the texture is used as the grout pattern instead of the color swatch. When off, the color of the grout is displayed, and clicking the color swatch displays the Color Selector (page 1–161).

**None**—Acts as a target where you drag and drop maps for the grout. When you click this button with a map assigned, the software displays the rollout for the map. You return this button to None (removing the assigned map) by dragging and dropping a None map from the Map/Material Browser.

**Horizontal Gap**—Controls the horizontal size of the grout between the tiles. This value is locked by default to the vertical gap, so that both values change as you edit one or the other. To unlock them, click the lock icon.

**Vertical Gap**—Controls the vertical size of the grout between the tiles. This value is locked by default to the horizontal gap, so that both values change as you edit one or the other. To unlock them, click the lock icon.

**% Holes**—Sets the percentage of holes in the tiled surface caused by missing tiles. The grout shows through the holes.

**Rough**—Controls the roughness of the edges of the grout.

**Miscellaneous group**

**Random Seed**—Randomly applies patterns of color variation to the tiles. Does not require any other setting to generate completely different patterns.

**Swap Texture Entries**—Swaps the texture maps or colors between the tiles and the grout.

**Stacking Layout group**

Note: This group of controls is active only when Custom Tiles is selected in Standard Controls rollout > Pattern Setup > Preset Type.

**Line Shift**—Shifts every second row of tiles a distance of one unit.

**Random Shift**—Randomly shifts all rows of tiles a distance of one unit.

**Row and Column Editing group**

Note: This group of controls is enabled only when Custom Tiles is selected in Standard Controls rollout > Pattern Setup > Preset Type.

**Row Modify**—When on, creates a custom pattern for rows, based on the values of Per Row and Change. Default=off.

- **Per Row**—Specifies which rows to change. When Per Row equals 0, no rows change. When Per Row equals 1, every row changes. When Per Row is a value greater than 1, the change appears every N rows: a value of 2 changes every second row, a value of three changes every third row, and so on. Default=2.

- **Change**—Changes the width of tiles in the affected rows. A value of 1.0 is the default tile width. Values greater than 1.0 increase the...
width of tiles, and values less than 1.0 decrease it. Range=0.0 to 5.0. Default=1.0.

A value of 0.0 is a special case: When the Change value is 0.0, no tiles appears in that row, and the underlying material shows through.

**Column Modify**—When on, creates a custom pattern for columns, based on the values of Per Column and Change. Default=off.

- **Per Column**—Specifies which columns to change. When Per Column equals 0, no columns change. When Per Column equals 1, every column changes. When Per Column is a value greater than 1, the change appears every \( N \) columns: a value of 2 changes every second column, a value of three changes every third column and so on. Default=2.

- **Change**—Changes the height of tiles in the affected columns. A value of 1.0 is the default tile height. Values greater than 1.0 increase the height of tiles, and values less than 1.0 decrease it. Range=0.0 to 5.0. Default=1.0.

A value of 0.0 is a special case: When the Change value is 0.0, no tile appears in that column, and the underlying material shows through.

**3D**

3D maps are patterns generated procedurally in three dimensions. For example, Marble has a grain that goes through the assigned geometry. If you cut away part of an object with marble assigned as its texture, the grain in the cutaway portion matches the grain on the object’s exterior. The following 3D maps are available in 3ds Max:

- **Cellular (page 2–1664)**: Generates a cellular pattern that’s useful for a variety of visual effects, including mosaic tiling, pebbled surfaces, and ocean surfaces.

- **Dent (page 2–1667)**: Generates three-dimensional bumps over a surface.

- **Falloff (page 2–1670)**: Generates a value from white to black based on the angular falloff of the face normals on the surface of the geometry. The Falloff map provides greater flexibility when creating opacity falloff effects. Other effects include Shadow/Light, Distance Blend, and Fresnel.

- **Marble (page 2–1673)**: Simulates the grain of marble with two explicit colors and a third intermediate color.

- **Noise (page 2–1674)**: Noise is a turbulence pattern in three dimensions. Like Checker in 2D, it is based on two colors, either of which can be mapped.

- **Particle Age (page 2–1675)**: Alters the color (or map) of a particle based on the particle’s life.

- **Particle MBlur (page 2–1676)**: (MBlur is short for Motion Blur.) Alters the opacity of the leading and trailing ends of particles based on their rate of movement.

- **Perlin Marble (page 2–1677)**: An alternative, procedural marble map with a turbulence pattern.

- **Planet (page 2–1678)**: Simulates the contours of a planet as seen from space.

- **Smoke (page 2–1679)**: Generates fractal-based turbulence patterns to simulate the effects of smoke in a beam of light, or other cloudy, flowing mapping effects.

- **Speckle (page 2–1680)**: Generates a speckled surface for creating patterned surfaces that can simulate granite and similar materials.

- **Splat (page 2–1681)**: Generates a fractal pattern similar to splattered paint.
Stucco (page 2–1682): Generates a fractal pattern similar to stucco.

Waves (page 2–1683): Creates watery or wavy effects by generating a number of spherical wave centers and randomly distributing them.

Wood (page 2–1684): Creates a 3D wood grain pattern.

Coordinates Rollout (3D)

By adjusting coordinate parameters, you can move a map relative to the volume of the object to which it is applied.

Interface

Source—Chooses the coordinate system to use. There are four options:

- **Object XYZ**—Uses the object's local coordinate system.
- **World XYZ**—Uses the scene's world coordinate system.
- **Explicit Map Channel**—Activates the Map Channel field. You can choose any channel from 1 to 99.
- **Vertex Color Channel**—Assigns vertex colors as a channel. See *Editable Mesh* (page 1–996) for details on assigning vertex color.

See also *Vertex Color Map* (page 2–1693).

When one of the map channels is set, it locks the map into position on the vertices of the object so that the map "sticks" to the object as it deforms during animation.

When an object is deforming through its own local space (for example, when it is bending or twisting), the object appears to move through the map, because it passes through the XYZ coordinates of the 3D texture.

**Map Channel**—Unavailable unless the source is Explicit Map Channel. When available, you can choose any channel from 1 to 99.

**Offset**—Moves the map pattern along the specified axis.

**Tiling**—Tiles (page 3–1022) the map pattern along the specified axis and makes the pattern narrower.

**Angle**—Rotates the map pattern along the specified axis.

**Blur**—Affects the sharpness or blurriness of the map based on its distance from the view. The farther away the map is, the greater the blurring. The Blur value blurs maps in world space. Blur is primarily used to avoid aliasing (page 3–907).

**Blur Offset**—Affects the sharpness or blurriness of the map without regard to its distance from the view. Blur Offset blurs the image itself in object space. Use when you want to soften or defocus the details in a map to achieve the effect of a blurred image.
Chapter 16: Material Editor, Materials, and Maps

Cellular Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Cellular

Cellular maps create the goblet textures.

The Cellular procedural map generates a pattern that’s useful for a variety of visual effects, including mosaic tiling, pebbled surfaces, and even ocean surfaces.

Tip: The Material Editor sample slot doesn’t show the cellular effect very clearly. For a better visual aid to getting the effect you want, assign the map to geometry and render the scene.

See also

For functionality shared with other 3D maps, see the following topics:

Coordinates Rollout (3D) (page 2–1663)
Output Rollout (page 2–1621)

Procedures

Example: To create confetti:
1. Assign the Cellular map as a Diffuse map.
2. Set the parameters as follows:
   Cell Color (use RGB values after clicking color swatch): 202, 75, 171

Example: To create alien skin:
1. Assign the Cellular map as a Diffuse map.
2. Set the parameters as follows:
   Cell Color (use RGB values after clicking color swatch): 52, 107, 58
   Variation: 0.0
   Division Colors (use RGB values after clicking the color swatch):
   - First: 112, 119, 64
   - Second: 143, 137, 112
   Cell Characteristics:
   - Circular
   - Size: 7.9
   - Spread: 0.61
   - Fractal: on
   - Iterations: 2.0
   Thresholds:
   - Low: 0.17
   - Mid: 0.64

Example: To create alien skin:
1. Assign the Cellular map as a Diffuse map.
2. Set the parameters as follows:
   Cell Color (use RGB values after clicking color swatch): 202, 75, 171
   Variation: 55
   Division Colors (use RGB values after clicking the color swatch):
   - First: 127, 150, 197
   - Second: 0, 119, 163
   Cell Characteristics:
   - Circular
   - Size: 2.4
   - Spread: 0.43
   - Fractal: off
   Thresholds:
   - Low: 0.19
   - Mid: 0.65
   - High: 0.86
3. Copy the Diffuse map to the Bump map. If you increase the Bump amount, increase the Cellular bump map's Bump Smoothing value as well.

**Example: To create a tile mosaic:**

1. Assign the Cellular map as a Diffuse map.
2. Set the parameters as follows:
   - Cell Color (use RGB values after clicking the color swatch): **141, 120, 87**
   - Variation: **54**
   - Division Colors (use RGB values after clicking the color swatch):
     - First: **128, 128, 128**
     - Second: **221, 221, 221**
   - Cell Characteristics:
     - Chips
     - Size: **7.0**
     - Spread: **0.35**
     - Fractal: off
   - Thresholds:
     - Low: **0.42**
     - Mid: **0.76**
     - High: **1.0**
3. Assign a Mix map as the Bump map.
4. Click Material/Map Navigator to display the Navigator. Copy the Cellular Diffuse map by dragging it from the Navigator to the Color #2 map window of the Mix map.
5. A dialog is displayed. You are asked if this should be an instance or a copy. Select Copy and click OK.
6. Assign a Noise map to the Color #1 map window of the Mix map.
7. Set the Noise parameters as follows:
   - Noise Type: Fractal
   - Levels: **6.0**
   - Size: **9.3**
8. In the Mix Parameters rollout of the Mix map, set the Mix Amount to **0.5**.
9. Go to top level of the material. In the Maps rollout, set Bump Amount to **82**.

**Interface**

**Cell Color group**

These controls specify the color of the cells.

- **Color swatch**—Displays the Color Selector (page 1–161). Choose a color for the cells.
- **Map button**—Assigns a map to the cells, rather than a solid color.
- **Check box**—When on, enables the map. When off, disables the map (cell color reverts to the color swatch).
- **Variation**—Varies the color of the cells by randomly altering RGB values. The higher the variation, the
greater the random effect. This percentage value can range from 0 to 100. At 0, the color swatch or the map completely determines the cell color. Default=0.

Division Colors group
These controls specify the color of the divisions between cells. Cell divisions are a ramp between two colors or two maps.

Color swatches—Display the Color Selector for choosing a cell division color.
Map buttons—Assigns a map to one of the cell division colors.
Check boxes—When on, enables the associated map. When off, disables the associated map (the division color reverts to the color swatch).

Cell Characteristics group
These controls change the shape and size of the cells.

Circular / Chips—With Circular, the cells are circular. This gives a more organic, or bubbly look. With Chips, the cells have linear edges. This gives a more chipped or mosaic appearance. Default=Circular.
Size—Alters the overall scale of the map. Adjust this value to fit the map to your geometry. Default=5.0.
Spread—Alters the size of individual cells. Default=0.5.

Bump Smoothing—When you use a cellular map as a bump map (page 2–1506), you might encounter aliasing or jagginess at the boundaries of the cells. If this occurs, increase this value. Default=0.1.

Fractal—Defines the cellular pattern as a fractal, thus enabling the three following additional parameters. Default=off.

Iterations—Sets the number of times the fractal function is applied. Caution: Increasing this value increases rendering time. Default=3.0.

Adaptive—When on, the number of fractal iterations is set adaptively. That is, the number of iterations increases the closer the geometry is to the scene’s point of view, and decreases in the distance. This reduces aliasing and also saves time while rendering. Default=on.

Roughness—When you use the Cellular map as a bump map (page 2–1506), this parameter controls how rough the bumps are. When Roughness is zero, each iteration is half the strength of the previous iteration, and half the size. As Roughness increases, each iteration is closer in strength and size to the previous iteration. When Roughness is at its maximum value of 1.0, each iteration is the same size and strength as the previous. In effect, this turns off the fractalization. Roughness has no effect unless Iterations is greater than 1.0. Default=0.0.

Thresholds group
These controls affect the relative size of cells and divisions. They are expressed as normalized percentages (0 to 1) of the sizes specified by the default algorithm.

Low—Adjusts the size of the cells. Default=0.0.
Mid—Adjusts the size of the first division color, relative to the second. Default=0.5.
High—Adjusts the overall size of divisions. Default=1.0.
Dent Map

Dent map gives texture to the cup on the left; cup on the right has same pattern, but without dents.

Dent is a 3D procedural map. During scanline rendering, Dent creates a random pattern based on fractal noise. The effect of the pattern depends on the map type.

Effect of default parameters
Defaults: Iterations=2, Size=200, Strength=20

Dent was designed to be used primarily as a bump map, and its default parameters are optimized for this usage. As a bump map, Dent renders three-dimensional dents over the surface of an object. Editable parameters control the size, depth, and complexity of the denting effect.

Dent can also be used with other maps. With a diffuse color map, for example, the two colors assigned to Dent mix in random swirls over the surface of the object. Either of the colors can be replaced by other maps.

Dent bump maps
At left, default parameters produce fairly uniform dents over surface.
At right, increased Strength parameter creates a deeper and more irregular pitting effect.

Dent diffuse maps
At left, Dent as a two-color diffuse map.
At right, colors replaced with Dent and Marble maps.

See also
For functionality shared with other 3D maps, see the following topic:
Coordinates Rollout (3D) (page 2–1663)

Procedures
To make a Dent map:
1. In the Material Editor, click a sample slot to make it active.
2. Open the Maps rollout.
3. Click Bump or other map button to display the Material/Map Browser.
4. Double-click Dent in the list of map types.
   The Material Editor displays the Coordinates and Dent Parameters rollouts.
   The active sample slot updates to show the Dent effect.
To replace a color:
1. Click a color swatch labeled Color #1 or Color #2.
2. In the standard Color Selector (page 1–161), choose a replacement color.
   The color updates in the color box and sample slot.

To swap a color:
- Click Swap.
  The position of the two colors is reversed in the color boxes and sample slot.

To replace a color with a map:
1. Click a Map bar marked None next to one of the color swatches.
   The Material/Map Browser is displayed.
2. Select a map from the list.
   The sample slot updates to show the map in place of the color.

Interface

Size—Sets the relative size of dents. As the size increases, the number of dents decreases when other settings are the same. Default=200.

Decreasing Size creates the appearance of tiny dents spaced fairly evenly. The effect can resemble a "sand-covered" surface.

Increasing Size creates the appearance of distinct grooves and gouges on a surface. The effect sometimes has a "hardened lava" look.
**Dent Map**

**Iterations**—Sets the number of calculations used to create the dents. Default=2.

Dent is based on a fractal-noise equation. During rendering, a dented surface is calculated one or more times to produce the finished effect. Each calculation pass is an iteration.

As a surface is calculated, each iteration adds to the number of dents and the complexity and randomness of the final surface (dents become dented).

The Dent texture requires heavy calculation, especially at higher iterations. This can slow down rendering time considerably.

**Size**—Sets the density of the dent pattern. At low settings, the pattern is dense. As Size increases with other settings held constant, the pattern becomes increasingly sparse.

**Strength**—Sets the color strength in the dent pattern. At low settings, Color #1 (black) dominates the pattern. As Strength increases, Color #2 (white) replaces Color #1.

**Iterations**—Sets the color iterations in the dent pattern. At low settings, Color #1 is dominant. As iterations increase, Color #2 gradually increases in the pattern.

Dent is applied as a diffuse map in the following examples. Colors are default black and white.

- **Size=1000, Iterations=3**
- **Strength=5, 20 (default), and 100**

- **Size=500, Strength=20**

The three spheres have uniform settings for size and strength. Only the number of iterations varies.

**Swap**—Reverses the position of colors or maps.

**Colors**—Allows choice of two colors where appropriate for a color component (such as Diffuse). Defaults=black for Color #1 and white for Color #2.

Dent can create patterns in an object’s color as well as its surface. By using Dent as a diffuse color map, the entire surface is affected.

- **Size=500, Strength=60**
- **Iterations=2**

Two colors are mixed to produce a random pattern, governed by size, strength, and iteration settings. The default colors are black and white, but either can be replaced or swapped.

- Left sphere: Sets the color to black and white.
- Middle sphere: Replaces white with red.
- Right sphere: Swap black and red.

By adjusting Strength, Size, and Iterations parameters, you vary the Dent patterns on a diffuse color map.

- Size sets the density of the dent pattern. At low settings, the pattern is dense. As Size increases with other settings held constant, the pattern becomes increasingly sparse.
- Strength sets the color strength in the dent pattern. At low settings, Color #1 (black) dominates the pattern. As Strength increases, Color #2 (white) replaces Color #1.
- Iterations sets the color iterations in the dent pattern. At low settings, Color #1 is dominant. As iterations increase, Color #2 gradually increases in the pattern.
Chapter 16: Material Editor, Materials, and Maps

Strength=20, 50, and 100
Size=500, Iterations=2

Iterations=2, 4, and 8
Size=500, Strength=20

Maps—Replaces colors with maps in the dent pattern. The check boxes enable or disable their associated map.

You can assign maps to one or both of the Dent color slots. Any kind of map can be used, including Dent. The map overrides the assigned color, which has no effect.

In the three spheres below, the assigned colors are progressively replaced with maps. Parameters of the original Dent map are the same for all spheres.

Size=500, Strength=60, Iterations=2
Left sphere: Applies Dent as a diffuse map. Color #1 is black; Color #2 is red.
Middle sphere: Replaces black with Dent map (all defaults).
Right sphere: Replaces red with Marble map (all defaults).

Falloff Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Falloff

Falloff map creates the appearance of translucency.

The Falloff map generates a value from white to black, based on the angular falloff of the face normals on the surface of the geometry. The direction used to specify the angular falloff varies, depending on the methods you choose. However, with the default settings, the map generates white on faces whose normals point outward from the current view, and black on faces whose normals are parallel to the current view.

Falloff map provides a greater variety of opacity falloff effects than those in the Falloff settings in a standard material’s Extended Parameters rollout (page 2–1471). You assign the Falloff map as an opacity map (page 2–1503). However, you can also use Falloff for special effects, such as an iridescent look.

Note: When old files that use Falloff maps are brought into 3ds Max, the old Falloff interface is displayed, replacing the new Falloff interface.

See also

For functionality shared with other 3D maps, see Output Rollout (page 2–1621)
Procedure
To control opacity using a Falloff map:
1. Assign the Falloff map as an opacity map.
2. Render to see the effect.
3. Adjust the falloff parameters to vary the effect.

Interface
Falloff Parameters rollout

Front : Side—By default, "Front : Side" is the name of the group at the top of this rollout. Front : Side indicates Perpendicular/Parallel falloff. This name changes depending on the falloff type selected. In all cases, the name on the left refers to the top set of controls, and the name on the right to the bottom set.

The controls are as follows:
- Click the color swatches to assign colors.
- Use the numeric fields and spinners to adjust the relative strength of the colors.
- Click the buttons marked None to assign maps.
- Turn on the check boxes to activate the maps; otherwise the colors are used. These are on by default.

Falloff Type—Chooses the kind of falloff. Five options are available:
- **Perpendicular/Parallel**—Sets the angular falloff ranges between face normals that are perpendicular to the falloff direction and normals that are parallel to the falloff direction. The falloff range is based on a 90-degree change in face normal direction. (Default.)
- **Towards/Away**—Sets the angular falloff ranges between face normals that face toward (parallel to) the falloff direction and normals that face away from the falloff direction. The falloff range is based on a 180-degree change in face normal direction.
- **Fresnel**—Based on adjustments to the Index of Refraction (IOR). Results in dim reflections on surfaces facing the view, with much brighter reflections on angled faces, creating highlights like those on the sides of a glass.
- **Shadow/Light**—Adjusts between two subtextures based on how much light is falling on the object.
- **Distance Blend**—Adjusts between two subtextures based on Near Distance and Far Distance values. Uses include reducing aliasing on large terrain objects and controlling the shading in non-photorealistic environments.

Falloff Direction—Chooses the direction of falloff. Five options are available:
- **Viewing Direction (Camera Z-Axis)**—Sets the falloff direction relative to the camera (or screen). Changing object orientation doesn’t affect the falloff map. (Default.)
- **Camera X/Y Axis**—Similar to Camera Z-Axis. For example, using Camera X-Axis with the Toward/Away falloff type runs the gradient from left (Toward) to right (Away).
Chapter 16: Material Editor, Materials, and Maps

- **Object**—Uses an object whose position determines the falloff direction. Click the wide button next to Object in the Mode Specific Parameters group, and then pick an object in the scene. The falloff direction is the direction from the point being shaded toward the object’s center. Points on the side toward the object center get the Towards value, and those away from the object get the Away value.

- **Local X/Y/Z Axis**—Sets the falloff direction to one of the object’s local axes. Changing the orientation of the object changes the falloff direction.

- **World X/Y/Z Axis**—Sets the falloff direction to one of the world coordinate system axes. Changing object orientation doesn’t affect the falloff map.

When no object is chosen, the falloff direction uses the local X, Y, or Z axis of the object being shaded.

**Mode Specific Parameters group**

The first parameter applies and is available only when you set **Falloff Direction** to Object:

- **Object**—Picks object from scene and puts its name on the button.

The following are parameters for the Fresnel falloff type:

- **Override Material IOR**—Allows change to the Index of Refraction set by the material.

- **Index of Refraction**—Sets a new Index of Refraction. This option is unavailable unless Override Material IOR is turned on.

The following are parameters for the Distance Blend falloff type:

- **Near Distance**—Sets the distance at which the blend effect begins.

- **Far Distance**—Sets the distance at which the blend effect ends.

**Extrapolate**—When on, the effect continues beyond the Near and Far distances.

**Mix Curve rollout**

Using the graph on the Mix Curve rollout, you can precisely control the gradient produced by any falloff type. You see the resulting gradient in the bar below the graph.

**Move flyout**

- ![Moves a selected point in any direction, limited by the unselected points on either side.](image)

- ![Constrains movement to the horizontal.](image)

- ![Constrains movement to the vertical.](image)

**Scale Point**—Scales the selected point within the range of its gradient. On a Bezier corner point, this control is effectively the same as a vertical move. On a Bezier smooth point, you can scale the point itself or either handle. As with the move controls, scale is limited by the unselected points on either side.

**Add Point flyout**

- ![Adds a Bezier corner point anywhere on the graph line. The point makes a sharp angle when moved.](image)
Adds a Bezier smooth point anywhere on the graph line. Handles attached to the point create smooth curves when moved. On a Bezier smooth point, you can move the point or either handle.

Delete Point—Removes selected points.

Reset Curves—Returns graph to its default, a straight line between 0 and 1.

Marble Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Marble

Marble map used for the balusters

The Marble map produces a marbled surface with colored veins against a colored background. A third color is automatically generated.

Note: Another way to create marble is to use the Perlin Marble Map (page 2–1677).

See also

For functionality shared with other 3D maps, see Coordinates Rollout (3D) (page 2–1663).

Procedures

To create a Marble map:

1. Click a map button to assign a map.
2. Choose Marble in the Material/Map Browser, and then click OK.

To adjust the size of Marble veins:

• In the Marble Parameters rollout, change the Size value to change the overall scale of the vein pattern, and change Vein Width to change the width of veins relative to the overall scale. The larger the Size value, the wider the veins. The larger the Vein Width value, the more veins appear relative to the overall pattern.

To change vein color:

1. In the Marble Parameters rollout, click a color swatch to display the Color Selector (page 1–161).
2. Adjust the color.
3. Click Close to dismiss the dialog.

To use a map for a vein:

• In the Marble Parameters rollout, click a map button to assign a map to a color.

To swap the two vein colors:

• In the Marble Parameters rollout, click Swap.

To adjust mapping coordinates:

• In the Coordinates rollout, adjust Offset, Tiling, or Angle.

Interface

<table>
<thead>
<tr>
<th>Marble Parameters</th>

</thead>
<tbody>
<tr>
<td>Color #1: None</td>
</tr>
<tr>
<td>Color #2: None</td>
</tr>
</tbody>
</table>
Size—Sets the spacing between the veins.

Vein Width—Sets the width of the veins.

Swap—Switches the position of the two colors or maps.

Color # 1 and Color # 2—Displays the Color Selector (page 1–161). Select one color for the veins (color 1) and another for the background (color 2). A third color is generated from the two colors you select.

Maps—Selects the bitmaps or procedural maps (page 3–997) to appear in the veins or in the background color.

Turn on the check boxes to make the maps active.

### Noise Map

Material Editor > Maps rollout > Click a Map button. >
Material/Map Browser > Noise

Noise map used for the edges of the street

The Noise map creates random perturbation of a surface based on the interaction of two colors or materials.

See also

For functionality shared with other 3D maps, see the following topics:

---

### Procedures

To change a component color:

1. In the Noise Parameters rollout, click a color swatch to display the Color Selector (page 1–161).
2. Adjust the color.
3. Click OK to dismiss the dialog.

To use a map for a component:

- In the Noise Parameters rollout, click a map button to assign a map to a color.

To swap the two component colors:

- In the Noise Parameters rollout, click Swap.

To adjust mapping coordinates:

- In the Coordinates rollout, adjust Offset, Tiling, or Angle.

---

### Interface

Note: For the Noise map, the tiling and mirroring controls are disabled in the Texture Tiling And Output rollout.

#### Noise Parameters

- **Noise Type**—
  - Regular—(The default.) Generates plain noise. Basically the same as fractal noise with the Levels setting at 1. When the noise type is set to

---
Regular, the Levels spinner is inactive (because Regular is not a fractal function).

- **Fractal**—Generates noise using a fractal algorithm. The Levels option sets the number of iterations for the fractal noise.

- **Turbulence**—Generates fractal noise with an absolute value function applied to it to make fault lines.

**Size**—Sets the scale of the noise function, in 3ds Max units. Default=25.0.

**Noise Threshold**—When the noise value is above the Low threshold and below the High threshold, the dynamic range is stretched to fill 0 to 1. This creates a smaller discontinuity (technically, 1st order instead of 0 order) at the threshold transition and produces less potential aliasing.

- **High**—Sets the high threshold. Default=1.0.
- **Low**—Sets the low threshold. Default=0.0.

**Levels**—Determines how much fractal energy is used for the Fractal and Turbulence noise functions. You can set the exact amount of turbulence you want, and also animate the number of fractal levels. Default=3.0.

**Phase**—Controls the speed of the animation of the noise function. Use this option to animate the noise function. Default=0.0.

**Swap**—Switches the position of the two colors or maps.

**Color # 1 and Color # 2**—Display the Color Selector so you can choose one or the other of the two principal noise colors. Intermediate color values are generated from the two colors you select.

**Maps**—Select the bitmaps or procedural maps to appear in one or the other noise color.

Turn on the check boxes to make the maps active.

---

**Particle Age Map**

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Particle Age

The Particle Age map is for use with particle systems. Typically you assign the Particle Age map as a Diffuse map, or in Particle Flow with the Material Dynamic operator. It alters the color (or map) of a particle based on the particle’s life. The particles in a system begin as one color. At a specified age, they begin changing (by interpolation) to a second color, and then they change again to a third color before they die out.

Tip: This map works well with the Particle MBlur map. For example, you could assign Particle Age as a diffuse map and Particle MBlur as an Opacity map. Another way to use Particle Age is in the mask channel of a Blend material. In this case, you could set up two of the colors to white, and one to black, which would make the particles change materials over their age. In addition, you could set up one of the two materials with an effects
channel (page 3–946) and use a Glow (page 3–355) filter on it through Video Post.

**See also**

For functionality shared with other 3D maps, see Output Rollout (page 2–1621).

### Interface

| Color #1 | Sets the color of a particle at its birth. Click the button to the right of the color swatch to assign a map instead of a solid color. The check box turns the map on or off. |
| Age #1 | Sets the age where a particle starts changing from Color #1 to Color #2, expressed as a percentage of the particle’s entire life. |
| Color #2 | Sets the color of a particle in mid-life. You can also assign a map to this color. |
| Age #2 | Sets the age where a particle’s color equals Color #2, expressed as a percentage of the particle’s entire life. |
| Color #3 | Sets the color of a particle at its death. You can also assign a map to this color. |
| Age #3 | Sets the age where a particle changes to Color #3, expressed as a percentage of the particle’s entire life. |

The Particle MBlur (Motion Blur) map is for use with particle systems (page 3–990). The map alters the opacity of the leading and trailing ends of particles based on their rate of motion. The map is usually applied as an opacity map, but you can use it as a diffuse map for special effects.

The following conditions must be in effect to achieve particle motion blur:

- The Particle MBlur map must be in the same material that is assigned to the particles. For best results, it should be assigned as an opacity map.
- The particle system must support the Particle MBlur map. Particle systems that support Particle MBlur include PArray, PCloud, Super Spray, and Spray.
- In the particle system’s Particle Rotation rollout, in the Spin Axis Controls group, the Direction of Travel/MBlur option must be on.
- In this same group, the Stretch spinner must be greater than 0 to stretch the particles as a percent of their length based on the particle Speed setting.
• The correct type of particle must be used. MBlur works on all particle types except Constant, Facing, Metaparticles, and PArray Object Fragments. Also, in the Standard Particles category, MBlur does not support the Triangle and SixPoint particle types.

• The material assigned to the particle system must not be a Multi/Sub-Object material.

Interface

Color #1—A particle approaches this color as it reaches its slowest speed. By default, this color is white to provide the opaque end of the range for an opacity map.

Color #2—A particle approaches this color as it speeds up. As a default, this color is black to provide transparency in an opacity map.

Typically, you don’t need to change either of these two colors.

Sharpness—Controls the transparency, relative to the speed. If Sharpness is set to 0, the entire particle is blurry and transparent, no matter how slow it is traveling. The default works well in many cases. Default=2.0.

Perlin Marble Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Perlin Marble

The Perlin Marble map generates a marble pattern using the Perline Turbulence algorithm. This map is an alternative to Marble (page 2–1673), which is also a 3D material.

See also

For functionality shared with other 3D maps, see the following topic:

Coordinates Rollout (3D) (page 2–1663)
**Size**—Sets the size of the marble pattern. Change this to change the scale of marble, relative to the object’s geometry. Default=50.

**Levels**—Sets the number of times the turbulence algorithm is applied. Can range from 1.0 to 10.0. The higher the value, the more complicated the marble pattern. Default=8.0.

**Color 1 and Color 2 groups**

The controls in these groups are identical. They determine the two main colors of the marble.

**Color swatch**—Click to display the Color Selector (page 1–161), and change the color.

**Map**—Click to assign a map instead of a solid color. The check box turns the map on or off.

**Saturation**—Controls the saturation of the color in the map, without altering the color displayed in the color swatch. Lower values darken the color, and higher values lighten it. Range=1 to 100; Default=85 for Color 1, 70 for Color 2.

**Swap**—Click to swap Color 1 and Color 2.

---

**Planet Map**

Planets are 3D maps that use fractal math to simulate the colors on the surfaces of a planet. You can control the size of continents, percent of ocean coverage, and so on. This map is meant to be used as a diffuse map. It does not work well as a bump map.

Tip: The Material Editor’s sample slot doesn’t show the planet effect very clearly. To help get the effect you want, double-click the sample slot to get a larger sample slot, or assign the map to geometry and render the scene. Another way to preview the planet map is to use the Material Editor Options dialog (page 2–1436) to set the 3D Map Sample Scale to equal a main dimension of the object you are applying the map to. For example, if you want to use the planet map on a sphere with a radius of 20, change the map scale from 100 (the default) to 20.

**See also**

For functionality shared with other 3D maps, see the following topic:

*Coordinates Rollout (3D)* (page 2–1663)

---

**Interface**

**Continent Size**—Sets the size of the fractal noise pattern used to generate the continents. The higher the value, the larger the continents. Default=40.
**Island Factor**—Sets the size of the fractal noise pattern used to generate islands and mountains. Can range from 0 to 100. At 0, the geography is very low. Higher settings create a more rugged landscape. Default=0.5.

**Ocean %**—Sets the percentage of the planet’s surface that is covered by water. Default=60.0.

**Random Seed**—Sets the seed for pseudo-random generation of the pattern. Changing this number can change the pattern completely, even if other settings remain the same. On the other hand, a different Planet map with the same settings including the same Random Seed will appear the same.

**Water Colors group**

The colors in these three swatches are applied to the water areas of the planet surface.

**Water colors**—Click a swatch to display the Color Selector (page 1–161) and change the color. Color #1 is the “center” area of the water mass, Color #2 surrounds Color #1, and Color #3 surrounds Color #2, meeting the land.

**Land Colors group**

The colors in these five swatches are applied to the land areas of the planet surface. Their arrangement continues that of the water colors.

**Land colors**—Click a swatch to display the Color Selector (page 1–161) and change the color. Color #4 is the shoreline of the land, meeting the water; Color #5 comes next, working toward the center of the land mass. Color #8 is at the center of the land mass.

**Blend Water/Land**—When on, the boundary between water and land is blended, giving a hazy appearance. When off, the boundary between water and land is sharp.

---

**Smoke Map**

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Smoke

Smoke map used to create clouds in the sky

Smoke is a 3D map that generates amorphous, fractal-based turbulent patterns. It’s primarily designed for animated opacity mapping (page 2–1503) to simulate the effects of smoke in a beam of light, or other cloudy, flowing mapping effects.

**See also**

For functionality shared with other 3D maps, see the following topic:

*Coordinates Rollout (3D) (page 2–1663)*

**Interface**

- **Size**—Changes the scale of the smoke “clumps.” Default=40.
# Iterations—Sets the number of times the fractal function is applied. The higher the value, the more detail within the smoke, but the longer the calculation time. Default=5.

Phase—Shifts the turbulence within the smoke pattern. Animate this parameter to animate the movement of the smoke. Default=0.0.

Exponent—Makes color #2, representing the smoke, sharper and more wispy. As this value increases, the smoke “tendrils” become smaller within the pattern. Default=1.5.

Swap—Exchanges the colors.

Color #1—Represents the smokeless portion of the effect.

Color #2—Represents the smoke.

Because this map is usually used as an opacity map, you can adjust the luminance of the color values to alter the contrast of the smoke effect.

- Click a color swatch to change the color. Usually you only need to do this to adjust luminance.
- Click a map button to assign a map instead of a solid color. Turn on the check box to activate the map.

Speckle Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Speckle

Speckle map used for rocks

Speckle is a 3D map that generates a speckled surface pattern that’s useful for diffuse mapping (page 2–1498) and bump mapping (page 2–1506) to create granite-like and other patterned surfaces.

See also

For functionality shared with other 3D maps, see the following topic:

Coordinates Rollout (3D) (page 2–1663)

Interface

Size—Adjusts the size of the speckles. Use this to make the speckles match your geometry. Default=60.

Swap—Exchanges the two color components.

Color #1—Represents the color of the speckles.
Color #2—Represents the color of the background. Click one of the swatches to display the Color Selector (page 1–161) and change one of these component colors.

Maps—Click a button to assign a map that replaces one of the color components. Turning off the check box turns off the associated map (the Speckle map reverts to the associated color component).

Splat Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Splat

Splat map used for the patterns in ice cream

Splat is a 3D map that generates a fractal surface pattern that is useful as a Diffuse map (page 2–1498) for creating a pattern similar to splattered paint.

See also

For functionality shared with other 3D maps, see the following topic:

Coordinates Rollout (3D) (page 2–1663)
Stucco Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Stucco

Stucco map used for a plaster wall

Stucco is a 3D map that generates a surface pattern that is useful for bump mapping (page 2-1506) for creating the effect of a stuccoed surface.

See also

For functionality shared with other 3D maps, see the following topic:

Coordinates Rollout (3D) (page 2-1663)

Interface

Size—Adjusts the size of the indentations. Use this to make the scale of the stucco match your geometry. Default=20.

Thickness—Blurs the border between the two colors. At 0, the borders are sharp. The higher the Thickness, the more the borders are blurred and the less distinct the indentations are. When you use Stucco as a bump map, the indentations are very faint at 0.5 and disappear at values not much greater. Default=0.15.

Threshold—Determines how much of Color #1 is mixed with Color #2. At 0, only Color #2 is displayed; at 1, only Color #1 is displayed. Default=0.57.

Swap—Exchanges the two color components.

Color #1—Represents the color of the indentations.

Color #2—Represents the background stucco color.

Click one of the swatches to display the Color Selector (page 1-161) and change one of these component colors.

Tip: Because the Stucco map is meant to be used as a bump map, usually you don’t need to adjust the default colors.

Maps—Assigns a map to replace one of the color components. Turning off the check box turns off the associated map (the Stucco map reverts to the associated color component).
Waves Map

Material Editor > Maps rollout > Click a Map button. > 
Material/Map Browser > Waves

Waves map used for the pool in the fountain

Waves is a 3D map that creates watery or wavy effects. It generates a number of spherical wave centers and randomly distributes them over a sphere. You can control the number of wave sets, the amplitude, and the speed of the waves. This map works effectively as both a diffuse and bump map at the same time. It can also be useful in combination with an opacity map.

Interface

Waves is a 3D map that creates watery or wavy effects. It generates a number of spherical wave centers and randomly distributes them over a sphere. You can control the number of wave sets, the amplitude, and the speed of the waves. This map works effectively as both a diffuse and bump map at the same time. It can also be useful in combination with an opacity map.

**Interface**

- **Num Wave Sets**—Specifies how many wave sets are used in the pattern. Wave sets are groups of radially symmetrical waves that originate from randomly computed points along the surface of an imaginary sphere inside the object (a circle, in the case of 2D wave distribution). For calm water, set this to a low number. Use a high number for choppy water. Range= 1 to 50; Default=10.

  **Wave Radius**—Specifies the radius, in 3ds Max units, of the imaginary sphere (3D distribution) or circle (2D distribution) whose surface is the origin of each wave set. A large radius produces large circular wave patterns, while a small radius produces dense, smaller waves. Default=800.

  **Wave Len Max** and **Wave Len Min**—Define the interval used to randomly chose each wave center. If these two values are close together, the water appears more regular. If they’re farther apart, the water is less regular. Default Max=50.0; Default Min=5.0.

  **Amplitude**—Adjusts the strength and the depth of the waves by increasing the contrast between the two colors. Default=1.0.

  **Phase**—Shifts the wave pattern. Animate this parameter to animate the motion of the pattern.

  **Distribution 3D/2D**—3D distributes the wave centers on the surface of an imaginary sphere, affecting all sides of a 3D object. 2D distributes the wave in circles centered on the XY plane, which is more appropriate for flat water surfaces such as oceans and lakes.

  **Random Number Seed**—Provides a seed number to generate the water pattern. The pattern changes with each seed, but all other settings are maintained.

  **Swap**—Exchanges the colors.

  **Color #1 and #2**—Click the color swatches to change the colors used in the pattern. Use one color for the wave troughs and the other for the wave peaks.

You can also click the map buttons to replace one or both colors with a mapped pattern. The check box enables or disables the map.
Wood Map

Material Editor > Maps rollout > Click a Map button. > 
Material/Map Browser > Wood

Wood map used for the seat of the bench

Wood is a 3D procedural map that renders a wavy 
grain-like pattern throughout the volume of an 
object. You can control the direction, thickness, 
and complexity of the grain.

Wood is primarily intended as a diffuse color map. 
Two colors assigned to Wood mix to form the 
grain pattern. Either of the colors can be replaced 
by other maps.

Wood can also be applied to other map types. 
When used as a bump map, Wood renders the 
grain pattern as a three-dimensional engraving of 
the surface.

Wood used as a bump map

Procedures

To replace a color:
1. Click a color swatch labeled Color #1 or Color 
   #2.
2. In the standard Color Selector (page 1–161), 
   choose a replacement color.
   The color updates in the color box and sample 
   slot.

To exchange colors:
  • Click Swap.
   The position of the two colors is reversed in the 
   color boxes and sample slot.

To replace a color with a map:
1. Click a Map bar marked None next to one of the 
   color swatches. This displays the Material/Map 
   Browser.
2. Select a map from the list.
   The sample slot updates to show the map in 
   place of the color.

Interface

Coordinates rollout

Wood mapped to a box and cylinder
Tiling—Controls grain complexity or "distortion." By increasing this parameter along a given axis, the grain becomes increasingly compressed and wavy along that axis. Default=1.0 (X, Y, and Z axes).

Box A shows the default on all three axes. Boxes B and C show progressively higher Tile settings for the X axis. Increasing Tile on other axes produces similar effects.

![A: Tile, X axis=1.0 (default)<br>B: Tile, X axis=4.0<br>C: Tile, X axis=8.0<br>Grain Thickness=3](image)

Rotated Grain: By rotating the direction of the grain around an axis, you change the rendered effect. In the right cube, the Y axis is set to 90. This rotates the grain direction 90 degrees around the Y axis so that the grain is now running along the Z axis.

Other Angle Effects: Varying a single angle can create distorted grain effects (cylinder at left). Varying the three angles by a uniform amount keeps the grain running parallel through an object (cylinder at right).

![Angle=0,0,0 (defaults) and 0,90,0<br>Radial, Axial Noise=1 (defaults)<br>Grain Thickness=3](image)

![Angle=0,30,0 and 30,30,30<br>Radial, Axial Noise=1 (defaults)<br>Grain Thickness=3](image)

(See Coordinates Rollout (3D) (page 2–1663) for a description of the other parameters in this rollout.)

Angle—Controls grain direction.

Default Grain: Wood is rendered with the grain running along the X axis of the object. This is illustrated by the left cube below. The default angle is 0 for X, Y, and Z axes.

![Angle=0,0,0 (defaults) and 0,90,0<br>Radial, Axial Noise=1 (defaults)<br>Grain Thickness=3](image)

![Angle=0,30,0 and 30,30,30<br>Radial, Axial Noise=1 (defaults)<br>Grain Thickness=3](image)
Defaults: Grain Thickness=7, Radial Noise=1.0, Axial Noise=1.0

**Grain Thickness**—Sets the relative thickness of the color bands that make up the grain. Default=7.

The effect of thickness is relative to the context of the object. A grain that appears unrealistically wide on a small table might be acceptable on a large overhead beam.

Decreasing Grain Thickness creates grain lines that are closer together. The effect can resemble the fine grain of slow-growth hardwoods. At 0, grain disappears, resulting in what can look like composition board made from sawdust.

Increasing Grain Thickness creates grain lines that are farther apart. The effect can resemble tropical woods that grow continuously.

Grain thickness is shown increasing with identical noise settings.

---

**Radial Noise**—Sets the relative randomness of the pattern on a plane perpendicular to the grain, the circular ring structure (cylinder B). Default=1.0.

Noise settings let you set the randomness or "irregularity" of the grain pattern in two directions. Without any noise, rings and grain are uniform and look inorganic (upper-left cylinder). The defaults for both parameters produce moderate irregularities (upper-right cylinder).

---

**Axial Noise**—Sets the relative randomness of the pattern on a plane parallel with the grain, along the length of the grain (cylinder A). Default=1.0.

---

**Swap**—Exchanges the position of the colors.

**Colors**—Selects any two colors for the grain pattern. Defaults=brownish yellow for Color #1 and dark brown for Color #2. Either color can be replaced or swapped.
The choice of colors, along with grain pattern, is the primary way to represent different types of wood. In fairly uniform woods like yellow pine or redwood, the two colors are often near the same settings (examples B and C). Lighting also makes a difference in the apparent colors.

A: Default colors
B: Color #1=RGB 160,125,50
   Color #2=RGB 170,135,25
C: Color #1=RGB 140,90,0
   Color #2=RGB 130,80,50
   Grain Thickness=3
   Other settings at defaults

Maps—Replace colors with maps. The check boxes enable or disable their associated maps.

You can assign maps to one or both of the Wood color slots. Any kind of map can be used, including Wood. The map overrides the assigned color, which has no effect.

The left box uses defaults. The right box is the same, except that Color #1 has been replaced with a Checker map, whose colors have been changed to wood tones.

Compositor

Composers are meant specifically for compositing other colors or maps. In image processing, compositing images refers to superimposing two or more images to combine them.

The following compositor maps are supplied with the software:

Composite (page 2–1688): Composites multiple maps. Unlike Mix, Composite doesn’t have explicit controls for the amount of mixing. Instead, it bases the mix amount on the maps’ alpha channel.

Mask (page 2–1689): A mask is a map itself, used in this case to control where a second map is applied to the surface.

Mix (page 2–1689): Mix mixes two colors or two maps. You can adjust the amount of mixing using a blend level you specify. The blend level can be mapped.

RGB Multiply (page 2–1691): Combines two maps by multiplying their RGB and alpha values.
Composite Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Composite

Composite map combines stars, moon, and a glow into the sky.

The Composite map type is made up of other maps (page 3–968), which are overlaid on top of one another using the alpha channel (page 3–907). For this type of map, use overlay images that already contain an alpha channel.

The controls for a Composite map are essentially a list of the maps it combines.

Viewports can display the multiple maps in a composite map. For multiple map display, the display driver must be OpenGL (page 3–841) or Direct3D (page 3–844). The software display driver (page 3–840) does not support multiple map display.

**Procedures**

To assign a map:

1. In the Composite Parameters rollout, click a map button. The Browser is displayed.

2. Choose a map type.

**To change the number of maps to composite:**

1. In the Composite Parameters rollout, click Set Number.

2. In the subdialog, choose the number of maps you want, and then click OK.

**Warning:** If you reduce the number of maps, previously assigned maps can be lost.

**Interface**

<table>
<thead>
<tr>
<th>Set Number</th>
<th>Number of Maps: 2</th>
</tr>
</thead>
</table>

- **Map 1:** None
- **Map 2:** None

**Set Number**—Sets the number of maps to be composited.

**Map 1, Map 2, and so on**—Choose the button to add a map. Use the check boxes to enable or disable the associated map.

If there are more maps than the Material Editor can display in the Composite Parameters rollout, use the scroll bar on the right to move among them.
**Mask Map**

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Mask

Mask map applies labels to the fire extinguisher.

With the Mask map, you can view one material through another on the surface. The mask controls where a second map is applied to the surface.

By default, lighter (whiter) areas of the mask are opaque, showing the map. Darker (black) areas of the mask are transparent, showing the underlying material. You can use Invert Mask to reverse the mask’s effect.

**Interface**

These are the controls for the Mask map:

**Map**—Selects or creates the map to be viewed through the mask.

**Mask**—Selects or creates the map to use as a mask.

**Invert Mask**—Inverts the effect of the mask.

---

**Mix Map**

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Mix

Mix map blends skull and crossbones with the reflected scene.

With the Mix map, you can combine two colors or materials on a single side of the surface. You can also animate the Mix Amount parameter, and draw map morphing (page 3–974) function curves to control how the two maps are blended over time.

Viewports can display both maps in a mix map. For multiple map display, the display driver must be OpenGL (page 3–841) or Direct3D (page 3–844). The software display driver (page 3–840) does not support multiple map display.

**See also**

For functionality shared with 3D maps, see the following topic:

*Output Rollout (page 2–1621)*

**Procedures**

**To change a component color:**

1. In the Mix Parameters rollout, click one of the two color swatches to display the Color Selector (page 1–161).
2. Adjust the color.
To use a map as a component:
1. In the Mix Parameters rollout, click a map button next to one of the two color swatches.
   The Material/Map Browser is displayed.
2. Select a map type.

To exchange the two component colors:
• In the Mix Parameters rollout, click Swap.

To control the mix amount:
• In the Mix Parameters rollout, adjust the Mix Amount value.
  Mix Amount is the percentage of Color #2 used in the mix.
  You can also control the mix amount by using a map.

To control the mix amount using a map:
1. In the Mix Parameters rollout, click the map button next to Mix Amount.
   The Browser appears so you can
2. Select a map type.
   The intensity of pixels in this mixing map controls the mix. When the intensity is close to 0, one of the component colors or maps is visible; when it is close to full intensity, the other component is visible.
   Tip: Using a Noise map for the mixing map can give good effects that have a natural appearance.
   In the Mix Parameters rollout, Mix Amount is inactive while a map is assigned to this parameter. If Use Curve is off, the mixing map is used as is. If Use Curve is on, you can shift the effect of the mixing map’s gradient ramp, offsetting it one way or the other and revealing more or less of the mix components.

To control the mix amount using the mix curve:
1. In the Mixing Curve group, turn on Use Curve.

2. Change the shape of the curve by adjusting the Transition Zone values.

Interface

Swap—Exchanges the two colors or maps.

Color # 1, Color # 2—Displays the Color Selector (page 1–161) to select the two colors to be mixed.

Maps—Select or create the bitmaps or procedural maps to be mixed instead of each color.
   The check boxes enable or disable their associated maps.
   Black areas of the map reveal color #1, and white areas of the map reveal color #2. Gray values reveal intermediate mixes.

Mix Amount—Determines the proportion of the mix. 0 means only Color 1 is visible on the surface, 1 means only Color 2 is visible. You can also use a map instead of the mix amount. The two colors will mix in greater or lesser degree according to the intensity of the map.
Mixing Curve group

These parameters control how gradual or how sharp the transition between the two colors being mixed will be. (This really only has meaning when you have a map applied to Mix Amount.)

Tip: Try mixing two standard materials using a noise map as a mask for some interesting mottled effects.

Use Curve—Determines whether the Mixing Curve effects the mix.

Transition Zone—Adjusts the level of the upper and lower limits. If the two values are the same, the two materials will meet at a definite edge. Wider ranges give more gradual mixing.

RGB Multiply Map

The RGB Multiply map is typically used for bump maps (page 2–1506), where you might want to combine two maps to achieve the correct result.

This map combines two maps by multiplying their RGB values. For each pixel, the red of one map is multiplied times the red of the second map, the blue times the blue, and the green times the green.

If the maps have alpha channels, RGB Multiply can output either map’s alpha channel, or a new alpha channel created by multiplying the alpha channel values of the two maps.

You can also make one of the maps a solid color. This tints the other map.

Interface

Color #1, Color #2—Click a map button to assign one of the maps. The check box disables or enables the map. To tint one of the maps, turn off the other map and click its color swatch to choose the tint color, using the Color Selector (page 1–161).

Alpha From group

The buttons in this group let you determine how to generate alpha for the map. If neither map has an alpha channel, these options have no effect.

Map #1—Uses the first map’s alpha channel.

Map #2—Uses the second map’s alpha channel.
**Multiply Alphas**—Generates a new alpha channel by multiplying the alpha channels of the two maps.

**Color Modifier**

Color Modifier maps alter the color of pixels in a material. Each of the following maps uses a specific method to modify the color:

- **Output** (page 2–1692): Applies bitmap output functions to parametric maps, such as Checker, that don’t have these settings. These functions adjust the colors of the map.
- **RGB Tint** (page 2–1693): Tints the color of a map based on red, green, and blue values.
- **Vertex Color** (page 2–1693): Displays the effects of assigned vertex colors in the rendered scene. You assign vertex colors from the editable mesh.

**Output Map**

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Output

With Output map, you can apply output settings to procedural maps, such as Checker or Marble, that don’t have these settings.

**Interface**

Output Parameters rollout

In this rollout, you choose the map to apply the output controls to.

**Map**—Displays a modal version of the Material/Map Browser so you can choose the map type.

The check box turns the map on or off.

**Output rollout**

The controls in this rollout are the same as for maps with a built-in output option. See **Output Rollout** (page 2–1621).
RGB Tint Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > RGB Tint

RGB Tint map

RGB Tint adjusts the value of the three color channels in an image. Three color swatches represent these channels. Changing a color swatch adjusts the value of its associated color channel.

The channels are named Red, Green, and Blue for their default colors, but you can assign them any color. You are not limited to variations of red, green, and blue.

Procedures

To tint a map:

1. In the RGB Tint Parameters rollout, click the Map button marked None.
   The Material/Map Browser is displayed.
2. Select the map you want to tint
3. Click the R, G, or B color swatch.
   The Color Selector (page 1–161) is displayed.
4. Choose a new color.
   The red, green, or blue value of each pixel in the underlying map changes accordingly.

To change the saturation of one color in an image:

1. Click the R, G, or B color swatch.
2. On the Color Selector, increase or decrease Value to vary the color from light to dark.

To replace one color with another:

1. Click the R, G, or B color swatch.
2. On the Color Selector, increase or decrease Hue to change the color.

Interface

R/G/B—The red, green, and blue (page 3–1001) color swatches display the Color Selector (page 1–161) to adjust the value of the specific channel.

Map—Displays the Material/Map Browser to select the map to be tinted.

The check box turns the effect of the map on or off.

Vertex Color Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Vertex Color

Mapping vertex colors

Vertex Color map makes any vertex coloring applied to an object available for rendering. You
can assign vertex colors using the *VertexPaint Modifier* (page 1–936), the *Assign Vertex Colors* utility (page 2–1734), or the vertex controls for an editable mesh (page 1–1003), editable patch (page 1–975), or editable poly (page 1–1029).

While vertex color assignment is primarily used for special applications, such as game engines or radiosity renderers, you can also use it to create colorful, gradient surface effects. You can also use it in design visualization: Use the *VertexPaint Modifier* (page 1–936) to paint your landscape different colors to represent grass, shrubbery, parking areas, etc., and then use Vertex Color map to use the vertex coloring in your rendered images. Incidentally, when you use the *Terrain object’s* (page 1–347) Color By Elevation function, the software assigns a material that uses a Vertex Color map as the diffuse component.

**Tip:** To view vertex colors in a viewport, right-click the object, choose Properties from the quad menu, and then turn on Vertex Channel Display in the Display Properties group.

**Procedure**

**To use the vertex color map:**

1. Assign vertex colors to an object.
2. Assign a material to the object, then assign a Vertex Color map to the material’s diffuse component.
3. Optionally, if manipulating the map channels with the *Channel Info utility* (page 2–1738), choose a map channel or sub-channel to render.
4. Render the scene.

**Interface**

These parameters let you define which map channel or sub-channel is to be rendered. One application is to support usage of the Vertex Color map in conjunction with the *Channel Info utility* (page 2–1738).

The settings are interlinked; changing one parameter will change the other two, as appropriate.

**Map Channel**—Lets you specify which map channel to use. Range=0 to 99. Default=0.

Notes regarding this setting:

- If you set Map Channel to a channel that doesn’t contain any vertex coloring data, attempting to render will generate a Missing Map Coordinates error message. To resolve this, apply vertex coloring to that channel.
- By default, the vertex coloring in map channel 1 is a color gradient derived from the UVW texture coordinates by converting UVW values to RGB values. Thus, at UV=0,0 (the lower-left corner of the map), the coloring is black; at UV=1,0, the coloring is red, and at UV=1,1 (the upper-right corner), the coloring is yellow (red + green=yellow). You can change these colors with a tool such as *VertexPaint modifier* (page 1–936).
- Map Channel cannot be set to a negative value, thus the map doesn’t support rendering of the vertex illumination (-1) or vertex alpha (-2) channel.
Reflection and Refraction Maps

Sub Channel—Lets you can specify that the map will use either the Red, Green, or Blue sub-channel of the specified map channel, or all sub-channels.

Channel Name—After assigning the material with the Vertex Color map to an object with named map or vertex-color channels (see Channel Info Utility (page 2–1738)), you can click Update, and then, from this drop-down list, choose a named map channel from the object.

Update—Refreshes the contents of the Channel Name drop-down list. Use Update after applying the material to an object, or after adding channels to the object.

Note: There could be conflicts if one material with a Vertex Color map is assigned to objects with different named Map Channels, where one channel’s name may be displayed in preference to another’s.

Flat Mirror Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Flat Mirror

Flat mirror map reflects the ice-cream shop's interior.

The Flat Mirror (page 3–942) map produces a material that reflects surrounding objects when it is applied to a collection of coplanar faces. You assign it as a material’s reflection map (page 2–1508).

Reflect/Refract maps don’t work well for flat surfaces because each face reflects part of the environment based on where its surface normal points. Using this technique, a large flat face can reflect only a small part of the environment. Flat Mirror automatically generates a reflection that encompasses a larger part of the environment, to better simulate a mirror-like surface.

Rules for Using Flat Mirror

Flat Mirror cannot generate reflections correctly unless you observe these rules:

- Assign Flat Mirror to selected faces only.

There are two ways to do this. You can make the Flat Mirror material a sub-material of a Multi/Sub-Object (page 2–1594) material, or you can use the Apply To Faces With 1D control.
If you assign Flat Mirror to multiple faces, the faces must lie in a plane.

Non-coplanar faces in the same object cannot have the same Flat Mirror material. In other words, if you want two different planes of an object to have flat reflections, you must use a Multi/Sub-Object material. Assign Flat Mirror to two different sub-materials, and assign different material IDs to the two different planar faces.

The material ID used by the Flat Mirror sub-material must be unique to the coplanar faces in the object.

If you assign Flat Mirror using Apply to Faces with ID, faces without that ID display the nonreflective components (diffuse color, and so on) of the material with the Flat Mirror reflection map.

Procedures

To assign a flat mirror to one face of an object:
1. In the Material Editor, create a standard material.
2. Assign a Flat Mirror map as the material’s reflection map.
3. In the Flat Mirror Parameters rollout > Render group, turn on Apply To Faces With ID, and choose the material ID number the mirrored face will have.
4. Follow the next set of steps for assigning the material to the object.

To assign a flat mirror using a Multi/Sub-Object material:
1. In the Material Editor, create a Multi/Sub-Object material.
2. Click one of the unused material buttons in the Multi/Sub-Object material’s parameters.
3. In the new Standard sub-material, open the Maps rollout and click the map button for Reflection.
4. In the Material/Map Browser, choose Flat Mirror, and then click OK.

Flat Mirror controls are similar to those for automatic reflection and refraction.
5. Apply Edit Mesh to the object, and then in the stack view area of the modifier stack display (page 3–760), choose Face as the sub-object level.
6. Select a single face or multiple faces that lie in a single plane.
7. Assign the faces the material ID corresponding to the Flat Mirror sub-material slot.

Using a Multi/Sub-Object material, you can apply Flat Mirror to different faces of the object that are not coplanar. However, faces that are not coplanar must use different sub-material slots, otherwise the software doesn’t correctly generate the flat mirror reflections.
Blur group

Apply Blur—Turns on filtering to blur the maps. Antialiasing is also applied to the Distortion effect, if any, when Apply Blur is turned on.

Blur—Affects the sharpness or blurriness of the generated map based on its distance from the object. The farther away the map is, the greater the blurring. Blur is primarily used to avoid aliasing (page 3–907). It's a good idea to use a small amount of blurring for all maps in order to avoid the scintillation or aliasing that can occur when pixel details are reduced off in the distance. Default=1.0.

Render group

First Frame Only—The renderer creates the automatic flat mirror only on the first frame.

Every Nth Frame—The renderer creates the automatic flat mirror based on the frame rate (page 3–944) set by the spinner.

Use Environment Map—When off, environment maps are ignored by the mirror during rendering. It's useful to turn this off when you have mirrors in the scene and you're rotoscoping against a flat screen environment map. A screen environment map does not exist in 3D space the way the other environment-map types do, and will not render properly. Default=on.

Apply to Faces with ID—Specifies the material ID number where you want the mirror assigned. You can assign a flat-mirror material to an object without having to make it a component of a Multi/Sub-Object (page 2–1594) material. The restriction is that the other faces on the object must be able to use the nonmirrored properties of the same material (its diffuse color, and so on). If the other faces need completely different material characteristics, you need to use a Multi/Sub-Object material.

For example, if you have an object, such as a box, with unique material IDs for each side, you can use Apply To Faces With ID to specify the side of the box that will show the mirror reflection. The remaining sides of the box will have the same material characteristics, but without the reflection.

Distortion group

To simulate irregular surfaces, you can distort the flat-mirror reflections. Distortion can be based on a bump map or on noise controls built into Flat Mirror material.

None—No distortion.

Use Bump Map—Distorts the reflection using the material's bump map.
A flat mirror surface that has a Bump map will appear bumpy, but its reflection won’t be distorted by the bumps unless you use this option.

**Use Built-In Noise**—Distorts the reflection using the settings in the Noise group.

**Distortion Amount**—Adjusts the amount of distortion to the reflected image. This is the only value that affects the amount of distortion. No matter how high the Bump map’s Amount spinner is set, or how extreme the Noise settings, if this Distortion Amount is set to 0, no distortion appears in the reflection itself. This control is inactive when None is chosen.

**Noise group**

The controls in this group are inactive unless you choose Use Built-In Noise as the active distortion type.

**Regular**—Generates plain noise. Basically the same as Fractal noise with the Levels setting at 1. When the noise type is set to Regular, the Levels spinner is inactive (because Regular is not a fractal function).

**Fractal**—Generates noise using a fractal algorithm. The Levels setting determines the number of iterations for the fractal noise.

**Turbulence**—Generates fractal noise with an absolute value function applied to it to make fault lines.

**Phase**—Controls the speed of the animation of the noise function. A 3D noise function is used for the noise, so that the first two parameters are U and V and the third is phase.

You can animate this parameter to animate the noise effect.

**Size**—Sets the scale of the noise function. Smaller values give smaller chunks of noise.

**Levels**—Sets the number of fractal iterations or turbulence (as a continuous function).

---

**Raytrace Map**

Raytrace map creates highly reflective and refractive surfaces.

Raytrace map provides fully raytraced reflections and refractions. The reflections and refractions it generates are more accurate than those produced by the reflect/refract map (page 2–1699). Rendering raytraced objects is slower than using Reflect/Refract. On the other hand, Raytrace is optimized for rendering 3ds Max scenes, and you can further optimize it for your scene by excluding specific objects or effects from raytracing.

You can also use the **Raytrace material** (page 2–1512), which uses the same raytracer to generate accurate, raytraced reflections and refractions. The differences between Raytrace map and Raytrace material are:

- You use Raytrace map as you do other maps. This means you can add raytraced reflections or refractions to any kind of material.
- You can assign Raytrace map to material components other than reflect or refract,
although these are the main ways to use this map.

- Raytrace map has more extensive attenuation controls than Raytrace material.
- Raytrace map often renders more quickly than Raytrace material.

Raytrace Map and Raytrace material have the same name because they use the same raytracer and share global parameters.

Note: Raytracing does not always work correctly in orthogonal viewports (left, front, and so on). It works correctly in perspective viewports and camera viewports.

Interface

The interface for the Raytrace map is contained in four rollouts:

- Raytracer Parameters Rollout (page 2–1704)
- Raytrace: Attenuation Rollout (page 2–1706)
- Raytrace: Basic Material Extensions Rollout (page 2–1707)
- Raytrace: Refractive Material Extensions Rollout (page 2–1708)

The Reflect/Refract map produces a reflective or refractive surface. To create reflection, assign this map type as the material’s reflection map (page 2–1508). To create refraction, assign it as the refraction map (page 2–1509).

Note: A reflective object can reflect another reflective object. In real life, this creates a virtually infinite number of interreflections. In 3ds Max, you can set the number of interreflections in a range from 1 to 10. You set this Rendering Iterations parameter in the Render Scene dialog (page 3–12).

This map works by using six renderings in the form of a cube that surrounds the objects. Reflect/Refract views the cubic maps from the perspective of the pivot point (page 3–995) of the object, mapping them onto the object’s surface as a spherical reflection map.

You can choose to generate the cubic maps automatically, or to load previously created maps.

A reflective surface reflects the surrounding maps like a mirror. A refractive surface creates
the illusion that the surrounding maps are seen through the surface.

Note: Reflect/Refract is meant to be used with curved or irregularly shaped objects. For mirror-like flat surfaces that you want to reflect the environment accurately, use Flat Mirror (page 2–1695) material. For more accurate refractions, especially for an object in a refractive medium (such as a pencil in a glass of water), use Thin Wall Refraction material (page 2–1703).

**Automatic Cubic Maps**

When you choose automatic cubic maps, 3ds Max generates the maps based on the perspective of the mapped object’s pivot point. Automatic maps are based on the geometry of the scene.

The advantage to using automatic maps is that the six views are automatically generated at rendering time and can be easily updated for each frame of an animation. The disadvantage is that regenerating the maps increases rendering time. In addition, the maps exist only for the rendering and can’t be edited or otherwise manipulated.

In the Material Editor, automatic reflections or refractions reflect or refract the background of the sample slot.

**Assigning Cubic Maps**

When you choose to load cubic maps from files, you use the controls in the From File group. The advantage to using From File is that the bitmap files already exist and take less rendering time. In addition, you can edit the bitmap images.

The disadvantage is that it’s more difficult to use bitmaps to render an animation because first you need to create the animated bitmaps.

**Important:** Assigned cubic maps must be square, and each of the six maps must be the same size.

You can automatically load six bitmaps at once if the six bitmaps have valid cubic-map file names.

The first part of all six file names must be the same, and the last part is an underscore followed by a two-letter abbreviation of the map position, as shown in the following table:

<table>
<thead>
<tr>
<th>Last Part of Cubic Map File Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>_UP</td>
<td>Up</td>
</tr>
<tr>
<td>_DN</td>
<td>Down</td>
</tr>
<tr>
<td>_LF</td>
<td>Left</td>
</tr>
<tr>
<td>_RT</td>
<td>Right</td>
</tr>
<tr>
<td>_FR</td>
<td>Front</td>
</tr>
<tr>
<td>_BK</td>
<td>Back</td>
</tr>
</tbody>
</table>

For example, if you have six bitmaps on disk, labeled view_up.bmp, view_fr.bmp, view_lf.bmp, and so on, when you click one of the file buttons and choose the bitmap for that position, all six views are loaded.

If you select a bitmap whose name doesn’t follow the convention, or you select one with a valid cubic-map name but assign it to the wrong button, only that bitmap will be loaded.

Since all assigned bitmaps must be the same size, when you assign a new bitmap to one of the windows, the sample slot doesn’t update automatically. This avoids generating an error message each time you assign a bitmap. Once you’ve assigned all six maps and are sure they are square and the same size, click the Reload button to update all of the maps and redisplay the sample slot.

You can also use the Reload button to see your changes after you’ve edited one of the cubic maps by using a paint program.

**Rendering Cubic Maps**

The controls in the Render Cubic Map Files group let you generate the maps automatically and save them to disk. Use the To File button to specify the
folder and file name of the Up (_UP) bitmaps. Click Pick Object and Render Maps, and then click the object to map. The software creates the files and also assigns them to the six From File map buttons.

Rendering cubic maps has the same effect as automatic with the advantage that map rendering doesn’t have to take place at scene rendering time. The disadvantage is that you can’t create an automatically animated reflections or refractions this way.

Using Animated Cubic Maps

The cubic maps can be animations instead of bitmaps. Be sure that each is square and all have the same resolution. If you want the animated reflections to match animated changes in the scene, use automatic maps and set them to render every Nth frame.

Procedure

To generate and save cubic maps:

1. In the Source group, choose From File.
2. In the Render Cubic Map Files group, click the button next to To File.
   A file dialog is displayed. Type a name for one of the six cubic bitmap files. You’re specifying the name of the Up bitmap. There are two ways to do this:
   • Specify the entire file name; for example, myview_up.bmp.
   • Specify the file prefix and extension only; for example, myview.bmp.
   Important: You must specify at least a prefix and extension. The "_UP" is added automatically.
3. Click Pick Object and Render Maps.
4. Click an object in your scene where you want the six views rendered. This is usually the same object where you will apply the material, but it doesn’t have to be.

After selecting the object, a rendered frame window is displayed while the six views are rendered and saved to disk. Their file names then appear in the six buttons in the From File group. Each of the six file names is identical, except for a two-letter suffix indicating the direction of the rendered view.

Interface

Source—Chooses the source of the six cubic maps.
Automatic—Automatically generates by looking out in six directions from the pivot of the object with the material, then mapped onto the surface during rendering. When on, the options in the Automatic group are active, letting you choose whether the maps will be generated only once, or regenerated at specified frames in the animation.
From File—When on, you can specify the bitmaps to use.

When From File is active, the controls in the Render Cubic Map Files group are also available. You can generate the six cubic reflection maps automatically and save them to files, where you can load them with the From Files controls.

Size—Sets the size of the Reflect/Refract maps. The default value of 100 produces distinct images. Lower values lose progressively more detail.

Use Environment Map—When off, environment maps are ignored by Reflect/Refract map during rendering. It’s useful to turn this off when you have mirrors in the scene and you’re rotoscoping against a flat screen environment map. A screen environment map does not exist in 3D space the way the other environment-map types do, and will not render properly.

Blur group

Apply—Turns on filtering to blur the maps.

Blur Offset—Affects the sharpness or blurriness of the map without regard to its distance from the object. Use Blur Offset when you want to soften or defocus the details in a map to achieve the effect of a blurred image.

Blur—Affects the sharpness or blurriness of the generated map based on its distance from the object. The farther away the map is, the greater the blurring. Blur is primarily used to avoid aliasing (page 3-907). It’s a good idea to use a small amount of blurring for all maps in order to avoid the scintillation or aliasing that can occur when pixel details are reduced off in the distance. Default=1.

Atmosphere Ranges group

If your scene contains environmental Fog (page 3–282), the cubic maps must have near and far range settings to properly render the fog from the point of view of the object assigned the material. The Near and Far spinners in this group let you specify a fog range relative to the object.

Near—Sets the near range for fog.

Far—Sets the far range for fog.

Get From Camera—Uses the Near and Far atmosphere range settings of a camera in the scene. Click this option, and then select the camera. These values aren’t dynamically linked to the camera object. They are simply copied from the camera’s range values at the time you click the camera. If the camera’s range values later change, the map’s Near and Far values remain the same.

Automatic group

This controls are active only when Automatic is the active source for the Reflect/Refract maps.

First Frame Only—Tells the renderer to create automatic maps only on the first frame.

Every Nth Frame—Tells the renderer to create animated auto maps based on the frame rate (page 3–944) set by the spinner.

From File group

These controls are active when From File is active as the Reflect/Refract source. Here you assign the six bitmaps to be used as the cubic maps.

Up/Down/Left/Right/Front/Back—Assigns one of the six cubic maps. If the map is one of a set of six with the correct file name, all six are loaded.

If the map doesn’t follow file naming conventions, or you assign it to a button of a different position (_UP to Front, for example), only that map is assigned. You must assign the others manually.

Reload—Reloads the assigned maps and updates the sample slot.
You can edit one or more of the cubic maps using a paint program, then click Reload to update the material and the scene.

Render Cubic Map Files group

**To File**—Choose a file name for the Up map (_UP).

**Pick Object and Render Maps**—Active when you choose a file. Click to turn on, then select the mapped object to render the six cubic maps. Assign the cubic maps to the six From File buttons.

### Thin Wall Refraction Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Thin Wall Refraction

**Thin wall refraction**

Thin Wall Refraction simulates the "jog," or offset effect, you find when you view part of an image through a plate of glass. For objects that model glass, such as a Box in the shape of a window pane, this map is faster, uses less memory, and provides a much better visual effect than the Reflect/Refract map.

**Tip:** At 100% refraction and opacity, you can see no diffuse color or mapping, and there is not much illusion of a refractive material. The effect is invisible. In the Maps rollout of the parent material, set Refraction Amount to 50%, and in the Basic Parameters rollout, set Opacity to a value greater than 0.

### Procedure

**To assign the Thin Wall Refraction map to a material:**

1. Click the Map button for Refraction in the material’s Maps rollout.
2. In the Material/Map Browser, choose Thin Wall Refraction.
3. Adjust the map’s parameters.
4. In the parent material, set the Refraction Map Amount to 50%.
5. Assign the material to an object.

### Interface

**Blur group**

These controls are for antialiasing.

**Apply Blur**—Turns on filtering to blur the maps.

**Blur**—Affects the sharpness or blurriness of the generated map based on its distance from the object. The farther away the map is, the greater the blurring. Blur is primarily used to avoid aliasing (page 3–907). It’s a good idea to use a small amount of blurring for all maps in order to avoid the scintillation or aliasing that can occur when pixel details are reduced off in the distance. Default=1.0.
Render group
These controls affect how the refraction should behave in animations.

First Frame Only—Tells the renderer to create the refracted image only on the first frame.
This is the fastest option. You can use it if the camera and refractive object don’t move.

Every Nth Frame—Tells the renderer to regenerate the refracted image based on the frame rate (page 3–944) set by the spinner.
Every single frame provides the most accurate result, but takes longest to render.

Use Environment Map—When off, environment maps are ignored by the refraction during rendering. It’s useful to turn it off when you have refractions in the scene and you’re rotoscoping against a flat screen environment map. A screen environment map does not exist in 3D space the way the other environment map types do, and will not render properly. Default=on.

Refraction group
These controls are specific to the Thin Wall Refraction effect:

Thickness Offset—Affects the size of the refractive offset, or jog effect. At 0, there’s no offset, and the object can appear invisible in the rendered scene. At 10.0, the offset is at its greatest. Range from 0.0 to 10.0; Default=0.5.
Note: The IOR (index of refraction) spinner in the parent material’s Extended Parameters rollout also affects the offset effect.

Bump Map Effect—Affects the magnitude of refraction due to the presence of a bump map. This parameter multiplies the current bump map Amount in the parent material. Reduce this value to reduce the effect of the secondary refraction; increase this value to increase the effect. If there is no bump map assigned, this value has no effect. Default=1.0.
If there is unevenness in the surface of the glass, there is a secondary refraction. Thin Wall Refraction generates this secondary refraction if the material also has a bump map present. The algorithm guesses at the scaling of the secondary refraction, and can create too large an effect. If this happens, scale the effect down by reducing this value to less than one.

Raytrace Map Rollouts

Raytracer Parameters Rollout
Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Raytrace > Raytracer Parameters rollout

This rollout contains the main controls for the Raytrace map (page 2–1698).

Interface
Local Options group

Enable Raytracing—Turns the raytracer on or off. Default=on.

Even with raytracing off, Raytrace material and Raytrace map still reflect and refract the environment, including both the environment map for the scene, and the environment map assigned to the Raytrace material.

Raytrace Atmospherics—Turns the raytracing of atmospheric effects on or off. Atmospheric effects include fire, fog, volume light, and so on. Default=on.

Enable Self Reflect/Refract—Turns self reflection/refraction on or off. Default=on.

Can an object reflect itself? For example, a teapot’s body reflects the teapot’s handle, but a sphere will never reflect itself. If you don’t need this effect, you can improve render time by turning off this toggle.

Tip: If you have a transparent object such as glass, and have self reflect/refract turned on, you don’t have to make the object 2-sided (page 3–901). The raytracer sees back faces when exiting refractive objects.

Reflect/Refract Material IDs—When on, the material reflects effects assigned to material IDs in the renderer’s G-buffer (page 3–946) on or off. Default=on.

By default, Raytrace material and Raytrace map reflect effects assigned to a material’s ID, so that G-buffer effects are not lost. For example, if a raytraced object reflects a lamp made to glow with the Video Post Glow filter (Lens Effects Glow), the reflection glows as well.

Trace Mode group

With options in this group, you select whether to cast reflected or refracted rays.

Auto Detect—If assigned to the material’s Reflection component, the raytracer will reflect. If assigned to Refraction, it will refract. If you assign Raytrace to any other component, you have to manually specify whether you want reflected rays or refracted rays. (Default.)

Note: Auto Detect might fail when you use Raytrace map in a material with a strong bump map. When you use a strong bump map, choose one of the explicit options.

Reflection—Casts reflected rays off the object’s surface.

Refraction—Casts refracted rays into or through the object’s surface.

Note: Raytrace reflects and transmits the IDs in material effects channel (page 2–1443) (G-buffer (page 3–946)), so it can create glowing reflections, and so on.

Local Exclude—Click to display the local Include/Exclude dialog (page 2–1531).

An object that is excluded locally is excluded from this map only.

Tip: Using exclusion lists is one of the best and simplest ways to speed up the raytracer.

Background group

Use Environment Settings—Respects the environment settings of the current scene.

Color Swatch—Overrides the environment settings with the specified color.

Map Button—Overrides the environment settings with the specified map.

By specifying an environment map, you override the environment map for the scene as a whole. Both reflection and refraction use the scene-wide environment map unless you use this option to specify another map. With this control, you can use different environment maps on a per-object
basis, or provide an environment to specified objects when the scene as a whole has none.

Raytraced Reflection and Refraction Antialiaser group

Controls in this group let you override the global antialiasing settings for raytraced maps and materials. They are unavailable if antialiasing is turned off globally. To turn on antialiasing globally, choose Rendering > Raytrace Globals to display the Global Raytracer Settings dialog (page 2–1528).

On—When on, uses antialiasing. Default=unavailable unless global antialiasing is turned on; on if global antialiasing is turned on.

Drop-down list—Chooses which antialiasing settings to use. There are three alternatives:

- **Use Global Antialiasing Settings**—(The default.) Uses the global antialiasing settings.
- **Fast Adaptive Antialiaser**—Uses the Fast Adaptive antialiaser, regardless of the global setting.
- **Multiresolution Adaptive Antialiaser**—Uses the Multiresolution Adaptive antialiaser, regardless of the global setting.

...—The button with the ellipsis to the right of the drop-down list displays another dialog to let you set antialiasing controls locally. The dialog displayed depends on which alternative you chose in the drop-down list, as follows:

- **Use Global Antialiasing Settings**—Clicking ... displays the Global Raytracer Settings dialog (page 2–1528).
- **Fast Adaptive Antialiaser**—Clicking ... displays the Fast Adaptive Antialiaser dialog (page 2–1533).
- **Multiresolution Adaptive Antialiaser**—Clicking ... displays the Multiresolution Adaptive Antialiaser dialog (page 2–1534).

When you change settings for an antialiaser locally, you don’t affect the global settings for that antialiaser.

Raytrace: Attenuation Rollout

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Raytrace > Attenuation Rollout

When a ray is reflected off an object or refracted through it, by default the ray travels through space forever, with no attenuation (page 3–912). The controls in this rollout allow you to attenuate rays, so their strength diminishes over distance.

In the Raytrace map (page 2–1698), attenuation is implemented by a clipping algorithm. Objects beyond the maximum attenuation range aren’t even considered by the raytracer. Because of this, assigning attenuation can speed up rendering time.

Interface

Falloff Type—Choose the falloff to use.

- **Off**—Turns off attenuation. (Default.)
- **Linear**—Sets linear attenuation. Linear attenuation is calculated between the start and end range values.
- **Inverse Square**—Sets inverse square attenuation. Inverse square attenuation is calculated beginning at the start range, and doesn’t use the end range. Inverse square is the actual attenuation rate for light in the real world. However, it doesn’t always give the effect you want in a rendered scene.

- **Exponential**—Sets exponential attenuation. Exponential attenuation is calculated between the start and end range values. You also specify the exponent to use.

- **Custom Falloff**—Specifies a custom curve to use for attenuation (falloff).

  **Start Range**—The distance in world units where attenuation begins. Default=0.0.

  **End Range**—Sets the distance in world units where the ray is fully attenuated. Default=100.0.

  This is not used by inverse square attenuation.

  **Exponent**—Sets the exponent used in exponential falloff. Default=2.0.

  This is used only by exponential attenuation.

**Color**

These controls affect the behavior of light rays as they attenuate out. By default, as a ray fades out, it is rendered as the background color.

You can set a custom color instead.

- **Background**—As the ray attenuates out, returns the background (either the scene’s background or the background specified locally in the Raytracer Parameters rollout) rather than the actual color of what the reflected/refracted ray sees. (Default.)

- **Specify**—Sets the color that is returned by the ray as it attenuates out.

  If you choose not to use the background color, black or gray usually work best as the attenuation color.

**Custom Falloff group**

These controls are inactive unless the Falloff Type is set to Custom Falloff.

- **Custom Falloff**—Uses the falloff curve to determine the falloff between the start and the end ranges.

  These are the controls for custom attenuation. The custom attenuation curve is at the left. The gray scale bar below the curve shows how the curve will affect the falloff as light rays diminish in strength.

  **Near**—Sets the strength of the reflected/refracted ray at the start range distance. This is a normalized percentage that can range from 0.0 to 1.0. Default=1.0.

  **Control 1**—Controls the shape of the curve near the curve start. Default=0.667.

  **Control 2**—Controls the shape of the curve near the curve end. Default=0.333.

  **Far**—Sets the strength of the reflected/refracted ray at the end range distance. This is a normalized percentage that can range from 0.0 to 1.0. Default=0.0.

**Raytrace: Basic Material Extensions Rollout**

This rollout contains controls for fine-tuning the effect of the Raytrace map (page 2–1698).

**Interface**

<table>
<thead>
<tr>
<th>Basic Material Extensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reflectivity/Opacity:</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Specular Highlight:</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Bump Map Effect:</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
Reflectivity/Opacity—These controls affect the intensity of the raytracer’s results.

- **Spinner**—Controls the amount of raytracing used by the material it is assigned to. Analogous to the Output Amount parameter in the Output rollout of the Bitmap map type (page 2–1631).

- **Map button**—Assigns a map that controls the amount of raytracing. You can vary the amount of raytracing used over the surface of the object.

- **Check box**—Enables or disables the map.

Tint—With these controls, you can tint the colors returned by the raytracer. Tinting applies only to reflected colors; it doesn’t affect the material’s diffuse component.

- **Check box**—Turns basic tinting on or off. Default=off.

- **Color swatch**—Assigns a tint color for reflections. Default=white.

- **Amount spinner**—Sets the amount of tinting used. Default=1.0.

- **Map button**—Assigns a map to use for tinting. You can vary the tint colors over the surface of the object.

- **Check box**—Enables or disables the map.

**Bump Map Effect**—Controls the effect of a bump map on rays that the surface reflects and refracts. For example, you might want to make a glass object highly bumpy, but reduce the bump effect on refracted parts of the scene.

Bump Map Effect equals 1.0.
The refraction of tiles behind the glass is distorted by the bump map.

Bump Map Effect equals 0.0.
The refraction of tiles behind the glass is not distorted.

Bump Map Effect is active only when raytracing is enabled.

---

**Raytrace: Refractive Material Extensions Rollout**

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Raytrace > Refractive Material Extensions Rollout

With the controls in this rollout, you can fine-tune the effect of the Raytrace map (page 2–1698) on a material’s refraction component.
Interface

<table>
<thead>
<tr>
<th>Refractive Material Extensions:</th>
</tr>
</thead>
</table>

**Internal Density Effects:**

- **Color**—With these controls, you can specify a transmission color based on thickness. The density color gives the appearance of color within the object itself, like tinted glass.
  - **Enable**—Turns color density on or off.
  - **Color swatch**—Displays a Color Selector (page 1–161). Choose the transmission color.
  - **Amount**—Controls the amount of density color. Reducing this value reduces the density color effect. Range=0 to 1.0. Default=1.0.
  - **Color Map**—Assigns a map to the density color component. Use the check box to enable or disable the map.
  - **Start and End**—A thin piece of tinted glass is mainly clear, while a thick piece of the same glass has more color. Start and End Distance, expressed in world units, adjust the fog effect based on the object’s dimensions. Start is the position in the object where the density color begins to appear (default=0.0). End is the position in the object where the density color reaches its full Amount value. To have a lighter effect, increase the End value. To have a heavier effect, reduce the End value.

**Fog**—Density fog is also a thickness-based effect. It fills the object with a fog that is both opaque and self illuminated. The effect is like smoke trapped in a glass, or wax at the tip of a candle. Colored fog in tubular objects can resemble neon tubes.
  - **Enable**—Turns fog on or off.
  - **Color swatch**—Displays a Color Selector (page 1–161) for choosing the fog color.
  - **Amount**—Controls the amount of density fog. Reducing this value reduces the density fog effect and makes the fog translucent. Range=0 to 1.0. Default=1.0.
  - **Color Map**—Assigns a map to the fog component. Use the check box to enable or disable the map.
  - **Start and End**—Start and End Distance controls, expressed in world units, adjust the fog effect based on the object’s dimensions. Start is the position in the object where the density fog begins to appear (default=0.0). End is the position in the object where the density fog reaches its full Amount value. To have a lighter effect, increase the End value. To have a heavier effect, reduce the End value.

**Render objects inside raytraced objects**—Turns the rendering of objects inside raytraced objects on or off. Default=on.

**Render atmospherics inside raytraced objects**—Turns the rendering of atmospheric effects inside raytraced objects on or off. Atmospheric effects include fire, fog, volume light, and so on. Default=on.

**Treat Refractions as Glass (Fresnel effect)**—When on, applies a Fresnel effect to the refraction. This can add a bit of reflection to the refracting object, depending on the viewing angle of the object. When off, the object is refractive only. Default=on.
mental ray Shaders

In mental ray, a shader is a function that calculates light effects. There can be shaders for lights, cameras (lens shaders), materials, shadows, and so on.

Note: In 3D modeling, the more common usage of “shader” signifies an algorithm that specifies how a surface responds to light. (The shaders for standard 3ds Max fall into this category.) With the mental ray renderer, “shader” has a more general sense of any algorithm used in rendering.

The mental ray renderer (page 3–78) can render most types of 3ds Max materials and maps. See 3ds Max Materials in mental ray Renderings (page 3–83). In addition, if you have enabled mental ray extensions (see mental ray Preferences (page 3–837)), you can apply a variety of shaders to materials. Materials designed for use with the mental ray renderer have specific components to which you can assign a shader. And for standard 3ds Max material types, the mental ray Connection rollout (page 2–1461) lets you add mental ray shading.

Warning: When you use the scanline renderer, mental ray shaders typically appear as black or white surfaces, or they are ignored entirely.

You assign a mental ray shader the same way you do a map. In the Material/Map Browser (page 2–1412), mental ray shaders appear with a yellow icon, instead of the green icon used for maps.

- Bump (3dsmax)
- Cellular
- Checker
- Composite
- Dent
- DGS Material (3dsmax)
- Dielectric (base)
- Dielectric Material (3dsmax)
- Edge (lume)
- Facade (lume)
- Falloff
- Flat Mirror
- Glass (lume)
- Glow (lume)
- Gradient

mental ray maps in the browser’s list are shown with yellow icons.

The shaders listed in the Browser depend on which type of shader component you have chosen in the Material Editor. For example, when you assign a Surface shader, the Browser lists a variety of shaders and standard 3ds Max maps. But when you assign a more special-purpose Contour shader, the Browser lists only those shaders that generate contour lines.

Note: Other kinds of special-purpose shaders include shaders for cameras and lights. Buttons to assign camera shaders are found on the Render Scene dialog’s Camera Effects rollout (page 3–101), and the buttons to assign light shaders are on a light object’s mental ray Light Shader rollout (page 2–1345) (which appears only on the Modify panel, not the Create panel).

The shaders listed in the Browser come from several libraries that are provided with 3ds Max. Shaders created specifically for 3ds Max are described in this document. Shaders provided with the mental images or lume shader libraries have their own online documentation. The following topics link to the descriptions of specific shaders:
- **Custom Shaders for 3ds Max** (page 2–1711) links to descriptions of the shaders provided in the product-specific library, 3dsmax.mi.
- **mental images Shader Libraries** (page 2–1712) links to descriptions of the shaders provided in the three standard mental ray libraries from mental images: base.mi, contour.mi, and physics.mi.
- **Shaders in the Lume Tools Collection** (page 2–1713) includes links to descriptions of shaders in the lume library, lume.mi.
- The **Car Paint** (page 2–1576) material is also available as a shader, with the same set of parameters.
- The **mr Sun** (page 2–1319), **mr Sky** (page 2–1318), and **mr Physical Sky** (page 2–1321) shaders are components of the mental ray **Sun & Sky** (page 2–1313) solution.

Note: When you wire the parameters of an object whose material has mental ray shaders assigned, names of shader parameters might differ from those in the Material Editor interface. Also, parameters not supported by 3ds Max might appear as blanks in the wiring menu.

### mental ray Shaders not Provided with 3ds Max

If your installation includes shader libraries other than those listed in this reference (whether obtained from a third-party source, or custom written), then the Browser might list those shaders as well. Documentation for third-party or custom shaders should come from the shader’s provider.

### Where Shaders Are Installed

Shaders provided with 3ds Max are installed in the subdirectory `\mentalray\shaders_standard\`, below the 3ds Max root directory. The `\include` folder is for the M1 include files, and the `\shaders` folder is for the DLLs.

Third-party shaders should not be installed in `\shaders_standard`. They should be installed either in `\shaders_3rdparty` or `\shaders_autoload`. If a third-party shader is present in `\shaders_autoload`, it is loaded automatically when you start 3ds Max. If a third-party shader is present in `\shaders_3rdparty`, you must update the file `3rdparty.mi` so it explicitly loads the shader. The M1 file `\shaders_3rdparty\3rdparty.mi` contains comments that explain how to add load statements.

**Note:** Shaders listed in the M1 file are loaded in reverse order: that is, from the bottom of the list to the top.

---

### Custom Shaders for 3ds Max

For use with the **mental ray renderer** (page 3–78), 3ds Max provides a number of custom shaders. These are the following:

- **3D Displacement Shader** (mental ray) (page 2–1714)
- **Bump Shader** (mental ray) (page 2–1716)
- **DGS Material Shader** (mental ray) (page 2–1717)
- **Dielectric Material Shader** (mental ray) (page 2–1719)
- **Environment Shader** (mental ray) (page 2–1721)
- **Height Map Displacement Shader** (mental ray) (page 2–1722)
- **Material to Shader** (mental ray) (page 2–1723)
- **Shader List** (mental ray) (page 2–1723)
- **UV Generator Shader** (mental ray) (page 2–1724)
- **UV Coordinate Shader** (mental ray) (page 2–1728)
mental images Shader Libraries

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Pick a mental ray shader other than a custom 3ds Max shader or a lume shader.

Note: Shaders appear in the Browser only if the mental ray renderer is the currently active renderer.

The shaders provided with standard libraries from mental images are meant for use with the mental ray renderer (page 3–78). There are three standard libraries: Base Shaders (base.mi), Physics Shaders (physics.mi), and Contour Shaders (contour.mi).

Note: In the mental image libraries, the names of base shaders have the prefix “mib_” and the names of contour shaders have the prefix “contour_”. These prefixes don’t appear in the 3ds Max user interface or in the table that follows. (Names of physics shaders have no conventional prefix.)

The following table lists the mental images library shaders provided with 3ds Max.

Tip: When you follow a link to the documentation for mental images library shaders, scroll up a bit in your browser. The links tend to go directly to the shader’s declaration code, and often there are some introductory paragraphs directly above the code. If the link goes to the beginning of a section, scroll down instead.

XYZ Generator Shader (mental ray) (page 2–1729)
XYZ Coordinate Shader (mental ray) (page 2–1730)
Shaders in the LumeTools Collection

The LumeTools Collection of shaders provide a variety of naturalistic effects when used with the mental ray renderer (page 3–78). In the Material/Map Browser, the name of these shaders is followed by “(lume).” These are the lume shaders provided with 3ds Max:

- Beam
- Distortion
- Edge and Edge Shadow
- Facade
- Glass
- Glow
- Landscape
- Metal
- Mist
- Night

Note: You can also access the mental images shader help by choosing Help > Additional Help, highlighting Mental Ray Standard Library in the list, and then clicking Display Help.

Connect Parameter to Shader Dialog (mental ray)

Some mental ray shaders return multiple values. If you choose one of these, a Connect Parameter To Shader dialog appears. Choose one of the return values in the list, and then click OK.

Important: UV Coordinates (page 2–1728) and XYZ Coordinates (page 2–1730) are the only shaders with multiple return values provided with 3ds Max. You might encounter multiple return values in shaders provided with other shader libraries or custom shader code.
The components for some mental ray materials and shaders can be assigned other shaders. For these components, the main shader button is accompanied on the right by a small button. If no shader is assigned, or the shader assigned has only a single return value, the button is disabled and shows a dot in the middle. If the shader assigned can return multiple values, text appears in this button, and a tooltip shows the parameter name. Clicking the button displays the Connect Parameter To Shader dialog, allowing you to change the parameter being used.

### Interface

**List of return values**—Lists the parameters that the shader returns. The type of each parameter is indicated in parentheses, following the parameter’s name.

**Show Compatible Only**—When on the list shows only the return values whose type is compatible with the component the shader is assigned to. When off, shows all return values from the shader, whether they are compatible or not. Default=on.

---

### 3ds Max Custom Shaders

#### 3D Displacement Shader (mental ray)

A 3D Displacement shader displaces the geometry of surfaces. The effect is similar to displacement mapping of a standard material. You can apply mental ray displacement to any kind of object, unlike standard displacement mapping, which is restricted to surface models (meshes, patches, polys, and NURBS surfaces).

Displaced surfaces are smooth if the displaced polygons share normals; otherwise, the displaced surfaces are faceted. Also, unless normals are shared, faces can become separated in the displaced mesh. To prevent this, make sure adjacent surfaces belong to the same shading group.

When the mental ray renderer is the active renderer, mental ray displacement is the only displacement method used, unless your scene includes a Displace modifier (page 1–629), which always uses standard 3ds Max displacement.

Tip: Before you render, you can disable or enable displacement by using the Displacement toggle in the Options group on the Common Parameters rollout (page 3–27).

Global settings for the mental ray displacement method are in the Displacement group on the
Shadows And Displacement rollout (page 3–114) of the Render Scene dialog’s Renderer panel.

mental ray Displacement (page 3–96)
mental ray Connection Rollout (page 2–1461)
mental ray Material (page 2–1544)

Interface

3D Displacement (3dsmax) Parameters rollout

Note: The button to the right of the Factor and Direction Strength controls is a shortcut shader button. Clicking one of these buttons displays the Material/Map Browser (page 2–1412) so you can assign a shader to this component. When a map or a shader has been assigned to a component, this button displays the letter “M,” and the comparable button on the Shaders rollout displays the map or shader name.

Object Independent—When on, the displacement effect is independent of the size of the object’s bounding box. When off, the displacement effect is scaled according to the size of the object. Default=on.

Scaling the displacement based on object size is the standard behavior for regular 3ds Max displacement mapping.

Displacement Length—This is the length of displacement when Object Independent is on, the extrusion map is at 100 per cent (white) and the Extrusion Strength equals 1.0. Lower gray levels in the extrusion map, or other values of Extrusion Strength, scale the amount of displacement. When Object Independent is off, this value is disregarded. Default=1.0.

Extrusion Strength—Controls the height of the displacement. This value is a multiplier: at the default value of 1.0, the map’s effect is unchanged. Greater values increase the effect of the map, and lower values decrease it. Default=1.0.

Extrusion Map—Click to display the Material/Map Browser (page 2–1412) and choose a map to use for the displacement. Displacement maps apply the gray scale of the map to generate the displacement. Lighter colors in the 2D image push outward more strongly than darker colors, resulting in a 3D displacement of the geometry.

Direction Strength—Controls the strength of the direction shader. Default=0.0.

Important: Adding a direction shader has no visible effect unless you set Direction Strength to be greater than its default value of zero. (Direction Strength values less than zero have no effect.)

Direction Map—Click to display the Material/Map Browser (page 2–1412) and choose a shader to use for the map direction. The direction of the displacement is perturbed according to the RGB values of the shader output or map pixels. Red values offset in the U axis, Green values offset in V, and Blue values offset in W (using the object-local UVW coordinates).

Shaders rollout

The controls on this rollout let you assign a map or shader to the Factor or Direction Strength parameters. Click the button for a component to display the Material/Map Browser (page 2–1412).
and assign the map or shader. Use the toggle at the left to turn the effect of the map off or on.

The button to the right of each main shader button is for shaders that can return multiple parameters. If a shader that returns multiple parameters is assigned to the component, the button’s tooltip shows the parameter name. Clicking the button displays a Connect Parameter To Shader dialog (page 2–1713), which lets you change which parameter is being used.

Important: UV Coordinate (page 2–1728) and XYZ Coordinate (page 2–1730) are the only shaders with multiple return values provided with 3ds Max. You might encounter multiple return values in shaders provided with other shader libraries or custom shader code.

Bump Shader (mental ray)

Material Editor > mental ray material > Click the button for the Surface or Bump component. > Material/Map Browser > Bump (3dsmax)

Note: Shaders appear in the Browser only if the mental ray renderer is the currently active renderer.

The Bump shader provides bump mapping for the mental ray renderer. Bumps are created by perturbing face normals before the object is rendered, using the same method as bump mapping (page 2–1506) for the scanline renderer.

Warning: Although you can assign a Bump shader to the Surface component, if you assign only a Bump shader, the surface will render as black. For the Surface component, use the Bump shader in a Shader List (page 2–1723), or for the mental ray material (page 2–1544), use the Bump component itself.

Bump (3dsmax) Parameters rollout

Multiplier—Adjust the bump effect by multiplying the map values. Negative Multiplier values reverse the bump effect: hollow areas now protrude, and raised areas become hollow. Default=1.0.

Map—Click to display the Material/Map Browser (page 2–1412) and choose a map to use for generating bumps. Bump mapping uses the intensity of the map to affect the surface of the material. The intensity affects the apparent bumpiness of the surface: white areas protrude, and black areas recede.

Shaders rollout

The controls on this rollout let you assign a map or shader to the Multiplier parameter. Click the button for a component to display the Material/Map Browser (page 2–1412) and assign the map or shader. Use the toggle at the left to turn the effect of the map off or on.

The button to the right of the main shader button is for shaders that can return multiple parameters. If a shader that returns multiple parameters is assigned to the component, the button’s tooltip shows the parameter name. Clicking the button displays a Connect Parameter To Shader dialog (page 2–1713), which lets you change which parameter is being used.

Important: UV Coordinate (page 2–1728) and XYZ Coordinate (page 2–1730) are the only shaders with multiple return values provided with 3ds Max. You might
encounter multiple return values in shaders provided with other shader libraries or custom shader code.

DGS Material Shader (mental ray)

Material Editor > mental ray Connection rollout >
Unlock the Surface or Photon component. > Click the shader button for the Surface or Photon component. >
Material/Map Browser > DGS Material (3dsmax)

Material Editor > mental ray material > Click the button for the Surface or Photon component. > Material/Map Browser > DGS Material (3dsmax)

Note: Shaders appear in the Browser only if the mental ray renderer is the currently active renderer.

DGS stands for Diffuse, Glossy, Specular. This shader is a mental ray phenomenon (a scripted shader tree) that provides a physically accurate simulation of a surface. With the mental ray Connection rollout of a basic 3ds Max material, or a mental ray material, you can assign the DGS Material shader to either the Surface or Photon component.

Despite the similarity in name, this shader is distinct from the DGS material (page 2–1580). Both, in turn, provide a custom 3ds Max interface to the “DGS Material Photon” shader that is part of the mental images physics library.

Interface

Parameters rollout

- DGS Material (3dsmax) Parameters

Diffuse
Glossy Highlights
Specular
Shiny
Transparency
Index (D) Refraction
Lights

Note: The button to the right of the first six controls is a shortcut shader button. Clicking one of these buttons displays the Material/Map Browser (page 2–1412) so you can assign a shader to this component. When a map or a shader has been assigned to a component, this button displays the letter “M,” and the comparable button on the Shaders rollout displays the map or shader name.

Diffuse—Click the color swatch to display a Color Selector (page 1–161) and change the material’s diffuse color.

Glossy Highlights—Click the color swatch to display a Color Selector and change the color of glossy highlights.

Specular—Click the color swatch to display a Color Selector and change the color of mirror reflections. When the specular color is white, the material is 100 percent reflective, like a mirror. When the specular color is black, the material does not reflect any of its surroundings.

Shiny—Sets the width of glossy highlights. The larger this value, the smaller the highlights. Default=30.0.
Transparency—Specifies the transparency. The effective range of Transparency is from 0.0 to 1.0. At 0.0 the material is fully opaque. At 1.0 it is fully transparent. Default=0.0.

Warning: You can set the value of Transparency to be greater than 1.0, but this has no effect. An anomaly of the user interface for shaders in the mental ray and lume libraries, is that spinner values are not “clamped” to lie within their effective ranges, as they are for controls in 3ds Max.

The value of Transparency also indirectly specifies the reflectivity of the material, which is calculated as 1.0 minus the Transparency value.

Index Of Refraction—Specifies the IOR. In the physical world, the IOR results from the relative speeds of light through the transparent material and the medium the eye or the camera is in. Typically this is related to the object’s density. The higher the IOR, the denser the object. Default=1.5.

See Extended Parameters Rollout (Standard Material) (page 2–1471) for a list of IOR values for commonly encountered materials.

Note: When the IOR equals 1.0, there is no refraction, and calculating the transparency can take less time than when the material is refractive.

Lights—When on, the material is illuminated only by those lights specified in the list. When Lights is turned off, all lights in the scene affect the material. Default=off.

The remaining light controls are unavailable unless Lights is turned on.

- List of lights—Displays the lights you have chosen to illuminate this material.
- Add—Adds a light to the list. Click Add to turn it on, then click the light object in a viewport.
- Replace—Replaces a light in the list. Highlight a light’s name in the list, click Replace to turn it on, then click the replacement light object in a viewport.
- Delete—Deletes a light from the list. Highlight a light’s name in the list, then click Delete.

Shaders rollout

The controls on this rollout let you assign a map or shader to one of the basic parameters of the DGS Material shader. This is comparable to mapping a component of a standard material; by adding shaders, you can create a shader tree that generates complex effects.

Click the button for a component to display the Material/Map Browser (page 2–1412) and assign the map or shader. Use the toggle at the left to turn the effect of the map off or on.

The button to the right of each main shader button is for shaders that can return multiple parameters. If a shader that returns multiple parameters is assigned to the component, the button’s tooltip shows the parameter name. Clicking the button displays a Connect Parameter To Shader dialog (page 2–1713), which lets you change which parameter is being used.

Important: UV Coordinates (page 2–1728) and XYZ Coordinates (page 2–1730) are the only shaders with multiple return values provided with 3ds Max. You might encounter multiple return values in shaders provided with other shader libraries or custom shader code.

For all the DGS Material shader components, the available mental ray shaders are the same:
Dielectric Material Shader (mental ray)

Material Editor > mental ray Connection rollout > Unlock the Surface or Photon component. > Click the shader button for the Surface or Photon component. > Material/Map Browser > Dielectric Material (3dsmax) or Dielectric Material Photon (3dsmax)

Note: Shaders appear in the Browser only if the mental ray renderer is the currently active renderer.

The Dielectric Material shader creates transparent, refractive materials that are physically accurate. A dielectric material, such as glass, is a material whose surface transmits most light that strikes it at angles close to perpendicular (90 degrees), but reflects most light that strikes at glancing angles (close to zero degrees).

When applied to the Surface component, this shader affects the surface’s appearance. When applied to the Photon component, it affects its photon behavior for caustics and global illumination. (The Glass material is a mental ray phenomenon (a scripted shader tree) that is equivalent to a mental ray material (page 2–1544) with a Dielectric Material shader assigned to both its Surface and Photon components, with the parameter settings identical for both.)

Note: This material does not use a shadow shader, so shadows will always be opaque unless you use a Dielectric Material shader for the Photon component, and generate caustics when you render.

Adjacent Refractive Materials

Two controls, Outside Light Persistence and Index Of Refraction (Out), are for situations where you are modeling two adjacent refractive materials. Consider a drink in a martini glass. The glass
has an index of refraction (IOR) of 1.5, while the alcohol in the glass has an IOR of about 1.3. To create a physically accurate model of this situation, use three glass materials: one for the glass itself, one for the alcohol, and a third material for the surfaces where they touch each other. For this third material, set the “inside” IOR to 1.3, and the outside IOR to 1.5.

### Interface

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Light Persistence</td>
<td></td>
<td>In conjunction with the Persistence Distance, controls the percentage of light that the volume transmits. For example, if the color is set to R=G=B=0.5 and the Persistence Distance is set to 2.0, then objects with a thickness of 2.0 units will appear 50 per cent transparent. Default=white (R=G=B=1.0). Because transparency depends on the thickness of the object, objects with varying thickness show different transparency depending on the angle from which they are viewed.</td>
</tr>
<tr>
<td>Index Of Refraction (out)</td>
<td>0.0</td>
<td>Sets the IOR on the other side of a surface. When set to the default of zero, this control has no effect. See the section “Adjacent Refractive Materials,” above. Default=0.0.</td>
</tr>
<tr>
<td>Persistence Distance</td>
<td>1.0</td>
<td>In conjunction with the Light Persistence color, controls the percentage of light that the volume transmits. It is the distance at which light transmission is reduced to the percentage specified by the Light Persistence RGB values. Default=1.0. If you specify an Outside Light Persistence color, that setting also uses the Persistence Distance.</td>
</tr>
<tr>
<td>Ignore Normals</td>
<td></td>
<td>When on, the renderer does not use normals to decide whether a light ray is entering or leaving the object. Normally, the shader uses normals to decide whether a ray is entering or leaving an object. (It is entering if the normal points toward the ray, leaving if the normal points away from the ray.) This can present a problem for rendering objects whose normals are not unified. When Ignore Normals is on, the shader decides whether a ray is entering or leaving the object by counting the number of times the ray has intersected the object. Default=off.</td>
</tr>
<tr>
<td>Opaque Alpha</td>
<td></td>
<td>When on, refracted rays that touch the environment don’t generate a transparent alpha value. (This is how 3ds Max usually treats the environment.) When off, refracted rays that touch the environment render a transparent alpha value, which can help if you plan to use the rendering as part of a composite. Default=off.</td>
</tr>
</tbody>
</table>

### Light Persistence—

In conjunction with the Persistence Distance, controls the percentage of light that the volume transmits. For example, if the color is set to R=G=B=0.5 and the Persistence Distance is set to 2.0, then objects with a thickness of 2.0 units will appear 50 per cent transparent. Default=white (R=G=B=1.0).

### Index Of Refraction (out)—

Sets the IOR on the other side of a surface. When set to the default of zero, this control has no effect. See the section “Adjacent Refractive Materials,” above. Default=0.0.

### Persistence Distance—

In conjunction with the Light Persistence color, controls the percentage of light that the volume transmits. It is the distance at which light transmission is reduced to the percentage specified by the Light Persistence RGB values. Default=1.0.

If you specify an Outside Light Persistence color, that setting also uses the Persistence Distance.

### Ignore Normals—

When on, the renderer does not use normals to decide whether a light ray is entering or leaving the object. Normally, the shader uses normals to decide whether a ray is entering or leaving an object. (It is entering if the normal points toward the ray, leaving if the normal points away from the ray.) This can present a problem for rendering objects whose normals are not unified. When Ignore Normals is on, the shader decides whether a ray is entering or leaving the object by counting the number of times the ray has intersected the object. Default=off.

### Opaque Alpha—

When on, refracted rays that touch the environment don’t generate a transparent alpha value. (This is how 3ds Max usually treats the environment.) When off, refracted rays that touch the environment render a transparent alpha value, which can help if you plan to use the rendering as part of a composite. Default=off.
**Phong Coefficient**—When greater than zero, generates Phong highlights on the surface. The highlights appear in the sample slot. In general this value must be greater than 10 for highlights to be apparent. Default=0.0.

---

**Environment Shader (mental ray)**

Material Editor > mental ray Connection rollout > Assign a shader to the Environment component. > Material/Map Browser > Environment (3dsmax)

Material Editor > mental ray material > Assign a shader to the Environment component. > Material/Map Browser > Environment (3dsmax)

Note: Shaders appear in the Browser only if the mental ray renderer is the currently active renderer.

The Environment shader lets you specify an environment that is local to the material. Controls for the Environment shader are similar to those for a scene’s environment on the Render Scene dialog’s Environment panel. However, the local Environment shader doesn’t affect the scene background. Instead, it provides an environment that the material can reflect or refract.

If an environment map is present, it generates the reflections or refractions, and they are not ray traced.

**Parameters rollout**

Note: The button to the right of the UseAlpha and Color controls is a shortcut shader button. Clicking one of these buttons displays the Material/Map Browser (page 2–1412) so you can assign a shader to this component. When a map or a shader has been assigned to a component, this button displays the letter “M,” and the comparable button on the Shaders rollout displays the map or shader name.

**UseAlpha**—When on, uses the map’s alpha channel, if it has one. The alpha channel specifies those portions of the map that are transparent or translucent. Default=off.

**Color**—Click the color swatch to display a Color Selector (page 1–161) and choose a color to use as the environment.

**Map**—Click the button to display a Material/Map Browser (page 2–1412) and choose a map to use as the environment.

**Shaders rollout**

The controls on this rollout let you assign a map or shader to the UseAlpha and Color parameters. Click the button for a component to display the Material/Map Browser (page 2–1412) and assign the map or shader. Use the toggle at the left to turn the effect of the map off or on.

The button to the right of each main shader button is for shaders that can return multiple parameters. If a shader that returns multiple parameters is assigned to the component, the button’s tooltip shows the parameter name. Clicking the button displays a Connect Parameter To Shader dialog (page 2–1713), which lets you change which parameter is being used.

**Important:** UV Coordinates (page 2–1728) and XYZ Coordinates (page 2–1730) are the only shaders with multiple return values provided with 3ds Max. You might
encounter multiple return values in shaders provided with other shader libraries or custom shader code.

**Height Map Displacement Shader** (mental ray)

Material Editor > mental ray Connection rollout > For the Displacement component, turn off the lock button. > Click the button for the Displacement component. > Material/Map Browser > Height Map Displacement (3dsmax)

Material Editor > mental ray material > Click the button for the Displacement component. > Material/Map Browser > Height Map Displacement (3dsmax)

Note: Shaders don’t appear unless the mental ray renderer is the currently active renderer.

The Height Map Displacement shader displaces the geometry of surfaces, and is specifically intended for use with height maps generated by normal mapping; see *Creating and Using Normal Bump Maps* (page 3–150).

**Important:** When applying a material containing this map to an object, the mental ray Displacement > Smoothing option must be off. If such materials are applied to all objects in the scene, you can turn off **Smoothing globally**. Otherwise, turn off smoothing for each object whose material uses a height map via the Object Properties > mental ray panel (page 1–126) (turn off Use Global Settings and then turn off Smoothing).

**Tip:** Avoid the temptation to apply MeshSmooth to a model when creating a height map for it. This changes the shape of the model so the height values will not be correct. The low-res model must have exactly the same shape when the map is created and when it is used for displacement. Also, MeshSmooth does not use the same algorithm as the mental ray displacement smoothing, so using both forms of smoothing won’t work perfectly. The best results are obtained by not smoothing the low-res model when the map is created and also not using mental ray smoothing.

Also, avoid using a paint program to modify the height map. The values in the height map depend on the shape of both the low-res and high-res models, and it’s easy to damage the mathematical accuracy. If you paint any changes onto the map, you must be careful to preserve the faceted look, and avoid the temptation to blur away the facets.

You might try painting in Additive and Subtractive mode to add or subtract to the displacement, because Normal mode will set a fixed displacement, making it difficult for an artist to control the result.

Height Map Displacement (3dsmax) Parameters rollout

Be sure to enter the same values for Minimum and Maximum Height as the equivalents on the Projection Options dialog, as specified below.

**Minimum Height**—The “Min Height” value specified on the *Render to Texture: Projection Options* dialog (page 3–165) when creating the height map. Default=-10.0.

**Maximum Height**—The “Max Height” value specified on the *Render to Texture: Projection Options* dialog (page 3–165) when creating the height map. Default=10.0.
Options dialog (page 3–165) when creating the height map. Default=10.0.

**Height Map**—The height map itself (usually a bitmap).

---

**Material to Shader (mental ray)**

Material Editor > mental ray Connection rollout > Assign a shader. > Material/Map Browser > Material to Shader

Material Editor > mental ray or DGS material > Assign a shader. > Material/Map Browser > Material to Shader

Note: Shaders appear in the Browser only if the mental ray renderer is the currently active renderer.

Lets you use a regular 3ds Max material as a shader. Depending on the component to which this shader is assigned (Surface, Shadow, Displacement, Volume, and so on), the mental ray renderer uses the appropriate material component.

For example, if you want a mental ray material’s Surface component to look like a standard material you have, assign Material To Shader as the Surface shader, and then assign it the standard material.

Note: Material To Shader doesn’t work as an environment background. Use the original 3ds Max material, instead.

Tip: To edit the material assigned to Material To Shader, you can drag the button to an unused sample slot in the Material Editor (be sure to choose Instance when prompted). Or you can follow these steps:

1. In an unused sample slot, create the material and adjust its settings.
2. Save the material to a library.
3. Assign the Material To Shader to its component.
4. When you click the Material To Shader’s shader button, browse from the library and load the material you prepared in advance.

If you need to further adjust the material, you can repeat these steps (without having to reassign the Material To Shader).

---

**Interface**

---

**Material button**—Click to display the Material/Map Browser (page 2–1412) and choose the material to use for shading.

---

**Shader List (mental ray)**

Material Editor > mental ray Connection rollout > Assign a shader. > Material/Map Browser > Shader List

Material Editor > mental ray, DGS, or Glass material > Assign a shader. > Material/Map Browser > Shader List

Note: Shaders appear in the Browser only if the mental ray renderer is the currently active renderer.

The Shader List shader provides an interface for constructing a mental ray shader list. A shader list combines the effect of multiple shaders: each shader is called in turn, the first one’s output being treated as input to the next, and so on.

---

**Interface**

---
List of shaders—Shows the names of the shaders in the list. Highlight a shader’s name to alter its position in the list, or to access its parameters. Each active shader in the list is called in order, from top to bottom.

Up—Moves the selected shader up in the list.

Down—Moves the selected shader down in the list.

Add Shader—Displays a Material/Map Browser (page 2–1412) so you can choose a shader to add to the list.

Remove Selected—Removes the selected shader from the list.

Selection group

On—When on, the shader is active. When off, the shader is inactive and isn’t called. You can use this toggle to disable a shader without removing it from the list entirely.

Shader button—Shows the name of the currently selected shader. Click the button to view that shader’s parameters in the Material Editor.

UV Generator

Material Editor > Any shader with a Coords parameter (or other vector value). > Click the shader button. > Material/Map Browser > UV Generator (3dsmax)

Material Editor > mental ray Connection rollout > Unlock the Surface component and click the shader button. > Material/Map Browser > UV Generator (3dsmax)

Material Editor > DGS material > Assign a shader to any component. > Material/Map Browser > UV Generator (3dsmax)

Note: Shaders appear in the Browser only if the mental ray renderer is the currently active renderer.

The UV Generator shader returns 2D mapping coordinates. You can use its settings to adjust a 2D map. The parameters for this shader are equivalent to parameters on the Coordinates rollout for 2D maps (page 2–1625).

Interface

The interface for this shader consists of two rollouts:

UV Generator Parameters Rollout (page 2–1725)

Shaders Rollout (UV Generator) (page 2–1727)
UV Generator Parameters Rollout

Material Editor > Any shader with a Coords parameter (or other vector value). > Click the shader button. > Material/Map Browser > UV Generator (3dsmax) > UV Generator (3dsmax) Parameters rollout

Material Editor > mental ray Connection rollout > Unlock the Surface component and click the shader button. > Material/Map Browser > UV Generator (3dsmax) > UV Generator (3dsmax) Parameters rollout

Material Editor > DGS material > Assign a shader to any component. > Material/Map Browser > UV Generator (3dsmax) > UV Generator (3dsmax) Parameters rollout

Note: Shaders appear in the Browser only if the mental ray renderer is the currently active renderer.

The parameters for this shader are equivalent to parameters on the Coordinates rollout for 2D maps (page 2–1625).

Interface

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MapSlotType</td>
<td>0</td>
<td>Chooses whether the map is applied as an environment map or a texture map. Default=0 (Texture).</td>
</tr>
<tr>
<td>EnvType</td>
<td>1</td>
<td>If the map is applied as an environment map, this value chooses the mapping type. If</td>
</tr>
</tbody>
</table>

- 0 is for a Texture map.
- 1 is for an Environment map.
the map is applied as a texture map, this value is ignored. Default=4 (screen).

- 1 is for Spherical.
- 2 is for Cylindrical.
- 3 is for Shrink-Wrap.
- 4 is for Screen.

Screen projection projects as a flat backdrop in the scene. See *UVW Map Modifier* (page 1–922) for a description of spherical, cylindrical, and shrink-wrap projection.

**MapChannel**—If the map is applied as a texture map and UVWSource is set to 0 (Explicit), this value sets the map channel index; otherwise, this value is ignored. Range=1 to 99. Default=1.

**UVWSource**—If the map is applied as a texture map, this value chooses the source of UVW coordinates. If the map is applied as an environment map, this value is ignored. Default=0 (Explicit).

- 0 is for Explicit.
  - When Explicit is the source, use MapChannel to set the specific map channel.
- 1 is for Object XYZ.
  - Object XYZ uses planar mapping based on the object’s local coordinates (disregarding the pivot point location). For rendering purposes, planar mapping doesn’t project through to the back of the object unless you turn on ShowMapOnBack.
- 2 is for World XYZ.
  - World XYZ uses planar mapping based on the scene’s world coordinates (disregarding the object’s bounding box). For rendering purposes, planar mapping doesn’t project through to the back of the object unless you turn on ShowMapOnBack.

**ShowMapOnBack**—When on, planar mapping (Planar from Object XYZ, or with the UVW Map modifier) projects through to render on the back of the object. When off, planar mapping doesn’t render on the object’s back. Default=on.

This toggle is available only when Tiling is off in both dimensions. Its effect is visible only when you render the scene.

Note: In viewports, planar mapping always projects to the back of the object, whether Show Map On Back is turned on or not. To override this, turn off Tiling.

**UOffset**—Changes the U position of the map in UV coordinates (page 3–1028). The map moves in relation to its size. Default=0.0.

For example, if you want to shift the map its full width to the left, and half its width downward from its original position, you enter -1 in the U Offset field and 0.5 in the V offset field.

**UScale**—Determines the number of times the map is tiled (page 3–1022) (repeated) along the U axis. Default=1.0.

**UWrap**—Turns tiling on or off in the U axis. Default=on.

**UMirror**—Mirrors (page 3–1022) the map left-to-right along the U axis. Default=off.

**VOffset**—Changes the V position of the map in UV coordinates. Default=0.0.

**VScale**—Determines the number of times the map is tiled (repeated) along the V axis. Default=1.0.

**VWrap**—Turns tiling on or off in the V axis. Default=on.

**VMirror**—Mirrors the map top-to-bottom along the V axis. Default=off.

**UAngle, VAngle, and WAngle**—Rotate the map about the U, V, or W axis (in degrees). Default=0.0.

**UVAxis**—Changes the mapping coordinate system used for the map. The default UV coordinates project the map onto the surface like a slide projector. The VW and WU coordinates rotate
the map so that it is perpendicular to the surface. Default=0 (UV).

- 0 is for UV.
- 1 is for VW.
- 2 is for WU.

**Clip**—When on, UVs are clipped. When off, UVs are wrapped. Default=on.

**Blur**—Affects the sharpness or blurriness of the map based on its distance from the view. The farther away the map is, the greater the blurring. The Blur value blurs maps in world space. Blur is primarily used to avoid aliasing (page 3–907). Default=1.0.

**BlurOffset**—Affects the sharpness or blurriness of the map without regard to its distance from the view. Blur Offset blurs the image itself in object space. Use this option when you want to soften or defocus the details in a map to achieve the effect of a blurred image. See Blur / Blur Offset (page 3–918). Default=0.0

**Noise**—When on, noise settings affect the map. When off, no noise is applied. Default=off.

**Animate**—Determines if the noise effect is animated. This parameter must be turned on if you intend to animate the noise. Default=off.

**Amount**—Sets the strength of the fractal function, expressed as a percentage. If the amount is 0 there is no noise. If the amount is 100 the map becomes pure noise. Default=1.0.

**Size**—Sets the scale of the noise function relative to geometry. At very small values, the noise effect becomes white noise. At large values, the scale can exceed the scale of the geometry, in which case it has little or no effect. Range=0.001 to 100. Default=1.0.

**Level**—Or iterations: the number of times the function is applied. The effect of the level is dependent on the Amount value. The stronger the amount, the greater the effect of increasing the Level value. Range=1 to 10. Default=1.

**Phase**—Controls the speed of the animation of the noise function. Default=0.0.

**RealWorldMapSize**—Controls the scaling method used for texture mapped materials that are applied to the object. The scaling values are controlled by the Use Real-World Scale settings found on the applied material’s Coordinates rollout. Default=on.

---

### Shaders Rollout (UV Generator)

**Material Editor > Any shader with a Coords parameter (or other vector value). > Click the shader button. > Material/Map Browser > UV Generator (3dsmax) > Shaders rollout**

**Material Editor > mental ray Connection rollout > Unlock the Surface component and click the shader button. > Material/Map Browser > UV Generator (3dsmax) > Shaders rollout**

**Material Editor > DGS material > Assign a shader to any component. > Material/Map Browser > UV Generator (3dsmax) > Shaders rollout**

**Note: Shaders appear in the Browser only if the mental ray renderer is the currently active renderer.**

The controls on this rollout let you assign a map or shader to one of the basic parameters of the UV Generator shader. This is comparable to mapping a component of a standard material; by adding shaders, you can create a shader tree that generates complex effects.
The button to the right of each main shader button is for shaders that can return multiple parameters. If a shader that returns multiple parameters is assigned to the component, the button’s tooltip shows the parameter name. Clicking the button displays a Connect Parameter To Shader dialog (page 2–1713), which lets you change which parameter is being used.

**Important:** UV Coordinates (page 2–1728) and XYZ Coordinates (page 2–1730) are the only shaders with multiple return values provided with 3ds Max. You might encounter multiple return values in shaders provided with other shader libraries or custom shader code.
The XYZ Generator shader returns 3D mapping coordinates. You can use its settings to adjust a 3D map. The parameters for this shader are equivalent to parameters on the Coordinates rollout for 3D maps (page 2–1663).

**Interface**

The interface for this shader consists of two rollouts:

- **XYZ Generator Parameters Rollout (page 2–1729)**
- **Shaders Rollout (XYZ Generator) (page 2–1730)**

The parameters for this shader are equivalent to parameters on the Coordinates rollout for 3D maps (page 2–1663).

**CoordinateSystem**—Chooses the source coordinate system. Default=0 (Object XYZ).

- 0 is for Object XYZ.
  
  Object XYZ uses the object's local coordinate system.

- 1 is for Explicit Map Channel.
  
  Lets you use the MapChannel value to choose any channel from 1 to 99.

- 3 is for World XYZ.

**MapChannel**—When Explicit Map Channel is the coordinate system source, this value lets you set the
map channel; otherwise, it is ignored. Range=1 to 99. Default=1.

**Offset**—Moves the map pattern in X, Y, and Z. Default=(0.0, 0.0, 0.0).

**Tiling**—Tiles (page 3-1022) the map pattern in X, Y, and Z, and makes the pattern narrower. Default=(1.0, 1.0, 1.0).

**Angle**—Rotates the map pattern in X, Y, and Z. Default=(0.0, 0.0, 0.0).

**Blur**—Affects the sharpness or blurriness of the map based on its distance from the view. The farther away the map is, the greater the blurring. The Blur value blurs maps in world space. Blur is primarily used to avoid aliasing. Default=1.0.

**BlurOffset**—Affects the sharpness or blurriness of the map without regard to its distance from the view. Blur Offset blurs the image itself in object space. Use when you want to soften or defocus the details in a map to achieve the effect of a blurred image. Default=0.0.

---

**Shaders Rollout (XYZ Generator)**

<table>
<thead>
<tr>
<th>Material Editor &gt; Any shader with a Coords parameter (or other vector value) &gt; Click the shader button. &gt; Material/Map Browser &gt; XYZ Generator (3dsmax) &gt; Shaders rollout</th>
</tr>
</thead>
<tbody>
<tr>
<td>Material Editor &gt; mental ray Connection rollout &gt; Unlock the Surface component and click the shader button. &gt; Material/Map Browser &gt; XYZ Generator (3dsmax) &gt; Shaders rollout</td>
</tr>
<tr>
<td>Material Editor &gt; DGS material &gt; Assign a shader to any component. &gt; Material/Map Browser &gt; XYZ Generator (3dsmax) &gt; Shaders rollout</td>
</tr>
</tbody>
</table>

**Note:** Shaders appear in the Browser only if the mental ray renderer is the currently active renderer.

The controls on this rollout let you assign a map or shader to one of the basic parameters of the XYZ Generator shader. This is comparable to mapping a component of a standard material; by adding shaders, you can create a shader tree that generates complex effects.

---

**Interface**

<table>
<thead>
<tr>

<tr>
<td>Blur</td>
<td>None</td>
</tr>
<tr>
<td>BlurOffset</td>
<td>None</td>
</tr>
</tbody>
</table>

---

The button to the right of each main shader button is for shaders that can return multiple parameters. If a shader that returns multiple parameters is assigned to the component, the button's tooltip shows the parameter name. Clicking the button displays a Connect Parameter To Shader dialog (page 2-1713), which lets you change which parameter is being used.

**Important:** UV Coordinates (page 2-1728) and XYZ Coordinates (page 2-1730) are the only shaders with multiple return values provided with 3ds Max. You might encounter multiple return values in shaders provided with other shader libraries or custom shader code.

---

**XYZ Coordinate Shader (mental ray)**

<table>
<thead>
<tr>
<th>Material Editor &gt; Any shader with a Coords parameter or other vector value. &gt; Click the shader button. &gt; Material/Map Browser &gt; XYZ Coordinate (3dsmax)</th>
</tr>
</thead>
</table>

**Note:** Shaders appear in the Browser only if the mental ray renderer is the currently active renderer.

This shader is identical to the XYZ Generator shader (page 2-1729), except that it returns two values instead of one.

- The XYZ coordinate (same value as XYZ Generator would return)
This value is named XYZ.

- The XYZ coordinate's derivative
  
  This value, also a vector, is named dXYZ.

When you choose this shader, a Connect Parameter To Shader dialog (page 2–1713) is displayed, prompting you to choose which of the two values to use. You can later change the choice of value by using the “dot” button to the right of the main shader button.

**Interface**

The XYZ Coordinate shader has the same parameters as the XYZ Generator shader. See XYZ Generator Parameters Rollout (page 2–1729) for a description of the basic settings.

---

**Normal Bump Map**

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Normal Bump

The Normal Bump map lets you use a texture-baked Normals map (see Baked Texture Elements (page 3–146)). Typically you assign it to a material’s Bump component, Displacement component, or both. Using the map for Displacement can correct edges that otherwise look unrealistically smooth; however, this adds faces to the geometry.

**Tip:** A Normals map for the indicated material component is generated automatically if you turn on Output Into Normal Bump in the Selected Elements Unique Settings group of the Render To Texture dialog’s Output rollout (page 3–160).

**Interface**

[Diagram showing interface elements]

**Normal**—As a rule, contains a Normals map generated by Render To Texture (page 3–144).

Use the toggle to enable or disable use of the map (default=on). Use the spinner to increase or decrease the map’s effect.

**Additional Bump**—This optional component can contain an additional map to modify the bump or displacement effect. It is treated as a regular bump map (page 2–1506).

Use the toggle to enable or disable use of the map (default=on). Use the spinner to increase or decrease the map’s effect.

**Channel Direction group**

By default, the Normals map’s red channel indicates left versus right, while green indicates up versus down (and blue indicates vertical distance). The controls in this group let you adjust that interpretation.

- **Flip Red (X)**—Flips the red channel so that left and right are reversed.
- **Flip Green (Y)**—Flips the green channel so that up and down are reversed.
- **Swap Red & Green**—Swaps the red and green channels so that normal mapping rotates 90 degrees.
Method group

The Method group lets you choose which coordinate to use on the normals. These controls are the same as those in the Projection Options dialog (page 3–165).

- **Tangent**—(The default.) Project at a tangent to the target object’s surface.
  
  This is the method to use for objects that both move and deform, such as animated characters.

- **Local XYZ**—Project using the object’s local coordinates.
  
  This method can be used for stationary or moving objects, but not for objects that deform: if the object deforms, the projection will appear incorrect at some frames.

- **Screen**—Project using screen coordinates; that is, flat projection in the Z axis. X is horizontal, increasing in a positive direction to the right; Y is vertical, increasing in a positive direction upward; and Z is perpendicular to the screen, increasing in a positive direction toward the viewer.
  
  This method is useful mainly for stationary objects seen only from a single angle; for example, a statue seen through a window.

- **World**—Project using world coordinates.
  
  This is useful mainly for objects that don’t move or deform; otherwise, a moving object with world-projected normals will appear to “swim” through the texture.

Camera Map Per Pixel Map

Material Editor > Maps rollout > Click a Map button. > Material/Map Browser > Camera Map per Pixel

The Camera Map Per Pixel map lets you project a map from the direction of a particular camera. It is meant as an aid to 2D matte painting: You can render a scene, adjust the rendering using an image-editing application, then use this adjusted image as a matte that is projected back onto the 3D geometry.

Tip: Final rendering can be slow. Script-driven network rendering (page 3–173) can help improve performance.

Limitations

The Camera Map Per Pixel does not handle these situations:

- Animated objects.
  
  The projection does not use UVW mapping.

- Animated textures.

- Occlusion based on a Z-depth channel is handled in a limited way only.

Procedure

**To use Camera Map Per Pixel:**

1. Create the 3D model.
2. Set up a camera.
3. Set up the rendering resolution you want.
   
   To get good results, the plate should be at least 2K pixels; 3K to 6K, or higher is recommended.
4. Render the scene to an editable image format such as TIFF (page 3–634).
5. Render the scene again, this time to a format such as RPF (page 3–631) that has a Z-depth component. Make sure the Z option is turned on.
6. Use an image-editing application to make changes you want to the editable image.
7. Apply Camera Map Per Pixel to the diffuse component (page 2–1498) of the geometry on which you want the matte to appear. Use these settings:
   
   - Set Camera to the same camera you used for the renderings.
• Set Texture to the matte image you edited.
• Set ZBuffer Mask to the Z-depth rendering (the RPF or RLA file).
  Adjusting (which usually means increasing) the value of ZFudge can improve the quality of edges of the projection.
  Usually it is a good idea to have Remove Back Face Pixels turned on. Another way to adjust the projection edge is to adjust this control's Angle Threshold.
  Tip: If you have persistent problems with seams, try generating a mask with an alpha channel and using it to clean up the edge of the projection.
If you have multiple mattes to project, you might need to slice geometry to make each map’s target a separate object.

**Interface**

Map Channel—Sets which map channel to use. Default=1.

Camera—Click to turn on, then select a camera in the scene by picking it in a viewport or using the Select Objects dialog (page 1–78).

Once you have assigned a camera, its name appears on this button.

This camera should be the one used to render the map used in the Texture and ZBuffer Mask components.

Texture—Click to assign the texture to project. 3ds Max lets you assign any kind of map, but typically this will be a Bitmap (page 2–1631) that contains an image file that you first rendered from the same camera, then edited using a different application.

ZBuffer Mask—Click to assign a map that contains Z-depth data used to mask the projection from unwanted surfaces. Typically this will be an RPF file (page 3–631) or an RLA file (page 3–630) rendered using the same camera, with the Z channel option turned on.

Use the toggle to turn use of the ZBuffer Mask on or off. By default, it is off, and it is not turned on automatically when you assign the ZBuffer Mask.

• ZFudge—ZFudge values other than 1.0 add a margin of deviation to the use of the Z-depth data, letting you fine-tune the Z-Buffer masking. Default=1.0.

Mask—Behaves like the mask in the Mask map (page 2–1689): it lets you view one map through another. Black areas of the mask are transparent, white areas are opaque, and gray areas are partially transparent, based on the percentage of the gray.

• Mask Uses the Camera Projection—When on, the mask uses the same camera projection as the Texture and ZBuffer Mask. When off, it uses the object’s UVW coordinates. Default=on.

Remove Back Face Pixels—When on, sets the projection to exclude surfaces that face away from the camera, based on the value of Angle Threshold. Default=on.
Angle Threshold—Specifies the angle to use as a cutoff when removing backface pixels. Default=90.0.
At the default of 90 degrees, faces perpendicular to the camera, or at a greater angle, are not projected.

Material, Mapping, and Vertex Color Utilities

Assign Vertex Colors Utility
Utilities panel > Utilities rollout > More button > Utilities dialog > Assign Vertex Colors

The Assign Vertex Colors utility assigns vertex colors based on the material assigned to the object and the lighting in the scene. The utility applies a VertexPaint modifier (page 1–936) to the object when Assign To Selected is clicked. Once the VertexPaint modifier has been applied to the object, go to the Modify panel or click Edit to access the VertexPaint tools.

Tip: To render vertex colors, you must apply a material that has a Vertex Color map (page 2–1693) in its diffuse component. To view vertex colors in viewports, right-click the object, choose Properties (page 1–117) from the quad menu, and then turn on Vertex Color in the Display Properties group.

The Assign Vertex Colors utility supports light inclusion or exclusion when using the Scene Lights option.

All of the commands found within the Assign Vertex Color utility are also available from the Modify panel when a VertexPaint modifier has been applied to an object.

Vertex Colors and Radiosity
The Vertex Colors utility supports radiosity (page 3–51). If you use radiosity with assigned vertex colors, be sure to turn on the option Re-Use Direct Illumination From Radiosity Solution. This option is in the Rendering Parameters rollout. See Radiosity Controls (page 3–61). When this option is on, the renderer simply displays the vertex colors assigned by the radiosity solution: strictly speaking, it is not rendering at all.

The additional option Render Direct Illumination, also on the Rendering Parameters rollout, causes direct lighting not to be saved in the corresponding mesh. This corresponds to the options Radiosity, Render Direct Illumination, in which case Assign Vertex Colors gets indirect illumination from the radiosity mesh but renders direct illumination separately; or Radiosity, Indirect Illumination Only, in which case Assign Vertex Colors doesn’t apply direct illumination to vertices at all.

See also
VertexPaint Modifier (page 1–936)
Vertex Color Map (page 2–1693)

Procedures
To use the Assign Vertex Colors utility:
1. Assign materials to the objects you want to affect. These can be mapped or unmapped materials.
2. Light the objects.
3. Select the objects you want to affect.
4. Expand the Display Properties rollout in the Display panel and turn on Vertex Colors.
5. Access the Assign Vertex Colors utility.
6. Choose one of the Light Model options.
7. Choose one of the Color Assignment choices.
8. Click Assign to Selected.
VertexPaint modifiers are applied to the selected objects, and the vertex colors for the objects are taken from their materials and from the lighting in the scene, depending on the options you choose under Light Model.

Changing the material or the lighting in the scene won't change the vertex colors. To do this, click the Update All button.

Note: The new vertex colors are stored in the Vertex Paint modifier. If you want to access them, go to the Modify panel and access the parameters in the rollouts there. You can also use the tools found in the Vertex Paint floating dialog to create layers, paint, blur or adjust color. The Vertex Paint floater launches when you go to the Modify panel and the object is selected.

**Example: To use the Assign Vertex Colors utility on a specific object:**

1. Create a sphere with 24 segments.
2. Apply a mapped material to the sphere, and turn on Show Map In Viewports.
   
   The mapped sphere is displayed in the viewport.
3. Open the Object Properties dialog for the sphere, turn on Vertex Colors, and click OK.
4. With the sphere selected, open the Assign Vertex Colors utility.
5. Choose Shaded and turn on Use Maps.
6. Click Assign To Selected.
   
   A blurred version of the mapping appears on the sphere. The vertices are now colored based on the material and the lighting in the scene. The mapping is blurred because the resolution of the mesh at 24 segments is much lower than the pixel resolution of the map.
7. Go to the Modify panel and note the VertexPaint modifier.
8. Move down in the Stack to the creation parameters, click Yes at the warning prompt, and increase the Segments to 70.
   
   The new vertices shift the already assigned vertices.
9. Return to the VertexPaint level of the stack, and click Assign in the Assign Vertex Colors rollout. Had we returned to the Utilities panel, we would have added another Vertex Paint modifier to the stack; clicking Assign in the VertexPaint Modifier only updates that modifier.

Tip: Vertex colors will only show up in a rendered scene if you assign the Vertex Color map to the diffuse channel. However, if you do this, you can't properly update your vertex colors with the Assign Vertex Colors utility. The solution is to assign a Blend material to your object. Assign the straight diffuse bitmap to Material 1, and the Vertex Color map to Material 2 of the Blend. Switch to 100 percent of Material 2 when rendering, and 100 percent of Material 1 when updating the vertex colors.
Chapter 16: Material Editor, Materials, and Maps

Interface

Channel group
Here you'll find tools to choose which channel type the vertex color utility will assign. If you choose map channel, you can also specify the map channel ID number.

- Assign Vertex Colors

Channel
- Vertex Color
- Vertex Illum
- Vertex Alpha
- Map Channel
  Name: none

Light Model
- Lighting + Diffuse
- Lighting Only
- Diffuse Only

Color assignment
- Color by Face
- Color by Vertex

Rendering Options
- Shadows
- Mapping
  - No Radiosity
  - Radiosity, Reuse Direct Illum. from Solution
  - Radiosity, Render Direct Illumination
  - Radiosity, Indirect Illum. Only

Reminder:
- Regathering is disabled
- Radiosity Setup...

Assign to Selected
Edit...

Name—If a channel has a name defined, it will appear here. Channels can be named using the Channel Info Utility (page 2-1738).

Note: Although the Color, Illum, and Alpha channels have specific names, in fact 3ds Max does not enforce what kind of data is saved in them, and any of the three channels can contain four-channel (RGBA) vertex color data.

Light Model group
Provides options that let you specify how the surface of the object appears to be illuminated.
**Light Model**

- **Lighting + Diffuse**—Uses the current scene lighting and materials to affect the vertex colors.
- **Lighting Only**—Uses only lighting to assign vertex colors, ignoring material properties. When this option is chosen, Shadows and Mapping are disabled in the Rendering Options rollout.
- **Diffuse**—Uses the material’s diffuse color, ignoring the lighting.

**Color Assignment group**

Lets you specify how colors are interpolated across surfaces.

- **Color by Face**—(The default.) Colors are interpolated between the center of each face. Color By Face samples fewer points, so it is the quicker method. On the other hand, results are less accurate.
- **Color by Vertex**—Colors are interpolated between vertices. For each face, this method uses three points instead of one, so it is slower but usually more accurate. An exception can occur when an object’s shadow falls between two vertices: in such a case, the object should occlude lighting, but because only vertices are taken into account, the shadow is not calculated and a “light leak” occurs.

**Rendering Options group**

The options in this group let you choose whether to include shadows, texture maps, or a radiosity solution in vertex colors.

Note: You can save a radiosity solution in vertex colors, but not Light Tracer (page 3–44) illumination, which is not stored in the scene’s geometry.

- **Shadows**—When on, shadows are used when the vertices are shaded. Default=off.
  Tip: You can soften the shadow edge by using the VertexPaint modifier’s Paint or Blur tools.
- **Mapping**—When on, texture maps are used when the vertices are shaded. Default=off.
  The radio buttons specify how to use radiosity data.
  - **No Radiosity**—(The default.) Do not use the radiosity solution when assigning vertex colors.
  Note: This option is the only one available unless a radiosity solution (page 3–51) is present in the scene.
Radiosity, Reuse Direct Illum. from Solution—Includes radiosity in the vertex color assignments, and uses the direct illumination from the solution.

This is comparable to the choice Re-Use Direct Illumination From Radiosity Solution on the Rendering Parameters rollout (page 3–71).

This choice disables the Shadows toggle, because shadows don’t need to be recomputed.

Radiosity, Render Direct Illumination—Includes radiosity in the vertex color assignments, but uses a separate pass to render direct illumination.

This is comparable to the choice Render Direct Illumination on the Rendering Parameters rollout (page 3–71).

Radiosity, Indirect Illum. Only—Includes only indirect illumination from the radiosity solution in the vertex color assignments.

This choice disables the Shadows toggle, because shadows don’t need to be recomputed.

Reminder field—Displays a message that says whether regathering is enabled or disabled. Regathering provides the most accurate radiosity results, but it can add considerable time to radiosity calculations.

Radiosity Setup—Click to display the Advanced Lighting panel (page 3–44) of the Render Scene dialog, where you can set up and generate a radiosity solution.

This button is not available if the mental ray renderer is the active renderer.

Assign to Selected—Assigns vertex colors to the selected objects based on the assigned material, and the choices specified in the preceding group boxes. Assign to Selected creates a VertexPaint modifier and adds it to the stack of the selected objects.

Edit—Click to display the VertexPaint Paintbox (page 1–941), the floating dialog that holds the vertex painting tools.

This button is unavailable if you haven’t yet clicked Assign To Selected.

---

**Channel Info Utility**

Utilities panel > More button > Channel Info > Click Channel Info button.

Tools menu > Channel Info

The Channel Info utility gives game artists and others direct access to objects’ channel information that might not otherwise be easily available. All objects in 3ds Max have mapping channels, which hold information pertinent to texture mapping as well as vertex color, illumination, and alpha. Mesh objects also have geometry and vertex-selection channels. The Channel Info utility lets you view an object’s channels, give them meaningful names, delete unused channels, and copy information between channels.

The utility’s Map Channel Info dialog shows all the channel data for selected objects. It displays the number of channels, the number of vertices per channel, and how much memory the channel uses. It also lets you name channels, as well as clear (or delete), copy, and paste channels. Each of these commands except renaming puts a modifier on the stack to achieve the results.

Note: Channel Info supports mesh, polygon, and patch objects. It does not support NURBS objects.

**See also**

This map and utility and these modifiers work in conjunction with Channel Info:

* Vertex Color Map (page 2–1693)
Skin Utilities (page 2–700)
Select By Channel Modifier (page 1–785)
UVW Mapping Add Modifier (page 1–933)
UVW Mapping Clear Modifier (page 1–933)
UVW Mapping Paste Modifier (page 1–934)

Procedure

To use the Channel Info utility:

This procedure is a guide to basic usage of the Channel Info utility. For more detailed usage methods and examples, see the tutorial Using the Channel Info Utility.

1. Select an object or objects to use with the utility.
2. Open the utility.
   
   The Map Channel Info dialog opens.
3. To create a map channel, click any channel and then click the Add button.

   The new, empty channel appears at the end of the list.
4. Most channels have three components. For example, a mesh or map channel has X, Y, and Z components, and an alpha channel has R, G, and B components. To expand all three-component channels, click the SubComp button. To collapse all expanded channels, click SubComp again.
5. To copy one channel to another, click the source channel, click Copy, and then click the destination channel and click Paste.

   In some cases, you might need to expand or collapse the component display (see previous step). For example, when copying a vertex selection (vsel) channel to a map channel, you must paste the vsel channel to a component channel.
6. To minimize a channel’s memory footprint, click the channel and then click the Clear button.

   This removes most all or of the data from the channel, so first make sure the data is unnecessary or is available elsewhere. If the cleared channel is the last one in the list, it might be deleted from the list.

Interface

The primary user interface of the Channel Info utility is the Map Channel Info dialog, which you open by clicking the utility’s Channel Info button on the command panel. This modeless dialog shows information about all map channels belonging to the current selection, at the object level. If you change the selection, the dialog automatically updates to reflect the selection.

The dialog consists of two parts: a button toolbar at the top, and a tabular display of map channels belonging to each object in the current selection.

Channel Info toolbar

Copy—Copies the channel data from the highlighted channel to the copy buffer, where it becomes available for pasting. After you copy a channel, its name appears on the line below the button toolbar.

Paste—Pastes the contents of the copy buffer to the highlighted channel.
You can copy and paste only between channels with the same topology, or you can copy from any channel to a channel with no vertices.

Source and destination channels need not be of the same type. For instance, you can copy from a mesh channel to a map channel, and vice-versa.

**Name**—Lets you rename the highlighted channel. Click this button to open a small dialog that displays the current channel name and lets you edit this name or enter a new one from the keyboard.

**Clear**—Use this function to remove channels or delete data from a map channel (including alpha, illumination, and vertex color channels). Clear has no effect on geometry or vertex selection channels.

The specific result depends on the type of object and which channel you clear. In terms of reducing the object’s memory footprint, the utility is most effective with Editable Poly objects.

- **Geometric primitive or Editable/Edit Mesh object**—Deletes the highlighted texture map channel if it is the last map channel in the object, and it’s not the default map channel (1:map). If the highlighted channel is not the last, Clear deletes all vertices in the channel. The faces remain, so the memory-footprint reduction is partial.

  Note: This also applies to objects that collapse to editable mesh, such as Loft objects.

- **Editable Poly object**—Deletes the highlighted texture map channel if it is the last map channel in the object, and it’s not the default map channel. If the highlighted channel is not the last, Clear deletes all vertices and faces in the channel.

- **Patch object**—Deletes the highlighted texture map channel if it is the last map channel in the object, and it’s not the default map channel. If the highlighted channel is not the last, Clear has no effect.

Note: When you use the Clear function, the software adds a UVW Mapping Clear modifier to the object’s modifier stack. You can recover the deleted data by removing the modifier from the stack, or changing its Map Channel setting.

**Add**—Appends a new map channel to the object’s channel list. If multiple objects are selected, Add becomes available only after you click a track, so the software knows which object to add the channel to.

Note: If you apply mapping with a channel number higher than any existing channels, the software automatically creates all intermediate channels. For example, if you apply a UVW Mapping modifier to a standard object and set Map Channel to 5 in the modifier, the software adds map channels 2, 3, 4, and 5.

**SubComp**—Toggles display of the channels’ subcomponents. When displayed, you can rename, copy, and paste each subcomponent independently of its parent channel.

Each channel except vsel has three subcomponents. Mesh and map channels' subcomponents are labeled X, Y, and Z; those of alpha, illumination, and vertex color channels are R, G, and B (red, green, and blue).

**Lock**—Retains the current mapping data information in the table even if you change the selection.

For example, if you want to see mapping data for a specific object or objects constantly, first select the objects and then click Lock. Thereafter, if you select different objects in the viewport, the table continues to display the data for the selection when you clicked Lock. If you turn off Lock, the table updates to show data only for the current selection.

If you click Update when Lock is on, the software will refresh the table contents to reflect the current selection, and then retain that data.
**Update**—Refreshes the displayed data to reflect any changes in the objects or mapping, or, when Lock is on, the selection.

For example, if you apply mapping to an object, or change its mapping, click Update to display the changes in the Map Channel Info dialog.

**Channel Info table**

The table functions similarly to a spreadsheet. If not all rows or columns are visible, you can scroll the table using standard methods, including rolling the mouse wheel for vertical scrolling. To highlight a row, click anywhere in the row. You can highlight only one row at a time. To resize a column, drag the vertical divider at the right of the column heading. To automatically set a column’s width to the size of the longest entry, double-click the vertical divider to the right of the column heading.

Following is a brief explanation of each of the columns in the table:

- **Object Name**—The name of the object. If you change the name in the Modify panel, click the dialog’s Update button to display the new name in the dialog.

- **ID**—The type of channel. The available channel types are:
  - **mesh/poly**—The object’s mesh or poly data, depending on whether it’s a mesh or poly object: vertices and faces. You can copy this channel and paste it to any other three-component channel.
    
    This channel is not available for patch objects.
  - **vsel**—The vertex selection. You can copy this channel and paste it to other channels’ subcomponents.
    
    This channel is not available for patch objects.
  - **-2:Alpha**—The vertex alpha channel. You can transfer all vertex alpha values between objects with the same topology by copying and pasting this channel.

- **Channel Name**—The name of the channel. By default, a channel has no name, as indicated by the entry “-none-”. To name or rename the channel, click the channel to highlight it and then click the Name button at the top of the dialog, or right-click

You can apply vertex alpha information to objects with the **Vertex Paint modifier** (page 1–936), and to editable surfaces with the Vertex Properties settings (**editable poly** (page 1–1034)) and Surface Properties (**editable mesh** (page 1–1005) and **editable patch** (page 1–978)).

- **-1:illum**—The vertex illumination channel. You can transfer all vertex illumination values between objects with the same topology by copying and pasting this channel.

You can apply vertex illumination information to objects with the **Vertex Paint modifier** (page 1–936), and to editable surfaces with the Vertex Properties settings (**editable poly** (page 1–1034)) and Surface Properties (**editable mesh** (page 1–1005) and **editable patch** (page 1–978)).

- **0:vc**—The vertex color (vc) channel. You can transfer all vertex color values between objects with the same topology by copying and pasting this channel.

You can apply vertex color information to objects with the **Vertex Paint modifier** (page 1–936), and to editable surfaces with the Vertex Properties settings (**editable poly** (page 1–1034)) and Surface Properties (**editable mesh** (page 1–1005) and **editable patch** (page 1–978)).

- **1:map**—The default mapping channel. You can transfer all UVW mapping information between objects with the same topology by copying and pasting this channel.

You can create additional mapping channels by various means, including with the Channel Info utility.
the channel and choose Name from the right-click menu.

Note: Most channels can be split into subcomponents. You can name the subcomponents separately from the channel itself.

**Num Verts**—The number of vertices in the channel. To paste one channel to another, they must have the same number of vertices.

Some channels have faces but no vertices. This is typically the case with Alpha, Illumination, and vertex color channels in newly created non-poly objects. In such cases, these channels function as placeholders for the corresponding data should you add it later. They do consume a small amount of memory, so if you have no intention of using a channel, you can save some memory by converting the object to Editable Poly.

**Num Faces**—The number of faces in the channel.

If a channel has faces but not vertices, that means it’s a placeholder. See Num Verts, above, for more information.

**Dead Verts**—The number of unused map vertices in the channel. Such vertices can be left over from sub-object editing.

**Size(KB)**—The approximate amount of memory consumed by the channel. Use this figure to check for unused channels that are using up memory.

---

**Clean MultiMaterial Utility**

Material Editor > Utilities menu > Clean MultiMaterial

Select an object. > Utilities panel > More button > Clean MultiMaterial > Click Find All button.

The Clean MultiMaterial utility parses Multi/Sub-Object materials and displays any that contain sub-materials are not assigned to any material IDs in the scene. You can then choose to remove any unused sub-materials, thus consolidating your Multi/Sub-Object materials.

This utility searches an entire scene. You do not need to select objects or materials.

**Procedures**

**To clean all materials:**

1. Open a scene.

2. On the Material Editor, open the Utilities menu and choose Clean MultiMaterial.

The Clean Multi-Materials dialog opens, displaying the following:

The dialog displays a list of all Multi/Sub-Object materials that contain unassigned sub-materials. All the Multi/Sub-Object materials are automatically turned on, and thus subject to cleaning.

3. Click the OK button.
All unused sub-materials are deleted and the dialog closes.

**To clean specific Multi/Sub-Object materials:**

When you create a Multi/Sub-Object material, you might create extra sub-materials in anticipation of objects that haven’t been added to the scene yet. In such cases, you can prevent the utility from removing the extra sub-materials.

1. Open a scene.
2. On the Material Editor, open the Utilities menu and choose Clean MultiMaterial.

The Clean Multi-Materials dialog opens.

3. In the list, turn off any Multi/Sub-Object materials you do not want to clean.

4. Click OK.

All unused sub-materials are deleted from the indicated materials and the dialog closes.
Interface

The Clean dialog presents you with a list of all Multi/Sub-Object materials in the scene that contain unassigned sub-materials. You can then select materials from which to remove unassigned sub-materials.

The dialog consists of two parts: a status field at the top and a list of Multi/Sub-Object materials.

Status Field

The Status Field is not interactive. It displays prompts about the unused materials.

Materials list

This list displays Multi/Sub-Object materials that have sub-materials that are not currently being used in the scene. When the Clean MultiMaterial utility opens, it lists all Multi/Sub-Object materials with unused sub-materials and turns them on to be cleaned. Click the check box next to a material name to turn it off and prevent the utility from cleaning it.

Clean—Deletes unused sub-materials from Multi/Sub-Object materials that are turned on.

Cancel— Cancels the operation.

Instance Duplicate Maps Utility

Material Editor > Utilities menu > Instance Duplicate Map

Utilities panel > More button > Instance Duplicate Maps > Click Find All button.

The Instance Duplicate Maps utility searches an entire scene for materials that have duplicate Bitmap maps and give you the option to instance them. If your scene has different materials that use the same texture maps, creating instances will reduce the load on your video card, which can improve viewport performance.

For example, if you render a scene containing three materials that reference the texture map MyMap.bmp, the software searches for that texture map three times: once for each material it is used in. However, if you use the Instance Duplicate Maps utility, you can create instances of the duplicate maps so the renderer will find the first reference to MyMap.bmp and use it for any subsequent material that uses the same maps.

This utility searches an entire scene. You do not need to select objects or materials.

Note: In order to be eligible for instancing, the Bitmap maps must be identical in all aspects with regard to their initial settings. For example, if two materials use the same bitmap image applied as Diffuse maps, but have different initial Tiling settings, their maps aren't eligible for instancing.

Animation is not supported as a criterion for determining duplication, so any differences in the animation of Bitmap map parameters will be
lost from the use of this utility. For example, if two materials use the same bitmap image applied as Diffuse maps, and have the same initial Tiling settings, but their Tiling settings are animated to different subsequent values, after using the utility both maps will have the same animation as the first map.

**Procedures**

**To instance all duplicate maps:**

1. Open a scene.
2. On the Material Editor, open the Utilities menu and choose Instance Duplicate Map.

The Instance Duplicate Maps dialog opens, displaying the following:

The dialog displays a list of all texture maps found to have exact duplicates in the scene. The search will include all copies found to have identical paths and settings.

3. Click the Instance All button.

All identical maps are instanced and the dialog closes.

**To instance only specific maps:**

Perhaps you only want to instance a few of the texture maps found in specific materials.

Note: You have to select at least two maps from the Duplicates list

1. Open a scene.
2. On the Material Editor, open the Utilities menu and choose Instance Duplicate Map.

The Instance Duplicate Maps dialog opens.

3. From the Duplicated Textures list, click the arrow button to open the list of duplicated textures and choose a texture you want to instance.
4. From the Duplicate list, select at least two map entries. If you don't select at least two entries, you will see a warning in the status field at the top of the dialog.

5. Click Instance. Since all three of the maps were instanced, the dialog now shows there are 42 duplicated textures.

6. Continue instancing texture or click Close when you are done.

Interface

The primary user interface of the Instance Duplicate Maps utility is the Instance Duplicate Maps dialog, which you open from the Utilities menu in the Material Editor. This utility works
globally, so you do not need to select objects or materials in order to use it.

The dialog consists of three parts: a status field at the top, a drop menu containing duplicated texture maps and a list of map names and the materials that belong to.

**Status Field**

The Status Field is not interactive. It shows you prompts and warnings about the duplicate textures and maps. Some of the messages displayed in this section include:

- “No duplicate textures were found in the scene.” – when the utility is run in a scene containing no duplicates.
- “Select duplicates and press “Instance” to consolidate.” – when the utility is run in a scene containing duplicates.
- “The selected duplicates contain parameters that are animated. Animation is not supported as criteria for determining duplication so differences in the animation will be lost.” – when animation is present in a set of duplicates.
- “At least two maps must be selected in order to proceed.” – when the Instance button is pressed with one or no duplicates selected.

**Duplicated Textures list**

This drop-down list contains all the maps in the scene found to be identical in every way, including texture map path and name, and initial parameter settings. The number after “Duplicated Textures” indicates how many sets were found in the scene. This list appears with the first entry visible and once active can be scrolled using the up/down arrow keys.

**Duplicates list**

When you choose a texture in the Duplicated Textures list, the software displays its duplicates in the Duplicates list, showing the map name and the name of the parent material. The number after “Duplicates” indicates how many copies were found in the scene. Textures in this list can be chosen individually. Only duplicates chosen in this list will be consolidated into the final instance if you click the Instance button. The name of the resulting instance is that of the first chosen duplicate in the list.

**Instance All**—Performs the consolidation on all duplicates in the scene regardless of selections made from the Duplicated Textures or Duplicates lists.

**Instance**—Performs the consolidation on only the duplicates chosen on the Duplicates list. Selected duplicates will disappear from this list after consolidation. If all are selected, the corresponding texture will disappear from the first list as well.

**Close**—Closes the operation at its current point.
